Take a line equal to the length of the instrument, and divide this line in the ratio required; then apply the shorter or longer part of the line thus divided on the length of the instrument when shut, from the extremity of the longer or shorter legs to an intermediate point, to which bring the axis of the pin, and the compasses will be set in the ratio required.

Thus, let A D be a straight line divided in E; make A B equal to the length of the instrument; join D B, and draw E C parallel to D B, cutting A B at C; shut the instrument; take either distance C A or C B, lay the shorter, C B, and apply it from the shorter end of the instrument; push the slider along the slit until the centre of the pin coincides with the other extremity, and the instrument will be set in the ratio required.

As this problem is essential in most of the following, the reader is directed not to pass it, but to understand it thoroughly before he proceeds farther.

**Problem II. Fig. 2.**

Given any number of lines, A, B, C D, E F, G H, &c. (fig. 2.) to find a series of other lines, which will have the same ratio in every two corresponding lines, given one line a b of the series required, corresponding to A B of the series given.

Set the proportional compasses in the ratio of A B to a b by problem I.; then if A B be greater than a b, take the distance C D, with the remote extremities, and make e f equal to the distance contained between the near extremities, and a b will have the same ratio to e f, which A B has to C D; in like manner take the distance E F, with the remote extremities, and make e f equal to the distance contained between the points of the near extremities, and e f will have the same ratio to e f, that C D has to E F; or a b will have the same ratio to e f, that A B has to E F, and thus the remaining lines g h, &c. will be found in the same manner; but if the line A B in the given series be less than a b, the given line of the series required, the lengths C D, E F, &c. must be taken with the shorter ends of the compasses, and the lines e d, e f, &c. made respectively equal to the corresponding distances contained between the extremities of the longer ends.

**Problem III. Fig. 3.**

To divide a given line in the same proportion as another given line is divided.

Let A E be a given line, divided into the parts A B, B C, C D, D E, and let it be required to divide the line a e in the same proportion.

Set the compasses in the ratio of the whole lines A E and a e, then take the distances A B, B C, C D, D E, with the same legs which were applied in taking the distance A E, and with the other legs corresponding to the distance a e, make a b, b c, c d, d e, respectively equal to the distance between the points of these legs, and a b, b c, c d, d e, will have the same ratio to one another, that A B, B C, C D, D E, have to one another.

**Prop. IV.**

To divide a straight line, A X, No. 2, in continued proportion, given the extreme part A B.

Set the compasses in the ratio of A X to B X by problem I.; contract the points of the longer legs to B X, then with the shorter legs cut off the distance X C; again contract the distance between the points of the longer legs to X C, thus found, and with the shorter legs cut off the distance X D; and thus by setting the distance between the points of the longer legs to the last distance found, the shorter legs will give the succeeding part by transferring the distance between the shorter legs from X towards A.

By continuing this operation, as many points may be found as may be necessary for the purpose required; then A B : B C : C D : D E : E F : F G, &c. ; that is A B : B C :: C D : D E : E F : F G, &c.

Any question in the rule of three may be resolved by the proportional compass and a plane scale; thus, suppose three articles of the same kind to cost two shillings; what will eight cost? Set the compasses in the ratio of 2 to 3 by problem I.; extend the points of the shorter legs to 8 on the scale; then apply the longer legs to the scale, and the measure indicated, will be the fourth proportional, as required.

Where there is a great disproportion in the terms of the ratio, it would be more eligible to use two scales; thus, suppose it were required to find a fourth proportional to the numbers 30, 3, and 45, any convenient scale for the antecedents 30 and 45, and any convenient larger scale for the consequents 3 and the answer; then by problem I. set the compasses in the ratio of the distance 30 on the scale of the antecedents to the distance 3 in the scale of the consequents; then take 45 from the scale of the antecedents with the legs first applied to the same scale, and the other legs will give the distance 45, or 45 1/2, the answer as required, by applying the distance between their points on the scale of the consequents.

By this any proportion, whether in lines or numbers, may be resolved.

**Prop. V. Fig. 4.**

Given two straight lines A B and C D, tending to an inaccessible point, and a point E in position, to draw a straight line through the point, E, so that all the three straight lines A B, C D, and that which is required to pass through the point, E, may have the point of concourse.

Through the given point E, draw F G, meeting A B at F, and C D at G; draw HI parallel to F G, cutting A B at H, and C D at I; set the proportional compasses in the ratio of the two straight lines F G and H I; then F G being greater than H I, take the distance G E with the longer legs, and make J K equal to the distance between the points of the shorter legs; draw a straight line through the points E and K; then if the straight lines A B, C D, E K be produced, they would have one common point of concourse.

**Corollary.**—Hence, if A B and C D (fig. 5.) be two straight lines, and if E, G, I, L, be several points in a straight line P Q, meeting A B in P, and C D in Q; then drawing any line R S parallel to P Q, cutting A B at R, and C D at S, and setting the proportional compasses in the ratio of P Q to R S; then P Q being longer than R S, take the distances Q E, Q G, Q I, Q L, with the longer legs, and apply the distances contained between the points of the shorter legs respectively from S to F, from S to H, from
from S to K, and from S to M; and drawing the lines EF, GH, IK, LM, the lines thus drawn would all have one common point of concourse, if produced with AB and CD.

Fig. 12. shews the application of this problem and its corollary, in drawing the representations of the horizontal lines which regulate the heights of doors and windows in the perspective representation of a building, when the vanishing points of the sides A and C are not in the picture, and when all the points through which these lines pass are in the corner of the building, or any other convenient line.

**Prob. VI.** Fig. 6.

Given two straight lines A and CD, tending to an inaccessible point, and any number of points E, G, I, in position, not in a straight line; to draw a straight line through each of the points E, G, I, tending to the same point with A and CD.

Through the point E, draw any line AC; through the point G, draw LM parallel to AC, cutting AB at L, and CD at M, and through the point I, draw NO also parallel to AC, cutting AB at N, and CD at O; draw any line PQ parallel to AC; cut the proportional compasses in the ratio of AC to PQ; take the distances CM, CO, with the longer legs, and make QR, QS respectively equal to the distances contained between the points of the shorter ends; draw RT, SU parallel to PQ, cutting AB in T, U; make O, R, S, respectively equal to CE, MG, OI; and draw the straight lines ES, IT, GG, and E, S, I, G, G, will tend to the same point with A and CD.

**Prob. VII.** Fig. 8.

Given the representation \(a'' b'' c'' d'' e'' f''\) of the end of a right cylinder, the original having its axis parallel to the picture, the vanishing line VL of the plane of that end, through a given point a in any perpendicular a'' to VL, to draw the representation of the other end of the cylinder.

Let \(d'' a'' a\) cut the vanishing line VL at u; draw \(b'' b, c'' c, d'' d, e'' e, f'' f\), parallel to \(d'' a'' a\), cutting VL respectively at \(w, w, y, z, z\); let the proportional compasses in the ratio of \(u d''\) to \(u a''\); then \(u d''\) being greater than \(u a\), take the distance \(w b\) with the longer legs, and make \(w b\) respectively equal to the distance contained between the points of the shorter ends; find the remaining points \(e, d, f, c\, f\) in the same manner, and through the points \(a, b, c, d, e, f\) draw a curve, which will be the representation of the other end of the cylinder.

Or, if the base \(a b c d e f\) were given, the top would be found in the same manner by making the ratio of the shorter legs to the longer legs as \(u a\) to \(u d''\), and taking \(w b\) with the nearer extremities, and making \(w b\) equal to the distance of the remote extremities, and finding the remaining points \(e, d, f, c, f\) in the same manner.

In the same manner any section \(a' b' c' d' e' f'\) may be found.

This application of the proportional compasses is exceedingly useful in the representation of bows, when required in the fronts of buildings, as is shewn by fig. 9, which exhibits the elementary lines of the perspective of a house. Here the horizontal terminations of the apertures are readily represented by only drawing perpendicular lines which may be the vertical terminations of the said apertures, and which would therefore be required at all events. The same description of words as in the problem, apply to this figure, as in figure 9, to which the problem refers.

**Prob. VIII.**

Given the representation of any point on the picture, and the interfacing and vanishing lines of the plane it is in, to find the height of a representative line, the original of which is parallel to the picture.

Set the proportional compasses in the ratio of the distance between the interfacing and the vanishing lines, and the distance of the point from the vanishing line, then take the length of the original line with the longer legs, and the opposite points will give the height of the line required.

**Example.**—Suppose the distance between the vanishing and interfacing lines to be three inches, and the distance between the representation of the point or foot of the line to be two inches, and the height of the original line to be six inches, required the perspective height of the fame. Set the proportional compasses in the ratio of 3 to 2, extend the longer legs of the compasses to fix inches, and the extent between the opposite shorter legs will be the height of the line required, which, in this case, will be four inches.

**Scholiwm.**—By this method all the heights of the representation of a solid may be found without any additional lines whatever; but in order to expedite the work when the original object is of different heights in the same plane parallel to the picture, or where the same height is required to be found upon two or more points, it will be eligible to draw a straight line through one of the points, cutting the one or more lines on which the heights are to be found, and the same setting of the compasses will do for as many heights as are to be railed upon the line so drawn.

**Example.**—Suppose a cylinder to be represented, its base is an ellipse, to find any two points in the height of the cylinder; draw a straight line parallel to the vanishing line, to cut the representation of the base of the cylinder in two points; upon each point of section draw a perpendicular; set the proportional compasses in the ratio of the distance between the interfacing and vanishing lines, and either point and the vanishing line; then take the height of the cylinder between the points of the long legs, and the distance of the opposite points, and the distance between the opposite points will give the perspective height upon each perpendicular from the foot thereof.

In the application which has hitherto been made of the proportional compasses, the sides of the instrument have not required any gradations of parts; the construction of the scales to be affixed on the proportional compasses for this purpose is as follows.

**Prob. IX.**

To construct the scale of lines for the proportional compasses. Let AC be a scale of lines, found in the usual manner; and let CA be produced to R, making AR equal to the radius; draw RD at any convenient angle with RC; make RD equal to the length of the proportional compasses, and join CD; draw A9 parallel to CD, and as 9 at the point C is the chord of 90, the point 9 in RD will be the point for the index of the slider to be set to; then if the legs of the compasses be set to any angle, the distance between the points corresponding to D will be to the distance between the points corresponding to R,
PROPORTIONAL COMPASS.

as the line of 90° is to radius. In like manner, join D 8 and the next point 8 in the line A C, and draw A 8 parallel to D 8, cutting R D in 8; then the point 8 in R D will be the point for the index of the slider to be set to; then if the ends of the proportional compasses corresponding to R be extended to any radius, the extent of the ends corresponding to D is the line of 80 degrees corresponding to that radius: in like manner, the points 6, 5, 4, 3, 2, 1, will be found in R D, so that 1, 2, 3, 4, 5, 6, 7, 8, 9, in R D, are the graduations on the side of the proportional compasses corresponding to 10°, 20°, 30°, 40°, 50°, 60°, 70°, 80°, 90°; so that if the index be set to any of these numbers, and the points corresponding to R be extended to the radius, the distance between the opposite points will be the line of that number of degrees. The cofines have the same divisions as the lines, but are numbered in the contrary way.

In the same manner, by placing the radius in the same straight line with a common scale of lines or tangents from zero on A, so as to lengthen the line A C of tangents, by adding the said radius A R, and forming the extension R C, and drawing R D at any convenient angle with R C, then dividing B D as in the problem; then R D will contain the graduations of a scale of tangents, to be inferred on the side of the proportional compasses: so that when the index or mark upon the slider is brought to any of these numbers, the end corresponding to R being opened to the radius, the end corresponding to D will be the line or tangent of the angle corresponding to that number. See the figure.

Fig. 10. shows the application of the method to a scale of tangents.

Examples.

Ex. 1. Fig. 13.—To make an angle of 30° at a given point A in the straight line A B.

With any convenient radius A B describe an are B C; let the index to 30° on the line of chords, then extend the points of the instrument corresponding to B to the radius A B, and with the opposite points let off the distance B C on the arc, and join C A, then C A B is the angle required.

Ex. 2.—To find the tangent of 40° to any given radius within the limits of the points corresponding to R.

Set the index to 40° on the line of tangents, and extend the points R to the radius, then the extent between the opposite points will be the tangent of 40°, as required.

Ex. 3.—To find the sine of 20° to any given radius within the limits of the points corresponding to B.

Set the index to 20° on the line of sines, then extend the points corresponding to R to the radius given, and the extent between the opposite points will be the sine of the angle, as required.

Ex. 4.—To find the cofine of 50°, the radius being given within the limits of the instrument.

Set the index to 50° on the line of cofines; extend the points corresponding to R to the radius, and the opposite points will be the cofine of the angle required.

Ex. 5.—The chord, sine, cofine, or tangent of any number of degrees being given, to find the radius.

Extend the points corresponding to D to the chord, sine, cofine, or tangent, and the opposite points corresponding to R will be the radius of the circle required.

Prob. X.

To draw the representation of a house, by making the centre of the picture the dividing point, having the dimensions of the building given.

Fig. 12.—Let V L be the vanishing line, h k the intersecting line, and C the centre of the picture; and let the building touch the intersecting line in A, also let the vanishing points of the sides be supposed to be given.

Set the proportional compasses to the cofine of the angle which the one side of the building (viz. say that on the right) makes with the intersecting line by Ex. 4. Prob. IX. say 30°; then with the ends of the instrument corresponding to R, take the original measures from a plan; or if the measures are known in feet, &c. take them from a scale without being at the trouble of drawing a plan; take the distance of the corner of the building, and the nearest side (say 3 feet 6 inches) from the scale, with the remote points, and with the opposite points let off the distance A b on the intersecting line; take the breadth of the window from the scale (say 3 feet) with the remote points, and with the opposite points let off the distance b c on the intersecting line; take the breadth of the next pier from the scale (say 4 feet) with the remote points, and with the opposite points set off the distance A k; set off the breadth of the piers from h to j, and from A to i in the same manner; draw the lines A h and A k to the vanishing points of the sides.

From the points b, c, d, e, f, g, h, as also from i, j, k, draw lines to C, cutting A h at b, c, d, e, f, g, h, and A k at i, j, k; from the points of section draw perpendiculars to V L; let the heights of the apertures, and the height of the building itself, upon the corner A A', say that the fills of the lower windows are three feet high, the windows fix feet, the space between the lower windows and the upper four feet, the upper windows four feet also, and the distance to the parapet three feet; therefore make A l equal to three feet, l m equal to fix feet, m n equal to four feet, n o equal to four feet, and o A' equal to three feet, exactly to the scale or natural measures of the building; from these points of section draw lines to the vanishing points, and complete the whole representation. In setting up the heights, common dividers may be used. By the last setting of the proportional compasses, if the thickness of the walls are taken from the scale by the remote ends marked R, and the distance of the two opposite points be set upon the intersecting line from the points e, e, g, towards A; and if from the points of section lines be drawn to C, the centre of the picture, to cut the represeative base line A b of the building, and perpendiculars be drawn from the points of section in A b, these perpendiculars will give the reveals of the windows, that is, they will show the thickness of the walls on the sides of the windows.

Prob. XI. Fig. 13.

From a given point A, in a given straight line A B, to draw a straight line A C, so that A B and A C shall contain an angle of a given number of degrees.

Set the index of the proportional compasses to the chord of the angle; then from the point A, with any radius describe the arc B C of a circle; extend the longer legs to the radius A B, and with the opposite legs set off a chord B C
BC upon the arc from the point B, where it cuts the leg, and draw the line AC, and BAC will be the angle required.

**Prop. XII.**

Given the vanishing line of a plane, its centre and distance, and the inclination of a line in that plane to the interfection, to find the vanishing point of the line, without having recourse to draw any lines in the vanishing plane.

Let the angle which the original line makes with the interfection be 30°; subtract 30° from 90°, and 60° will remain; bring the index of the proportional compasses to 60° on the line of tangents; extend the extremities of the compasses marked R to the radius; then let the distance of the opposite extremities from C to D (fig. 14.), on the vanishing line V L, and v will be the vanishing point of the line, as required.

The proportional compasses will answer to any distance of the eye from the vanishing line, however great, by taking one-half, one-third, one-fourth, &c. of the distance of the vanishing line, as will be found most convenient with the extremities marked R; then repeating the distance between the points of the opposite extremities two times, three times, four times, &c. accordingly.

*Example.*—Let it be required to find the vanishing points of a rectangle, supposing the right-hand side to be placed at 45° with the interfection line.

Subtract 40° from 90°, the number contained in a right angle, and the remainder, 50°, will give the angle made by the primary or shortest radial, and the radial of the right-hand side, or the angle made by the original side of the rectangle on the right hand, and a perpendicular in the original plane to the interfection line; then the angle contained between the primary radial and the radial of the left-hand side of the rectangle will be 40°. Now suppose the length of the picture to be 12 inches, and the spectator to stand at 2 feet, or 24 inches, from the centre of the vanishing line; and suppose the proportional compasses to be 62 inches, which is the usual length: divide 24 into 6 equal parts, each of these parts in this instance will contain 4 inches; slide the index of the instrument to 50° on the line of tangents, then with the legs R take the extent of 4 inches, or the sixth part of 2 feet, and repeat the distance of the opposite points on the vanishing line from the centre C of the picture towards the right hand fix times to v, and v will give the vanishing point. To find the vanishing point of the left-hand side: as the radial of this side makes 40° with the primary radial, slide the index of the instrument to 40° on the line of tangents; then with the legs R take the extent of 4 inches, or the sixth of 2 feet; then repeat the distance between the points of the opposite ends from the centre of the picture towards the left hand fix times to V, and V will be the vanishing point of the left-hand side of the rectangle.

The vanishing points of all lines whatever may be found in this manner, having the angle formed by the interfection line and the original: for this is always equal to the angle formed by the radial and the parallel of the eye; and because that the distance of a vanishing point from the centre of the picture is the tangent of the angle made by the primary radial and the radial of the line, the primary radial being radius, the proportional compasses being set as above, will give the true vanishing point.

*Scholium.*—None of the lines on the proportional compasses, except the tangents, require the slide to be less than half the length of the Shank, deducting that part of the slide from the centre of the pin; the tangents therefore cannot be infected higher than 45°; and indeed the higher tangential numbers would be of little use, as the radius would be shortened by such increases; now this would be attended with greater inaccuracy and more labour. If the gradations, however, do not exceed 45°, the distance of the extremities of the compasses may still be extended to six inches: but in order to find the tangent of any greater number of degrees than 45°, we have only to subtract that number of degrees from 90°, and the remainder is the complement of the angle; then it will be as the tangent of the complement is to radius, so is radius to the tangent itself.

From these observations it will be very easy to find the vanishing point of any line, whatever number of degrees the radial of that line forms with the primary radial, as may be seen in the following problem.

**Prop. XIII.**

To find the vanishing point of a line, the radial of which makes a greater angle with the primary radial than 45°, the vanishing line and its centre being given, as also the primary radial.

Subtract the given angle from 90°; set the index of the compass to the tangent of the remaining angle; take a convenient aliquot part of the distance of the eye from the vanishing line, and set the legs marked R to that distance; and upon any straight line A E, with the ends R, set off the distance A B; take the distance A B with the opposite ends, and set off the distance A D; then let V L be the vanishing line and C its centre; then, according as the original line or its radial is on the right or left, the distance A D must be set to the right or left of the centre of the picture, as often as the radial is supposed to contain the distance of the points upon the legs marked R.

*Example.*—Suppose the radial of the line to make an angle of 50° with the primary radial, and the length of the primary radial to be three feet, to find the distance of the vanishing point from the centre of the picture.

Subtract 50° from 90°, and the remainder is 40°; set the index to the tangent of 40°; take the ninth part of the primary radial, or 4 inches, and extend the ends opposite to those marked R to 4 inches, or the ninth part of the distance, and repeat the distance of the legs marked R on the vanishing line nine times from the centre to the right or left hand accordingly, and the extremity of the distance so repeated from C is the vanishing point required.

The reason of this operation is evident, since the radius is a mean proportional between the tangent of the angle and the tangent of its complement, and therefore as the tangent of the complementary angle is to the radius, so is the radius to the tangent itself.

If the object to be drawn be a rectangle, making unequal angles with the interfection line, the angles made by the radials of the sides, and the primary radial, being equal to the angles made by the sides of the rectangle and the interfection line, or a line drawn through the other corner parallel to the interfection line; let the proportional compasses to the tangent of the least angle; extend the legs marked R to the distance, or to any part of the distance that the compasses will admit of; let the distance of the opposite legs, or repeat that distance as often as the primary radial contains parts, from the centre to the right or left, and the point of extension will give the vanishing point of that side of the rectangle; extend the ends opposite to R to the primary radial, or that portion of it before-mentioned that the compasses will admit of, and the extension between the extremities of the legs marked R being set from the centre on the other side of it of the vanishing line, or repeated
PROPORTIONAL COMPASS.

Suppose one of the angles 40°, the other will be 50°; add 40 to 90, the sum is 130; the half of 130 is 65; subtract 40 from 65, and the remainder is 25°; then the tangent of 25°, set on the other side of 40 from the centre of the picture, will give the distance of the vanishing point of the line, the radial of which makes 40 with the primary radial. Again, add 50 to 90, the sum is 140, the half is 70; subtract 50 from 70, and the remainder is 20°; then the tangent of 20° being set from the centre of the picture upon the other side of the angle formed by the primary radial, and the other radial containing 50, will give the distance of the said radial.

Again, suppose the less angle to be called \(v\), and the greater \(w\); then \(\frac{v + 90}{2} - v = \frac{90 - w}{2} = 45 - \frac{w}{2}\), gives the distance of the other vanishing point set on the contrary side of the centre; thus, if

\[
w = 60, \quad \text{then} \quad 45 - \frac{w}{2} = 15, \quad \text{then set the tangent of} \quad 15°
\]

as directed; and thus the tangent of the remainder of half the angle contained by the primary radial, and the radial from 45°, gives the vanishing point; or take the tangent of half the complement of the said angle, and set it on the vanishing line from the centre of the picture on the other side, and it will give the vanishing point.

**Prob. XIV.**

Given the angle which the radials of any two original lines make with each other, and the angle which one of them makes with the primary radial, to find a dividing point which shall be common to the same measures or scale, so as to cut off a portion from the indefinite representation of each line, such that the portions may be the representations of the two original lines.

N.B. When one of the angles which the primary radial makes with the one radial is given, that with the primary radial and the other radial may be found by subtracting the one given from the whole angle contained by the radials. This being obtained, proceed as follows: subtract the less angle formed by the one radial and the primary radial from half the angle contained by the radials of the original lines; then if the tangent of the remaining angle be set on the vanishing line, on the side of the primary radial which has the greatest angle, it will give the dividing point required.

Let us call the whole angle \(A\), then the half is \(\frac{A}{2}\); call the less angle made by the primary radial and the one radial \(B\), then \(\frac{A}{2} - B\) is the difference; find the tangent of \(\frac{A}{2} - B\); then the greater angle made by the primary radial and the other radial being \(A - B\), set the tangent of \(\frac{A}{2} - B\) from \(C\), on the vanishing line on the side of \(A - B\), and the extremity of the distance will give the dividing point required.

**Example 1.** Suppose the angle contained by the two radials to be 100°, and the lesser angle to be 40°, then the greater
greater will be 60°: now the half of 100 is 50; subtract 40°, the lesser angle, from 50°, there remains 10°: set the index of the proportional compasses to 10° on the line of tangents; take the length of the primary radial with the legs marked R, and set off the distance contained by the opposite points from the centre of the picture on the vanishing line, on the side of the primary which has the angle of 60°, and the extremity of the distance is the dividing point.

Example 2.—Suppose the angle contained by the radials to be 80°, the lesser angle to be 30°, and consequently the greater 50°; the half of 80° is 40°; subtract 30° from 40°, and 10° remain. Set the index of the proportional compasses to the tangent of 10°; take the length of the radial with the legs marked R, and set off the distance of the point contained by the opposite legs from C on the vanishing line, on the side of the angle of 50°, and the extremity gives the dividing point.

PROB. XV.

Given the sun's altitude on a plane, the height of a line, and the length of its shadow on that plane, the orthographical representation of a cornice, with a section of the same, also the feet of the sun's rays, to find the shadow of the cornice.

Let fig. 15, N° 1, be the cornice or architrave, and N° 2 be a profile or section perpendicular to the arcades, or edges of the mouldings; draw b B for the indefinite representation of the shadow of a line represented by the point b, N° 1, and let b B be the distance the shadow is thrown from the point b, and consequently B will be the shadow of b: from all the external angles draw c E, e E, g G, I H. Now let, N° 2, is the length of the line represented by the point b, N° 1; set the proportional compasses in the ratio of b I, N° 1, to b B, N° 2; make c C, N° 2, equal to b B, N° 1; take o P, N° 2, with the shorter ends, and make e E, N° 1, equal to the distance between the points of the remote ends; take g r, N° 2, with the shorter legs, and make g G, N° 1, equal to the distance between the points of the remote ends; join B C; draw C D parallel to M C, and draw E F parallel to e d; draw E F parallel to e K, and G F parallel to g f; draw G H parallel to g l, and B B D E F G H I will be the shadow from one side; draw the lines M L, K J, parallel to b B, c C, &c., to meet K b and I i at L and J, then will M L and K J be the shadows upon the other side.

To find the shadows upon the planes of the face: in the representation of the M line of the arris line, take any point, v, and draw s w parallel to b B, or c C, &c.; also, in the representation of k, of the next arris line, take any point, x, and draw y x parallel to b B, or c C; take the distance d e with the shorter ends of the proportional compasses, and make s w equal to the distance between the points of the longer legs; also take the projection f s with the shorter legs, and make x y equal to the distance contained between the points of the remote ends; through the points s w and y draw L u and J Q parallel to M z, which will terminate the breadth of the shadow upon the face.

The reason of this operation is evident, since the distance that a shadow will be thrown by a line perpendicular to a plane, is as the length of the line; and the shadow of a line parallel to a plane will be projected on the plane parallel to the line which projects the shadow, and that every two parallel lines in the original object are also represented by parallel lines.

PROB. XVI.

The representation of a cylinder with a square abacus or cap being given, to find the shadow of the cap upon the cylindrical surface, the axis of the cylinder being parallel to the plane of projection, and the shadow of a line perpendicular to the axis of the cylinder, and in a plane passing along the said axis, and through the luminaries.

Let A B C D E F G H, fig. 16, be the plan of the cylinder, and H I M N that of the cap; and let W X Y Z be the elevation of the cylinder, and i m u that of the cap, and let I B be the projection or representation of a ray on the plan, from the corner of the abacus at I, cutting the plane of the cylinder at B; draw L F parallel to I B, to touch the semicircle in F, and to cut I M at L; draw F V perpendicular to L F, V being the centre of the semicircle, and F will be the point of contact; in I M take any number of intermediate points J, K, and draw J C, M D, K E, parallel to I B, cutting the semicircle in C, D, E; draw B P, C Q, D R, E S, F T, parallel to the axis of the cylinder, cutting the arc under i of the abacus in p q r s t; set the proportional compasses in the ratio to the distance which I B will throw the shadow, and suppose I B to be greater than the length of its shadow; take the distance I B with the longer legs; make p b equal to the distance contained between the points of the opposite ends; take the distance J C with the longer legs, and make q c equal to the distance contained between the shorter legs; take the distance M D with the longer legs, and make r d equal to the distance contained between the opposite points; and the points b, c, d, will be obtained. In the same manner, the points e and f will be found; through the points b, c, d, e, f, draw a curve, and the curve thus drawn will be the shadow of the upper edge of the abacus; the sun's rays will be in a tangent plane to the cylindrical surface at F f. The part of the edge of the shadow which falls upon the representation of the cylindrical surface from i to b will be straight.

In the same manner, if the representation of a cylinder caped with a square abacus, having the same axis with the cylinder, be given, and the representation of the sun's rays on the plane, supposing the axis of the cylinder perpendicular to the plane of projection, the shadow of the abacus may be found upon the cylindrical surface, and thus for every other prismatic object.

PROB. XVII.

To describe the logarithmic spiral by a series of points to be found in the curve, the centre, and two opposite points in a straight line passing through the centre, being given in the curve.

Let Z, fig. 17, N° 1, be the centre, and let the straight line A E pass through Z, and let A and E be two opposite points, the one, A, on the one side, and the other, E, on the other side of the centre Z; through Z draw G C at right angles to A E: bisect the angle A Z C by the straight line B F; also bisect the angle E Z C by the straight line D H; find Z C a mean proportional between Z A and Z E; also find Z B a mean proportional between Z A and Z C; draw any straight line a X, N° 1, and set the proportional compasses in the ratio of Z A to Z B; take the distance Z A with the points of the longer legs, and find that distance from X to a, N° 1, and make X B equal to the distance contained between the shorter legs; contract the points of the longer legs to X B, and with the shorter legs set off the distance X c; contract the distance between the points of the longer legs, and the parts a b, c d, of the straight line X a, will be in geometrical progression. In the same manner, the points e, f, g, h, i, &c., may be found, which will continue the series of parts as far as there may be any occasion; make Z A, N° 3, equal...
equal to $Xa$, $N$ to $Xb$, $ZC$ equal to $Xc$. 
In the same manner the points $D, E, F, G, H, I, &c.$ may be continued through any number of revolutions; a curve being drawn through all the points will give the spiral required.

Scholium.—As the tracing of the curve depends very much on the eye of the person who performs this operation, by the following method a curve may be drawn with a pair of compasses, provided that the points do not approach very rapidly to the centre. To describe any quadrant, take the length of the radius that bisects its line extremity of the curve, describe an arc, and with the fame radius from the other extremity describe another arc cutting the former; then from the point of intersection of the two extremities, describe another arc between the two extremities, and it will pass through the middle point very nearly; thus, take the distance $ZB$ as a radius; from the extremity $A$ of the arc $ABC$ describe an arc near the centre; from the point $C$, with the same radius, describe another arc, cutting the former near the said centre $Z$; then from the point of intersection describe the arc $AC$, and the arc thus described will pass through the point $B$ very nearly. In the same manner the successive parts of the curve may be described. The curve thus formed will be so near as not to be detected by the eye.

PROB. XVIII.

To draw the representation of the meridians of a solid of revolution upon a plane parallel to the axis of the solid, given an axial section, which is a section of the solid parallel to a plane parallel to the said axis.

Let $abcdeijkls$, (fig. 18.) be the axial section, and $q$ the axis itself, $as$ the base perpendicular to $q$; in $aq$ take any number of points $s, t, u, v$, through these draw $bb, cc, dd, ee, hh, kl$, meeting the curve on the one side at $b, c, d, e,$ and on the other at $i, j, k, l,$ then it is obvious that the lines $bb, cc, dd, ee, hh, kl$, will be bisected; now, supposing the meridians to be formed on the surface of the solid by the intersection of planes at equal angles round the axis, and that one of these planes is parallel to the plane of projection, and let $awfa$ be the representation of that plane; draw $AB$ parallel to $af$: produce $aq$ to meet $AB$ at $w$; from $w$ as a centre, with the radius $qA$ or $gf$, describe the circumference $A 1 2 3 4 5 B$; divide the circumference into five equal parts by the points of intersection $1, 2, 3, 4, 5$; draw $3x$ and $4y$ perpendicular to $AB$, cutting $AB$ at $x$ and $y$, make $ql$ equal to $xy$. Set the proportional compasses in the ratio of $qa$ to $qI$; take the distance $rb$ with the longer legs, and with the opposite legs set off the distance $rm$; then take the distance $se$ with the longer legs, and with the opposite legs set off the distance $sn$; then take the distance $td$ with the longer legs, and with the shorter legs set off the distance $tO$; lastly, take the distance $ue$ with the longer legs, and with the shorter legs set off the distance $up$; then draw the curve $lwmpvn$, which will be one of the meridians as required.

In the same manner, all the others may be found.

Besides the uses of the proportional compasses, which have already been shown, they may be applied to trigonometry in finding the sines and cosines of triangles; suppose in a right-angled triangle, that the two legs were given to find the angles; the analogy is, as the one sine is to the other sine, so is radius to the angle opposite the latter sine: let the proportional compasses in the ratio of the two sines containing the right angle; then the index will show the tangent of the angle on the line of tangents.

Again, suppose the hypotenuse and one of the legs were given to find the angles, the analogy in this will be, as the hypotenuse is to the given leg, so is radius to the fine of the angle opposite to that leg; let the proportional compasses in the ratio of the hypotenuse to the given leg, and the index will be against the fine of the angle.

Lastly, suppose the angles and the hypotenuse to be given, the method of proceeding in this case is exactly the reverse of the last; thus, let the proportional compasses to the fine of the angle, then extend the longer legs to the hypotenuse of the angle, and the shorter legs contain the length of the leg required.

In the same manner, if the angles and one of the legs were given to find the other leg, let the proportional compasses to the tangent of the leg required, then take the length of the given leg with the longer legs, and the distance between the points of the shorter legs will be the leg of the triangle, as required.

PROPORTIONAL PART. See PART.

PROPORTIONAL SCALES, called also logarithms, are the artificial numbers or logarithms, placed on lines, for the ease and advantage of multiplying, dividing, &c. by means of compasses, or of sliding rules.

They are, in effect, only so many lines of numbers, as they are called by Gunter, but made angle, double, triple, or quadruple; beyond which they seldom go. See GUNTER'S SCALE, SCALE, &c.

PROPORTIONAL SPIRAI. See SPIRAL.

PROPORTIONALITY, a term used by Gregory de St. Vincent, for the proportion that subdivides the exponents of four ratios.

PROPORTUM, or PURPORT, in our Law Books, the intention or meaning of any thing. "Secundum proportum dicitur" of any thing, interfert, &c. confpecti"

PROPOSITION, PROPOSITIO, in Logic, part of an argument, in which some quality, either negative or positive, is attributed to a subject.

Chauvin defines proposition, a complete, copious sentence, indicating or expressing something either true or false, without ambiguity: as Xantippe is a bad wife. If anafs fly, he must have wings.

Others, more philosophically, define proposition, a speech uttered or produced, to signify some judgment of the mind. Or, again, a proposition may be defined, a sentence in which two or more ideas or terms are joined and disjoined by one affirmation or negation.

A proposition consists of two terms; the one, that of which we affirm or deny, called the subject; the other, the thing affirmed or denied, called the predicate, or predicate. These two are either joined, or separated, by the intervention of some copula or disjunctive.

Thus in the proposition, God is just; the subject, God, is joined with the attribute, just, by the verb substantive, is. The schoolmen call the two terms the matter, and the copula the form of the proposition.

Now, as terms may be either singular, or common and universal, if the subject of a proposition be a common term, taken in all its extent, the proposition is called universal: as, every anthfe is blind.

This is called a division according to the subject, or a division arising from the quantity.

If the common term be only taken in an indeterminate part of its extent, the proposition is called particular: as, some anthfe are wicked.

If the subject of the proposition be singular: as, George is king of England.

If no term, either of universality or particularity, be prefixed to a subject, in its own nature general, the proposition is indefinite: as, angels are noble creatures.

Those propositions which have only one subject, and one predicate,
predicate, are called single. And these are again either simple or complex: a purely single proposition is that whose subject and predicate are made up of single terms, but if either or both be made up of complex terms, the propositions are called complex; which fee. Tho\'se that have several subjects or predicates, are called compound: each proposition of this kind contains in it two or more propositions, which are either plainly expressed, or concealed and implied. The former are distinguished into six kinds, viz. copulative, disjunctive, conditional, causal, where two propositions are joined by causal particles, relative and dative. The latter comprehend exclusive, exceptive, comparative, as, pain is the greatest affliction; inceptive, and dejective, which relate to the beginning or ending of anything, and continuative, as, Rome remains to this day.

Some writers add under this class of propositions, another division of them into direct and indirect. A direct proposition is that in which a higher or more general thing is predicated of a lower and more particular: as, man is an animal. Others will have it, that in which the subject stands as a matter receiving, and the predicate as a form received: as, Peter is learned. An indirect proposition, according to some, is that in which an inferior is predicated of an higher: as, an animal is man. According to others, it is that in which the subject stands as the form, and the predicate as the matter: as, every rational is man.

Propositions considered with regard to their form or copula, or according to their quality, are divided into affirmative and negative. An affirmative proposition is that when the idea of the predicate is supposed to agree to the idea of the subject, and is joined to it by the word is or are, as, God is a spirit. A negative proposition is when the predicate is not supposed to agree with the subject, and is disjoined from it by the particles is not, are not, &c. as, Man is not innocent.

There is another division of propositions among scholastic writers, into pure and modal; which may be called a division according to the predicate. Propositions are said to be pure, when they imply or involve nothing besides their matter and form, or when they merely express that the predicate is connected with the subject: as, Man is rational. A modal proposition is that which, beside the pure matter and form, involves some mode, or manner of connection between the predicate and the subject: as, it is necessary man be rational. Hence such a proposition is said to consist of a mode and a dictum; the mode denotes some circumstance which affects the proposition; as, it is necessary: the dictum is the rest of the proposition, that man be rational.

There are four of these modes very famous: viz. necessary, possible, impossible, and contingent. Others produce other modes; as, true, false, certain, uncertain, probable, &c.

To modal propositions, some philosophers refer exclamatory, exceptive, and refractive propositions; all which are denoted by a common name, expository propositions, because requiring some explanation to make them clearly understood.

Propositions, according to their sense or signification, are distributed into true and false. A true proposition represents things as they are in themselves, or joins those ideas and terms together, whose objects are joined and agree; or disjoin those ideas and terms, whose objects disagree or are disjoined; as, every bird has wings; a brute is not immortal. A false proposition is that which represents things otherwise than they are in themselves, or joins those ideas or terms whose objects disagree, or disjoin those whose objects agree; as, birds have no wings; brutes are immortal.

Propositions according to their different degrees of evidence, are distinguished into certain and dubious. A certain propo-

ition is that where the evidence of the agreement or disagreement of the ideas is so strong and plain, that we cannot withhold nor delay our assent; which assent is distinguished by the name of knowledge; which fee. (See Certitude and Evidence.) A dubious or uncertain proposition is where there is any obscurity upon the agreement or disagreement of the ideas, so that the mind does not clearly perceive it, and is not compelled to assent or dissent; such uncertain propositions are called opinions. See on this subject, Watt's excellent Introduction to Logic, part ii. chap. 1. and 2.

A syllogism consists of three propositions, major, minor, and conclusion. An enthymeme, of two.

The schoolmen make several other species and divisions of propositions, as, a proposition de primo adjacente, where the subject and predicate are both included under the verb: such are, veni, vidi, vici. Proposition de secundo adjacente is, where either the subject or predicate is included in the verb; as I love, or I write. Proposition de tertio adjacente is, where both the subject and predicate are express, and stand distinct from the verb; as, the king is jilted. This proposition is the rule or standard of all the others; so that whatever proposition can be reduced to it, is legitimate; and what cannot, is not.

Propositions, Contradictory, Contrary, Reduplicative. See the adjectives.

Propositions, Conversion, Opposition, and Reduction of. See Conversion, &c.

Proposition, in Mathematics, is either some truth advanced and shewn to be such by demonstration; or some operation proposed, and its solution shewn.

If the proposition be deduced from several theoretical definitions compared together, as this; a parallelogram is double of a triangle, standing on the same base, and of the same altitude: it is called a theorem.

If it be deduced from a praxis or series of operations, it is called a problem; as to find a third proportional to two given quantities.

Indeed, in philosophy, the proposition is only part of a theorem; viz. that which shews what agrees to such a thing under such conditions, and what not: in which sense it is distinguished from the demonstration, which shews the reason why the understanding conceives that to agree to it.

Again, strictly speaking, the proposition is only a member of a problem, viz. that which shews what is required to be done; in which sense it is distinguished from the solution, which renews the several things to be done in order to effect what is required; and from the demonstration, which proves, that by doing the things enjoined in the solution, the thing required in the proposition is truly done.

Proposition, in Poetry, denotes the first part of an epic poem, in which the author proposes, or lays down, briefly and in general, what he has to say in the course of his work.

The proposition, F. Boffa observes, is to contain the bare matter of the poem, i.e. the action, and the persons that are to execute it, both human and divine.

This is what we have in the Iliad, the Odyfsey, and the Aeneid. The action proposed in the Iliad, is the wrath of Achilles; that of the Odyfsey, the return of Ulyfsey; and that of the Aeneid, the translation of the Trojan empire into Italy.

The same author observes, that the divine persons are named in all three propositions. Homer, e. gr. declares, that what happens in the Iliad, is by the will of Jupiter; and that Apollo was the cause of the quarrel between Agamemnon and Achilles: the same poet says, it was Apollo
Apollo prevented the return of Ulysses's companions; and Virgil mentions the Deities, the will of the gods, and the anger of Juno. But they all three dwell chiefly on the person of the hero, as if he were the matter of the poem.

Yet there is some difference, in this respect, in the three poems; in that Achilles is named in the Iliad; but Ulysses and Æneas are not: they are only pointed at, and that in such general terms, as if it were supposed they were known before.

This practice seems to fall in with the first intention of the poet; who is to feign an action without names, and who, as Arifotole fays, does not relate the action of Achilles, nor Ulysses, nor Æneas, nor any particular perfon, but of an universal, general, and allegorical perfon.

Add to this, that the character which the poet is to give his hero, and his whole work, is expressed in the proposition, both by Homer and Virgil.

The whole Iliad is anger and violence: it is Achilles's character, and it is what the poem commences with. The Odyffeя prefents us in the firft verse with the prudence, diftinnction, and address, which make the charaftcr of Ulysses, and the bifiuenf of the poem: And Άνδρος τολυμφότον. And we fee the piety and mildnefs of Æneas in the beginning of the Latin poem:  "Inifigienm pietate virum."

As to the manner of the proposition, Horace contents himself to prescribe modestly and fimplicity; not to promife much, nor raffe great expectations in the reader. Do not begin, fays he, like that wretched poet, who fet out with, Fortunam Priami cantabo, & noble bellum. How much better is that of Homer, Τίς μην Μ Αίδων, μυλα, virun? &c. He does not spend all his fire at once, and leave nothing but fmoke: From this feeble beginning, you fball foon fee bim rise to the wonder of Antipates, Scylla, Charybdis, and Polyphemus.

The fame mouldly we find in the proposition of the Æneid: if that of the Iliad be a little more furious, it is, perhaps, in conformity to the character of the poem, which is a fequence of violences and extravagances.

Add, that if the poet be to speak with modesty of his hero, much more is he to do fo of himfelf: thus Virgil only fays, Σαισιος αρθον, I fing the action of Æneas. Homer begs his Mufe to fay, or to fing. How far does Claudian fwear from these examples?

"—Audacì promere cantu
Mens congesta jubet; grellus removet, profani:
Jam futor humanos nofiro de peñ* e flofus
Exulpit, & totum spirat præcordia Pæbemu."

A short poem, e. g. an ode, &c. in which the violent train could be purfed to the end, might admit of fuch a pompous beginning. Thus we find Horace begin an ode much after the manner of Claudian:

"Odi profanum vulgus, & areco—
Carmina non prius
Audita Mufaram fæcandos
Virginibus puerisque canto."

But the length of an epic poem quite excludes all pompous propositions.

There is scarcely any fault we have yet observed a proposition liable to, but there is an infance of it in the proposition of Statius's Achilleid: he bids his Mufe render the deeds of the magnanimous son of Æneas, who was formidable even to the Thunderer. He adds, That he has worthily discharged a former undertaking; and that Thébes eftems him a second Amphion.

"Magnanimum Æacidem, formidatamque Tonanti
Progeniem, & patri vetitam incedere colo,
Diva, refer,—
Tu modo, fi veteres digno deplevimus haudus,
Da fontes mihi, Phæbè, novos, &c."

Propofition, in Rhetoric, is that part of a proof and regular discourse, in which the speaker lays down or profoes the subject upon which he designs to treat, in a diftingt and express manner. This firt employs his thoughts, though it ufually follows both the introduction and narration in the order of the discourse. As the proposition is the basis of his whole design, it is neccessary, in the firt place, that this be duly weighed, and reprefented to his mind in all the different views, in which he can place it; that he well considers the nature of it, the several parts of which it confists, and the particular force of each part. By this means he will be the better enabled to offer fuch arguments, as may be proper, in its defence, and to refute any objections which may be brought against it.

Orators ufe feveral methods of laying down the subject of their discourses. Sometimes they do it in one general proposition. We have an infance of this in Cicero's Speech to the Senate, the day after Cesar was killed, as it is given us by Dion Caffius, lib. xliv. p. 250. ed. Leuncav. in which his defign was to persuade them to peace and unanimity. This, fays he, being the flate of our Affairs, I think it neccessary that we lay aside all the diforders and enmity which have been among us, and return again to our former peace and agreement: And then he proceeds to offer his reasons for this advice.

At other times, in order to give a clearer and more diftingt view of their discourse, they subjoin to the proposition, the general heads of the argument by which they endeavour to support it. This method Cicero ues in his seventh Philippic, cap. 3. where he fays: If, who have always commended and advised to peace, am againfle a peace with Mark Antony. But why am I overfe to peace? Because it is bafe, because it is danegourous, and because it is impracticable: and I befpeef you to bear with me your ufal candour, while I make out these things. See Partition.

But fome orations, especially of the demonstrative kind, do not require any particular proposition, being little more than a continued narrative or illuration of the subject: of this fort is that of Cicero, in which he returns thanks to Cesar, in the name of the Senate, for pardoning Marcellus; and his inveftive againft Pifo: as likewise Phiny's panegyrick in prafne of the emperor Trajan. Not but that fuch discourses are difpofed in a regular order, and under proper heads, though they are not laid down at firft in diftingt propositions.

Quintilian, Inftr. Orat. lib. iv. cap. 5. observes, that orators fometimes avoid laying down any direct proposition, when the chief thing they have in view may be disagreeable to thofe whom they address, for which reafon they take them off from attending to it, till they have ftrong prepared them for it, by offering fomething elfe, which, when proved, the other may with fels difficulty be admitted. Cicero makes ufe of this art in his defence of Ligarius. Ward's Or. vol. i. lea. 14.

PROPONENS, in Geography, a town on the W. coast of the island of Celebes. N. lat. 1° 16'. E. long. 119° 15'.

PROPUFECT, PROPHECTUS, among the Romans, the
the prefect's lieutenant; or an officer whom the prefect of the prenotium commissioned to do any part of his duty in his place.

In Gruter, p. ccclxx, the third insurcption mentions prenotiae of the prenotium under Gratian, in the city of Rome, and the neigbouring parts.

PROPREMENT, Fr. Rouxan has given this word a place amongst French musical technics; which in the execution of vocal or instrumental music, seems equivalent to our words, neat and clean.

PROPRETIS, Fr. Newton, English. The same author dehnes the execution of French melody, with all its appropriate agrements, or graces, proprietas, where it means propriety.

PROPRETOR, or PROPRIETOR, a Roman magistrat, who, having discharged the office of prentor at Rome, was sent into a province to command there with his former preteriory authority.

Proprietor was also an appellation given to those who, without having been prentors at Rome, were sent extraordinary into the provinces, to administer justice with the authority of prentors.

Proprietor is also a denomination given by some to those sent by the emperors into the provinces, which, upon partition in Augustus' time, fell to their lot: as the name propreful was given to those sent into the provinces that fell to the people's share.

PROPRIETY Governments in America. See the account of Charter Governments.

Proprietary Monks, were such as had reserved goods and effects to themselves, notwithstanding their formal renunciation of all at the time of their profession.

They are frequently mentioned in the Monast. Anglic. &c and were to be very feverely dealt with; to be excommunicated, deprived of burial, &c. "Monachi propriarii excommunicatur abbatibus, & ibi in morte proprietarius invenit, ecclesially careat sepulta, &c." Addit. ad Matt. Pat.

PROPRIETATE PROBANDA, in Law, is a writ to the sheriff to inquire of the property of goods divided, when a defendant claims a property upon a replevin sued.

Where a property is proved by the defendant, a repregiary properly lies not.

PROPRIETATIS ELIXIR. See Elixir

PROPRIETOR, or Proprietary, he who has the property or propriety of any thing.

Proprietor, in Law, is strictly such a one as has, or poiffesses, any thing as his own in the utmost degree; "Quae nullius arbitrio off obnoxiae." The term was formerly applied, in a particular manner, to him who had the fruits of a bencfe to himself, and his successor; as in ancient time, abots and priors had.

PROPRIETORS of Land, in Agriculture, such persons as hold landed property. It is observed by the author of the "Present State of Husbandry in Great Britain," that the lands in England and Wales are, at no very remote period, chiefly in the possession of the crown, the church, and great proprietors; but that, owing to several causes, noticed below, landed property has become of late more widely diffused, and new orders of proprietors have risen into confection, which has proved greatly advantageous to the state, not only in regard to improvements in husbandry, but also to the advancement of all the other arts.

The extent of landed property formerly vested in the crown, was very considerable; but during several reigns many imprudent grants were made to particular favourites, whereby it became much diminished. From the report given into parliament some years ago by the commissioners appointed to inquire into the landed revenues of the crown, it appears that the old and improved rent then payable, amounted only to £15,284l. 12s. 3d. The real annual value, however, far exceeds this sum; for, in the same account, it is stated, that the lands and eifates from which the above-mentioned rent is payable, were, by the latest surveys, ascertained to be worth 102,562l. 14s. 1d. per annum. The writer, however, disclaims any intention of throwing out the most diftant personal reflection to the prejudice of those in the management of the crown lands. It is well known, that these eifates are commonly let on leases of one, two, or three lives, or for a great number of years, on every renewal of which, fines (in Scotland called graffias) are exacted. These fines, paid at the commencement of the leases, and improved by compound interest during the currency of them, may perhaps in the end exceed, in some cases, any yearly additional rent that could be demanded.

It is suppos'd that it is impossible to form any correct idea of the lands now in possession of the church. They are commonly let on leases of twenty-one years, renewable every seven, on payment of a fine; and therefore the rent-roll must be rather nominal, than such as can convey any information in regard to the real annual value of the property. Suppose the clergy of England had a right to the tythes over the whole kingdom; that all the parishes were inclosed; and that an allotment of land was given in every case, in lieu of tythes, a judgment might be formed of the extent of land that would fall to be poiffessed by them, from the rule frequently adopted by those who act as commissioners under acts of parliament paff for inclosing certain parishes, namely, giving the clergymen one-sixth of the arable, and one-ninth of the pasture, or two-thirtieths of the whole. Including the lands in the possession of the religious corporations, it is probable they might amount to nearly one-fifth of the whole kingdom.

And it has been observed, that while the feudal system existed, the lords and great proprietors parcelled out considerable parts of their eifates among their vassals and dependents. Since the abolition of that system, the poiffessors of these lands have been generally known by the name of yeomen; a most niefeful and valuable class of men, who are at present proprietors of no inconsiderable share of the landed property of England. And the recent very great increase in trade and manufactures, and the consequent influx of money, have tended still more to the division of property, by the creation of a great number of small freeholds. Proprietors of extensive manors, who find it necessary to dispose of their eifates, (and this will happen in every country where the practice of entailing landed property does not prevail,) judged it for their interest to parcel them out in small lots, rather than sell them in entire manors. This having been for years the general practice, especially when the eifates were situated in the vicinity of great cities, or large manufacturing towns, merchants, and manufacturers, and the officers of our fleets and armies, have had opportunities of exercising that degree of genius and persevering industry in planning and executing agricultural improvements, which in the early part of life enabled them to lay the foundation for becoming proprietors. It is, therefore, concluded that the proprietors of England and Wales may be classed into two divisions. The crown, the religious corporations, or clergy, and the great landholders, or those who poiffess from 5000l. to 50,000l. a-year and upwards, form the first clafs; and probably poiffess nearly three-fifths of the whole. The second division, con$isting of that great body of gentlemen, holding
ing estates from 400l. or 600l. to 4000l. or 5000l. a-year; and the yeomanry, or those who possess from 30l. or 40l. to 50l. or 60l. of yearly rent; who are in possession of the remainder. These divisions have been much extended in the course of the last half century, and are still extending very rapidly.

In Scotland, however, the writer remarks, the crown can hardly be said to possess any landed property. But it is only a few years since that was the case; for, in consequence of the rebellions which happened in the years 1715 and 1745, the estates of several noble and respectable families were forfeited and annexed to the crown, on account of the active concern which the then proprietors took in those rebellions, in opposition to the established government. Highly to the honour of the British legislature, however, such of these estates as were unfold and annexed to the crown, were lately restored to the representatives of those families by act of parliament; an act which experience has already proved was politically right; as almost all the proprietors of those estates are now evincing their gratitude to their king and country, by exerting their utmost endeavours in the defence of both.

But here, previous to the abolition of popery in the year 1560, the clergy possessed landed property to a very great extent, but at that period the great proprietors who had (with a view to promote their own interests) encouraged and supported the promoters of the Reformation, when it was effected, feized on all the church lands, and in lieu thereof, and of the tythes which were formerly payable, allotted a certain quantity of money, or grain, or both, with a house, and a few acres of land, for the support and accommodation of each Protestant clergyman. As proprietors, therefore, this respectable, useful, well-informed, and deserving body, amounting to upwards of 900, rank very low, in comparison of what their predecessors did; for, in consequence of their offices, they only possess about 6000 acres of arable land. In this part of the kingdom, the feudal system was not only carried to a greater extent, but continued much longer in force than it did in England; and as manufactures and commerce began to flourish here only since the middle of the last century, a greater proportion of the landed property still remains in the hands of great proprietors, especially in the northern and more remote districts, where trade and manufactures are comparatively but little known. In Scotland, great proprietors alone, or those holding estates from 4000l. or 5000l. to 25,000l. a-year and upwards, may be said to be involved with the one-half of the whole kingdom. The other half is more generally divided; the greatest part of it being possessed by a numerous and respectable body of gentlemen in estates varying from 300l. or 400l. to 4000l. or 5000l. a-year, and the remainder by such as possess from 30l. or 40l. to 300l. or 400l. of yearly rent. There are not many of this last description, who, like the English yeomen, cultivate their own estates; being for the most part engaged in the naval, military, or civil departments of the state, few of them reside constantly in the country.

Mr. Marshall has remarked, in his work on landed property, in speaking of the management of estates, that the principal objects to be regarded are tenants farms, and their inhabitants, whether occupiers or labourers. And that the others are woodlands; which are now generally, and properly, kept distinct from tenant farms; excepting such plots as are requisite to the due occupancy of the farm lands. Also the waters and quarries that are not let with the tenant lands; and mines, whether in hand or tenant: together with the abstract rights attached to an estate; as tithes, manorial rights, chief rents, &c. &c.

And, lastly, demeane lands, whether they are kept in hand, for domestic purposes, or as a remnant of improvements for the use of the estate. The importance of which are, he thinks, obvious, for, says he, it were folly to purchase an estate, and equally imprudent to improve one, unleas to be afterward duly managed; so as to secure a profitable return for the money laid out. But that, before the profits which issue from landed property, there are other considerations which the proprietor of a tenanted estate cannot overlook. He differs essentially from the possessor of ordinary property. He is not in possession of the lands only, but also of their inhabitants. For, although in England tenancy are not bought and sold, as other live stock; yet when an estate is under lease, tenants may be said to be as firmly rooted in the soil as the oaks are which grow upon it. And even where tenants are at will, and labourers without certainty, such are, in general, their attachments to their native soil, and their natural connections, that to be driven from them is banishment—a patriot prejudice, which is planted in human nature, and which ought to all times, and especially at present, to be kindly cherished. And in this country the possessor of an extent of territory has infinitely more power over its inhabitants than government itself. He may not only banish the native inhabitants, but he may depopulate the country, or may increase its population, as to his pleasure may seem meet. By changing the inhabitants, he may change the manners of a country, as from vice to virtue, or the reverse; and has it thus in his power to render the little world around him, as well as himself, miserable or happy; according to the principles of management he pursues. What inducements there are to men of fortune, to bend their minds cheerfully to their territorial concerns, and improve them in the best and most advantageous manner. See Tenant, and Farm.

However, though the promotion of such improvements be obviously of the greatest consequence and advantage to such proprietors as well as the public, they are in many cases strangely neglected, and even in some disencumbered. It has, indeed, been observed in a paper in a useful periodical work, the writer of which, after stating that the situation is highly favourable, the tenantry, eager to improve their farms, knowledge diffeminatet, and capital accumulated, that strange as it may appear, many very considerable land owners rather betray a disposition to retch, than to expedite real improvements. The terms of the leases are often arbitrary, and the landlord is too often reluctant in contributing a reasonable proportion towards permanent improvements, which are in themselves absolutely necessary, and of which it is equally prepotent and unjust to exact or expect the execution totally at the tenant's expense, more especially as the usual duration of his lease is seldom adequate to indemnify him. Even some proprietors do not only contribute reluctantly, but nearly refuse every portion of their interest. They accept the highest offer for the naked farm, and provided the stipulated rent be regularly paid, they appear indifferent how the tenant accommodates himself. They, indeed, express wishes to see their lands improved, but the honour of their motives may be doubted. Straightened circumstances do not by any means seem to form an excuse for this backwardness. It perhaps ought to be attributed to jealousy against their inferiors, and a desire of immediate aggrandisement, by pocketing an additional income without deduction. Such reasons as these are, however, entitled to no merit. But he does not intend to throw out reflections on all the land owners in his part of the country; for if some of them had not adopted a more liberal way of proceeding, agriculture would never have made the progress
among us which it has already done; at present, it would, however, be easy to prove that the landlords are, upon the whole, more backward than the tenantry. Many do not choose to become converts to their real interests, or to the lasting good of their country, but prefer a continuance of their liberal policy of laying hold of what they can at the time, and allowing futurity to shout for itself. Under such a fylem, the tenant must be a drudge: his mind, broken down by his situation, disqualifies him for exertion, even though the necessary means were to come into his possession.

His family, rudely educated, are only fit for labourers or low mechanics; and one great link of the chain which connects an enlightened society is thus rejected or destroyed.

It is the advice of Mr. Middleton, that every proprietor of a large landed estate should occupy one of his own farms, which, by being cultivated on the most improved scientific principles, may teach the neighbouring tenantry the best practice, by the most powerful of all means, that of example. If this, which seems to be at present more attended to, was general, much advantage no doubt would be the consequence of the proceeding.

**PROPRIETY**, in Grammar, is where the direct and immediate significancy of a word agrees to the thing it is applied to.

In which sense propriety is used in opposition to a figurative or remote significancy. Propriety of language denotes the selection of such words as the best usage has appropriated to those ideas, which we intend to express by them; in opposition to low expressions, and to words and phrases which would be less significant of the ideas that we mean to convey. To preserve propriety in our words and phrases, we must avoid low expressions; supply words that are wanting; take care not to use the same word in different senses; avoid the injudicious use of technical phrases, equivocal or ambiguous words, unintelligible expressions, and all such words and phrases as are not adapted to our meaning. See Murray's Eng. Gram. vol. i. p. 411, &c.

**PROPTOMA, or PROPTOSIS, from τρόπος to fall out, in Surgery, a falling down, or displacement, of any part of the body.**

**PROPYLÆUM, προπύλαιον, the porch of a temple, or great hall. See ATHENS.**

Hence propyleum is also used figuratively, in matters of learning, for an introduction, apparatus, or prodomus, to some greater work. In this sense, we say, the propyleum of the Jefuits at Antwerp, &c.

**PROQUESTOR, PROQUÆTOR, the queller's lieutenant, or a person who discharged the office of queller in his stead, without the deputation of the senet.**

The word is chiefly applied to an officer appointed by the governor of a province to discharge the queller after the decease of the queller, or when he went to Rome without being succeeded by another queller, till the senate and people should send a new one.

**PROÆ OS, in Anatomy, a bone of the cranium, called also os occipitis.**

**PRO RATA, in Commerce, a term sometimes used among merchants, for in proportion.**

Thus, when speaking of any undertaking, they say, each person must reap the profit, or fulfill the loss, pro rata to his interest; it is meant, each shall gain or lose, in proportion to the sum he put in stock.

**PRO RATA Portionis, in Law. See ONERANDO pro rata portionis.**

**PROROGANDA Assisa. See Assisa.**

**PROROGATION, PROROGATIO, the act of prolonging, adjourning, or putting off, to another time.**

**PROROGATION of Parliament. See Parliament.**

The **proroguing** of the lower house of convocation is a power vested in the archbishop with the consent of the suffragans.

**PROSAIC NUMBERS.** See Numbers.

**PROSCASCO, in Geography, a town in Italy, in the Friuli; eight miles N. of Friuli.**

**PROŞCARABÆUS, in Zoology, the name by which some call the meloe, a genus of four-winged flies. See Oil Beetle.**

**PROSCENIUM, in the Ancient Theatre, was an eminence on which the actors performed their parts.**

The proscenium answered to our stage. It consisted of two parts among the Greeks; one particularly so called, where the actors performed; the other was the logion, where the fingers and the mimics acted their parts. Among the Romans, the proscenium and pulpitum were the same thing.

**PROSCHÆTERIA, πρόσχατερα, in Antiquity, a day of rejoicing, kept when a new-married wife went to cohabit with her husband.**

**PROSCHEWA, in Geography, a town of Prussia, in the palatinate of Culin; 18 miles N.E. of Thorn.**

**PROSCHOWITZ, a town of Austrian Poland; 55 miles E.N.E. of Cracow.**

**PROSCLYSMA, a word used to express an irration, or sprinkling of any part with a fluid, as the throwing water in the face in cases of fainting, &c.**

**PROSCRIPTION, PROSCRIPTIO, a publication made in the name of the chief or leader of a party, by which he promises a reward to any one who shall bring him the head of one of his enemies.**

**Sylla and Marius, by turns, proscribed each other's adherents. Under the triumvirate, a great part of the bête and braves of the Romans fell by proscription.**

The term took its rise from the practice of writing down a list of the peron's names, and polting it in public; from pro, and fribus, I write.

**PROSDEOCEMUS DE BLODEMANNIS, in Biography, was one of the earliest writers on music, at the beginning of counterpoint. Among the Vatican MSS. there is a treatise on music in parts or counterpoint, by an Italian of this name, written in 1412. It is chiefly an exposition and commentary of the doctrines contained in the "Practica Mendablemus" of John de Muris, in his "Speculum Musicum." Padre Martini was in possession of the tract of John de Muris, under the title of "Practica Mendablemus Cantus: Mag. Joan. de Muris, di Normandia, alias Parisenfis, cum expost Prosfeci de Beldeamandis patav. MS. an. 1404."

**PROSE, PROSA, the natural language of mankind, loofe, and unconfined by poetical measures, rhymes, &c. In which sense it stands opposed to versfe.**

The word comes from the Latin profe, which some will have it derived from the Hebrew poras, which signifies expendit; others deduce it from the Latin pro fines, or prorsus, going forwards; by way of opposition to versfe, or turning backwards; as is necessary in writing verse.

Though profe hath its connexions, which fultain it, and a structure which renders it numerous, it ought still to appear free: its character conflits in running eafy, and unrestrained.

Poets very rarely have the talent of profe; the habit of wearing chains fitsfall upon them, even when the chains are off. St. Evremond compares profe writers to foot-travellers, who walk with lefs noise, but more security, than the cavaliers.

**PROSEKNEN, in Geography, a town of the duchy of Magd.-burg; seven miles N. of Wifmar.**

**PROSECUTION. To make men liable to criminal prosecutions**
prosecutions by the law of England, it is required that they have the use of reason, and that they be *fut juris*. On the first account the law indulges that infants under the age of discretion, idiots, and lunatics, whatever the nature of the fact may be; and even against the person of the king, as it has been held of late; neither will it suffer one who becomes *non compos* after he has committed a capital offence, to be either arraigned or executed. See *Lunatic*, and *Infant*.

As to an offender's being *fut juris*, it is to be observed, that neither a son, nor a servant, nor any other person, except a femer covert, is excused on the account of acting by command or coercion of another. See *Feme covert*.

The prosecution in the several proceedings towards the punishment of the offender proceeds upon the commitment, and denotes the manner of their formal accusation. This is either upon a previous finding of the fact by an inquest, or grand jury, or without such previous finding. The former mode is either by *prevention*, or *indictment*, which fee. The other methods of prosecution are without any previous finding by a jury, to fix the authoritative stress of verifimilitude upon the accusation. One of these, by the common law, was when a thief was taken *with the mainour.* (See *Mainour*.) This was taken away by several statutes; so that the only species of proceeding at the suit of the king, without a previous indictment or commitment by a grand jury now seems to be that of information, which fee. There is another method of prosecution, at the suit of the subje, called an *appeal*, which fee.

**Prosecution of Felons.** See *Larceny* and *Rewards*.

**PROSECUTOR, in Law,** is he that pursues a cause in another's name.

In criminal proceedings, or prosecutions for offences, the king is prosecutor. All offences are either against the king's peace, or his crown and dignity; and are so laid in every indictment. For though in their consequences they generally fear (except in the case of treason and a very few others) to be rather offences against the kingdom than the king; yet, as the public, which is an invisible body, has delegated all its powers and rights, with regard to the execution of the laws, to one visible magistrate, all affronts to that power, and breaches of those rights, are immediately offences against him, to whom they are so delegated by the public. He is therefore the proper person to prosecute for all public offences and breaches of the peace, the person injured in the eye of the law. See *King* and *Preliminary*.

**PROSEG, or Proseco, in Geography,** a town of Istria, celebrated so long ago as the time of Augustus for its wine, so that his wife Livia used it as a cordial in her old age; its qualities are described by Pliny. The ancient name of this town was *Peucetium;* seven miles N.W. of Trieste.

**PROSELYTE, Proselytus, a new convert to the faith.**

The word is Greek, προσελθω, which, in Latin, signifies *advena*; in English, stranger, or one arrived out of another country.

The term was much used in the primitive church. The Jews too had their proselytes, who, from being Gentiles, embraced Judaism; either wholly, or in part.

Among the Hebrews there were two sorts of proselytes; one called *proselytes of righteousness*, or *proselytes of the covenant*, who became complete Jews, by submitting to the rite of circumcision, and were in all respects united to the Jewish church and nation; they were denominated proselytes of the covenant, because they were received into the covenant of God by circumcision, which was named the blood of the covenant, because, according to St. Paul (Gal. v. 3.) men were bound by it to observe the ceremonial law; and they were called proselytes of righteousness, on account of their acknowledging and observing the whole ceremonial law, to which the Jews, and the Pharisees in particular, attributed their being accounted righteous before God. At their admission there were three ceremonies performed: circumcision, baptism, and a sacrifice, generally consisting of two turtle doves and two young pigeons. After these ceremonies the proselyte received a new name, and no longer owned any relations in the world. See John iii. 3., Luke, xiv. 21., 2 Cor. xx. 16., Eph. v. 10., Acts ii. 2.

It is said in the Talmudical writings, that though they were regarded as Jews, they were admitted to no office, and were treated with great contempt.

The latter were called *proselytes of the gate*, who did not embrace the Jewish religion, so as to be obliged to receive or observe the ceremonial law, and yet were suffered to live among the Jews under certain restrictions; as that they should not practice idolatry, nor worship any other god before the God of Israel; that they should not blaspheme the God of Israel; that they should keep the Jewish sabbath, so far as at least as to refrain from working on that day. Besides forswearing idolatry, they were under an obligation to observe the seven precepts, which, as the Talmudists pretend, God gave to Adam and afterwards to Noah, who transmitted them to posterity. The first of these precepts forbids idolatry, and the worship of the stars in particular; the second recommends the fear of God; the third forbids murder; the fourth adultery; the fifth theft; the sixth enjoins respect and veneration for magistrates; and the seventh condemns eating of flesh with the blood. This law, as the Rabbins say, was added after God had permitted Noah to eat the flesh of animals. No ceremony was performed at the admission of these proselytes. Maimonides expressly says, that they were not baptized. These strangers were permitted to worship the God of Israel in the outer court of the temple, which, for that reason, was called the court of the Gentiles.

Dr. Lardner, with whom Dr. Doddridge and others also agree, is of opinion that there was but one sort of proselytes among the Jews. They were circumcised, and thus they became Jews by religion, and were admitted to eat the passover, and to partake of all religious privileges, as the Jews by descent did. They were called "strangers, or proselytes within the gates, and sojourners," as they were allowed to dwell, or sojourn among the people of Israel. And they were so called, because they could not possess land. For according to the law of Moses, the whole land of Canaan was to be given to the 12 tribes of Israel, the descendants of the patriarch Jacob. (See Exod. xii. 48. 49. Lev. xvi. 8. 13. 15. Num. xix. 14. xv. 15.) A proselyte was a man circumcised according to the law of Moses, or a Jew by religion. This is the sense of the word in all the texts of the New Testament where it is used. (Matt. xxviii. 15. Acts ii. 20. vi. 5. xiii. 43.) Dr. Lardner thinks that the notion of two sorts of Jewish proselytes cannot be found in any Christian writer before the 14th century or later. Cornelius is not called a proselyte in the New Testament. This learned writer pays no regard to what the later Jewish Rabbinists say of the method of initiating proselytes by circumcision, baptism, and sacrifice. See Lardner's Works, vols. vi. and xi. Doddridge on the Acts.

**PROSELZHEIM, or Broselheim, in Geography,** a town of the duchy of Wurzburg; seven miles N.E. of Wurzburg.

**PROSENDOF, a town of Bavaria; five miles N.N.E. of Bamberg.**

**PROSPÉRINA, in Botany,** a name given by some authors to chamomile.
PROSERPINACA, said by Linnaeus to be derived from Proserpinda, from its creeping. It is also, according to Marty

Gen. Ch. Cal. Perianth superior, of three cleft, acute, permanent leaves. Cor. none. Stam. Filaments three, awl-shaped, spreading, the length of the calyx: anthers twin, oblong, acute. Pfl. German inferior, triangular, very large; style none; stigmas three, downy, thickish, the length of the flaments. Peric. Drupa small, dry, ovate, triangular, three-winged, crowned by the permanent, closed calyx. Seed. Nut rather bony, triangular, three-celled; kernels oblong, affixed to a thread.

1. P. palustris. Linn. Sp. P. l. 129. Aét. Upf. for 1741. 81. (Trixis palustris; Grat. n. t. 24. f. 8.)—Leaves linear-lanceolate, serrated, the bottom ones pinnatifid. Native of ditches and pools between Canada and Carolina, flowering in July.—Root annual, creeping. Stems a foot high, roundish. Leaves alternate, falked; lower ones imornaed, pinnatifid, with linear segnents. Flowers axillary, solitary. Nut whitish, with a pale reddish kernel. Linnaeus says the fruit is like that of a Polygonum.

2. P. peclinata. Pursh. v. t. 92. Lamarck. Illistr. t. 50. f. 1.—Leaves all pinnatifid in a pedyminate mannter.—Found in overflowed places, and ditches, from New Jerffy to Carolina, flowering in July and August. Michaux confiders this but as a variety of the last species, and calls it P. palus- tris B, but Pursh thinks it is certainly a distinct species. He never found the two growing promiscuously, or near one another. We adopt this entirely on the authority of the latter author, without having never seen either a specimen, figure, or description.

PROSERPINE, in Mythology, the daughter of Jupiter and Ceres, wife of Pluto, stolen by him out of Sicily, and carried to his subterranean dominion, where she was the partner of his empire. The poets and painters represent her with a dark complexion, and a melancholy air in her face. Statur (Theb. 8. v. 11.) affirms her the employment of keeping a register of the dead, and marking down all that should be added to that number. He also says, (lib. 5. Sylv. 1. v. 257.) that when any woman dies who has been a remarkable good wife in this world, Proserpine prepares the spirits of the best women in the other to make a proccision to welcome her into Elysium with joy, and to strew all the way with flowers where she is to pass. See Ceres and Koreia.

PROSEUCHÆ, derived from προσεύχη, prayer, or ora-
tories, in Antiquity, were the places of prayer among the Jews, and nearly the same as their synagouges. But the synagouges werc originally in the cities, and were covered places; whereas, for the most part, the proseuchæ were out of the cities, and upon the banks of rivers, having no covering, except, perhaps, the shade of some trees, or some covered galleries.

Dr. Prideaux mentions another distinction in respect to the service performed in them; in synagouges, he says, the prayers were offered up in public forms in common for the whole congregation; but in the proseuchæ they prayed as in the temple, every one apart for himself. Comm. part 2. book 6. vol. ii. p. 556 &c. edit. 10.

After all, it remains a question with some whether the synagogues and the proseuchæ were anything more than two different names for the same place; the one taken from the people's assembling in them, the other from the service to which they were more immediately appropriated, viz. prayer.

PROSKAUR or PRUKSAUR, in Geography, a town of Silefia, in the principality of Oppeln; 6 miles S. of Oppeln. N. lat. 56° 31'. E. long. 17° 51'.

PROSKEN, a town of Pruflia, situated on the Lick; 10 miles S.E. of Lick.

PROSLAMBANOMENOS, in the Ancient Greek Musit', was the first note of their scale, whether ascending or descending.

It was usual among the Greeks to consider a descending as well as an ascending scale; the former proceeding from acute to grave, precisely by the same intervals as the latter did from grave to acute. The not distinguishing of these two scales has led several learned moderns to suppose, that the Greeks, in some centuries, took the proslambanomenos to be the lowest note in their syllem; and in other centuries to be the highest. But the truth of the matter is, that the proslambanomenos was the lowest or highest note, according as they considered the ascending or descending scale. The learned author of this remark, thinks this distinction of the ascending or descending scales conducive to the variety and perfection of melody: but he says, he never met with above one piece of music, where the composer appeared to have any intelligence of that kind; and this piece was above one hundred and fifty years old.

We with the author had told us where this piece of one hundred and fifty years old was to be seen, and by whom it was composed: as we are not yet convinced of the Greeks having a descending as well as an ascending scale; though Dr. Pepu/eh affirms roundly, and without the least modification of doubt, or even coincedes to allege a single reason or proof in defence of his opinion, that it was usual among the Greeks to consider a descending as well as an ascending scale; the former proceeding from acute to grave, precisely by the same intervals as the latter did from grave to acute. The first found of each was the proslambanomenos." Phil. Trans. N' 1766. xi. 226, and Marty's Abrigd. vol. x. part 1. p. 261.

No instances of these inverted scales are to be found, however, in Aristoxenus, Euclid, or any of the oldest and best writers. Boethius, Brenninius, and some other of the more modern compilers, have, indeed, puzzled the ear by ambiguous expressions, which seem to bear such construction. Meibom. in Gaudenc. p. 33. et Wallis in Brenninus, p. 364, et seq.

It seems, however, as if all this doubt and perplexity had arisen from the want of precision in the musical nomenclature of the Greeks. The prepositions προς, μια, μιας, περί, and the adjectives προς, μας, μας, μας, have manifestly been applied to sounds more to express their situation in the stave and diagrams, than the length of the strings, or the gravity and acuteness of their tones.

Dr. Wallis, in his Appendix to Ptolomy's Harmonics, explains this difficulty in the following manner.

"The Greeks called hypate, supreme, though it is the lowest found or string of the tetrachord; and μέθα, μέθα, or lowest, though the most acute. (This Henry Stephens acknowledges at the word μιας, that he defines ultimam fumim: and parameter, itna proximam); therefore those who
P R O

first made use of these names, applied them differently from us, calling grave, high, and acute, low. And thus Nicomachus, p. 6, calls Saturn, the highest of the planets, Hypate; and the moon, the lowest, with respect to us, Nete. Boethius, likewise, in his Treatise on Music, places, in all his diagrams, the low founds at the top, and the high ones at the bottom. But, he concludes, that we must not attend to the original import of these words, sumus and imus, but understand hypate and nete as *field* and *left*, or *principal* and *extreme*, as Aristides Quintilianus has done, p. 10.3

In the first, or Mercurian lyre, the longest string, which produced the lowest sound, from being placed highest in the instrument, as is the case with the modern harp, was called hypate, the *highest* found; and nete, for the same reason, was afterwards, upon the extension of the scale, called *lowest*, though the most acute. Trite, the third string from the top of the two last tetrachords, had its name, as in our violins, by comparison with the smallest strings. From a passage in Aristides Quintilianus, it seems as if the Greeks, in naming and numbering the notes of their scale, made it a rule always to go *towards* mele, and end with it, as being the regulator of the other notes, and situated in the *medium* of the voice. This is confirmed by the problem of Aristeotle already cited, and this confirms what has been already observed of the order of the alphabetic notation, in which mele is always expressed by omega. It seems, therefore, as if the Greeks ascended the lower octave of the diapason, and descended the upper one; otherwise it is not easy to see why the strings of the upper octave should have names referring, as they evidently do, to a descending series, in an order opposite to those of the lower octave.

Tones, in the compound names of the notes, evidently means *next in order*; parpate, in the lower octave, then is *accent*; paranete, in the upper octave, plainly *defect*. The name is implied in tripe. But the term nete, *left*, looks very like accent again — *And darknes was upon the face of the deep!* — These contradictions may account in some degree for the great perplexity about the scale; they are curious however, and as well worth observing, perhaps, as any matters of this kind.

The prosolambanomenos was one of those founds which the ancients called *stables*, from their remaining fixed throughout all the genera and species.

For a farther account of the prosolambanomenos, see Greek Music.

PROSNITZ, or Prostigow, in Geography, a town of Moravia, in the circle of Olmutz; 8 miles S.S.W. of Olmutz. N. lat. 49° 35'. E. long. 17° 3'.

PROSODIA, ποιονια, in Antiquity, a sacred song, or hymn sung in honour of the gods. It differed from the prosodia with an omega, ποιονια, which was a song sung in concert with some musical instrument.

PROSODIUM, ποιονιον, according to Jul. Pollux, was the name of a canticle in honour of Apollo, composed by Eumelus of Corinth, cited by Paulanias and Athenaeus, as one of the most ancient musicians of Greece.

PROSOY. Though it has been observed that prosody, according to its derivative acceptation from ποιονιον, chiefly signifies the accent of syllables, yet both in its generally received and enlarged sense, as well as from its derivation ποιος; and ἀριθμός, it implies, as the sequel will exemplify, all that can affect *articulated* harmony, in verse or prose. It is common, therefore, to include under this term, accent, *emphases*, *quantity*, *pause*, *tone*, and the laws of *verification*. Our remarks concerning the two former have been already given, as our readers will find, in the alphabetic series of this work; and on which we shall here offer nothing more than what is required by a precise and accurate explanation of the third particular of this article, or

QUANTITY.—From the many that have written on this subject, and that have assigned, with much precision and care, rules to determine the quantity of the syllables composing the ancient languages, we might almost naturally infer, that what syllabic quantity actually was among the ancients, is, at this time, known amongst the moderns; but the case is otherwise. To determine whether a syllable is long or short, and to produce our rule from the grammarian or the poet, are by no means difficult; but to define what quantity was, in the age when its nature was not determinable from the mouldering manuscript, or the hieroglyphic symbols of our modern ciphers; when the criteria for the ear, which Quintilian declares cannot be ocularly estimated, were obtained from the only legitimate and effectual source, the vita vox, is a task too arduous for us to undertake; at least at a time when the lip and the tongue, the proper proprietors of this faculty, are fallen into dust; and all that was once argumentative in the senate, eloquent in the forum, and harmonious on the stage, are now but silence and oblivion. From the ashes, however, we, together with every tribe of antiquarians, have gleaned our quota; and from the scattered fragments, the imperfect records, the broken monument, the sepulchral mansion, and the relics of the general ruin, have very shrewdly, in common with our fagacious brethren, collected, what we call, our rules, when, alas! they are but conjectures.

To obtain an adequate idea of the difficulties attending a just perception of the ancient elocution, we must recollect, that not only were there fifteen vowel sounds, represented by fix letters, but each of these was again susceptible of one of three accents, the acute, the grave, or the circumflex. And though the Greeks remedied this in part, by two additional characters, yet to express the mere duration of their syllables, there remains an obvious deficiency. Besides, every intelligent observer will admit, that elocution is nothing but a species of music, since every thing implied by the duration of a syllable, the mood or general time of delivery, accent, emphasis, pause, tone, and cadence, are properties which may be very adequately expressed on paper, in musical composition, or, more completely, by a good organ. The duration of a syllable is perfectly analogous to the relative difference between a minim and a crotchet; the mood, to the general time, whether quick or slow, observed in the whole composition; accent and emphasis, being an elevation or depression of the voice, are actually the variation from one note to another; pause is, by musicians, under the term a *rest*, only changed in name; tone, implying all that modulation of the voice effected by the tranquil, plaintive, or enwrapped mind, is what the complete organ very nearly effects by the different tones termed the diapason, fessiquarter, principal, and, occasionally, by the swell; and the cadence is but the return of the air and notes to the same key to which the whole composition is set. Though these several properties are comprehended but seldom in the idea of all that is requisite to read an oration, or a poem, yet they do not exceed, but are really short of the qualities that constitute the complete orator, or the poet. Hence we easily perceive, that of all that once gave eloquence to the orations of Cicero, and harmony to the strains of Virgil, we now retain but a concatenation of vowels and consonants, and, comparatively speaking, but a lifeless syllilation. Notwithstanding, however, this latitude for doubt, and the difficulties to which the question is liable, several, with little hesitation, define the quantity of a syllable to be the duration of the voice in pronouncing it. But whilst this, on
PROSODY.

the one hand, renders the whole poetic fabric consistent, it is, on the other, not a little at variance with the customary and established pronunciation of many who are amongst the principal advocates of prodigious orthoepy, as well as with the manner in which the language is frequently pronounced among the moderns, at least by the British nation at large. To the youth committed to our care, we prefer the laws of quantity, and oblige them, on pain of disciplinary con-sequences, to pronounce the first syllable of *prògagus* short, and that of *cópia* long, because the former is a tri- brac, and the latter a dactyl; but we not only allow them, but accustom ourselves to pronounce *népos, fides, globus, and conjunctivum*, as though those several syllables were respectively long. And thus, whilst we contend that every syllable, foot, and verse, ought to have its due and requisite quantity, and, in partial instances, discontinue the violation of either; and whilst we define this quantity to be a duration of the voice, in such a manner that a long syllable shall occupy twice the time of a short one, and that a dactyl shall equal, in the duration of time, a spondee, in any case where habit, however degenerate, has formed our prepos-session, we admit violations, with the loss of metre, equally incompatible. Thus, in pronunciation, we give the same time to the iambic foot, the pyrrhic, and the dactyl; as we do to the spondee, the choree, and the tribrac; and with equal facility convert the tribrac and the anapest into the dactyl; and the acatalectic hexameter into the brachyca- tectic, or rather into what is at once delitute of all rule or defi- nition. This is certainly an evident incoherency, the dif-creditable continuance of which becomes a greater impediment to the prodigious acquisitions of youth than is generally imagined, and demands not only the consideration, but the agreed and united disjunction of all that advocate the cause of classical erudition.

The English are accused, not only of departing from the genuine found of the Greek and Latin vowels, but of violat-ing the quantity of these languages more than any other European nation. The author of the Essay on the Harmony of Languages, gives us a detail of the particulars by which this accusation is proved; and this is a picture of the English pronunciation of Latin, so accurate as to give it every claim to our citation.

"The falsification of the harmony by English scholars in their pronunciation of Latin, with regard to effential points, arizes from two causes only: first, from a total inattention to the length of vowel sounds, making them long or short merely as chance directs; and secondly, from founding doubled consonants as only one letter. The remedy of the last fault is obvious. With regard to the first, we have already observed that each of our vowels has its general long found, and its general short found totally different. Thus, the short found of *e* lengthened is expressed by the letter *a*, and the short found of *i* lengthened is expressed by the letter *e*. And with all these anomalies usual in the application of vowel characters to the vowel sounds of our own language, we proceed to the application of vowel sounds to the vowel characters of the Latin. Thus, in the first syllable of *sidus* and *nominem*, which ought to be long; and of *mifer* and *būs*, which ought to be short; we equally use the common long found of the vowels; but in the oblique cases, *fides*, *nominis*, *miferis*, *oculōs*, &c. we use quite another sound, and that a short one. These strange anomalies are not in common to us with our southern neighbours the French, Spaniards, and Italians. They pronounce *sidus*, according to our orthography, *scidus*, and in the oblique cases prefer the same long found of the *i*. *Nominem* they pronounce as we do, and prefer in the oblique cases, the same long

found of the *o*. The Italians also, in their own language, pronounce doubled consonants as distinctly as the two most discordant mutes of their alphabet. It is a matter of cu-riosity to observe with what regularity we use these solecisms in the pronunciation of Latin. When the penultimate is ac-cented, its vowel, if followed by a single consonant, is always long, as in Dr. Fother's examples. When the antepenultimate is accentuated, its vowel is, without any regard to the requisite quantity, pronounced short, as in *mirabilis, frigidos*; except the vowel of the penultimate be followed by a vowel, and then the vowel of the antepenultimate is, with as little regard to true quantity, pronounced long, as in *mane, redens, alium, imperium*. Quantity is, however, violated, to make *i* short, even in this case, as in *oblivio*, *vinca*, *virium*. The only difference we make in pronunciation between *vinca* and *omnia*, is, that to the vowel of the first syllable of the former, which ought to be long, we give a short sound; to that of the latter, which ought to be short, we give the same sound, but lengthened. *U* is always, before a single consonant, pronounced long, as in *humerus, fugiens*. Before two consonants, no vowel sound is ever made long, except that of the diphthong *au*, so that whenever a doubled consonant occurs, the pre-ceding syllable is short.

In speaking of improper pronunciation as arising from the want of due attention to quantity and accent, Mr. Pickbourn, the ingenious author of a Discourse on the English Verb, justly observes, (Monthly Magazine, No. 135.) "That scholars err in their pronunciation of, 1st, words of two syllables having the first short, as *equus*; 2dly, words of three syllables having the first long and the second short, as *fidera*; 3dly, polyvocal *accented* on the antepeni-ultimate; as *juvenilibus, interea*, &c.; and lastly, words end- ing in a long vowel, as *domini*, or in a long vowel and a single consonant, as *dominis*. These errors arise in part from the want of distinguishing between the long and short powers of the vowels, and in part, from the indistinct and confused notion which we have of accent. For, when it falls on a short syllable, we often make that syllable long; and when it falls on a long one, we sometimes make it short. Accent does certainly affect quantity; that is, it makes the accented syllable a little longer than it would be without it. But its operation is never so great, as to make a short syllable become long, nor does the privation of accent make a long syllable become short; for there are degrees of time both in long and short syllables. All short syllables are not equally short; nor are all long ones equally long." This remark is fully confirmed by a passage quoted by Dr. Warner (in his *Metron Arifon*) from Quinilian: "Et longis longiores, et brevis bre-viores syllabae." The second syllable of *amārus*, being ac-cented, is a little longer than the second syllable of *amā-runt*, though they are both long syllables; and the first syllable in *legi*, being accented, is a little longer than the first syllable of *legi*, which is deprived of accent, though they are all long syllables. In pronouncing such words as *animus*, *dominus*, *oculōs*, &c. though the vowels retain their short sound, yet the stress of the voice laid on the first syllable increases the impression which that syllable makes on the ear, and consequently, diminishes the impression made by that which follows it.

We have already observed, that since in the English lan-guage, diphylables accented on the first syllable, generally have that syllable long, we have, very improperly, applied this rule to all Latin diphylables, because they are accented on the first syllable. Hence we say, *quæs*, *cómo*, *miser*, *némus*, *vōgō*, *vīgō*, *līgōr, tīmōr*, &c. making the first syllable
PROSODY.

able long, or at least nearly so. Why do we not pronounce the first syllables of ëgues, ëtmes, mifer, nêmâtis, as we do the first syllables of genitives, ëquitis, ëcômitis, mîsî, nêmâriâ? And why do we not pronounce such words as vígor, vîgor, líquor, as we do the English words vígor, vîgor, líquor? And the first syllable of timor, as we do the first syllable of timorius, and of the English word timorâ? If we pronounced the first syllable of the adjective word mâtis, as we do the first syllable of the English word males, we should probably distinguish it from mâtes, an apple tree. By an attention to this rule we should easily distinguish between the present and perfect tenses of many verbs, as vînît and vînît, fûgit and fûgit, légît and légît, &c. Again, since many English words of three syllables accented on the first have that syllable short, we have, therefore, hastily concluded that all Latin trisyllables, accented on the first, must have that syllable short, unless it be long by position, and therefore, very improperly, we say, lîminis, limâte, sêminis, vîribus, dîcere, &c. Why do we not pronounce the first syllables of these words with a long vowel found, in the same manner in which we pronounce the first syllables of Timor, times, sêmen, vîres, dîce, &c? An attention to this remark would shew the difference between pôpûlus, a people, and pôpûlus, a poplar tree. In polysyllables accented on the antepenultimate we sometimes err in a similar manner, by giving a short sound to a vowel long by nature, as juvencûlis; and, at other times, by giving a long sound to a vowel naturally short, as in intrefa. But in words of this kind, we do not universally err, for few pronounce such words as dépojitum, consûltum, exûlitum, exûciûmus, &c improperly. Lastly, words ending in a long vowel, as domûus, or in a long vowel followed by a single consonant, such as dative and ablative of the first and second declension, and genitives singular, nominatives, accusatives, and vocatives plural of the fourth declension, as dominîtis, gradûis, should always be uttered with a long vowel found, though the accent or stress cannot ever fall on such syllables except by a very singular poetic licence. The fame judicious critic, in an ingenious little treatise on Metrical Poësy, adds, that, in accented antepenultimates, a short is commonly pronounced right, as in animal, but sometimes wrong, that is, with a long vowel found, as in gûle, fûcolor, tûce, cûstûris, Manûllus; a long is generally pronounced wrong in trisyllables, as pôbûlus, grumûma, ôchûma; but right in some polysyllables, as mûrûlia, mûralia, &c; and wrong in others, as fçzûcûla, leuvinûme, imaginûne. E short is sometimes improperly made long, as in nûtor, nûlitus, nîtlor, obûrquûmus, vênûet, invênûet, but it is generally pronounced right in trûpûdûs, gënuinûs, épûe, vûhûribûs, &c. E long is generally pronounced right in polysyllables, as carûfia; but wrong in trisyllables, as femûna, legûsus. I short is always right, as famûdes, consûlûs; i long, always wrong, as frûguilis, mittûs, frûgûres, frûguinûram, sêdûs, (noun and verb,) corovûcum, fûlînûs, dûvinûs, obînovûs. O short is generally pronounced right, as in dominûs, incûsum, but sometimes wrong, as in ôlim, mûrûens, mûroûs, infûduit. O long in some words is pronounced right, as ôlim, but in many others wrong, as pôbûlus, hûxturûsus. U short generally wrong, as ûcûdû, but not always, for ûfûgit is commonly pronounced right. U long always right, as lûminis, vocûminûs, &c.

Since in making these observations on quantity, we have been under the necessity of incidentally introducing Mr. Pickboura's opinion on the influence of accent on quantity, in justice to this part of the subject we are here obliged to offer a remark, which we find in Dr. Valpy's excellent Greek Grammar. This latter gentleman, in some degree, differs from the former. He observes, "that the elevation of the voice does not lengthen the time of that syllable, so that accent and quantity, by the best critics, are considered as perfectly distinct, and by no means inconsistent with each other. In our language the accent falls on the antepenultimate equally in the words liberty and library, yet, in the former, the tone only is elevated, in the latter, the syllable is also lengthened. The same difference exists in baron and baceon, in level and lever. In words of two and of three short syllables, the difference between the French and English pronunciation is striking. The former makes iambics and anapæsists, the latter chores and dactyles. The French say, fugûs, fugûmus; the English, fugûs, fugûmus. In many instances both are equally faulty; thus we shorten the long is in fôris, the plural of fôvûs; they lengthen the short is in ôris, the genitive of os. Indeed, both may be said to observe neither accent nor quantity."

This deviation from ancient quantity is not, however, peculiar to the English; for Beza complains in his country. "Hinc enim ut in Graeco oratione vel nullum, vel profusum corruptum numerum intelligas, dum multae breves producuntur, et contra plurimae longae corripiuntur." (Beza de Germ. Pron. Græc. Ling. p. 50.) Middleton makes the same remark concerning the Latin: "Erasimus se adiuide olim commemorat, cum die quodam solenni, complures legati ad Maximilianum Imperatorem fulutandi caufa adventissent; angulosque, Gallum, Germanum, Danum, Scotum, &c. orationem Latam, ita barbaræ ac valde pronunciasset, ut Italis quibufdam, nihil nihil riferum moverint, qui eos non Latinem fed fuæ quimque linguæ, locutos juraret." (Middleton de Lat. Pron.)

We have now stated at length the manner in which ancient quantity is violated by the moderns, and more particularly by the English. Every symptom of the disease being thus known, our following remarks will be a regular series of inquiries directed to its remedy. In the course of these investigations we are circumscribed by the following alternatives, one or the other must be the object of our decision: whether, in our pronunciation of the ancient languages, shall we adhere to the grammatical metre, though it certainly will in many instances occasion a practice discordant to our habitual predelection; or shall we maintain the English usage, though it should render dactyles, spondees, hexameters, pentameters, &c. merely ideal; at least, subjuncts not of auricular but of ocular perception.

Since the adoption of profoundial pronunciation occasions, in many instances, a practice so discordant to habitual usage and prepossessions of the schools, there are not wanting some, that contend for the continuance of the English custom. But since the inconveniences of this, as we have already pointed out, with any idea we can form of quantity, either in a poetic foot, a verse, or a poem, are so notorious, and manifestly render the pentameter and hexameter verse, and every poetic metre, imaginary and implicative, we cannot enter the lists on this side of the question. For he that shall choose to employ his time in enlarging on the beauties of the poet, beauties of which he has no apprehension, except through the medium of their violation, is certainly nearly allied to the virtuoso, that never gives his sentiments on the beauty and proportion of an edict, except on an actual demolition of all that constitutes them; and having reduced the whole into mutilated and disorganized confusion, he, with much apparent dissonance, delights on the beautiful order and symmetry of their coherence and general arrangement.

But, on the other hand, it may be asked; however an adherence to profoundial pronunciation might prove at variance with our current usage; and, however, with the incoherent
derate it might, until a more mature judgment was formed, be liable to the charge of affectation, would it not be one of the most successful auxiliaries to secure the retention of quantity in the memory of every learner? And as an adherence to it is grammatically unimpeachable, would it be the part of temerity and presumptuous innovation, to make the coincidence of pronunciation and the prosodic rule, the reciprocal echo and memorial auxiliary? We may add, that if we adhere to poetic quantity, the "Norma loquendi" is immutable and certain, but if we warp to fashion, like some erratic sphere, we seem to move in an eccentric orb; especially when we consider that there are the Italian, Spanish, French, German, and English fashions, and each of these, no doubt, is susceptible of variations tinted by every sub-ordinate provincialism.

Three methods present themselves to enable us to preserve the prosodial quantity.

1. To allow every vowel its prefixed duration, without altering the customary division of syllables, as nō-ta, lō-cus, &c.; but this will obliges us to throw the accent on the second syllable, as glō-bus, contrary to the laconic canon of Sæcius:

   "Accentum in fe ipfa monofylla dicit poenit."
   "Exeuit fedem dinifyllaononi priorem."
   "Ex tribus extollit primam penultima curta."
   "Exstollit fe ipfan quando eft penultima longa."

And it will very frequently occasion the following vowel to be long; as, tē-nē-o, contrary to, "Vocalis ante alteram in cadem dictione ubique brevis est."

2dly. If then we must abandon the preceding method, we have the alternative left of uniting to the preceding vowel the succeeding consonant, as nō-ta, lō-cus. But still some difficulty occurs, for, first, this method would be in many instances occasion pronunciations very harsh to our innumerable prepositions; as, grid-ūs, cād-o, plic-o, fūbē-o, bōn-us, jūbē-o, tē-nō, mān-e, jōnnum-e, rūs, trib-ūs, hō-nūs, fā-vor, fūt-ūs, jūg-ūm, fid-es, pēt-o, tim-or, tim-e-o, vid-e-o, "Homines tulentum illum globō-um."

3dly. To ʻtōma fūn cons-jug-li."

But is this really an objection? Have not culture and long established usage the power of warping the mind, and giving it prejudices against that which in its unbiased state it would have adjudged to be agreeable and elegant? This from innumerable instances we are affured to be a fact. But the argument need not rest here. For we may very reasonably inquire, is all this harshness of pronunciation of which we appear to be so sensible, actually chargeable on the ancients? Does it not arise rather from the mistaken ideas we have formed of the power of their vowels and consonants, which, if rectified, would render the harmony of pronunciation and prosodial quantity again consistent? It is here, however, incumbent on us to offer a few leading remarks, as may, under the further inquiries of the patient and perceiving philologist, tend to reconcile what might otherwise remain at variance.

Concerning the quantity of vowel sounds, Lipsius (de Pronun. Ling. Antiq.) has some singular remarks; and as they are calculated to afford some further information on this doubtful subject, we cannot with propriety withhold them. "Aliter omnino vocales longas pingere vetere solitum, aliter contracta. Nam his fortis ponebant ab exemplum hodiernum, illas geminabant, ut duplicacionis ipfa, duplicem et productum in ista oltentendit illum Sonum. Hanc usum scriperet priici mihi feminat; ut Victorinus Afer, Nævius et Livius, "cum longa syllaba scribinda effect, duas vocales ponebant." Quintilianus id vult, hic verba, "prorectas syllabas geminis vocalibus scripserit."

"O quod et O Graecum, compenfet Romula vox o."

In eodem modo, 1 longa, dicebat populus de arbre, voxem, orem, prætorem, et talia; propemodum ut nos Galli, fes, voix, nœfè; vos Belgé, (ita docuere me tui popularies, melius, qui et scribitis pariter et effectis Brot (panem), Schoof (finum), Boom (arborum). 1 mihi fucreper, latus et exilis. Ille, qui O Graecum exprimit, ite qui o cornendum. Varro fecì differunt, his verba, "Quidam reprehendunt quid prœt et luit dicimur in præterito et præteriti tempore. Falluntur, nam est, ac putant, alter. Quod in præterito u dicimus longum, prœt, luit, in præteriti breve." Hoc enim vult, prœt, luit, in præteriti tenuerit effecti, in præterito, prœt, luit." And this mode of expressing the sound, by French orthography, will in ours be exprest by prœt and luit.

"E, in Latin as well as Greek," fays Ainworth, "was pronounced ֶ." But from the circumstance of their anciently writing ῥλ ΤΛΙ ἈΓΑΕΙ ΤΤΧΙΙΙΙ for ῶ ῱γαζ ῱χ, it is to ַ that he attributes the power of ֶ. But since it is ambiguous, and the attempt inconclusive, to explain the found of one ancient vowel by another, the most satisfactory and decisive method, as far as it can be done, is to have recourse to the more immutable sounds of nature. Mon-ieur Launceloit, the learned author of the Port Royal Greek Grammar, in order to convey the sound of the long Greek vowel, tells us "it is a sound between the e and a; and that Eulathius, who lived towards the close of the 12th century, says that ֶ, ַָ ַָ, is a sound made in imitation of the bleating of a sheep; and to this purpose quotes the following verse of an ancient writer, Cratinus.

"O ἶ."
In a similar manner, the found of the long i is preferred to us by the word πίθος, which signifies to pip like a chicken; and since its note is nearly what we may express by pe-ep, the long power of that letter seems to have been equivocal to our e. Euphalius likewise remarks on the 499th v. of Iliad, I., that the word βαθις, ἤτοι ὁ τῆς κλεισθέρας ἐχθροτοῖς κατὰ τί; ταῦτα β', ἦν μίμησις προετοίμασα φωνή. Kretzschmar, i.e. G. Blum, is, according to the ancients, an imitation of the found of the clepsydra; et ß imitates the bleating of sheep. The clepsydra was an instrument to measure time by water; (and, it should be particularly observed, was occasionally employed to measure time for the regulations of orators, and in other recitations.) Abstraining the e in ße-ße from the effect of position before û, it will, as we shall determine hereafter, have the power of our e; and ße in ße-ße adequately imitates the noise of water running with intermissions out of a narrow-mouthed vessel; and, with the French pronunciation, with equal propriety, is signified by the word glouglou; but not quite so happily by ûe by the word guggle. Ainsworth seems to consider, that the long found of ÿ, was equal to û. To determine this, it may be useful to quote the word glàcio, to check as a hem (from xàxà), particularly since this word, among many others, will prove an irrefragable proof that ÿ amongst the ancients was equivocal to û, or hard, since glàk, glàk, is the sound produced by the hem after the period of incubation. The found of the long û is no less sincerely preferred by Plautus in Menæch. page 622. edit. Lambin, in making use of it to imitate the cry of an owl:

"Men. Egon' dedi? Pen. Tu, Tu, ἵτικ, inquam, vin' affere noctum,
Quae tu, tu, uque dicit tibi? nam nos jam nos defelli
fumus."

It appears here, says Mr. Foster, in his defence of the Greek accents, page 129, that an owl's cry was tu, tu, to a Roman ear; tor, to, to a French; and to, to, to an English one. Lambin, who was a Frenchman, observes on the pasage, "Alludit ad nocturn vocem tu, tu, seu tui, tui, tui." On this Mr. Walker remarks, that the English have totally departed from this found of the û in their own language, as well as in their pronunciation of Latin. Antonius confirms this power of û: "Ciceronis ignota fonis, ferale fonos U. Ferale ido, quia referit feralem illam avem." This also explains the reason of the Latin word hisbulu expressing the cry of an owl. Aristophanes has handed down to us the pronunciation of the Greek dishkong ûo ûo, by making it expressive of the barking of a dog. This is what is exactly preferred by nures and children to this day in ûou, ûou. This is the sound of the fame letters in the Latin tongue, not only in proper names derived from Greek, but in every other word, where this dishkong occurs. Most nations in Europe, perhaps all but the English, pronounce ùudio and ùaudo, as if written ùudio and ùaudo; the dishkong found like û in loud.

In prosecuting a further enquiry on the founds of ancient vowels, as preferred to us by the founds of nature expressed by words, on the etymology of which lexicographers judge the most appropiate remark to be "verba ex fono ÿeta," what light may resul from the following and similar expressions, the further investigations of philologists may determine. Balo, ßo, to blest as a sleek; ûou, from ûou, to ûou as an ox; crocia, from xàxà or xàxà, which was, it appears, not pronounced croxt, but croxt, to croxt as a crown; to which we may add, ùepa, to ùek as a door; ùaufus, a buzz or ruffling; and ùerius, a creech owl. But ûno, to ûelp as a fox; binnio, to neigh as a horse; ùinnio, to ûinkle; are not, perhaps, sufficiently abstrait from consonant admixture to afford much additional intimation.

Platonic, secondly, to the short û, and of ÿ, as in cub, to their short unaccented û, i.e. when the accent rested on the following consonant. Hence, instead of being compelled to divide ùum-er-us, ùul-er-us, ùäp-e-o, ùäb-e-o, fo as to throw the accent on the latter consonant of the inflected syllable, we may adopt a distribution more reconcilable, at least with our habits, and by placing the accent on the first vowel instead of the following consonant, may give the short Roman accent û, the found of û in tube, and pronounce nearly as uyl-deer-us, ùul-deer-us, ùäb-deer, &c. Relative to jugum and conjugium, we shall here avail ourselves of a remark from Dr. Carey. "The word which in England we pronounce yugum, is in reality yugum, as the Germans, in fact, at this day, pronounce it. Of this, indeed, there is little doubt, since ùsulate was properly yakûb, and the Hebrew יגו, before a vowel, had the power of û. Now, by these remarks being warranted, let us, in the place of the accent on the first vowel of the root ùägum; secondly, to give the power of the middle û to the short Roman accent û; and thirdly, that of û to û before a vowel, we may avoid nearly all the harshness for which these words would otherwise have been notorious; as yû-gum, ùon-yû-gum. The fame unpleafantry may be removed from ùglûs, since the long Roman û is considered as equal to û, which is more exactly represented by our ûu; for ùaora was probably pronounced ùauria, since it is borrowed from the Hebrew ו, ùaur, and ùauria from ù, ùû (propius light), or ùauria. Therefore the middle û, as in note, may be ceded to the short Roman accent û, and for ùglûs, we may, more agreeably, say ùglûs-bus. Whatever may be done, however, in this way, we cannot but consider, here, as partial hints, given rather in the hope of calling forth the future investigations of the literati to an inquiry, the want of which has been long felt, than propose the present as a mature and establisht system. Doubtles it may not be easy to remove every difficulty, so as, in every instance, to reconcile the profodial pronunciation with our prejudices. Nor will it, perhaps, be done, until the influence of accent on quantity is more fully understood, nor unless it be clearly considered, whether the accent falls on the vowel or succeeding consonant. Many have undertaken to afflig the syllables, which constitute the feet of the accent, but few distinguish the augmented vowel from the accented consonant. And here, perhaps, the solution of the whole may be found. It is evident, that nû-lûs has the accent on the first syllable, and on the vowel of that syllable; hence it is easily preferred long. And, it is equally obvious, that honori- físus has the accent on the antepenultimate, and on the consonant f of that syllable; and, therefore, it may more rapidly inclines to an increased brevity. And the same distinction should have been allowed by the writer who have already cited, in the words he has quoted to prove the
The independence of accent and quantity. It is certainly true, that liberty and library are accented on the first syllable, which in the first instance is short, in the second long; but the former has the accent on the consonant, lib-er-ty; the latter on the vowel, li-brary. The same distinction exists in the words bazon and bazon, level and level. Now, in such words as grædus, cædo, pleno, fidus, trilus, timor, all which are accented on the first syllable, the question is, did the ancients throw the accent on the final consonant of the syllable? If so, that syllable will be pronounced with rapidity, to throw the stress on the accented consonant; and that pronunciation will be aptly expressed by the following distribution, græ-d-us, cæ-d-o, plie-o, fid-es, tril-us, tim-or. Or did they rather allow a distinction between an accented short vowel, and an unaccented short vowel, lengthening, in some degree, the former, in the same manner, as we have seen that a difference exists between an accented long, and an unaccented long syllable, in the examples aman and aman-e-runt; which will fully illustrate the remark of Quintilian, which we have cited before. This influence might allow an increas to their short accented a, e, and i, rather to their unaccented long found; so that, on this ground, distant at once with quantity and our propositons, we might pronounce, græ-du-s, că-d-o, plie-o, fid-es, tril-us, at-mar.

The second difficulty to which we are liable in our apprehension of the nature of ancient quantity, arises from that, which is said to be long by position. From this come have deduced an objection against the attempt to confine the present pronunciation to quantity; observing, that "if we would be consistent and unexceptionable in our adherence to a prorsam metre, we have to recollect, that the same word is often both long and short; as nec, when single, or not followed by a consonant; which by position we find long; as well as short, as in Fugi's nēe dira totes arces conscena. Then, if we invariably echo the quantity, we must, pro re natis, fay nec, and nec. diri, i.e. neck, and neck dire. And the improbability, that the ancients were to ready on every occasion to pronounce the same word both long and short, would incline us to infer, that we have no idea of what they meant by quantity."

This has given rise to a series of remarks in Mr. Walker's Treatise on Clasical Pronunciation, which, if they are not, in every instance, the most decisive, are at least the most ingenious that we have seen on the question, and with which it is impossible to dispute, in a full and impartial consideration of this subject.

"The long quantity of the ancients must arise either from a prolongation of the sound of the vowel, or from the delay of the voice, which the pronunciation of two or more consonants in succession are supposed naturally to require. Now, vowels were said to be either long by nature, or long by position. Those vowels which were long by position, were such as were succeeded by two or more consonants; as the first e in bason. If the long quantity of the ancients was the same distinction of the sound of the vowel as we make in the words cadence and magic, then the a in mater and pater must have been pronounced like our a in paper and matter; and those vowels which were long by position, as the a in Baccus and campus, must have been founded by the ancients as we hear them in the words bake and came. But if the long quantity of the ancients was no more than a retardation of the voice on the consonants, or that duration of sound which an assemblage of consonants is supposed naturally to produce, without making any alteration in the sound of the vowel, of such long quantity as this an English ear has not the least idea. Unlike the sound of the vowel be altered, we have not any conception of a long or short syllable; and the first syllables of banish, bonner, and banter, have, to our ears, exactly the same quantity. The same may be observed of fena, feminary, sentence, and sentiment;" (and if, as an ingenious inquirer into this subject has asserted, the ancients pronounced both the consonants in calidus, faile, &c. this seems to shorten, rather than lengthen, the vowel of the first syllable."

"If, however, the quantity of the ancients lay only in the vowel, which was lengthened and shortened in our manner by altering the sound, how strange must have been their poetical language, and how different from the words taken singly! And when these observations on the quantity of the ancients are collectively considered, shall we wonder that the learned and ingenious author of the Elements of Criticism should go so far as to assert that the dactyls and spondees of hexameter verse, with respect to pronunciation, are merely ideal, not only in thought, but that they were so with the ancients themselves? Few, however, will adopt an opinion, which will necessarily imply that the Greek and Latin critics were utterly ignorant of the nature of their own language; and every admirer of those excellent writers will rather embrace any explanation of accent and quantity, than give up Dionysius of Halicarnassus, Cicero, Quintilian, and Longinus. Suppose, then, as a last refuge, we were to try to read a Greek or Latin verse both by accent and quantity, and see what such a trial would produce."

"By quantity, let us suppose the vowel lengthened to express the long quantity; and by the acute accent, the rising inflexion; thus:

"Titre, tu paltule rechubans sub tegmine fagi,
Sylvestrem tenui musum meditaris avena.

"Titrye, tu pátulæ rēcubāns sub tegmine fagi,
Sylvestrum tenui musum meditāris avēna.

"Trétyre too pātule rēcubānes soōb tegmine fagi,
Seclveeltem tenui noofam meditaris avena.

"Mēn eēude Θεia, Παλιάδωι Αχιλλος
Οδυσσεων, ᾧ μη' Αχιλλος αλλί Θνθν.

"Mēn eēude Θεia, Παλιάδωι Αχιλλος
Οδυσσεων, μη' Αχιλλος αλλί Θνθν.

"Mein-en ē-eye-de These-ay Pei-lei-ē-dyo A-kil-lei-ōe
Ow-lom-ēn-ein hel moo-re ā-kay-ōes al-gē thē-ēi-ēi.

"Now there are but four possible ways of pronouncing these verses, without going into a perfect long. One is to pronounce the accented syllable with the falling inflexion, and the unaccented with the same inflexion in a lower tone; which is the manner in which we pronounce our own words, when we give them the accent with the falling inflexion. The second is to pronounce the accented syllable with the rising inflexion, and the unaccented syllables with the same inflexion in a lower tone; which we never hear in our own language. The third is to pronounce the accented syllable with the falling inflexion, and the unaccented syllables with the rising inflexion, in a lower tone. And the fourth, to pronounce the accented syllable with the rising inflexion, and the unaccented with the falling, in a lower tone. None of these modes, but the first and last, do we ever hear in our own language; the second and third seem too difficult to permit us to suppose that they could be the natural current of the human voice in any language. The first leaves us no possible means of explaining the circumflex; but the last, by doing this, gives us the strongest reason to suppose that the Greek and Latin acute accent was the rising inflexion, and the grave the falling inflexion, in a lower tone."
To render Mr. Walker's remarks, as they relate to the influence of accent on quantity, a little more familiar to our readers, it may be useful to state, that his ideas of accent comprehend the qualities of high and low, rising and falling. His acute accent is higher than the grave, effected by a rising slide of the voice; the grave is lower than the acute, and effected by a falling slide. All this may be very conveniently illustrated by the violin; for whilst the tone (louder or softer) is produced by the greater or lesser streps of the bow, the finger sliding upwards on the first string, in flowing time, will give the acute or rising accent, as on a long syllable, or when the vowel is accented. The sound upward slide, with a quicker movement, will express the same accent on a short syllable, or when the accent falls on the following consonant. And by a downward slide, either in slow or quick time, the grave accent is equally imitated on a long or short syllable.

Our opinion, however, deducible from the analogy of quantity long by position, is not such as to occasion our hesitation relative to the nature of quantity in general. But we are persuaded, first, that quantity long by nature, and long by position, were, as it respects the vowel, different. We are confirmed in this by Lipsius, whose remark is, "Sylla, quae natura longa, et a diis distinguat debet, sola positione longa existit. Id est, idcirco tantiud quod duabus consonantibus adjuvita sit, quibus praonuntiandis necesse est moram interponendi, ut in longa producitur et pene ultima quin in longa. Praetera pro qualitate consonantium quae vocabales ipsas precedent, vel conquisuit, inter longas alia longiores, inter breves alia breviores reperientur. Sed hic subtilius persequi, nostrum non esse instiuit. Admoneri tamen pueri debent et affueri, ut hic omnia discrimina expedite observent, sine quo numeris cognitione et usu fieri non posse puto ut de numeris orationis recte judicent."

But an irrefragable argument that quantity long by position was really different from that long by nature, is deducible from such founds as nature has faithfully handed down to us: as in the word *fallopus* or *fillopus*, which signifies the noise produced by the percussion of inflated cheeks, which *fallopus* pronounced short, as it respects the vowel, will very well resembte; but that similarity becomes entirely lost, on lengthening it. On this word, see Priscian, lib. i. cap. 4, Faciolatus, and Perf. lat. 5. 13. "Nec fallopus timidus intendis rumprop buccas." The same observation may be made from the word *edol*, already quoted, which signifies the noise effected by water, flowing with intermissions, from a narrow-mouthed vessel.

Hence it appears, that syllables indifferently spelt with one or two consonants, which are always long, are not strictly entitled to the quantity equal to that of a vowel long by nature; as in *litis* or *littus*, *litera* or *lettera*, *firma* or *firma*. Secondly, if then quantity long by nature was different from that long by position, we may suppose that the quantity of the former confined in the duration of the vowel found, and that of the latter in the length of the syllable. To explain this more particularly, let us suppose, first, that the regular quantity of a short syllable, generally, *σωλυμένων*, comprehends either, 1st, a single syllable, as the first syllable of *λευ*: or, 2ndly, a consonant and a vowel, as *γέ-να*: or, 3dly, a mute and a liquid, which could be founded as a single letter, followed by a vowel, as *τρί-φορ*; or, 4thly, even three consonants and a following vowel, provided the three consonants could be founded as one; as *μίτο-πας*. So that the regular quantity of a short syllable is reducible to two letters. The only exceptions to this were in such syllables, as custom, for some special reason, as in the case of derivation from *r*, *s*, *t*, &c., which had made long; and in the case of monosyllables, as *mi*, *il*, *et*, &c., which properly are long, since there being no half of the voice to leave the first and proceed to the coalition of a second syllable, the first receives, from this exception, a more leisure-effect, or such a compensation as its diminutive and detached condition seems naturally to require. Secondly, that if to the end of this short syllable we join a consonant, this forms that addition in quantity, which is to be considered rather as a syllabic augmentation, than any temporal duration of the voice; it may alter the found, but it does not, in every case, perceptibly protract it; as *κλεφ* equal to *κλεφθ*, *φοιν* to *φοινθ*, *πτοκ* to *πτοκα*, and *ρεκ* to *ρεκθ*. Hence all monosyllables and final syllables, beginning and ending with a consonant, are long; except they end in *b*, *d*, *t*, *l*, *r*, *s*, *m*, or in consonants preceded by the Greek short vowels, and a few other exceptions established by poetic usage. But if such syllables occur in the middle of a word, the following syllable must begin with a consonant; as *κοφοι*, *θλγος*, &c.; otherwise the consonant is joined to the following syllable, as *κλοσ-μυς*. And, lastly, when the succeeding syllable begins with a mute and a liquid, in consequence of the coalition and unity of sound, having the effect only of one consonant, they are joined to the following syllable, and thus the first may remain short: *i.e.* instead of *πατρίς*, *πτολέμα*, and *πάλ-ταρις*, which would be long, we may divide and pronounce *πατ-ρίς*, *πτολέμα*, and *πάλ-ταρις*.

Now, concerning the question whether the ancient poetry should be read chiefly according to accent or quantity, which has lately been much agitated, may we not reasonably infer, that since the precise nature of accent does not seem to be determined, and therefore if, in reading, either must give way to the other, (for which, however, there is no absolute necessity,) it is certainly better, that what is in some degree uncertain should yield to that which is more accurately ascertained. By reading according to quantity, we, however, meant the breaking down, splitting, or destroying the words by flowing to the feet only; but pronouncing the words of a verse, so as to give, as much as possible, its due quantity, in the real time, to every syllable. And as much as to this mode of reading, we can add an attention to accent, emphasis, tone, pause, and cadence, whether metrical or lentential, infomuch, doubtless, will the pronunciation be the more correct and harmonious. Although it cannot, perhaps, in every case, be determined in what manner, precisely, the ancients founded the vowels; one thing, however, seems certain, that they did not give a long sound to a short vowel, or a short sound to a long vowel. In whatever way we pronounce them we ought to attend to their quantity; with only this licence, that since, as has been now fully proved, a syllable long by nature was a reduplication of the same vowel, as *dicere*, *maius*, an apple tree; *pophius*, a poplar tree; and that long by position had no other length than its being sustained by the following consonants, as *dixi*, we are authorized to consider the prolongation of such syllables to confit not in the vowel, but in the consonant reduplication.

We have now had an opportunity of offering our sentiments on the nature of ancient quantity. But the nature of quantity, as observed in the English language, is at once so simple, unique, and, in general, so well known, that any enlargement on this part of the subject becomes unnecessary. It is sufficient to observe that a vowel or syllable is, in the English language, long, and requires double the
the time of a short one, when the accent is on the vowel; which occasions it to be slowly joined in pronunciation with the following letters; as fall, bake, horse, forecast. And that a syllable is short, and only of half the length of a long one, when the accent is on the consonant; which occasions the vowel to be quickly joined to the succeeding letters; as ürt, könnt, hängert. For such rules as are necessary to the determination of quantity in each of the three principal languages, we refer our readers to the article Quantity. See also Versification.

Prophony might be applied to music as well as grammar; as the true pronunciation, or execution and accents of passages, constitute their true expression.

PROSONOMASIS, προσωνομασία, a figure in Rhetoric, by which allusion is made to the likenesses of a found in several names or words; much the same with personomasis, or agnomination.

1. P. fruticosa. Linn. Mant. 66. Roxb. Coromand. v. 3. 45. t. 63. (P. fruticosa; Burm. Ind. 102. t. 25. f. 3.) —Common on the Coromandel coast, flowering at the close of the cold and beginning of the hot seafon.—According to Roxburgh this is a large tree, with a tolerably erect trunk. Bark deeply cracked, ash-coloured. Branches irregular, numerous, forming a globular shady head; some of the younger ones prickle. Leaves alternate, abruptly pinnate; leaflets from seven to ten pair, opposite, obliquely lanceolate, smooth, entire. Flowers in numerous, terminal spikes, small, yellow. Legume attenuated at both ends, jointed, smooth, pendulous. Seeds lodged in a brown mealy substance, which is eaten by the native Indians. It has a sweet, agreeable taste, and may be compared to the Spanish Algarabia, or Locust tree, Cerastania Siliqua.

PROSOPOLEPSIA, προσωπολέπσια, in Ethics, is used by some writers for that bodily impression, which inclines to the love or hatred, esteem or contempt of persons or things, on account of some slight or trivial circumstances attending them.

PROSOPOPÆIA, προσωποπαί, formed from προσωπος, person, and ποιειν, to make, or feign, or Perfonification, in Rhetoric, a figure, by which we make persons that are absent, or dead; or even things which are inanimate, as cities, &c. to speak.

The poets, in their fictions, make frequent use of the prospopæia; as also do the orators, in their painting of violent passions, which seem to transport, and make them forget themselves.

This figure is of very extensive use to the orator: when he thinks his own character not of sufficient weight to affect his audience in the manner he desires, he subsitutes a person of greater authority than himself to engage their attention. When he has severer things to say, and which may give offence, as coming from himself, he avoids this by putting them in the mouth of some other person, from whom they will be better taken; or makes inanimate nature bring a charge, or express a resentment, to render it the more affecting. And by the same method he chooses sometimes to secure himself from a suspicion of flattery, in carrying a compliment too high. In the management of this figure, care should be taken, that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

There are two kinds of prosopopæia; one direct, the other indirect. For an instance of the latter: Just gods, protectors of the innocent, permit the order of nature to be interrupted for one moment, and let this carafe resume the use of speech.

Influences of the former are found everywhere among the orators and poets: that which follows is a very beautiful one; found, by way of epitaph, on a tomb-stone: the dead wife addresses her surviving husband thus:

"Immatura peri: fed tu felicior, annos,
Vive tuos, conjux optime, vive meos."

This figure is of such importance both to the orator and poet, and contributes so much to give both beauty and effect to their respective productions, and to render them animated and impressive, that we shall enlarge on its origin, and its various kinds, and subjoin several appropriate examples of its use. Its origin may be traced to the constitution of human nature, which disposes us to animate all objects, and to give affections and affections, proceeding probably from our sens of pain and pleasure, which express themselves in an aversion from an attachment to certain objects, either animate or inanimate. A child turns to beat the ground, or the stone, that has hurt him, and most men feel some degree of affection for the old inanimate companions of their happiness, such as the houfe, in which they have palled many agreeable years, and the fields, trees, and mountains, among which they have often frolicked with delight. This strong impression of life, produced, more especially, by the more magnificent and striking objects of nature, has been, Dr. Blair conceives, one cause of the multiplication of divinities in the Heathen world. The belief of Dryads and Naiads, of the genius of the wood and the god of the river, among men of lively imaginations, in the early ages of the world, easily arose from this turn of mind. When their favourite rural objects aad often been animated in their fancy, it was an easy transition to attribute them to some real divinity, or some unseen power or genius which inhabited them, or in some peculiar manner belonged to them. From such dispositions evidently originates the figure called prosopopæia, which is the distinguishing ornament of poetry, and which appears so confpicuous in all compositions, where imagination or passion has any concern. This figure is nearly allied to the metaphor, and still more to the metonymy: it is to the latter what the allegory is to the metaphor. Thus when we say, "Youth and beauty shall be laid in the dust!" for persons poffeading youth and beauty, it is hard to determine whether it be a metonymy or a prosopopæia. Lyric poetry, in which the imagination seems to have the fullest indulgence, and which abounds with strong figures, is most favourable to personification. Of this figure, according to Dr. Loveth, there are two kinds: one, when action and character are attributed to fictitious, irrational, or even inanimate objects; the other, when a probable but fictitious speech is alligned to a real character. The former evidently partakes of the nature of the metaphor, and is by far the boldest and most daring of that class of figures. Dr. Blair reckons three different degrees of
this figure; the first, when some of the properties or qualities of living creatures are ascribed to inanimate objects; the second, when these inanimate objects are introduced as acting like such as have life; and the third when they are represented, either as speaking to us, or as listening to what we say to them. The first, and lowest degree of this figure is exemplified, most commonly, by adding an epithet to the object, as "a raging form," "a dreadful diabler," "a cruel diabler," &c. and it raises the style so little that it hardly deserves the name of personification, and might be called with simple metaphors. On some occasions, however, it adds beauty and Brightonness to an expression. In the second degree of this figure the personification becomes more feasible. It is observed by Dr. Blair, that the genius of our language affords us an advantage in the use of this figure. As with us, no substantive have gender, or are masculine and feminine, except the proper names of male and female creatures; by giving a gender to any inanimate object, or abstract idea, that is, by substituting the personal pronouns, he or she, in place of the pronoun it, we raise the style, and begin to personify. In Hebrew discourse this may be done to a good purpose, when speaking of religion or virtue, or our country, of any such object of dignity. An instance of this kind, in which natural religion is beautifully personified, occurs in a ferman of Bishop Sherlock's, in which he is comparing our Saviour with Mahomet: "Go," says he, "to your natural religion; lay before your Mahomet, and his disciples, arrayed in armour and blood, riding in triumph over the spoils of thousands who fell by his victorious sword. Shew her the cities which he set in flames, the countries which he ravaged and destroyed, and the miserable di trefs of all the inhabitants of the earth. When she has viewed him in this scene, carry her into his retirement; shew her the prophet's chamber; his concubines and his wives; and let her hear him all the day, and a divine commission to justify his valupt and lust. When she is tired with this prospect, then shew her the blessed Jesus, humble and meek, doing good to all the sons of men. Let her see him in his most retired privileges; let her follow him to the mount, and bear his devotions and supplications to God. Carry her to his table, to view his poor face; and hear his heavenly discourse. Let her attend him to the tribunal, and confer the patience with which he endured the scoffs and reproaches of his enemies. Lead her to his cross; let her view him in the agony of death, and bear his last prayer for his persecutors: 'Father, forgive them, for they know not what they do!'—When natural religion has thus viewed both, ask her, which is the prophet of God? But her answer we have already had, when the foul part of this scene through the eyes of the centurion, who attended at the cross. By him the spake, and said, "Truly, this man was the son of God." This passage, says Dr. Blair, is more than elegant, it is truly sublime. Personifications of this kind are the life and soul of poetry. They occur frequently in Homer, Shakspere, and Milton, as well as in other poets. The following personification by Milton, on occasion of Eve's eating the forbidden fruit, is peculiarly striking:

"So saying, her raff hand, in evil hour
Forth reaching to the fruit, the puch'd, the eat;
Earth felt the wound; and Nature, from her seat
Sighing, through all her works, gave signs of woe,
That all was lost." Book ix. 780.

The third and highest degree of personification is the boldest of all rhetorical figures; it is the expression of strong feeling and passion; and ought never to be attempted, unless the mind is considerably heated and agitated. Of this figure Milton has given a very fine example, in that moving and tender address, which Eve makes to Paradise, just before she is compelled to leave it:

"Oh! unexpect'd stroke, worse than of death!
Murt! thus leave thee, Paradise! I thus leave
Thee, native soil, these happy walks, and thades,
Fit haunt of Gods! where I had hope to spend
Quiet, though sad, the repose of that day,
Whose must be mortal to us both. O flowers!
That never will in other climate grow,
Nor my early visitation, nor my fall.
And who now shall rear thee to the sun, or rank
Your tribes, and water from th' ambrosial fount?"

This is altogether, says Blair, the language of nature, and of female passion.

This excellent writer proposes two great rules for the management of this form of personification. The first is, never to attempt it, unless when prompted by feeling passion, and never to continue it, when the passion begins to flag. The second is, never to personify any object in this way, but such as has some dignity in itself, or can make a proper figure in this elevation to which we raise it.

In prose compositions, this figure requires to be used with still greater moderation and delicacy; for here the imagination is not allowed the same liberty as in poetry, nor can the same affinities be obtained for raising passion to its proper height by the force of numbers, and the glow of style. Nevertheless, addresses to animate objects are not excluded from prose; but they have their place only in the higher species of oratory. This figure has uncommon force and expression, as it is used by Hebrew writers. What can be conceived more apt, more beautiful, or more sublime, than that personification of wisdom, which is so frequently introduced by Solomon? (See Prov. vii. 27-31.) How admirable is that celebrated personification of the divine attributes by the Psalmist? (Ps. 109. 11.) Such also are that in Habakkuk, of the plenteous marching before Jehovah, when he comes to vengeance (Hab. iii. 5.); that in Job, in which destruction and death is affinm of Jehovah, that he can only have had to come to their ears (Job. xxxvii. 22.); and that tremendous image, in Isaiah, of Hades, extending her throat, and opening her infaatable and immeasurable jaws. (If. v. 14.) There is another beautiful species of personification, which originates from a well-known Hebrew idiom; or that form of expression by which the subject, attribute, accident, or effect of any thing is denominated the Son of Jehovah, pronounced by Dr. Lowth to be the sublime of all poetical expressions, in one short poem, examples of almost every form of the personifica, and indeed of all that constitutes the sublime in composition. (See If. xiv. 4-27.)

After a critique upon this sublime ode of Isaiah, our learned writer concludes in the following manner: "How forcible is this imagery, how diversified, how sublime! how elevated the description, the figures, the sentiments!—The Jewish nation, the cedars of Lebanon, the ghofts of departed kings, the Babylonish monarch, the travellers who find his hopp, and last of all Jehovah himself, are the characters which support this beautiful lyric drama. One continued action is kept up, or rather a series of interesting actions are connected together in an incomparable whole: this, indeed, is the principal and distinguished excellence of the sublime ode, and is displayed in its utmost perfection in this poem of Isaiah, which may be considered as one of the most ancient, and
and certainly the most finished specimen of that species of composition, which has been transmitted to us. The personifications here are frequent, yet not confused; bold, yet not improbable: a free, elevated, and truly divine spirit pervades the whole; nor is there any thing wanting in this ode to defeat its claim to the character of perfect beauty and sublimity. If, indeed, I may be indulged in the free declaration of my own sentiments on this occasion, I do not know a single instance in the whole compacts of Greek and Roman poetry, which, in every excellence of composition, can be said to equal, or even to approach it." Blair's Lectures, vol. i. Lowth's Lectures, &c. vol. i.

PROSOR, in Geography, a town of Bosnia; 8 miles E. of Kalam.

PROSPECT, a town of America, in Hancock county, and district of Maine; containing 1300 inhabitants.

PROSPECT Harbour, lies on the S. coast of Nova Scotia, with cape Sambo and island eastward, and two leagues N.E. of St. Margaret's bay.

PROSPECT Hill, a town of Fairfax county, in Virginia; 14 miles from Washington.

PROSPECTIVE. See Perspective.

PROSPECTIVE GLAIS. See OPERA GLAIS.

PROSPER, in Biography, a saint in the Roman calendar, was a native of Aquitain, or Guerne, and born about the commencement of the fifth century. Some writers have ranked him with the ecclesiastical order, as bishop of Riez, in Provence, and others say, that he held the see of Rhégium in Italy. No ancient writer before the 12th century, has ever spoken of him in any other character than that of a layman, and the ablutions charity in ailing him that rank. He embraced, in early life, the sentiments of Augustinian, and was the occasion of that father writing his treatise concerning predestination and perseverance. After the death of Augustinian, he defended his character and doctrine against the attacks made upon them by the prelates of Marcellis. In the year 431 he went to Rome, and preferred accusations of hereby against the Gallican clergy who ventured to deviate from the system of his master, and obtained a letter from pope Celestine to the bishops of Gaul, in which the pontiff warmly supported the opinions of Augustinian. Sanctioned by the authority of his holiness, Prosper returned home, and re-established his zeal and industry in opposing the rapid progress which the Pelagian notions were making among his countrymen, both by disputations and conferences, and by his writings. After the year 440, he was sent for to Rome by pope Leo I., who made him his secretary, and principal combatant against the Pelagians in Italy. In the year 443 he was employed by the same pope in a mission against those heretics in Campania. The time of his death is not known, but it is tolerably well ascertained that he was alive beyond the year 460. In Dupin we have a lift of his works, and also of others imputed to him which are not genuine. He was possessed of much learning and eloquence, and the style of such pieces as are universally acknowledged to be his, is concise, vigorous, and elegant. Dupin. Moreni. See also Lardner, vol. iv. edit. 1788. ch. 34-5.

PROSPEROUS, in Geography, a village in the county of Kildare, where extensive cotton-works were erected at a great expense by Capt. Brooke, with parliamentary aid; but, says Mr. Rawson, "he had no knowledge of the buffets; he committed it to the care of others; of course every thing went to ruin." Prosperous is 182 miles W. by S. from Dublin.

PROSPHYSI. See ADHESION.

the surgeon will open the upper part of the bladder, and view the orifice of the urethra from above downward. But, in certain instances, it is alleged to be so considerable, that it projects some inches into the interior of the bladder. Such enlargement increases the bend of the urethra, and produces an impediment to the passage of the catheter, or bougie. Frequently, also, it raises the end of a found, so as to make it pass above a calculus, which, therefore, is not perceived. It is sometimes, likewise, such an impediment to the entrance of the found into the bladder, as cannot be surmounted without the utmost difficulty.

When the prostate enlarges, its consistence generally becomes much firmer than what is natural. The effects of such enlargement are very serious; for the sides of the urethra are then prefed together, while the projecting point of the gland in some measure prevents the urine from freely entering this canal, and, in many instances, it flows altogether. Besides, as the firmness of the gland is increased, its suppleness is diminished, so that it does not yield to the impulse of the urine, and little or none of this fluid is evacuated. The symptoms which this disorder produces, resemble those of a retention of urine arising from other causes.

When, in a case of difficulty of making water, the surgeon has had recourse to the catheter, and ascertained that such instrument may be readily introduced, he must next endeavour to learn whether the complaint depends upon the presence of a stone in the bladder. Should circumstances prove, however, that this is not the case, a disease of the prostate gland is to be suspected; especially if the catheter, or bougie, made use of, should meet with a sudden impediment, or pass with great difficulty, when the point of the instrument is near the neck of the bladder.

The attention of the practitioner must then be directed to the prostate, the state of which cannot be ascertained, unless the finger, properly oiled, be passed into the anus, and turned towards the pubes. If a hardnes should be felt in the situation of the prostate, extending as far as the finger can reach; if the indurated part should cause a projection, that can be distinctly felt through the coats of the rectum; and if, when the finger is moved about, in order to examine the extent of the swelling, the hardnes should be found to reach beyond the length of the finger, the surgeon may be certain that the prostate is considerably enlarged, and that it is the cause of all the patient's complaints.

In cases in which only the sides of the gland are enlarged, a bougie, or catheter, may readily be passed into the bladder; but the point of the gland which projects into this organ, frequently hinders the instrument from actually passing into its cavity. When the size of the prominence here alluded to is considerable, a bougie, or catheter, cannot be got over it without the utmost difficulty, because its apex then forms an angle with the passage. In such a case, it is necessary to be very cautious in the trials to pass an instrument, particularly when a metallic catheter is employed, as otherwise the part causing the obstruction would be injured. Here, certainly, a flexible catheter ought to be preferred; but the point of this sort of instrument may likewise hurt the prominent part of the gland; and should it be forced, its extremity will sooner bend backward than forward, so that it cannot be got into the bladder, but will rather penetrate the substance of the tumour.

Mr. Hunter, from whom we borrow these observations, has recorded an instance of this kind, where a surgeon pushed a catheter quite through the prominent part of the gland, in such a way, that the instrument at length reached the cavity of the bladder, and let out the urine; but the blood which flowed from the wounded part of the prostate, passed into the bladder. A second attempt was made to introduce a catheter; but without success. Mr. Hunter was consulted; he introduced a catheter as far as the part forming the impediment, and having discovered the enlargement of the prostate, he inclined the upper part of the catheter, so as to elevate its other end, and thus succeeded in getting it over the prominence. Unfortunately, the coagulated blood in the bladder floated up the holes of the instrument, and obliged Mr. Hunter to withdraw it several times, for the purpose of cleaning it. As the same inconvenience continued, he proposed performing a similar operation to lithotomy, in order to discharge the extravasated blood from the bladder; but the patient's death prevented the operation. An examination of the body fully proved the nature of the accident which had given rise to the extravasation.

Instructed by the observation of several facts of this description, Mr. Hunter made it a rule, whenever the urine did not flow out immediately the catheter was introduced, to push the instrument more forward, by inclining its handle so as to raise the other end of it, and get it into the cavity of the bladder. In this following method, Mr. Hunter never failed.

There are no means to be depended upon for dispersing a swelling of the prostate. Cicuta, burnt sponge, and sea bathing, are said to have sometimes answered the purpose. The pilula hydrargyri, with the extract of cicutis, has been recommended. Mr. Home has found suppositories of opium and hemlock, passed up the fundament, not only relieve the irritation, but even lessen the projection of the gland.

Some abscesses and ulcers of the prostate, which have been occasioned by strictures in the urethra, may be cured by removing the latter disease.

Whoever wishes a more particular account of the diseases of the prostate gland, should consult Baillie's Morbid Anatomy; Hunter's Treatise on the Venereal Disease; Home on Strictures, and on Diseases of the Prostate Gland.

PROSTATES, προστάτης, among the Athenians, was used to signify any patron to whose protection sojourners in that city committed themselves.

He was allowed to demand several services of them, in which, if they failed, or neglected to choose a patron, an action was commenced against them before the polemarchus, and their goods were confiscated. See SOJOURNERS.

PROSTHAPHÆRESIS, formed from στραφείν, ante, προ, and συνολος, adempius, in Astronomy, the difference between the true and mean motion, or true and mean place, of a planet; called also equation of the orbit, or of the centre, and simply the equation.

Prosthaphæresis amounts to the difference between the mean and equated anomaly.

Thus, suppose the circle A L M P N R (Plate XIX. Alfron. fig. 7.) the orbit of the earth, surrounded by the elliptic α, ω, =, &c. and suppose S the sun, and the earth in R, the mean anomaly will be the arc A P R, or calling away the semicircle, the arc R P, or the angle P C R; and the true anomaly, rejecting the semicircle, will be P S R, which is equal to P C R, and C R S: if then to the mean anomaly we add the angle C R S, we shall have the true anomaly P S R, and the earth's place, in the elliptic.

And here the angle C L S, or C R S, is called the prosthaphæresis, or equation, by reason it is sometimes to be added, and sometimes to be subtracted from the mean motion, that we may have the true motion or place of the earth. See Equation of the Centre.

PROSTHESIS, προσθήσις, in Grammar, a species of
metaphysics; being the prefixing of some letter or syllable at the beginning of a word: as in genet, pro navis.

This is also called apposition.

Prothesis, among Socrates, is the filling up of what was before wanting, by the apposition of new matter. Such, e. g. is the filling up of tissue with new flesh.

Prosthetas, Prosthetas, from protos, to apply, signify in Hippocrates, subdititious medicines, whether suppositories or phials.

Prostitutes and Prostitution. See Bawdy-House, Concubinage, &c.

Prostyle, Prostaxis, formed from pro, before, and stasis, column, in the Ancient Greek Architecture, a range of columns in the front of a temple.

Prostytas, Prostytas, in the Sculpture of the Ancients, images carved in such a manner as to be only half raised above the ground, or plain, on which they are formed. They seem to adhere to it, and have only one side exposed to view. To prostyle is opposed etoysis.

Prosynlogism, Prosynlogismus, is used, by some school-writers, for a reason or argument produced to strengthen or confirm one of the premises of a syllogism.

Others define prosynlogism, an argument composed of two syllogisms, fo diapore, as that the conclusion of the former is the major or minor of the latter: e. g. Every rational is ubilable; but every man is rational, therefore, every man is ubilable: but no as is ubilable, therefore no as is a man.

The major, or the second syllogism, may be omitted or understood; and some even contend, that it ought to be fo: to that, on their principle, a prothesis, or redundant syllogism, is when two syllogisms are fo contained in five propositions, as that the conclusion of the former is the major or minor of the latter.

Proszowice, in Geography, a town of Aulian Poland; 16 miles E. of Cracow.

Protogoras, in Biography, a celebrated Greek philosopher, was born at Abdera, in Thrace, in the year 619 B.C. He appears to have been of humble origin, and when young was obliged to gain his livelihood by working as a porter. In this capacity he was frequently employed in carrying loads of wood from the adjacent country to Abdera. Democritus met him with one of his usual burdens, and being struck with the neatness with which it was packed, asked if he had done it himself, to which he replied in the affirmative; the philosopher pleased with the ingenuity, desired the youth to follow him, saying he would present him with greater and better objects for the exercise of his talents. The young man readily complied, and Democritus took him home, maintained him at his own expense, and instructed him in the principles of philosophy. After this Protagoras went to Athens, where he opened a school, and acquired great reputation for eloquence, wisdom, and that subtilty in reasoning which was so much admired by the sophists. His public lectures attracted great numbers, who paid him liberally, and he became exceedingly rich. While he was growing in reputation and wealth, he incurred the displeasure of the Athenian state, by advancing doctrines favourable to impiety. Of this he was accused by different persons, and among others by one of his scholars, Eutolmus, who asserted, that in one of his books he had said, "concerning the gods I am wholly unable to determine whether they have any existence or not; for the weaknesses of the human understanding, and the shortness of human life, with other causes, prevent us from attaining this knowledge." Similar opinions were also to be met with in some of his other writings, and, on this ac-

count, they were ordered to be collected, and burnt in the market place, while the author himself was banished from Attica. He took refuge in Epirus, where he lived many years. Intending to remove to Sicily, he lost his life by shipwreck on his voyage thither, when he was about 70, or, as others say, 90 years of age. He was author of various pieces upon logic, metaphysics, ethics, and politics, but none of them are extant. He had, unquestionably, a leaning to scepticism, and is said to have taught that contradictory arguments may be advanced upon every subject; that all natural objects are perpetually varying; that the fenes convey different reports to different persons, and even to the same person at different times; that nevertheless, we have no other criterion of truth than our own perception, and cannot know that any thing is other wise than it appears to us. The doctrine of Democritus, that the atoms of which bodies are composed are in perpetual motion, Protagoras conceived that external objects are liable to such continual fluctuation, that nothing can certainly be known of them, and hence he concluded that nothing can be pronounced to exist, but that which is at any instant perceived by the senses, and that since these are perpetually varying, things themselves accordingly vary, so that, upon the same evidence, that of the fenes, contradictory opinions may be advanced. Endfield's Hist. Phil.

Protasis, Protasis, from protos, porcos, I hold forth, in the Ancient Drama, the first part of a comic or tragick piece, in which the several persons of the play are shown; their characters and manners intimated; and the action, which is to make the subject of the piece, proposed and entered upon.

The ancient protasis might go about as far as our two first acts. See Act.

Where the protasis ended, the epiphanis commenced.

Protaticus, Protaticus, a person who never appeared but in the protasis, or first part of the play: as Sophia, in Terence's Andria, &c.

Prote, in Geography, one of the Prince's islands, in the sea of Marmora, about three miles in circumference; healthy and uncultivated. The port is filled up.

Protea, in Botany, a name well chosen by Linneaus, to express the great diversity of habit in the species of this genus; at least as he understood it; for other botanists, both before and after him, have much contracted its limits; see Protea. Linn. Gen. ed. 1. 22.

Brown Tr. of Linn. Soc. v. 10. 74. Ait. Hort. Kew. v. 1. 188.

Gerrn. t. 51. (Eucaedron; Linn. Gen. ed. 6. 46.)

Gen. Ch. Common calyx many-flowered, of numerous, loosely imbricated, permanent secal; the innermost much the longest, expanded, and coloured. Cor. of one petal; tube simple, finally splitting longitudinally; limb in four concave segments, three of which cohere laterally. Nectary of four glands, alternate with the segments of the corolla, at the base of its tube. Stam. Filaments four, very short, inserted into the base of each segment of the limb; anthers oblong, incumbent, in the hollows of the segments. Pij. German superior, oblong; style awlshaped, permanent, the length of the corolla; stigma undivided, cylindrical, erect, more slender than the style. Peric. none. Seed. Nut solitary, oblong, all over, crowned with the hardened style, of one cell. Common Receptacle spotted, clothed with short permanent secal.

Eff.
PRO

Efl. Ch. Corolla separable into two unequal parts; limb four-cleft, with concave segments, bearing the stamens. Stigma cylindrical, more slender than the style. Nut superior, brittle all over, crowned with the permanent style. Common receptacle scaly. Common calyx imbricated, permanent.

Of this genus, as it now stands, Mr. Brown enumerates 39 species, 35 of which have terminal, the rest lateral, heads of flowers. All are natives of Southern Africa, except *P. Aethynica*, found only by Bruce in the country where it bears. Twenty-three are mentioned in Hort. Kew, as known in the British collections. The habit of the whole is shrubby; the height very various. Some few are almost stemless. Leaves entire, coriaceous. The flowers in many cacti are remarkable for their beauty and magnitude, the inner scales of the common *caules* being sometimes elegantly silky, so as to resemble black velvet. See the following examples.

P. *spectabilis*. Splendid Protea. Linn. Mant. 191. Brown n. 6. Ait. n. 3. Curt. Mag. t. 1185. —Leaves ovate-oblong, contracted at the base, smooth as well as the branches. All the scales silky; the inner ones somewhat dilated at the top; the middle ones likewise fringed. Style downy. Segments of the corolla with woolly points. Sent from the Cape of Good Hope, in 1786, by Mr. Maffon. It flowers in the greenhouse from March to June. The stem forms a large shrub. The leaves are obtuse, three or four inches long, and nearly half as broad. Flowers as big as a small artichoke, with rose-coloured scales, finely fringed with brown, and bearded with white.

P. *mellifera*. Honey-bearing Protea. Thumb. Diff. n. 37. Brown n. 16. Ait. n. 9. Curt. Mag. t. 346. (Leucadendron repens; Linn. Sp. Pl. 135, s.). —Leaves lanceolate, tapering at the base. Calyx turbinate; scales smooth; bearded; vilose. Tips of the corolla woolly. Style smooth, simple at the summit. An inhabitant of the Cape, long known in our gardens and herbariums; distinguished by its very glutinous, roce-coloured, smooth *caules*, which is almost as large as the foregoing. The branches are red and smooth. Leaves slightly ovate, or spatulate.

P. *muroiderifolium*. Dagger-leaved Protea. Salt. Parad. t. 24. Brown n. 20. Ait. n. 12. Curt. Mag. t. 933. Andr. Repof. t. 560. —Leaves linear-lanceolate, sharp-pointed; broad at the base. Scales of the calyx lanceolate, pointed, smooth. Stem erect, many-flowered. —Found at the Cape by Mr. Niven. Melville. Lee and Kennedy are said to have first raised it from seed, about the year 1803. It flowers in autumn. This is much smaller, in every part, than either of the above-mentioned, being a bush, only two or three feet high, with numerous, pungent, rather glaucous, fleshy-leaved, with scarcely two inches long. Flowers flesh-coloured, with a spreading, taper-pointed calyx, expanding above two inches.

P. *cordata*. Heart-leaved Protea. Thumb. Diff. n. 60. Ait. n. 19. Curt. Mag. t. 289. (P. cordifolia; Curt. Mag. t. 649). —Flowers lateral. Leaves roundish-heart-shaped, many-ribbed. Scales of the calyx smooth. —Sent from the Cape, by Mr. Maffon, about the year 1786. It blossoms in the spring, and is remarkable for the situation of its dull-crimson rooseval flowers, which grow out of the creeping stem, near the root, the leafy branches rising high above them, in a zigzag nearly upright position. The leaves are alternate, distant, nearly fleshy, broad, red-edged, of a very rigid coriaceous texture.

P. *humilis*. Low-flowering Protea. Brown n. 48. Ait. n. 22. (P. humiflora; Andr. Repof. t. 532). —Flowers lateral. Leaves linear-lanceolate, acute. Receptacle conical, with acute scales. —Found at the Cape, by Mr. Niven, who sent it to his patron Mr. G. Hibbert, about the year 1802. This is still more singular than the last, for its crowded radical flowers, whose colour is a dull-crimson red. The leafy branches are numerous, erect, a foot high. Leaves numerous, nearly linear, acute, smooth, two or three inches long.

**Protea**, in Gardening, contains plants of the ornamental, shrubby, exotic kind, of which the species cultivated are, the cone-bearing *protea* (P. coniferia); and the silvery *protea* (P. argentea). But there are several other species that may be cultivated for variety.

**Method of Culture.**—These plants are increased by seeds, procured from the places of their native growth; which, as soon as obtained, should be sown in pots filled with sandy loam, and placed in a moderate hot-bed; and when the plants are come up, moderate air should be given, or they should be placed in an airy glass cage, or towards the front of a greenhouse; and be afterwards managed as other similar exotics of that kind.

They are also sometimes raised by cuttings, in spring and summer, by the assistance of a hot-bed, in the same manner. They should not have much water afterwards, nor be treated in too tender a manner.

They are ornamental among other potted plants.

**PROTEACEÆ**, in Botany, a natural order of plants, the third in Jussieu’s sixth class, (where it is termed Protea, and the twenty-sixth of his general system. For other orders of this sixth class, see *Elagagni, Lauri*, and *Polygonaer*. The characters of the order in question are thus given by Jussieu.

Calyx, (rather corolla,) in four or five deep divisions, or tubular, with four or five segments, sometimes accompanied below by minute dots or scales. Stamens equal in number to the divisions of the flower, and inserted into their middle part. Gynaeum solitary, superior; style simple; stigma moily solitary. Seed one, either naked or enclosed in a seed-vessel; very rarely the latter is a capsule of one cell, with many seeds. Albumen none. Radicle inferior. Stem shrubby. Leaves either alternate, or clustered in a somewhat whorled manner. Flowers either distinct, or variously assembled upon a common receptacle, within the imbricated scales of a common calyx. Sometimes the *flamen* and *pilifer* are in separate individuals.

The genera in Jussieu are *Protea*, *Bankia*, *Rupaulia* of Aublet, *Brakelii*, and *Embathrium*.

Mr. R. Brown, in Trans. of Linn. Soc. v. 10. p. 15—226, has given a matterially different on this natural order, full of important remarks on the systematical distinctions, as well as on the geography of plants. In this treatise the *Proteaceæ* are divided into no less than 38 genera; *Auculis*, *Leucadendron*, *Peronophora*, *Iphagon*, *Protea*, *Leucospermum*, *Stearnia*, *Mimetes*, *Nerceptions*, *Steronchus*, *Spattula*, *Adenanthera*, *Guevina*, *Brakelii*, *Peronophora*, *Ceratocystis*, *Aphaidites*, *Symphysia*, *Belendena*, *Franklandia*, *Sinfor*, *Conofernum*, *Synnem*, *Acanthos*, *Coryaella*, *Hakea*, *Lambertia*, *Xylemthum*, *Orites*, *Rhopalæ*, *Knightsia*, *Eumหยoithium*, *Orcocallis*, *Telopea*, *Lomatia*, *Sterocarpus*, *Bankia*, and *Dryandra*. Most of these will be found in their proper places. Our *Dryandra* however is properly superfed by that of Mr. Brown, as being not really distinct from *Aleurites* of Forster.

**PROTECTION, PROTECTIO**, the shelter, defence, authority, and aid, employed by any one in behalf of the helpless or unhappy.

Active protection supposes power, interest, favour, &c. in the person that protects. *Passive protection*, on the contrary,
PROTECTIO is also used for a privilege belonging to ambassadors, members of parliament, &c. by which they and their domestics are secured from arrest, &c. See Embassador and Arrest.

Protection is sometimes also underfoot of the person of the protector. Such a cardinal has the protection of France. The protection of Spain is become vacant by the death of such a cardinal.

Protection, in Lava, in its general sense, denotes that benefit and safety which every subject, denizen, or alien, specially secured, hath by the laws.

Protection, in a more special sense, is used for an exemption or immunity given by the king to a person, to secure him against suits in law, or other vexations, upon reasonable causes moving him thereunto, and for a certain time.

Of this, Fitzherbert makes two kinds: the first he calls a protection _cum claufula volumus_; of which he mentions four cases: 1. A protection, _quia profecturus_, for him that is to pass over sea, in the king's service. 2. A protection, _quia moraturus_, for him who is already abroad in the king's service; as an ambassador, &c. 3. A protection for the king's debtor, that he be not sued, or attached, till the king be paid his debt; but by the statute 25 Edw. III. cap. 19. notwithstanding such protection, another creditor may proceed to judgment against him, with a stay of execution till the king's debt be paid; unless such creditor will undertake for the king's debt, and then he shall have execution for both. (See Arrest.) 4. A protection for a person in the king's service beyond sea, or in the marches of Scotland.

The second form of protection is _cum claufula volumus_, which is most commonly granted to a spiritual company, for their immunity from having their cattle taken by the king's ministers. But this may be also granted to a single person, either spiritual or temporal.

Protection extends not to pleas of dower, quaere impedit, affize of novel difficult, darren prententment, attentats, nor pleas before justices in eyre.

Protection from Impressio is a privilege allowed to certain persons to be exempt from being impressed. This is granted to apprentices to the sea-service, persons employed in the fisheries, coaling trade, &c.

Protection Island, in Geography, a small island in the gulf of Georgia, at the entrance of Port Discovery. N. lat. 48° 0'. E. long. 237° 20'.

PROCTOR, a person who undertakes to shelter and defend the weak, helpless, or diffraught.

God, and the magistrate, are the protectors of the widow and orphan. Among the heathens, Minerva was esteemed the protector of arts.

Every Catholic nation, and every religious order, has a protector residing at the court of Rome, who is cardinal, and is called the cardinal protector.

Protector is sometimes also used for a regent of a kingdom, made choice of to govern it during the minority of a prince.

Cromwell assumed the title and quality of lord protector of the commonwealth of England.

PROTECTORI, among the Romans, were the poorer sort of citizens, whose estate did not exceed fifteen hundred pieces of silver. They were distinguished from those who were worth little or nothing; these last being called capite consi.

PROTEST, in _Ancient Music_, a rest or pause, equal to a long syllable; differing from the _limma_, which was the rest for a short time or syllable.

PROTEST, in _Law_, is used for a caution, or call of witnesses, or an open affirmation, that a person does, either not at all, or but conditionally, yield his consent to any act; or to the proceeding of any judge in a court, in which his jurisdiction is doubtful; or to answer upon his oath farther than by law he is bound.

Any of the lords in parliament have a right to protest their different to any bill passed by a majority, with their reasons for such difference; which protest is entered in form. This privilege is said not to be very ancient: the commons have no right to protest.

Protest, in _Commerce_, is a summons made by a notary public to a merchant, banker, or the like, to accept or discharge a bill of exchange drawn on him; after his having refused either to accept or pay the same.

It is called a protest, because it contains a protestation, that the party will return the bill, and even take up money at interest; and charge all costs, damages, carriage, and re-carriage, on the refuser.

There are two kinds of protests, the one for want of acceptance, and the other for want of payment.

The first is to be made by the bearer of the bill, at the time of presenting it, in case the person on whom it is drawn refuses to accept it for the time, or the sum there expressed. See _Bill of Exchange_.

This protest must be made within the regular hours of business, and in sufficient time to have it sent to the holder's correspondent by the very next post after acceptance refused; for if it be not sent by that time, with a letter of advice, the holder will be conformed to have discharged the drawer and the other parties entitled to notice; and noting alone is not sufficient; there must absolutely be a protest to render the preceding parties liable. (Bull. N. P. 271. 2 Term Rep. 713.) But in this case the holder is not to send the bill itself to his correspondent: he must retain it, in order to demand payment of the drawer when it becomes due. When the bill becomes due, whether it was accepted or not, it is again to be presented for payment within the days of grace, and if payment be refused, the bill must be protested for non-payment; and the bill itself, together with the protest, sent to the holder's correspondent, unless he shall be ordered by him to retain the bill with the prospect of obtaining its discharge from the acceptor. As this protest on foreign bills must be made on the last day of grace, and immediate notice sent to the parties concerned, it seems established, that such a bill is payable, "on demand made at any time that day" within reasonable hours; and that the acceptor has not the whole day to pay the bill. 4 Term Rep. 170.

Besides the protest for non-acceptance, and for non-payment, there may be also a protest for better security. This is usual when a merchant who has accepted a bill happens to become insolvent, or is publicly reported to have failed in his credit, or absents himself from Change, before the bill he has accepted becomes due; or when the holder has any reason to suppose that it will not be paid; in such cases he may cause a note to demand better security, and on being refused, make protest for want of it; which protest must also be sent to the parties concerned, by the next post. (Mir. 27. Lord Raym. 743.) In such cases, however, the most general practice is to wait the regular time till the bill becomes due. Where the original bill is lost, and another cannot be had of the drawer, a protest may
may be made on a copy, especially where the refusal of payment is not for want of the original bill, but merely for another cause. 1 Show. 164.

But if a bill left for acceptance be lost, the person with whom it was left muft bind himself to payment, or else the bill may be protested immediately. It is customary, as a precaution against accident or miscarriage, to draw three copies of a foreign bill, and to send them by different post. They are denominated the first, second, and third of exchange; and when any of them is paid, the rest become void and of no value.

The effect of protest for non-acceptance, or non-payment, is to charge the drawer, or indorsers, not only with the payment of the original sum, but with interest, damages, and expenses; which latter confit usually of the exchange, re-exchange, commiffion, and poggage, together with the expenses of the protest. (Stra. 649.) The exchange is reckoned according to the course at fight from the place where the protest is made, to the place where the bill is to be paid by the drawer; and if it be not paid there, the re-exchange is then reckoned from the fame place to that where the bill is paid, and also double commission. The interest commences from the day when the demand was made. Whenever interest is allowed, and a new action cannot be brought for it, which is the case on bills and notes, the interest is to be calculated up to the time of signing final judgment. 2 Burr. 1886-7. 2 Term. Rep. 52.

The principal difference between foreign and inland bills of exchange at common law seems to have been this. A protest for non-acceptance or non-payment of a foreign bill was, and still is, essentially necessary to charge the drawer on the default of the drawer; nothing, not even the principal sum, could or can at this time be recovered against him without a protest; no other form of notice having been admitted by the custom of merchants as sufficient; but on inland bills, simple notice, within a reasonable time, of the default of the drawer, was held sufficient to charge the drawer, without the solemnity of a protest; the disadvantage arising from thence was this, that notice entitled the holder to receive only the sum in the original bill, which in many cases might be a very serious disadvantage; to remedy this inconvenience in some degree, the flat. 9 & 10 W. III. c. 17. and afterwards the flat. 3 & 4 Anne, c. 9. were passed; the professed intention of which acts was to put inland bills on the fame footing as foreign ones; so far as relates to the recovery of damages, intereft, and costs, (i.e. expenses,) by means of the protest they have done it; but there are several minute particulars, in which, from an attentive perufal of the acts, it will appear they still differ.

To the constitution of a Bill of Exchange, (which fee,) it is not necessary that the words "value received," should be inferted; and the want of these in a foreign bill, cannot deprive the holder of the benefit of a protest; but that benefit in cafe of non-payment is not given by the flatutes to inland bills, which want these words, and therefore they cannot be protested for non-payment; and the second act provides, that "where these words are wantinf, or the value is lefs than 20l. no protest is necessary, either for non-acceptance or non-payment," the safest construction of which seems to be, that inland bills, without the words "value received," or under 20l. shall continue as at common law, and shall not be entitled to the privilege of a protest, either for non-acceptance or non-payment.

An inland bill, payable at fo many days after "fight," cannot be protested at all, and no inland bill can be protested, till after the expiration of the three days of grace; notice of which protest is by the statute to be sent within fourteen days after the protest. 4 Term. Rep. 170.

There appears to be also another difference subsisting between foreign and inland bills of exchange; for where acceptance and payment both are refused on foreign bills, it seems neceffary that there should be a protest for each; but under the flat. 3 & 4 Anne, c. 9, it seems, that one protest for either, on an inland bill, is sufficient. On inland bills, where damages, intereft, and costs, (expenses,) are to be recovered, there is more indulgence in the time allowed for notice of non-payment than where only the principal sum is to be recovered; for when there is no protest for non-payment, presentation for payment must be made so early as the last day of grace, that the holder may give notice of non-payment by the next poll. That part of the flat. 3 & 4 Anne, c. 9, which puts notes on the fame footing with inland bills, makes no express provision for protesting them for non-payment; but there can be doubt that the practice under which such a protest is frequently made is founded in justice.

After a bill has been protested, it is sometimes accepted by a third person to save the reputation of the drawer, or of an indorfer; such an acceptance is called an acceptance "supra protest." The acceptor muft then appear in prorf, with witnesses, before a notary, and declare that he accepts it for the honour of such a person, and subscribe the bill thus:—Accepted, "supra protest." in honour of, &c. The fame may happen when the person upon whom a bill was drawn, having doubts about the drawer, protests it, but afterwards accepts it for the honour of one of the indorsers; in this case the bill muft be sent to the faid indorfer without delay. The person for whose honour a bill was accepted must reinfure the acceptor the amount of the bill, commiffion, and other charges, even though the acceptance should have taken place without his knowledge. If such a person approves of the acceptance, the bill may be paid without any farther protest; but if he should return no answer, or express his disapprobation of the acceptance, the bill must be formally protested for non-payment againfi him to whom the bill was directed; and on his perfiling to refufe payment, the acceptor may safely pay it for his account, as he can recover the amount.

As to several niceties relative to qualified acceptance, and protests under peculiar circumstances, see Beawes Lex. Merc. See also 1 Will. 185. Doug. 249.

At Paris the protest is to be made within ten days; at Hamburg within twelve days; at Venice, where all bills are paid in banco, the protest for want of payment is to be made within fix days; but then the bank is fuppofed open, otherwise no protest to be made; however, in 1808, the bank was disfcontinued, Venice having been incorporated with the kingdom of Italy in 1805: at Rome, protests for want of payment are to be made within fifteen days: at Leghorn, Milan, and Bologna, there is no time fixed: at Amsterdam, they are to be made within fix days.

The negociators of fome places, as those of Rome, M. Savary observes, do not look on themselves as obliged to protest in default of payment: but this opinion is contrary to univerfal custom, and natural reafon: fince, till after proteftation, they have no remedy or refoures against the drawer, or indorfer, nor any title to be reimbursed.

M. Ricard adds, that bills of exchange drawn from Amsterdam, or Antwerp, or Spain, are to be protefted, in default of payment, within fourteen days after they fall due; after which time the bearer fands the risk and chance of the non-protefted
Protested bill (not the drawer, or indorser), in case the party happens to fail after the said fourteenth day. See Bill of Exchange.

Protest, in Sea Language, is an instrument drawn up in writing, attested before a justice of the peace, by the master and a part of the ship's crew, after the expiration of a voyage, describing the severity of the said voyage, occasioned by tempestuous weather, heavy seas, an insufficient crew, or any other circumstances by which the ship has suffered, or may suffer, either in her hull, masts, rigging, or cargo. It is chiefly intended to shew, that such damages or misfortunes did not happen through any neglect or ill conduct of the master or his officers, Falconer.

The protest of the captain, so long as he is living, is in no case evidence on the one side or the other; the only use that can be made of it is to contradict his testimony, if he varies from it.

Protestando, in Law, is a word made use of to avoid double pleading in actions; it prevents the party that makes it from being concluded by the plea he is about to make, that if he cannot be joined upon it; and it also is a form of pleading, where one will not directly affirm or deny any thing alleged by another or himself. In the first case, it is where a man pleads a thing which he dares not affirm, or that he cannot plead for fear of making his plea double; as in title to lands by two defendants, the defendant must plead one of them, and put the word protestando instead of dicti; as to the other, that such a one died feised, &c. and in the last case, when one is to answer to two matters, and by the law he ought but to plead to one; then in the beginning of the plea he may say protestando, that such matter is not true, and add to his plea pro piseto dicti; and fo he may take issue upon the other part of the matter. Plowd. 276.

Finch 370.

Protestant, a name first given in Germany to those who adhered to the doctrine of Luther; because, in 1529, they protestted against a decree of the emperor Charles V. and the diet of Spires; and declared, that they appealed to a general council.

In a former diet, held at Spires in 1526, it was unanimously agreed to present a solemn address to the emperor, beseeching him to assent, without delay, a free and a general council; and it was also agreed, that in the mean time, the princes and states of the empire should, in their respective dominions, be at liberty to manage ecclesiastical matters in the manner they should think the most expedient, yet so as to be able to give to God and to the emperor an account of their administration, when it should be demanded of them. This decree was considered by the adversaries of the Reformation as almost equivalent to a toleration of Luther's opinions, and therefore, as soon as the emperor had concluded a treaty of peace with Clement VII., who now sat in the papal chair, he assembled the new diet at Spires in 1529; where the power which had been granted by the former diet to every prince, of managing ecclesiastical matters as they thought proper, until the meeting of a general council, was revoked by a majority of votes; and every change was declared unlawful, that should be introduced into the doctrine, discipline, or worship of the established religion, before the determination of the approaching council was known. Against this decree, the elector of Saxony, the marquis of Brandenburg, the landgrave of Hesse, the dukes of Lunenburg, the prince of Anhalt, together with the deputies of fourteen imperial or free cities, entered a solemn protest.

The name has been since also given to those who adhere to the sentiments of Calvin; and is now become a common denomination applied indiscriminately to all the sects, of whatever denomination, which have revolted from the Roman see.

Protestants, French. See Huguenots.

Protestant Dissenters. See Dissenters, and Non-conformists.

Protestant Succession. See Right of Crown.

Protestation, in Law, a solemn declaration made by some judiciary act, or proceeding against any oppression, violence, or injustice; or against the legality of a sentence, judgment, decree, or other procedure; importing, that the party is determined to oppose it at the proper time, &c. See Protest.

Protestation is defined by justice Walsh, a defence, or safeguard, to the party that makes it, from being concluded by the act he is about to do; so that issue cannot be joined upon it.

Protestation is defined by Plowden, a form of pleading, when one does not either directly affirm or deny any thing alleged by another, or which he himself alleges. Plowd. fol. 276. See Protestando.

Proteus, in Mythology, the son of Neptune and Phenice, or Oceanus and Tethys, who was reputed one of the gods of the sea, and supposed capable of foretelling future events, and of transforming himself into any shape at pleasure.

According to Diodorus Siculus, he was king of Egypt, and, after the manner of their kings, he sometimes used a lion, and sometimes a bull for his crest. He is said to have reigned two hundred and forty years after Moses, and by his distinguished knowledge of astronomy to be able to predict the revolutions of the planets.

No character in mythology is more celebrated than this sea-god, and the two greatest poets of antiquity, Homer (Odyss. lib. iv.) and Virgil (Georg. 4.), have vied with each other in delineating it. In order to separate the truth of history from fiction, we should collect and compare the accounts which ancient writers, such as Homer, Herodotus, Diodorus Siculus, Clemens Alexandrinus, Lythophorion, and several others, have given us of Proteus. All agree, that about the time of the Trojan war, Proteus was a king of Egypt, who kept his court at Memphis. According to Herodotus, he was the successor of Phoron, and had a temple at Memphis, which was splendid and magnificently adorned: and in this temple was a chapel dedicated to Venus. Diodorus Siculus calls him Cetes. The circumstance which seems to have given rise to the metamorphoses of Homer and Virgil seems to have been this: Proteus was a wise and eloquent prince, and the precaution which led him to avoid every danger answered the purpose of a prophetic spirit, which is ascribed to him. Homer and Virgil, by the qualities which they attribute to him, seem to be giving an allegorical description of a king, wise and provident, artful and inimitable, and not of a sea-monster, or a chameleon, that changed his form and figure. Nothing is more usual in the poets, and even in scripture, than those symbolic descriptions that figure a character under obscure terms; accordingly Proteus is distinguished from Neptune, because he was powerful at sea, and master of Carpathia, an island near Egypt, and hence he was afterwards styled a sea-god; and that he himself was a native of Paphle, in Thessaly.

Some authors allege, that Proteus was a skilful orator, who could easily prevail with those who conversed with him, to alter their sentiments. Heraclides of Pontus says, that the fable of Proteus comprehends the mystery of the formation of the world, and that his changes were designed
to teach us, that matter was capable of receiving all sorts of forms, and that Eidothea, who advises to bind her father, is divine Providence, which fixes this matter to certain subjects. According to Bryant, he was the patriarch Noah.

PROTEUS, in Natural History, an animaleule discovered by Baker in the flame-like matter taken from the side of a glass jar, in which small fishes, water-nails, and other such creatures, had been kept alive for two or three months, by giving them frequently fresh water. In sub stance and colour it resembles a fish; its shape is somewhat elliptical, but pointed at one end, whilst from the other a long, slender, and finely proportioned neck stretched itself out, and was terminated with a kind of head. Mr. Baker has described and given a figure of this microscopic animal, and denominated it Proteus from its various sudden transformations. Employment for the Microscope, vol. ii. c. 5.

PROTHESES, προθέσεις, derived from προθέσις, I expose to view, among the Greeks, the ceremony of laying the dead near the door till the time of their interment, with their feet outward; on which account the Romans called them portae.

PROTHESIS, a little altar in the Greek churches, on which a ceremony is performed, called by the name προθεσίς. On this altar the priests, with the other ministers, prepare every thing necessary to the celebration of masses, viz. the bread, wine, &c. After which they go in procession from this to the great altar to begin masses; carrying with them the species thus prepared.

PROTHONOTARY, Prothonotaris, Protonotary, a term properly signifying first notary; and which was anciently the title of the principal notaries of the emperors of Constantinople.

With us prothonotary, called also regentary, is used for an officer in the courts of king's bench and common pleas; the latter of which has three, the former one. See Court, &c.

Prothonotary of the king's bench records all actions civil, fixed in that court; as the clerk of the crown-office doth in all criminal causes.

Prothonotaries of the common pleas enter and inroll all declarations, pleadings, affizes, judgments, and actions: they also make out all judicial writs, as the venire facias, after issue joined; except habeas corpus, and diriging jurat, for which there is a separate office; writs of execution and seisin, of superfedation, of privilege, &c.; they inroll all recognizances acknowledged in that court, all common recoveries, make exemptions of records, &c.

Prothonotary, or Protonotary, is also an officer in the court of Rome, who has a degree of pre-eminence over the other notaries.

There is a college of twelve prothonotaries, called participants; because partaking in the fees of the expeditions in chancery.

They are ranked among the number of prelates, and wear the violet rochet, the hat, &c. They sit at all grand ceremonies, and have a place in the pope's chapel.

Their office is to dispatch the acts in grand causes, which the simple apostolical notaries dispatch in lesser causes: they may create apostolical notaries and doctors, to officiate out of the city.

Those out of the college have none of the privileges of the others, except the habit.

The prothonotaries were first established at Rome by pope Clement I. with design to write the lives of the martyrs.

PROTHYRIS, in the Ancient Architecture, is some times used for a quo in, or corner of a wall; otherwise called aecus. See Console.

Sometimes, also, for a cross-beam, or over-thwart rafter.

PROTHYRIS is also used, by Vignola, for a particular sort of key of an arch: an instance of which we have in his Ionic order; confiding of a roll of water-leaves, between two reglets and two fillets, crowned with a Doric cyma tium; its figure being much like that of a modillion.

PROTHYRUM, προθυρός, a porch at the outer door of a house or portal.

PROTIPIULA, in Entomology, a name given to a species of fly resembling the tipula, or long-legs, in many respects; but differing in regard to the essential character, which, in the tipula, is the having two heads growing on the anterior part of the head, and occasionally falling over the mouth, and closing its aperture; whereas the tipula wants.

PROTIVIN, in Geography, a town of Bohemia, in the circle of Prachatitz; four miles N. of Wodnian.

PROTO, formed from τρόπος, way, a word used in composition with divers terms in our language, to express a relation in priority; as in proto-martyr, proto-type, &c.

Proto-Canonical. See Deutero-Canonical.

PROTOCOLLOM, πρότερος, a term used in the ancient jurisprudence for the first leaf of a book, in which was the mark of the paper, or parchment.

It was even sometimes used for the mark itself; which was usually in the margin, but sometimes at the top of the page.

The forty-fourth Novel of Justinian forbids cutting the protocollolem of charters, which slew the year in which the paper or parchment was made, and the officer commissioned for the delivery of them; by means of which friends were frequently detected.

Protocollolem was also used for the first minute, draught, or summary, of an act to be passed, which the notary drew up, in short, in little table-books, to be afterwards enlarged at leisure.

PROTOFORESTARIUS was he whom our ancient kings made chief of Windsor forest, to take cognizance of all causes of death or mayhem there; after the manner of a lord chief justice in eyre.

PROTOGALAM, the term used by the ancients for what we call beverages, the first milk of a cow or other animal after her having brought forth young.

PROTOGNUS, in Mythology, the first man in the cosmogony of the Phoenicians, whose wife was Een; and of their posterity Sanchoniathon has given an account. According to Bryant, in his Analysis of Mythology, Protogonus was designed to represent the great patriarch Noah; who is described in the Orphic Hymns, 5, as the first of men; of a twofold state or nature, who wandered at large under the whole heavens, inclosed in an oviparous machine, (whence he was termed Ovum, ovo genius,) and who was (hieroglyphically) depicted with golden wings. The form was the parent of all mankind, who dispelled the mist and darkness with which every thing had been obscured.

PROTO-MARTYR, compounded of πρώτος, first, and μάρτυς, witness, the first martyr, or witnesses, who suffered death in testimony of the truth; as Abel, improperly reckoned so by some, in the Old Testament, and St. Stephen in the New.

PROTONOTARY. See Prothonotary.

PROTOPASCHITÆ, πρωτοπασχιτας, in Church History, heretics, who, after the manner of the Jews, celebrated the feast of Easter with unleavened bread. They were likewise called Sophians.

PROTO-
PRO

PROTOPLAST, Protoplastus, a title sometimes

given to our first father Adam, from the Greek πρότωνος, q. d. first formed.

PROTOS, Gr., the name of the first tone or ecclesiastic

al mode, in the Ambrosian chant.

PROTOTYPE, πρότοτος, the original, or model, by

which a thing is formed.

It is chiefly used for the patterns of things to be engraved, moulded, or cast.

PROTOTYPE, in Grammar, is sometimes

used for a primitive, or original word.

PROTRACTING, or Protraction, in Surveying,

the act of plotting, or laying down, the dimensions taken in

the field, by means of a protractor, &c.

Protracting makes one part of surveying.

PROTRACTING-PIN, a mathematical instrument, or rather

an appendage of an instrument called a protractor.

The protracting-pin is a fine needle, fitted into a handle,

used to prick off degrees and minutes from the limb of the protractor.

PROTRACTOR, a name of an instrument used in

Surgery, to draw out any foreign or disagreeable bodies

from a wound or ulcer, in like manner as the forceps.

Protractor is also an instrument used in Surveying,

by which the angles taken in the field with a theodolite, cir-

cumferentor, or the like, are plotted, or laid down, on

paper.

This protractor consists of a semicircular limb, A DB

(Plate I. Surveying, fig. 1.) of brass, silver, horn, or the

like, divided into 180°, and subtended by a diameter B A,

in the middle of which is a little notch, or lip, C, called

the centre of the protractor.

For the convenience of reckoning both ways, the degrees

are numbered from the left hand towards the right, and

from the right hand towards the left.

But this instrument is made much more commodiously by

transferring the divisions on the same circumference to the

edge of a ruler, whole side E F is parallel to A B, which

is easily done by laying a ruler on the centre C, and the

several divisions on the semicircumference A D B, and

marking the interections of that ruler on the line E F: so

that a ruler with these divisions marked on three of its sides,

and numbered both ways, as in the protractor, (the fourth

or blank side representing the diameter of the circle), is

of the same use as a protractor; and much better adapted to

a cale.

On the limb of the protractor are sometimes also placed

numbers, denoting the angles at the centres of regular poly-

gons: thus against the number 5, denoting the sides of a

pentagon, is found 72°, the angle at the centre of a

pentagon.

PROTRACTOR, Use of the: 1. To lay down an angle of

any given quantity, or number of degrees, e. gr. of fifty de-

grees, at any point, and with any given line, e. gr. Lay

the centre of the protractor on the given point, and the di-

ameter of the protractor on the given line; make a mark

against the given degree 50°, on the limb of the protractor;

through which, from the given point, draw a line; this

gives the angle required.

2. To find the quantity of a given angle.—Lay the centre

of the protractor on the point of the angle, and the diameter

on one of the lines forming it. The degree of the limb cut

by the other line, viz. 50°, is the number of degrees of the

angle required.

3. To inscribe any given regular polygon, e. gr. a pentagon,

in a circle.—Lay the centre and diameter of the protractor

on the centre and diameter of the circle, and make a dot

against the number of degrees of the angle at the centre,

viz. 72°. Through this dot and the centre of the circle
draw a line, cutting the circumference of the circle. To

the point of intersection, from the point where the diameter
cuts the circumference, draw a right line; this line will be a
side of the pentagon, which, being taken in the compasses,
and set off as often as it will go in the circumference, will
give points, which, being connected by lines, will form the
pentagon required. See Polygon.

4. To describe any regular polygon, e. gr. an octagon, on a
given line.—Subtract the angle at the centre, which the
protractor gives, e. gr. 45° from 180, the remainder 135
degrees is the angle included between two sides of the octa-
gon, one-half of which is 67½°. Applying then the di-
meter of the protractor over the given line, with the centre
over one extreme; make a dot against 67½°, to which from
the centre draw a line; apply the protractor to the other
end of the line, so as the centre be over the extreme, and
there set off another angle of 67½°.

From the point where the two lines thus drawn intersect,
as a centre, describe a circle with the interval of the given
line.

The given line will be one side of the octagon; which,
being set off as often as it will go in the circumference thus
drawn, will give points, which, being connected, will form
the octagon required.

PROTRACTOR, Improved, is an instrument much like the
former, only furnished with a little more apparatus, by
which we are enabled to set off an angle to a minute; which
is impracticable on the other.

The chief addition is an index fitted on the centre, and
moveable on it, so as to play freely and steadily over the
limb. Beyond the limb the index is divided, on both edges,
into sixty equal parts of the portions of circles, intercepted
by two other right lines drawn from the centre, so that each
makes an angle of one degree with lines drawn to the
affumed points from the centre.

To set off an angle of any number of degrees and minutes
with this protractor, move the index, so that one of the
lines drawn on the limb, from one of the fore-mentioned
points, may fall upon the number of degrees given; and
prick off as many of the equal parts on the proper edge of
the index as there are minutes given: thus, drawing a line
from the centre to that point so pricked off, you have an
angle with the diameter of the protractor, of the proposed
number of degrees and minutes.

Indeed it may be of good use to lay down an angle to a
minute, when we are able to take it to a minute: but, till
we have better needles, and Fuller theodolites, than are yet
made, the old protractor may serve very well.

PROTRUSORIS Ordo Exterior, in Anatomy, a name

given by Santorini to certain fæculi of the great zygo-
matic muscle, running under the fibby part of the lower lip.
See Lips.

PROTRUSORIS Interior Ordo, a name given by Santorini
to a muscle of the face, called by Albinus orbicularis oris;
and by Cowper and Douglas contríctor labiorum and
spheníter labiorum. See Lips.

PROTRYGIA, προτρήγας, in Antiquity, a festival in

honour of Neptune, and of Bacchus, surnamed προτρήγας, or
πρότρητος, από της τις είς, i. e. from new wine.

PROTTES, in Geography, a town of Austria; 10 miles
S. of Zillertal.

PROTUBERANCE, Protuberantia, in Anatomy,
denotes an eminence, whether natural, or preternatural,
that projects or advances out beyond the rest.

The orbicular protuberances of the third ventricle of the

brain.
brain are called **nates**; and the apophyses of the orbicular protuberances are called **tegles**.

The annular protuberance is the process of the medulla oblongata, in form of a ring; whence its name, first given by Willis.

**PROTZEN**, in *Geography*, a town of Bohemia, in the circle of Leitomeritz; 22 miles N. of Prague.

**PROVADSCIJK**, a town of European Turkey, in Bulgaria; 46 miles W. of Varna.

**PROVAT**, or **Pruat**, a town of European Turkey, in Bulgaria; 16 miles N.W. of Varna.

**PROVEDITIOR**, **Provetor**, or **Proveditor**, an officer in several parts of Italy, particularly at Venice.

There are various kinds of proveditors in Venice; as **proveditor of the commons**, who is nearly the same with the edile among the Romans, consul in Languedoc, and eschevin in other cities. Of these proveditors there are three.

The proveditors alle ragioni vecchie, alla biure, alla giustitia, &c. have the direction of matters relating to policy, throughout the figiory.

**Proveditor General of the Sea**, an officer whose authority extends over the whole fleet, when the captain-general is absent. He has, particularly, the disposal of the cash; and pays the seamen, and the soldiers.

The captain-general and proveditor are mutually spies over one another; though the proveditor be inferior to the general, yet is the power so divided, that one has authority without strength, the other strength without authority.

**PROVEN**, or **Proven** in *Geography*, a town of France, in the department of the Lys; 9 miles W. of Ypres.

**PROVENCA a Velha**, a town of Portugal, in the province of Beira; five miles N.W. of Idanha à Velha.

**PROVENCAL POETS**, in the *History of Literature*, a name given to certain professions of men who sprang up in Provence about the end of the tenth century, comprehending those that were called Troubadours, or Trouverres, Jongleurs, Cantadours, Violers, and Mufars, in whom the faculties both of music and poetry seemed to be united. The first of these were so denominated from the art which they professed of inventing or finding out, as well subjects and sentiments as rhymes, constituting what at that time was deemed poetry. The jongleurs are supposed to have taken their name from some musical instrument, on which they played, probably of a name resembling in its sound that by which their profession was distinguished; whence firmly the jugglers, guais iaculatoris, as Menage conjectures, who went about singing their verses in courts and the houses of noblemen, with a violin or harp, or other instrument, and were dressed in a peculiar habit, for the sake of entertaining in a burlesque manner their protectors and patrons. M. de Rivailiere derives jongleur from Anglo, a nail, whence anglour, a tricker of instruments with the nails. This etymology, says Dr. Burney (Hist. Mus. vol. ii. p. 267.), is probable; as the lyre, cithara, harp, lute, and guitar, the most ancient strung instruments, have at all times been played with the nails and ends of the fingers. The cantadours, called also chanteres, were fingers of songs and ballads, as were also the mufars; and the violars were players on the viol.

All these arts were comprehended, in the French language, under the general denomination of meneufraudie, meftraudie, and jonglerie.

The Provençal poets were not only the inventors and composers of metrical romances, fongs, ballads, and rhymes, to fo great a number, and of such a kind, as to raise an emulation in most countries of Europe to imitate them; but, if we may credit the Italian writers, the best poets of Italy, namely, Petrarch and Dante, owed much of their excellence to their imitation of the Provençals; and it is also said that the greater part of the novels of Boccace are taken from Provençal or ancient French romances. The learned Dr. Percy, in his *Etay* on the ancient English Minstrels, has given a very curious and satisfactory account of these fathers of modern poetry and music; and although he agrees that the several professions above enumerated were included under the general name of minstrel, he has, in the notes to that *Etay*, p. 42, with great accuracy assigned to each his distinct and peculiar office. Of the ancient writers of romance, a history is extant in the lives of the Provençal poets, written in French by J. Nostrasdamus, compiled and published at Lyons in 1575; but a much more satisfactory account of them is contained in the translation of this work into Italian, with many additions, by G. M. de Crefcimbini, and published, in 1710, under the title of "Commentarii Intorno all'Istory della Volgare Poetia." See Hawkins's *Hist. of Music*, vol. ii. p. 44. &c.

**PROVENCE**, in *Geography*, the name, before the revolution, of one of the richest provinces of France, bounded on the E. by Piedmont, on the S. by the Mediterranean, on the W. by the Venausin and the Rhône, which separates it from Languedoc. It produces wine, corn, and oil; its capital is Marseilles. It now comprehends the departments of the Var, the Mouths of the Rhône, and the Lower Alps.

**PROVEND**, or **Provender**, is properly a sort of vessel containing the measure of grains daily given to a horse, or other beast of labour, for his subsistence.

Some derive the word from the Latin provendus, or present.

Hence provender is also become a general name for all food of cattle. In monasteries, when the religious go to meals, they are paid to go to provend.

**PROVENCEALE, MARCELLO DA CENTO**, in *Biography*, born in 1575, was a disciple of Paolo Rofetti, and became very eminent as a painter of history and portrait. But his superior merit confinled in mosaic, which he executed with uncommon skill.

In the palace of cardinal Borghese, at Rome, there is a portrait of Paul V. in mosaic, by this master. It is wrought in imitation of the mosaic of the ancients; but it is such an imitation as excels all that can be seen of the originals. The face alone conveys of more than two millions of pieces, many of them being of no larger dimensions than a grain of sand, and it is most dexterously executed one of the greatest curiosities of Rome.

The first altar piece in mosaic for the Basilica of St. Peter, was wrought by Gianbatitla Calandri of Verceil, under the pontificate of Urban VIII. It was a St. Michael, from a design of Cefare d'Arpino; a considerable progress was then already made towards the modern style of art, which since has been carried to a still higher degree by the two Carpofori, Fabio, and T. Paolo his son, who made the mosaics of the St. Petrovillia, from the original of Guercino; the Communion of St. Jerome, from Dominichino; and the baptism of Christ, from Maratta. Tufeli's Pilkington.

**PROVER**, in *Law*, *probator*, an approver, or person who confessing felony, appeals, or accuses another of the same. He is thus called because he must prove what he alleges in his appeal; which proof is either by battle, or by the country, at his election who is appealed.

In 39 Edw. III. coram rege, rot. 97, Suff. a man became an approver, and appealed five, who all joined battle with him, and he overcame them all; four of them were accordingly
Solomon expresses the same sentiment in his own, parabolic, manner:

"The words of the wife are like goads,
And like nails that are firmly fix'd."  Eccl. xii. 11.

That is, they instantaneously inflame or affect the mind; they penetrate deeply, and are firmly retained. Even the obscurity that is generally attendant on excessive brevity has its use, in keeping alive the attention, and exercising the genius by the labour of the investigation; and also in the gratification accompanying knowledge, gained in some degree by our own efforts.

Another quality essential to a parable or proverb is elegance, which is inconsistent neither with brevity, nor with some degree of obscurity. Elegance in this connection respects the sentiment, the imagery, and the diction. Those proverbs, which are the plainest, most obvious, and simple, which contain nothing remarkable either in sentiment or style, are not to be accounted as delitute of their peculiar elegance, if they poise only brevity, and that neat, compact form, and roundness of period, which are of themselves sufficient to constitute a parable. See i Sam. xxiv. 13. Prov. x. 12.

Proverbs, in Scripture History, is the name of one of the canonical books of the Old Testament, containing a collection of moral sentences and maxims, adapted to the regulation of the conduct in every period and condition of life, and ascribed to Solomon; though some writers, among whom is Grotius, have expressed their doubts, whether Solomon was the author of this book.

This work, which affords a specimen of didactic poetry, belonging to the first rank of this kind of writing, consists of two parts. The first, serving as a proem or exordium, includes the nine first chapters; and is varied, elegant, sublime, and truly poetical; the order of the subject is in general excellently preferred, and the parts are very aptly connected among themselves. It is embellished with many beautiful descriptions and periphrases; the diction is polished, and abounds with all the ornaments of poetry; in many, it soars with elegance and splendour to any of the sacred writings. The other part, which extends from the beginning of the tenth chapter to the end of the book, consists almost entirely of detached parables or maxims, which poise little of the sublime or poetical, except a certain energetic and concise turn of expression.

PROVIZENDE, in Geography, a town of Portugal, in the province of Tras os Montes; 10 miles N. E. of Lamego.

PROVIDEN, a small island near the N. coast of Ceylon; 28 miles S.S.E. of Trincomaly.

PROVIDENCE, PROVIDENTIA, the conduct and direction of the several parts of the universe, by a superior intelligent Being.

The notion of a providence is very ancient, even in the heathen theology; we find Thales mentions it. It is founded on this supposition, that the Creator has not fixed and ascended the laws of nature, nor connected the chain of second causes, as to leave the world to itself; but that he still preserves the reins in his own hands, and occasionally intervenes, alters, retards, enforces, fulfils, &c. those laws, by a particular providence.

Some use the word providence in a more general sense, signifying by it that power or action by which the several parts of the creation are ordinarily directed.

Thus Damascenus defines providence to be that divine will by which all things are ordered and directed to the proper end. Which notion of providence supposes no laws at all fixed by the Author of nature at the creation; but that
that he referred it at large, to be governed by himself occasion-ally.

The ancients called providence by the names of fate, fortune, nature, destiny, necessity, &c.

The ancient Egyptians seem to have been the first who had the notion of a divine providence. Ammianus observes they reafoned thus: "Providence is so essential to a prince, that without it he cannot be, nor even be called, a prince; and the more august a prince is, the more perfect ought his providence to be. Since, then, God is the greatest and most august of all princes, to him must belong the most perfect providence."

The Epicureans deny any divine providence, as thinking it inconsistent with the cafe and repose of the divine nature, to meddle at all with human affairs.

Others deny the existence of a providence, from the feemingly unjust distribution of good and evil; which appear to fall indiscriminately on the just and unjust.

Simplicius argues thus for a providence: if God do not look to the affairs of the world, it is either because he cannot, or will not; but the first is absurd, since, to govern cannot be difficult where to create was easy; and the latter is both absurd and blafphemous.

In Plato's 15th Dialogue of Laws, he teaches excellently that (since what is self-moving is, by its nature, before that which moves only in consequence of being moved) mind must be prior to matter, and the cause of all its modifications and changes; and that, therefore, there is an universal mind posseeded of all perfection, which produced and which actuates all things — οὐκ εἰς τὸν ἀκριβῶς τὴν τούτων ἀκάλλυν γενετο πάντα ἑν ἴσεον πάντων ποιητήσον. After this he shews that the Deity exercises a particular providence over the world, taking care of small no less than great things. Οὐκ ἔχει οὖσαν εν ταῖς πάντων τῶν μεγίστων διαφορομενα. In proving this he observes, "that a superior nature of such excellence as the Divine, which hears, sees, and knows all things, cannot, in any instance, be subject to negligence or sloth; that the meanest and the greatest parts of the world are all equally his art or pollicion; that great things cannot be rightly taken care of without taking care of small; and that, in all cases, the more able and perfect any artificer is, (as a physician, an architect, or the ruler of the state,) the more his skill and care appear in little as well as great things. Let us not then (says he) conceive of God as worse than even mortal artificers."

The term providence, in its primary signification, simply denotes foresight; and if we allow the existence of a Supreme Being who formed the universe at first, we must necessarily allow, that he has a perfect foresight of every event, which, at any time, takes place in the natural or moral world. Matter can have no motion, nor spirit any energy, but what is derived from him; nor can he be ignorant of the effects which he will, either separately or conjointly, produce.

A common mechanic has knowledge of the work of his own hands; when he puts the machine, which he has made, in motion, he foresees how long it will go, and what will be the state and position of its several parts at any particular point of time: or, if he is not perfectly able to do this, it is because he is not perfectly acquainted with all the powers of the materials which he has used in its construction; they are not of his making, and they may therefore have qualities which he does not understand, and consequently cannot regulate. But in the immense machine of the universe there is nothing except that which God has made; all the power and properties, relations and dependencies, which created things have, they have both in kind and degree from him. Nothing, therefore, it should seem, can come to pass at any time, or in any part of the universe, which its incomprehensible Architect did not, from the moment his Almighty Fiat called it into existence, clearly foresee.

The providence of God is implied in his very existence as an intelligent creator; and it imports not only an abstract foresight of all possible events, but such a predispofition of causes and effects, such an adjustment of means and ends, as seems to us to exclude that contingency of human actions, with which, as expectants of positive rewards and punishments in another world, we firmly believe it to be altogether consistent.

By providence we may understand, not merely foresight, but an uniform and constant operation of God subsequent to the act of creation. Thus, in every machine formed by human ingenuity, there is a necessity for the action of some extraneous power to put the machine in motion; a proper construction and disposition of parts not being sufficient to effect the end; there must be a spring, or a weight, or an impulse of air or water, or some substance or other, on which the motion of the several parts of the machine must depend. In like manner, the machine of the universe depends upon its creator for the commencement and the conformation of the motion of its several parts. The power by which the inanimate particles of matter coalesce into felible lumps, as well as that by which the great orbs of the universe are reluctantly, as it were, retained in their courses, admits not an explanation from mechanical causes: the effects of both of them are different from such as mere matter and motion can produce; they must ultimately be referred to God. Vegetable and animal life, and increase, cannot be accounted for, without recurring to him, as the primary cause of both. In all these respects the providence of God is something more than foresight; it is a continual influence, an universal agency: "by him all things consist—and in him we live, and move, and have our being."

Much labour has been employed to account for all the phenomena of nature by the powers of mechanism, or the neccesary laws of matter and motion. But this, as we imagine, cannot be done. The "primary causes" of things must, certainly, be some powers and principles not mechanical; otherwise, we shall be reduced to the necessity of maintaining an endless progression of motions communicated from matter to matter, without any "first mover," or of laying, that the first impelling motion moved itself. The former is an absurdity too great to be embraced by any one; and there is reason to hope, that the essential inactivity of matter is at present so well understood, and so generally allowed, notwithstanding some modern oppugners of this hypothesis, that there can be but few who will care to avert the latter. All our reasonings about bodies, and the whole of natural philosophy, are founded on the three laws of motion, laid down by Sir Isaac Newton at the beginning of the "Principia." These laws express the plainest truths; but they would have neither evidence nor meaning, were not inactivity contained in our idea of matter. Should it be said, that matter, though naturally inert, may be made to be otherwise by divine power: this would be the same with saying, that matter may be made not to be matter. If inactivity belong to it at all, it must belong to it as matter, or solid extension, and therefore must be inseparable from it. Matter
ter is figured, moveable, discernible, inactive, and capable of communicating motion by impulse to other matter: these are not accidental but primary qualities of matter. Besides, matter void of inactivity, if we were to suppose it possible, could produce no effects. The communication of motion, its direction, the resistence it suffers, and its cessation, in a word, the whole doctrine of motion, cannot be conflisftently explained or clearly understood without supposing the inertia of matter. (See Matter and Resistance.) Self-moving matter must have thought and design; because, whenever matter moves, it must move in some particular direction, and with some precise degree of velocity; and as there is an infinity of these equally possible, it cannot move itself without selecting one of these preferably to and exclusively of all others, and therefore not without design. Moreover, it may be plainly proved that matter cannot be the ultimate cause of the phenomena of nature, or the agent, which, by any powers inherent in itself, produces the general laws of nature, without positing the highest degree of knowledge and wisdom, which might be easily evinced or exemplified by adverting to the particular law of Gravitation, which see. The philosopher, says an excellent writer, who overlooks the laws of an all-governing Deity in nature, contenting himself with the appearance of the material universe only, and the mechanical laws of motion, neglects what is most excellent, and prefers what is imperfect to what is supremely perfect, finite to infinity, what is narrow and weak, to what is unlimited and almighty, and what is passing to what endures for ever. (Maclaurin's Account of Sir Isaac Newton's Discoveries, b. iv. c. 9. § 1.)

Sir Isaac Newton thought it most unaccountable to exclude the Deity only out of the universe. It appeared to him much more just and reasonable to suppose that the whole chain of causes, or the several series of them, should centre in him as their source; and the whole system appear depending on him the only independent cause. Id. § 5.

If, then, the Deity pervades and actuates the material world, and his unceasing energy is the cause to which every effect in it must be traced; the spiritual world, which is of greater confluence, cannot be disregarded by him. Is there not one atom of matter on which he does not act; and is there one being about which he has no concern? Does not a stone fall without him; and does then a man suffer without him? The inanimate world is of no confluence abstracted from its subserviency to the animate and reasonable world: the former, therefore, must be preserved and governed entirely with a view to the latter. But it is not mere energy or the constant exertion of power that is discernible in the frame or laws of the universe, in maintaining the succession of men, and in producing men, and other beings; but wisdom and skill are also conspicuous in the structure of every object in the inanimate creation. After a survey of the beauty and elegance of the works of nature, aided by the perusal of Matt. vi. 28, &c. we may ask ourselves, Has God in the lowest of his works been lavish of wisdom, beauty, and skill, and is he sparing of these in the concerns of reasonable beings? Or does he lefs regard order, propriety, and fitness in the determination of their states? The answer is obvious.

Providence also implies a particular interposition of God in administering the affairs of individuals and nations, and wholly distinct from that general and incessant exertion of his power, by which he sustains the universe in existence. Some speculative men, however, conceive it to be very conformable to the nature of the supreme Being, as investigated by sober reasoning, that events deriving their existence from his immutable will as the primary cause of every thing, should succeed each other in a determinate order; or, in the language of one of the fathers, they held "the will of God to be the necessity of nature." In this providence, or predestination of all events, they acquiesce with gratitude and confidence; believing that it fully answers the ends of a constant superintendency, accompanied by occasional interposition; that confusion and chance are removed out of the universe; that all things have been, are, and will be working together for the final good of all; and that every particular thing, even what we call a miracle itself, comes to pass in its own proper time, according to a plan established by infinite goodness and wisdom before time was. To this reasoning, though not chargeable with Atheistic fatality, or subjective of all piety, it may be objected, that it renders all supplication unprofitable, (see Prayer,) the supreme Being inexorable, the human race impecunious, the order of nature immutable, and the future states of individuals and nations irreversible. Nevertheless, the weight of these objections will not be great in the opinion of those, who either acknowledge no religion but that of nature, or who think that the doctrine of the final happiness of all mankind is not inconsistent with the principles of Christianity.

Many, however, are of opinion, that an original establishment, such as that to which we have now been led, implies universal fatalism; and that in events happening amongst reasonable agents there must be infinite variations and uncertainties not possible to be regulated by it; and therefore they will think, that the other method of administering providence by interposition and constant influences will be the best adapted for bringing about a perfect regulation of events. Some persons are probably led into mistakes on the subject, by thinking of the manner in which it is most becoming the Deity to act, too strictly in conformity to that in which men are obliged to act. They have but little power, and therefore are obliged to be as frugal of it as possible. But to the Deity there is nothing difficult, and consequently nothing to influence him to choose one way of acting rather than another, besides its being more agreeable to rectitude, and more conducive to his end. The reason why the Deity has chosen to establish a course of nature is, the necessity of it as a means to produce happiness, and to give his reasonable creatures room for a proper exertion of their faculties, and for the practice of virtue. But independently of these observations, it must be very evident, that influences, consistent with the agency of free beings, and uniformly exerted to exclude every event from being excluded, and to produce perfect order in the administration of the world, are so far from not becoming the almighty and omnipotent parent, that we can conceive of nothing more worthy of him, or that can make his character appear more amiable. Nor is there any more reason to be prejudiced against them, than against the influence which the constitution of the world allows to every agent over events, in proportion to his power and knowledge. It is reasonable to believe, that his influence over events extends as much farther than that of any other being, and is as much more constant, as the relation in which he stands to beings is nearer, and his power and wisdom greater. Many persons think the excellent writer of the whole observations we have now been led to, who think that there are no constant influences of the Deity in directing events, are ready to acknowledge, and every one who believes that Christianity was proved by miracles, must acknowledge, that there are particular emergencies in which he does interpose in the affairs of the world. Allowing that the Deity has ever once interposed since the original establishment.
ment of things, there will remain no tolerable reason for imagining, that he does not interpose continually, as far as there is any occasion.

The doctrine of providence, as it has been above explained, may be evinced from the consideration of the divine perfections. The first case of all things must be regarded as a being absolutely perfect; and the idea of absolute perfection comprehends infinite power, wisdom, and goodness: hence we deduce the doctrine of providence. The Deity cannot be an indifferent spectator of the series of events in that world to which he has given being. His goodnights will as certainly engage him to direct them agreeably to the ends of goodness; as his wisdom and power enable him to do it in the most effectual manner. This conclusion is conformable to all our ideas of those attributes. Could we call that being good who would refuse to do any good which he is able to do without the least labour or difficulty? God is present every where. He fees all that happens, and it is in his power, with perfect ease, to order all for the best. Can he then posses goodnights, and at the same time not do this? A God without a providence is undoubtedly a contradiction. Nothing is plainer than that a being of perfect reason will, in every instance, take such care of the universe as perfect reason requires. That supreme intelligence and love which are present to all things, and from whence all things spring, must govern all occurrences, and exclude from the constitution of nature all real ill and disorder. These considerations prove what has been called a particular in opposition to a general providence. We cannot conceive of any reasons that can influence the Deity to exercise any providence over the world, which are not likewise reasons for extending it to all that happens in the world. As far as it is confined to generals, or overlooks any individual, or any event, it is incomplete, and therefore unsuitable to the idea of a perfect being.

One common prejudice against this doctrine arises from the apprehension that it is below the dignity of the Deity to watch over, in the manner implied in it, the meanest beings, and all the minutest affairs. To which it may be replied, that a great number of minute affairs, if they are each of them of some consequence, make up a sum which is of great consequence; and that there is no way of taking care of this sum, without taking care of each particular. This objection, therefore, under the appearance of honouring God, plainly dishonours him. Nothing is absolutely trifling in which the happiness of any individual, even the most insignificant, is at all concerned; nor is it beneath a wise and good being, to interpose in any thing of this kind. To suppose the Deity above this, is to suppose him above acting up to the full extent of goodnights and rectitude. The same eternal benevolence that first engaged him to produce beings, must also engage him to exert a particular providence over them; and the very lowest beings, as well as the highest, seem to have a kind of right to his superintendence, from the act itself of bringing them into existence. Every apprehension that this is too great a condescension in him is founded on the poorest ideas; for, surely, whatever it was not too great condescension in him to create, it cannot be too great a condescension in him to take care of. Besides, with regard to God, all distinctions in the creation vanish. All beings are infinitely, that is equally, inferior to him.

Another prejudice by which some minds may be influenced with respect to this subject, arises from the notion, that it must be some trouble to the Deity to superintend and direct all the immense variety of events in the universe. In order to obviate this prejudice, it should be considered that the whole of possibility is alike easy to infinite power and knowledge; and that it is a contradiction to imagine, by transferring human imperfections to the Deity, that they can become incumbered or perplexed.

But the chief and most common objection is that which is deduced from the supposed inconsistency of a particular providence with the liberty of reasonable agents, and the general laws of the world. Some perfons, conscious of their inability to reconcile the notion of human agency with that of divine predestination or foresight, have considered men as machines, and denied that they have any agency at all. Others have conceded to the human race freedom of thought and action; but have denied that God can certainly foresee free and contingent actions. (Socici Opera. tom. i. p. 549.) The objection now stated is excellently answered in the "Religion of Nature delineated" (§ 5.), where it is shown how by secret influences on the minds of men; by the introduction of different characters on the stage of the world at different times, and in proper places; by the miniftry of invisible beings, and a suitable adjustment of physical and moral causes and events to one another, it may be possible, consistently with the laws of nature and the liberty of mankind, to direct all occurrences in such a manner, that nothing on the whole unfit to be allowed, or unsuitable to any use, shall come to pass. We may here add, that if we ourselves had a greater acquaintance with the powers of nature, and nearer access to the minds of men, we could easily overrule and direct many events not at present in our power, agreeably to our own purposes, without the least infringement of the general laws of the world, or of the liberty of mankind. But how much easier must it be for that Being to do this absolutely and perfectly, to whom all the powers of nature are subject, who sees through all dependencies and connexions, and has constant access to the heart of every man, and can turn it whither he pleases? Where then can be the difficulty of believing an invisible hand, an universal and ever-attentive providence, which guides all things agreeably to perfect rectitude and wisdom; at the same time that the general laws of the world are left unviolated, and the liberty of moral agents is preferred? Some able writers on this subject have contented themselves with acknowledging that foresight appertains to God, and freedom to man, though they cannot, in any wise, comprehend the possibility of their co-existence. "I own freely to you," says Mr. Locke (Letter to Molyneux), "the weakness of my understanding, that though it be unquestionable that there is omnipotence and omniscience in God, our maker, and I cannot have a clearer perception of any thing than that I am free; yet I cannot make freedom in man consistent with omnipotence and omniscience in God, though I am as fully persuaded of both as of any truths I most firmly assent to. And therefore I have long since given off the consideration of that question, resolving all into this short conclusion; that if it be possible for God to make a free agent, then man is free, though I see not the way of it."

Here we may observe that it would be very difficult, if not impossible, to prove that it is more conformable to the nature of a wise and beneficent Being, to form a system where whole parts, material and spiritual, shall be all linked together in a fatal chain, than one which shall admit the contingency of human actions, and consequently seem to require, as a means of its perfection, the interposition of divine agency.

As to the argument against the interposition of God in the government of the world, which is taken from experience, it will imprefs different minds differently. Those who are acquainted with and believe the history of the Jewish nation, as delivered in the Bible, will find no great difficulty in admitting, that what has happened to one people may have happened
happened to another; that God may have governed the other families of the earth, if not in so visible, yet in as effectual a manner as he hath governed that of Judah. They will acknowledge the interposition of God, in what others will esteem the ordinary operation of phycical or moral causes; in storms, earthquakes, famines, pestilences, foreign wars, domestic discontents, peace, prosperity, and, indeed, in every event tending to exalt or deprave a nation. But those who are not acquainted with the Jewish history, and others who disbelieve the miraculous part of it, and attribute the singularity of their condition to the operation of their religious polity, will be able to deduce no evidence of God's government of the world from the history of the Jews; and reasoning logically, they will incline to maintain, that it cannot certainly be deduced from the history of any other nation, ancient or modern. Could we, indeed, acquit ourselves minutely, not merely with the civil or military transactions of particular ages and countries, but with the virtues and vices, the happiness and misery of all ages and all countries, from the beginning of the world; or, in other words, could we obtain a distinct and complete history of the human race, from the commencement of its existence to the present time, we should, without doubt, discern the arm of God clearly displayed in effecting the rife, regulating the progres, and accomplishing the destruction of particular states, in strict conformity to, or deviation from, the rule of moral rectitude. But the limitation of our views, and the momentary period of our existence, do not allow of our comprehending the whole of the divine economy, even in this world; and we should not therefore be surprised, that, as Dr. Clarke observes (Evid. of Nat. and Rev. Rel.) there should not in many ages be plain evidences enough either of the wisdom or of the justice and goodness of God, or of so much as the interposition of divine providence at all, to convince mankind clearly and generally of the world's being under his immediate care, and inspection, and government. If, indeed, the experience of the most perfect uniformity in the moral government of the world, could not, for such reasons as we have above stated, certainly enable us to decide concerning the manner of its being administered, whether by occasional interposition, or primenal ordination, we may properly enough conclude, that no argument can be justly drawn against this interposition from the want of such experience, from the real or imagined irregularity of that government. We but a small part of this government, either as to its extent or its duration. It may be more regular than it appears to us to be; there may be, which is most probable, no irregularity at all in it; but allowing it to subsist, and to be very considerable, it will be impossible for us to determine whether that irregularity proceeds from a want of God's interposition in the government of the world, or from what some might be apt, unwisely enough, to call a defect of power, wisdom, or goodness, in its original constitution. Our faculties are annihilated in the immensity of the divine nature; the eyes of our understanding are blinded by the inconvertible light of the Lord's glory; it sheweth us in and around us, adorning with ineffable splendour all his works, not suffering us to doubt, for a moment, concerning either the existence or the skill of the great architect of the universal; but checking our presumption, and baffling all our efforts, when we would explore the nature of his existence, or the mode of his operation. If our reason be inadequate, as it certainly is, to the investigation of the manner in which God administers the affairs of this world, we ought thankfully to embrace the light which revelation affords us in so obscure an enquiry. A single page of that gospel conveys to us more knowledge concerning the attributes of God and our relations to him than all the volumes of philosophy which unfitted reason ever produced. Open but the bible, and a subiect before dark to the human understanding, becomes as clear as the mid-day sun. The whole history contained in the scriptures is one uniform display of the divine superintendence of our affairs. Between the sacred history and other histories there is this striking difference, that whilst the latter seldom go higher than the passions of men and the power of nature for the sources of the events they relate, the former always carries up our thoughts to the first cause, and directs our views to God, as the guide and governor of whatever happens. (See II. xlv. 7. Amos, iii. 6. Psal. cxlviii. Prov. xvi. 33. Matt. x. 29, 30. Rom. xi. 36.) The scriptures also afford us a convincing argument for Providence, arising from the completion of the prophecies which they record. See Prophecy.

From the variety of considerations above suggested, and on which our restricted limits will not allow of our enlarging, we may reasonably infer, that there is a wise and benevolent providence, which extends to all events: and that its interposition and influence are not discernible by us, or distinguishable, in its exertions, from the common operations of natural causes, and the course of our own thoughts, is no more any reason for denying its reality, than it is for denying the real subsistence of our own souls, or the ubiquity of the divine essence, because they are not the immediate objects of sensible observation. In some instances, indeed, the interpositions of the Deity have been open and sensible, but such interpositions are very extraordinary; and to expect them in any common cases would be madness. The delusions of enthusiasm take their rise from hence, and consist chiefly in ascribing particular feelings, without reason, to supernatural suggestion; or in imagining that the directions of God's providence, and his influence on the soul, are capable of being particularly observed. It ought also to be remarked, with respect to the doctrine of providence, that it ought never to be explained in such a manner as to destroy the value of the agency of created beings. For other reflections on the subject of this article, tending to establish the doctrine of providence, to solve difficulties and answer objections against it, and to point out the practical uses to which the acknowledgment of it is subservient, we refer to Clark's Evidence of Natural and Revealed Religion; Butler's Analogy; Price's Dissertations, diff. i.; and the Bishop of Llandaff's Sermons, fem. vi.

Providence, in Mythology, a divinity among the ancients, whom they commonly represented under the figure of a woman leaning upon a pillar, holding in her left hand the cornucopia, and in the right a horn, which she points to a globe, at once to shew that all goods are derived from her, and that she extends her care over the whole universe. Sometimes she has other symbols, but this manner of representing her was the most common. The ancients, however, believed providence to be an attribute of the gods, as appears by several medals, upon which we read PROVIDENTIA DEO-RUM.

Providence, in Geography, one of the Bahama islands, and the second in size, being about thirty miles long and eight broad. Its chief commerce arises from ships driven on its coast, or making a winter's voyage to the continent of America, which put in here in order to obtain a supply of provisions. The provisions are brought hither from Carolina, and laid up in storehouses for this purpose: but the island itself produces little else than salt and brackenwood, which are carried over to Carolina. The inhabitants sow peas, which are gathered in six weeks, and Indian wheat,
which is productive in twelve weeks. Various kinds of fish are plentiful on the coast, and some parts of the island yield trees and plants in abundance. The principal harbour is dangerous on account of a bar, having only sixteen feet of water. The chief town is Nassau. N. lat. 25° 21'. W. long. 77° 20'.

Providence, an uninhabited island on the coast of Honduras, eleven miles long and four broad. It has a fertile soil, a plentiful supply of water, and might be easily fortified, as it was formerly by the Buccaneers. It is separated from the continent by a narrow channel. This island has neither serpents nor venomous reptiles. N. lat. 13° 20'. W. long. 89° 45'.—Alfo, a small island in the Indian sea. N. lat. 5° 0'. E. long. 78° 45'.—Alfo, a small island in the Indian sea. S. lat. 9° 10'. E. long. 52° 35'.—Alfo, a small island in the Pacific ocean. N. lat. 4° 21'. E. long. 127° 12'.

Providence, a county of America, in the state of Rhode Island, bounded on N. and E. by Massachusetts, W. by Connecticut, and S. by Kent county. It contains (1810) 10,071 persons. The towns of the fore-mentioned county, and the third town in New England, in point of population. It was settled in 1636, and is situated at the head of Narraganset bay, about a mile above the mouth of the Pawtucket. It is accessible by ships of the smallest size. The streets are level and well paved. Most of the business is carried on in a street on the E. side of the bay, nearly on a level with the water and parallel to it. The houses are chiefly new and well-built, but most of the elegant and splendid houses are on the other side. W. of the bay are four churches, one French, two Congregational, and one Baptist, and on the other side are three, one Congregational, one Baptist, and one Episcopalian. Two miles distant are some of the handomest edifices of the kind in the Union. The town library is deposited in the court-house. The population in 1810 amounted to 10,071 persons. The inhabitants are industrious and enterprising, and their commerce is extensive. Here are two ironworks, a number of silk factories, and several large cotton manufactories. The towns in Connecticut and Massachusetts, bordering on the Rhode Island frontier, trade chiefly with Providence. The town is rapidly increasing, and the new buildings are erected chiefly on the W. side of the bay. The Rhode Island college is situated in this town. (See College.) Providence is 44 miles S. by W. of Boston, and 291 N.E. of Philadelphia. N. lat. 41° 49'. W. long. 71° 23'.—Alfo, a township of New York, in Saratoga county, taken from Gaufay, and incorporated in 1796. —Alfo, a town of Bedford county, in Pennsylvania, containing 1402 inhabitants. —Alfo, a town of Elizabethtown, in New Jersey; containing 750 inhabitants. —Alfo, a town of Luzerne county, in Pennsylvania; containing 589 inhabitants. —Alfo, a river which falls into Narraganset bay on the W. side of Rhode island, navigable as far as Providence for ships of 500 tons, 30 miles from the sea, and affording fine fish, oysters, and lobsters.

Providence, Lower, a town of Montgomery county, in Pennsylvania; containing 904 inhabitants.

Providence, Upper, a town of Luzerne county, in Pennsylvania; containing 904 inhabitants.

Providence, North, a township of Providence county, in Rhode island, situated N. of Providence, and separated from the state of Massachusetts on the E. by Pawtucket river; containing 1758 inhabitants.

Providence, Upper, a town of Montgomery county, in Pennsylvania; containing 1395 inhabitants. —Alfo, a town of Luzerne county, in Pennsylvania; containing 561 inhabitants.

Providence, Great, a small island in the Pacific ocean, discovered by Dampier in 1699. S. lat. 6° 24'. E. long. 135° 53'.

Providence, Little, a small island in the Pacific ocean, discovered also by Dampier in 1699. S. lat. 6° 11'. E. long. 135° 29'.

PROVIDENTIA, in old Law Books, were provisions of meat and drink.

“Providentia vini ante adventum suum in cellaria erat centum deliriurn.” Knighton, anno 1354.

PROVIDENTIAL Channel, in Geography, a channel between some shoals in the South Pacific ocean, through which the Endeavour passed, nearly the N.E. coast of New Holland; 40 miles E. of Cape Willoughby.

PROVIDENTIAL Bank, a small circular island near the S.W. coast of New Guinea. S. lat. 5° 38'. E. long. 137° 50'.

PROVINCE, Provincia, among the Romans, was a country conquered by them, without the bounds of Italy; governed by a deputy, or lieutenant, and having peculiar laws and privileges. See Legatory.

Nicod derives the word a prael vivendo, living after off; but it is better deduced from pro and vicne, I overcome. Of these countries that part of France next the Alps was one; and it still retains the name Provence.

Province is now chiefly used for a canton, or division of a kingdom or commonwealth, comprehending several cities, towns, &c. all under the same government; and usually distinguished by the extent of the civil or ecclesiastical jurisdiction.

The provinces were anciently dukedoms, counties, &c. which have been since all reunited under the same chief.

The church distinguished its provinces by archiepiscopries, each containing a certain number of bishoprics.

In this sense England is divided into two provinces, Canterbury and York.

The monks make particular divisions of provinces, according to the antiquity and number of convents in each.

The United Provinces are the seven northern provinces of the Low Countries; which, revolting from the Spanish dominion, made a firm and perpetual alliance, offensive and defensive, at Utrecht, in the year 1579. They have lately undergone several revolutions, and their permanent condition is not yet decided.

Province, in Geography, an island in Delaware river, six miles below Philadelphia; joined to the main land by a dam.

Province Town, a town of America, situated on the hook of Cape Cod, in Barnstable county, Massachusetts, three miles N.W. of Race Point. Its harbour, which is one of the finest in the State, opens to the southward, and has depth of water for any ships. This was the first port entered by the English, when they went to settle in New England, in 1620. It has undergone various changes of prosperity and decline. It is now said to be rising, and contains 950 inhabitants, who depend upon the cod fishery, for which they employ about 30 sail, large and small, and in which they are very expert and successful. Their houses are one story high, and set upon piles, that the driving lands may pass under them. Their lands yield nothing, so that they are dependent upon Boston and the neighboring towns for every vegetable production. Their cows, of which they have about 50, are fed in winter on fedge, cut from the flats, in the spring on beach grass, growing at intervals.
on the shore, and in summer on what they find in the sunken ponds and marshy places that lie between the sand-hills, where they are seen wading, and even swimming, plunging their heads into the water up to their horns, and picking a scanty subsistence from the roots and herbs produced in the waters; 120 miles by land from Bolton. N. lat. 42° 5'. W. long. 70° 9'.

PROVINCIAL, PROVINCIALIS, something relating to a province.

Thus we say, provincial council, or synod, &c. See SYNOD and COUNCIL.

PROVINCIAL Conventions. See CONSTITUTION.

PROVINCIAL Establishments in America. See the account of CHARTER Governments.

In the monastic sense, denotes a person who has the direction and superintendency of several convents of a province, according to the division established in that order.

The general of the order has several provinces under him; the provincial several priors, abbots, &c.

PROVINE, PROVIN, a branch of a vine laid in the ground to take root.

PROVING of Guns, is an operation performed in order to determine whether they will bear the quantity of powder allotted for this purpose, or whether they are sufficiently strong for service. The rule of the board of ordnance is, that all guns under twenty-four pounders be loaded with a charge of powder, which weighs as much as the shot; i.e. a brass twenty-four pounder with 21 lb.; a brass thirty-two pounder with 26 lb.; and a forty-two pounder, with 31 lb. 8 oz.; the iron twenty-four pounder with 18 lb., the thirty-two with 21 lb. 8 oz., and the forty-two pounder with 25 lb. The brass light field-pieces are proved with a quantity of powder that weighs half as much as their shot; except the twenty-four pounder, which is loaded only with ten pounds. See GUN.

In the proof of all sorts of small arms, the quantity of powder used is the weight of the ball exactly. For the number of bullets used in proving muskets, carabines, and pistols, see BULLET.

When guns of a new metal, or of a lighter construction, are proved, then, besides the common proof, they are fired two or three hundred times, as quick as possible, loaded with the common charge allowed for actual service. In proving cannon, with a view of ascertaining their being well cast, without any cavities in the metal, and being fit to resist the effort of their charge of powder, the piece is laid upon the ground, supported only by a log of wood in the middle, of about five or six inches thick, to raise the muzzle a little; and then the piece is fired against a solid butt of earth. The instruments used in the proof of cannon are the searchers and relievers. Lieutenant-general Desaguliers has lately invented a curious instrument for finding the principal defects in pieces of artillery, which is no sooner introduced into the hollow cylinder of the gun than it discovers its defects, and particularly its not being truly bored, to which most of the injuries incident to pieces of artillery are owing. In the proof of mortars and howitzers, they are placed upon the ground, with some part of their trunnions or breech sunk below the surface, and resting on wooden billets at an elevation of about seventy degrees. The mirror is generally the only instrument for discovering the defects in these pieces. In order to use it, the gun must shine; the breech must be placed towards the sun, and the glases over against the mouth of the piece, and thus the flaws in the bore and chamber are observed. The Prussians prove their battering train and garrison artillery with a quantity of powder equal to half the weight of the shot, and by firing seventy-five rounds as quick as in real service, i.e. two or three rounds in a minute. Their light field-train, from a twelve-pounder or upwards, are proved with a quantity of powder equal to one-third of the weight of the shot, and fired a hundred and fifty rounds, at three or four rounds in a minute. From a twelve-pounder downwards, they are proved with a quantity of powder equal to one-fifth of the shot's weight, and fired three hundred rounds, at five or six rounds each minute, properly sponged and loaded. Their mortars are proved with the chambers full of powder, and the shells loaded. Three rounds are fired as quick as possible. The Dutch prove all their artillery by firing each piece five times; the first two rounds with a quantity of powder equal to two-thirds of the weight of the shot, and the three last rounds with a quantity of powder equal to one-half the weight of the shot. The French method of proof is the same with that of the Dutch. The Portuguese prove their artillery in the following manner:

| 42 | 6 rounds | 1 lb. shot; 3 oz. | then diminishing 1 lb. each round. |
| 32 | 6 rounds | 1 lb. shot; 2 oz. | diminishing 1 lb. each round. |
| 24 | 6 rounds | 1 lb. shot; 1 oz. | diminishing 2 lb. each round. |
| 12 | 6 rounds | 1 lb. shot; 1/2 lb. | diminishing 1 lb. each round. |
| 8  | 6 rounds | 1 lb. shot; 1/2 lb. | diminishing 1 lb. each round. |

They are fired only once every minute. Their mortars are proved by filling the chambers full of powder, a loaded shell, and the mortar rammed full of earth.

PROVING of Gunpowder. See GUNPOWDER, and POWDER-Triers.

PROVING of Wills, in Law. See PROBATE, EXECUTOR, and WILL.

PROVINS, in Geography, a town of France, and principal place of a district, in the department of the Seine and Marne; 11 poils S. E. of Paris. The town contains 5503, and the canton 9747; inhabitants, on a territory of 130 kilometres, in 14 communes. N. lat. 48° 34'. E. long. 35° 21'.

PROVISION, PROVISION, any thing got or procured, as necessary for the sustenance of life.

Salted of wholesome provisions is prohibited by 51 Henry III. Stat. 6. cap. 7. under pain of amercement for the first offence, pillory for the second, fine and imprisonment for the third, and abjuration of the town for the fourth. And by 12 Car. II. c. 25. § 11. any brewing or adulteration of wine is punished with the forfeiture of 100l., if done by the wholesale merchant; and 40l. if done by the vintner or retail trader.

PROVISIONS, Preservation of, is an art essential to the existence of a very numerous class of men who reside in situations where they must be furnished with provisions transported from a distance, or so preferred that they can be carried with them, as is the case at sea, and in remote colonies. To others it is of great importance in referring the produce of fruitful seafsons for future supplies.

The modes of preservation which are in use are as follows:

1. By salting either with dry salt, or in salt pickle.
2. By sugar, which is, however, confined to fruits and vegetable matters.
3. By drying up the juices and parts liable to the putrefactive fermentation, as is practised with a variety of herbs, as thyme, mint, balm, &c. and hay.

Drying is sometimes performed on fish and animal substances. The native Americans had a practice of preferring...
flesh for many months, by cutting it into slips, and drying it slowly and completely: the Buccaneers of the West Indies imitated this custom, and derived their appellation from this circumstance. Their method is described in our article Buccaneers. The food, thus prepared, may have been considered good by the American savages; but with us a flight falting is usually given to the meat before it is attempted to be dried, and hence our present method of drying does not differ from dry salting, except that the salting is more slight, and the drying more complete than used for hams or bacon, and the flesh must be cut into thin pieces, to render the drying effective.

4. By pickling in vinegar, as for vegetable pickles, and fish, as salmon, mackerel, sprats, &c. Another mode of pickling is in alcohol or spirits; though this is not practised for provisions (except some choice kinds of fruits), on account of the great expense of spirits: the custom of anatomists preferring their preparations in spirits, flows that it will succeed with animal matters.

5. By fo packing up the provisions in bottles, or other cale, as to effectually exclude the air, and thus prevent fermentation; there are of this class potted meats, which are covered up in melted fat, fat, or butter.

6. Another mode, discovered in France by M. Apert, has been brought to a high degree of perfection in this country, by M.ers. Donkin, Hall, and Gamble, whose process we shall describe further on.

7. By freezing meat or fish, and packing it in snow or ice, it may be preferred as long as the freezing is continued. This is very extensively practised in some cold countries; and has of late years been successfully employed in the bringing of fresh salmon from the northern Scotch fisheries.

Of all the methods of preserving meat, salting is the most universal, mariners being almost exclusively supported upon salted provisions; and to the inhabitants of towns and district, where provisions are scarce, it offers a valuable supply, by importation, from places where they have abundance: such is the case of Ireland, where a very principal trade is in salted pork and beef, for the supply of the English navy, and its coaling towns. Newfoundland is alike famous for its salted cod-fish, and the Dutch for their herrings.

Meat which is to be dry salted, such as bacon, hams, hung-beef, &c. is first rubbed very effectually with a mixture of salt, bay salt, and salt petre over every part; for should any of the surface escape, that part would not be preferred; and to avoid this defect, the rubbing must be repeated several times. The meat being kept in leaden pans or cales, will by its juices form a brine with the salt; which is from time to time taken up and poured over the meat repeatedly as it runs down. This is continued for a fortnight or three weeks, according to the size of the pieces of meat, till the salt has pervaded the whole substance. The meat is now removed from the brine, and the salt being rubbed off with dry coarse clothes, it is hung up dry to dry in a warm place, or in a chimney, if a smoky flavour is desired, as in hams, hung-meat, and red herrings. When properly dried, it will keep for a long time. For further particulars, see Ham, Herrings, &c.

Salting in pickle is conducted very nearly in the same manner, except, that after the meat has imbired the salt, it is packed in casks, and filled up with very strong brine, or salt pickle: indeed, if it is to be kept a long time, as for a sea voyage, it is packed solid with salt. In salting, a mixture of sugar is sometimes used, but this is more for producing a good flavour, than for the preservation.

In salting beef and pork on a large scale for the navy, it is begun immediately after the beast is killed, and before the meat is cold. The salt used is an equal mixture of bay salt and salt petre, pounded together, and prepared by heating in an oven; with this the warm meat is sprinkled over at the rate of about two ounces to the pound, if intended for long keeping; it is then laid by upon shelving boards for twenty-four hours, and a strong pickle drains from it: the salting is now repeated, the pieces are turned over, and then they lie for another twenty-four hours, by the time the salt will be all melted, and have penetrated the meat; it is now drained off, and each piece wiped with a dry coarse cloth. Previous to packing it in the cask, it must be well rubbed with common salt, mixed with sugar, (the salt being made hot in an oven before it is mixed,) and then applied, whilst hot, in the proportion of one-half the weight of the meat, and this will be a sufficient quantity to pack the cales up solid, the interfaces between the pieces of meat being filled up, which must be very carefully done, and the cooperating efficient, to render the cask tight. The size of the casks should be such, that their contents will be consumed very quickly after opening the cask, as the less the meat is exposed to the air the better. A great deal depends upon the meat being salted whilst it is warm, and with hot or dried salt; probably because its affinity for moisture is increased, and it thus strikes more readily into the meat, to mix with the juices thereof. Pork is treated in the same manner, but a smaller proportion of sugar is used. Meat thus preserved will keep good for the longest voyages, in any climate.

Salted meats are not far less nutritious than fresh, particularly when to highly salted, as is requisite for long keeping at sea. This is the principal cause of the scurvy, which so commonly afflicts seamen. Duhamel, in his "Santé des Marins," says: "The salt meat with which the crews of vessels are fed, is known to be one of the principal causes of the scurvy; it seems that the fame causes which operate to prevent the fermentation of meat, also render it difficult of digestion; though a small quantity of salt may be an obstacle in the way of putrefaction, the too abundant and frequent use which is made of it, must cause great obstructions in the smaller vessels of the body; and these obstructions cannot fail to overload the stomach of men who have to digest dry vegetables and bicuits, which failors advanced in years are not always able to chew completely. Bad digestion and obstruction in the lower vessels, may occasionally give rise to those ulcers in the mouth, and spots which denote the scurvy."

Salt communicates an unpleasent rough flavour to substances preserved by it, hardens the animal fibre, and renders it difficult of digestion; the longer the meat is kept, the more forcibly these objections apply. Another great defect is, that it is necessary to remove it, by washing away great part of the salt employed; and therefore all parts of the meat which are soluble in water, are carried away with the salt. The usual mode of washing practiced by the seamen, is to suspend the pieces of meat from the end of the ship's bowspirt, and thus by the waves and the pitching of the ship, it is constantly dipped in the water, and drawn out again till the superfluous salt is washed away, and it becomes fit for cooking. From some experiments which have been communicated to us on the salted beef used in the navy, it appeared that a keg of 56lbs. weight, when it had been a month in pickle, was opened, the bones were separated, and found to weigh 5lbs. 6 oz.; the meat was boiled by flame, and loft 15lbs. 10 oz. in that operation; the produce of meat fit for eating was, therefore, 35lbs. the total loss being 21lbs., or about 40 per cent.

Another barrel, containing 100lbs. of prime masts beef, was opened eight months after it was pickled, and was found
found to weigh 103 lbs., having gained 3 lbs. from being saturated with the pickle; the bones being cut out, weighed 9 lbs. 10 oz.; and in boiling it diminished 42 lbs. 14 oz.; leaving only 47 lbs. 8 oz.; so that more than half was lost. In a third experiment, a barrel containing 26 pieces of beef, of 8 lbs. each, when opened, had gained 5 lbs., as it weighed 213 lbs.; the bones in this weighed 13 lbs. 8 oz., and the wafle in boiling was 90 lbs. 14 oz., leaving 103 lbs. 10 oz. of good meat, after a loss of rather more than half.

The preservation of provisions by sugar is rarely practiced in the large way, being chiefly confined to preserving fruits for winter consumption, or for the decoration of plants, when reduced to syrups and essences. The general method is to put the fruit, with a sufficient quantity of sugar, into a vessel, which is placed on the fire, till the sugar, mixing with the juices which exude from the fruit, forms a strong syrup. The same effect will be produced by baking the fruit in a jar containing the sugar: after the heat has caused the syrup to sufficiently penetrate the fruit, it is suffered to cool, and then put close into pots or jars, which are filled up with the syrup, and covered close by paper, and a cover of a skin of bladder or leather is tied over the mouth. The paper which immediately covers the fruit is dipped in brandy, or other spirits, to preserve the surface from becoming mouldy, as it otherwise might do, and taint the whole.

Sugar, from the strength of its own flavour, conceals and destroys all other flavours in a greater or lesser degree, even that which we wish to preserve the enjoyment of, such as the piaentful acidity of certain fruits. A second inconvenience is that, a large quantity of sugar is required, in order to preserve a small quantity of some other vegetable matters, and hence the use of it is not only very costly, but even in many cases very pernicious. Thus, the juice of certain plants used in medicine cannot be reduced to a syrup or essence which will keep a long time, but by means of nearly twice the quantity of sugar: it results from this, that those syrups or essences contain much more of the properties of sugar than any other medicinal substance, and frequently the sugar, by counteracting the operation of the medicine, is hurtful to the patient.

Vinegar is used for preserving salmon, and some other kinds of fish; such are generally slightly salted first, and then boiled in the cafs, that they may be fit for the table when the cafs are opened; they are packed for keeping in barrels, which are filled up with good vinegar, and it is this which preserves them.

Many vegetables, such as cabbages, cucumbers, onions, &c. are preferred by pickling; the former of these is prepared in a very large way for the navy, it being found advantageous for the men, in long voyages, to use both vinegar, and vegetable food, to prevent scurvy; they call it "kraut." The largest and finest cabbages are used; they are cut up and salted some time in strong brine, then packed in the cafs, and filled up with vinegar which has been boiled with some spice, and is poured hot upon the cabbage. It requires no cooking when opened.

Potted meats are generally cooked and minced very fine before they are put up; this is done in jars, which being well filled, are then covered up by butter poured over the meat while in a melted state; this preserves the meat, by preventing the access of air. Mutton luet melted, and poured upon the meat, is still better, if it is to be kept long, or in a warm climate, as the butter then becomes too fluid. Whole joints, enveloped in this substance, may be kept in the West Indies, but not for a sufficient length of time to render it an effective method: the juice should be made from the fat of a sheep's kidney.

By Messrs. Donkin and Co's method, the meat or vegetable to be preferred is first partially cooked, by boiling, baking, roasting, or otherwise, and then enclosed in canisters, or cafes of metal, or in bottles of glass or glazed stone ware, which are very carefully closed, with every attention, to render them perfectly air-tight. In this state the cans or bottles are subjected to a second boiling, which is sufficient to complete the cooking. This boiling completely deprives that small quantity of air which is contained in the vessel of its oxygen, and consequently of its fermentation, and if the vessel is sound, the contents will remain unchanged for the longest periods of time which can ever be required. Nor do they become any worse for longer keeping, as salt provisions do by undergoing a progressive decomposition and change for the worse, and imbibing a greater quantity of salt, till at length they are not eatable. After the boiling of the vessels, a considerable diminution in the bulk of the contained air is found to take place, which is shown by the sides of the vessel (when made of a yielding substance, such as tinned plate) becoming concave on the outside, from the pressure of the atmosphere: from this circumstance, the atmospheric air has always a tendency to enter the vessel, and therefore the most minute leak will spoil the provisions. To render the vessels tight is the great difficulty in the process, and in this the English patentees have perfectly succeeded.

M. Aper, in France, was rewarded by the French government in 1810, and published an account of his process, which has since been translated into English. In this he observes, that his method consists in inclining the substances to be preferred in bottles, and corking them with the utmost care, for it is chiefly on the corking that the success of the process depends.

These inclined substances are boiled in a water-bath for a greater or lesser length of time, according to their nature, and are then withdrawn from the bath. M. Aper describes his laboratory to consist of four apartments, the first a kitchen, furnished with stoves, and all the utensils necessary for cooking the animal substances which are to be preferred; the second is a dairy, and appropriated to the preparation of milk, cream, and whey; the third apartment is used for corking the bottles, and tying the corks down with wires, also inclining the bottles in bags, to preserve their contents in the event of their breaking during the boiling; the fourth apartment is for the boiling; it contains three large but shallow copper boilers, placed upon stoves, raised on brick-work. These boilers are each furnished with a flat lid, fitted to rest upon the vessels within; and each boiler is furnished with a large cock below, to let out the water at a proper time. These large boilers are defined to receive the bottles or vessels containing the objects intended to be preferred, in order to apply the action of heat to them in a suitable manner, and thus they constitute to many water-baths. The reason why it is necessary that the boilers should be furnished with cocks is, that it would take up too much time to leave so large a body of water over a heated stove till it became cool; and that, on the other hand, it would do great injury to the substances to let them remain too long exposed to the heat.

The principle by which all substances of food are preferred and kept fresh is variable in its effects; but the result in particular cases will depend upon the fitness of each individual application of the principle to the substance which is to be preferred, attention being paid to its peculiar qualities. In every case the exclusion of air is a precaution of
of the utmost importance to the success of the operation; and a perfect knowledge of bottles, or other vessels to be used, of corks and corking, is requisite. Glass is to be preferred, as being the matter most impervious by air; and M. Aptel has not ventured to make any experiment with a vessel made of any other substance. The necks of ordinary bottles are generally too small; they are also ill made, and too weak to resist either the blows from the bat which drives the corks, or the action of the fire. He therefore caused bottles to be made with a rim or ring projecting within the interior surface of the neck, placed below, and resembling the form of the rim which is at the top of the exterior surface of the necks of ordinary bottles. The object of this was, that when the cork had been driven into the neck of the bottle three-fourths of its length, it should be compressed in the middle. In this manner the bottle becomes perfectly corked on the outside as well as within: the cork then opposes an obstacle to the swelling or expansion, which arises from the operation of heat upon the substances inclosed within the bottle. This mode of forming the neck of the bottle is the more indispensible, as the swelling will sometimes be so strong as to pull out corks of three or four lines in length, though confined by two iron wires crossed. The bottles and vessels should be made of a tough substance; and the glass ought to be of equal thickness in every part, or it is liable to break in the water-bath. Too much attention cannot be given to the good quality of the corks, which should be of eighteen or twenty lines in length, and of the finest quality: they should be compressed by biting the cork three-fourths of its length, by means of an instrument already described in our article Cork, beginning at the small end. The cork by this operation made more imperative, its pores are brought closer, it is somewhat lengthened, and its thickness is so much diminished at the extremity which is put into the mouth of the bottle, that a large cork may be made to enter a very moderate opening. The action of the heat within the vessel causes the cork to swell within, and the corking is thus rendered perfect. Before corking, care should be taken that those bottles containing liquor are filled only within three inches of the outer rim, lest they should burst, from the expansion occasioned by the application of heat to their contents. When the bottles contain vegetables, fruits, &c. they may be filled up to within two inches of the rim. The bottles are corked by driving the corks down with a bat or mallet, and being thus well stopped, the corks are fastened down with a couple of iron wires crossed over the cork, and twisted round the neck of the bottle: each bottle is then inclosed in a bag of canvas, or coarse linen cloth, made for the purpose, sufficiently large to inclose the whole of the bottle up to its neck. These bags are made in the shape of a muff, open at both ends; one of these ends is drawn with a string, leaving an opening of about the width of a crown-piece; the other end is provided with a couple of small strings to tie the bag close round the neck of the bottle.

For preserving solid and bulky substances, such as poultry, game, meat, fish, &c. M. Aptel employs glass jars, which have necks of two, three, or four inches diameter, and are of a larger or smaller size, according to the article they are to contain; they are furnished, like the bottles, with a projecting rim, not only to strengthen the neck, but also for receiving the iron wires which are to bind the corks: but he observes, that to cork up these vessels completely, is rendered more difficult, and demands especial care, from the large size of the mouth or neck, and the thinness of the cork, also from the ascending pores of the cork being against the grain of the bark; he therefore formed flippers of three or four pieces of cork, from twenty to twenty-four lines in length, cemented together the proper way of the grain, the pores of the cork being placed horizontally; he joined the pieces by means of tubing.

Having driven the flipper into the jar by means of the bat, he makes use of a compound luting, which is lime flaked in the air, by being sprinkled with water till it becomes reduced to a powder. This lime, mixed with cheese made of skimmed milk (fromage à la pie), and formed to the thickness of paste, produces a luting, which hardens rapidly, and which withstands the heat of boiling water; he covers the whole of the outside of the flipper with this luting, and covers the edge of the jar with hemp and strips of linen, placed above, close to the flipper, and hanging down to the rim. The bottles, or jars, being thus prepared, are placed upright in the boiler, or water-bath, which is filled with cold water up to the necks of the vessels; then closing the boiler with its lid, which is made to rest upon the vessels, the upper part of the lid is covered with a piece of wet linen, in order that the fides of the lid may exactly fit, and all evaporation from the water-bath be impeded as much as possible.

The fire being lighted, when the water-bath begins to boil, care must be taken to maintain the same degree of heat during the greater or less length of time required by the substances exposed to its influence, and then the fire put out as quickly as possible.

A quarter of an hour after the fire has been extinguished, the water is let out of the bath by means of the cork, and half an hour afterwards the boiler is opened; but the bottles are not moved till one or two hours after the uncovering, and this terminates the operations.

The utmost attention to cleanliness in all the utensils employed for the preparation of the substances to be preserved, is absolutely indispensible.

The author gives detailed instructions for the preparation of all kinds of provision; as meat, game, fow, gravy, jelly, eggs, milk, whey, vegetables of all kinds, &c.; but as the directions do not give any farther insight as to the principle, we shall conclude this account with the periods which he advises for boiling in the water-bath. Thus, for preserving boiled meat, the bones are taken out, and the meat half cooked; then inclosed in the jars, which are filled up with the broth or gravy of the meat, corked, luted, and tied up in the bags; the jars are after this boiled in the water-bath for one hour. Meat prepared in this way was found perfectly fresh at the end of a year and a half.

Nutritious gravy, for the use of sick fowlers and sailors, was put up in bottles, and boiled in the bath two hours.

Jelly, which has a previous cooking for a considerable time, requires only a quarter of an hour boiling in the bottles to preserve it.

Round of beef, mutton, fowls, and young partridges, are drenched as if for common use, but only three-fourths done, then packed up and boiled half an hour; the same for eels, carp, pike, &c.; these have been kept to eat for four months, and returned perfectly fresh, without the least change.

These results prove sufficiently that the preserving principle, applied with the same preparatory processes, and with equal care and precaution, will in general preserve all animal productions. But it is to be observed, that in the previous cooking of each article, it is to be only three-fourths drenched at most, in order that the remainder of
the requisite cooking may be communicated by the heat of the water-bath.

There is a number of articles which can bear an additional hour of boiling in the water-bath, without any danger, such as broth, gravy, jellies, and the effences of meat, poultry, and ham, the juice of the grape, and of plants, &c. But there are also others which will sustain a great injury from a quarter of an hour, or even a minute too much boiling: thus the refult will always depend upon the dexterity, intelligence, and judgment of the operator.

Meat which has, in the preparatory dreeing, as well as the boiling it received in the water-bath, obtained its due quantity of cooking, will, when it is taken out to be used, require only to be properly warmed, in order to produce both soup and meat; likewise poultry, game, and fih, which have received three-fourths of their dreeing in the preparatory process, and the remainder in the water-bath, as already pointed out, may, when taken out of the vefils, be heated to the proper degree, in order to be instantly served at table. If, for instance, the substance taken from the bottle, or jar, had not received either enough previous dreeing, or enough heat from the water-bath, it is immediately put on the fire to supply what is deficient. Consequently, when the operator has taken due care in making his preparations, having properly seasoned and dreeed the provisions, the ufe to be made of them afterwards will, at all events, be easy and convenient, for they will need only to be warmed; or they may, if necessary, be eated cold.

Substances thus prepared and preferred do not, as might be imagined, require to be consumed as soon as they are opened. Provisions may be used from a vefil eight or ten days after they have been uncorked, care being taken only to replace the cork as soon as the necufary part of the provision has been taken out. Besides, it is easy to regulate the size of the vefils according to the rapidity of the expected consumption.

New laid eggs are to be put up in a jar, and packed with rapslings of bread, to prevent their breaking; the jars are then boiled in the water-bath, heated to 200°: they were preferred six months by this process. Milk is to be boiled in an open pan, placed in the water-bath, till it is reduced to one-half its quantity, frequently skimming it, and half an hour before it is taken out of the bath it is to have the yolks of eight new eggs added to a quantity of about 15 pints of the concentrated milk; which being put into bottles, they are to be boiled in the water-bath for two hours. Cream, condensed by boiling to four-fifths of its quantity, and then boiled in the bottles for one hour, was so effectually preferred for two years, that it was made into butte at the end of that period.

For vegetables it is observed that the difference of climate renders the productions of different countries more or less early, and varies their qualities, kinds, and denominations. Attention must, therefore, be given by the operator to the circumstances of the spot in which he resides.

At Paris and its environs, June and July are the best months for preserving green peas, small Windsor beans, and asparagus. At a later period, these vegetables suffer greatly from heat and dryness. In August and September, artichokes, French beans, and cauliflower may be preferred.

In general, all vegetables intended to be preferred should be used as recently gathered as possible, and prepared with the utmost rapidity, so that there should be, as it were, but one step from the garden-bed to the water-bath.

Green peas are recommended to be taken when in a middling state of growth, and the larger being separated from the rest, they are bottled without previous boiling, and boiled in the water-bath an hour and a half, if the weather is cool and moist, or two hours in dry hot weather: the large peas are boiled by themselves for two hours, or two hours and a half, under similar circumstances.

Asparagus, instead of previous boiling, is merely dipped into boiling water, then put heads downwards into the bottles, which are only suffered to remain in the water-bath until the water boils.

Windor beans are bottled, and, without previous boiling, are boiled one hour in the water-bath; or if the skins of the beans have been first taken off, they are boiled one hour and a half.

Cauliflowers have their useless leaves taken off, and are plunged into boiling water, and then immediately into cold water, and being well drained, are closed up in jars, which are boiled for half an hour in the water-bath.

As the seasons vary, and are sometimes dry, and sometimes moist, it is obvious that it is necessary to study, and adapt the various degrees of heat required according to the season. Attention to this circumstance must never be disregarded. For instance, in a cool and damp year, vegetables are more tender and conftantly more sensitive to the action of fire. In this case the water-bath should be made to boil seven or eight minutes less; and in dry seasons, when vegetables are firmer and better able to support the action of fire, seven or eight minutes more boiling should be added to the time specified.

The first notice of this important discovery in England was by a patent taken out in 1810, by Mr. Durand, who received the communication from France; the patent-right has since been transferred to Messrs. Donkin, Hall, and Gamble, who have established a considerable manufactory in Blue Anchor road, Bermondsey, which they permitted us to inspect. Their kitchen for cooking, and harder for cooling the meat before it is packed up, are very complete, and they have considerably improved upon the French mode above-described, by substituting, in most cases, canisters of tinned iron for the glass jars and bottles; they are made by very carefully folding up the tin plates to form circular or oval boxes, of dimensions suited to what they are intended to contain; and these, when filled with the prepared meat, have lids folded down upon them very closely: they are then boiled in the water-bath, but do not require that preparation of gradually heating and gradually cooling, which must be observed with glass vefils, which would otherwise be subject to break. The canisters may be put into the bath when the water is boiling, and taken out when finished, another lot being put in, so as to keep constantly going. Immediately the canisters are withdrawn, they are carefully examined, to discover and stop the leaks, and the boxes are then well varnished, to prevent rust. Another great advantage arises from the use of tin canisters, viz. that they will, in the course of a fortnight’s trial, afford a criterion to judge of the progress being effectually performed; for as the vessel cools after the operation of the water-bath, the lid and bottom of the canisters become concave; and their remaining so, insafilly indicates that their contents will keep fresh; but if fermentation takes place, gales will continue to be generated until the top and bottom become convex, which circumstance denotes the contents to be ippoit. After every precaution has been taken to render the closure of the canisters perfect, they are ticketed, to explain their contents, weight, and the date of preparation, and are hung up in a room, heated to that temperature which is found most conducive to fermentation, if any can be generated: here they remain from three weeks to a month, and if their fides continue concave, they are
are then considered as being fit to send out. This criterion of perfect preservation is obtained by the English patentees, which was not the case with M. Apert, who describes no method of trial, except an examination of the glass bottles after the boiling, to find if they had any flaws or flaws, or faults in the corks, which could admit the air. Indeed the tin canisters are more likely to be tight than the glass vessels, from the circumstance that they admit of being more nearly filled up with the meat or gravy; because the expansion which takes place in the boiling, is in some degree permitted by the fides, top, and bottom of the canisters becoming convex. In the subfequent cooling also, the yielding of the fides to a concave form relieves the pressure of the atmosphere; whereas, in a bottle which cannot yield, there is always a partial vacuum or rarefaction within the vessel, and the atmospheric air preffes to enter at the most minute leak in the cork, with much more force than on the tin vessel, in which the elasticity of the tin plates to assume their plane surfaces, is the only force to caufe the air to enter into the vessel.

For milk, soups, peas, and other similar articles, the patentees employ bottles, but have found reason to prefer a strong kind of earthen-ware, well glazed, to glass, being less expensive and hazardous, either in the preparation or in carriage.

We have been thus particular in the details of this process, as we consider it an object of great importance to the health and comfort of the men, to whom this country is so greatly indebted for its present affluence, that no pains should be spared to render their condition as comfortable as possible. The obvious advantages of the discovery are, that provisions so prepared will entirely supersede the necessity of taking out live flocks to sea, which, exclusive of its own incumbrance in a ship, must be accompanied with that of its provender and fresh water. Much room, trouble, and expense will be saved, besides the loss sustained by bad weather, disease, and the wasting of the animals, which always takes place in a voyage. Being ready dressed, such meat may be eaten cold, or, if preferred, heated in a few minutes, by which fuel will be saved, and the difficulty of cooking at sea in bad weather rendered of little importance. They are well calculated for all expeditions of boats’ crews, landing-parties, &c.

The salutary effects which the army and navy would derive from even an occasional supply of fresh provisions, cannot be too highly appreciated, as it would most effectually contribute to the reformation of the health and services of the sick and wounded, and eventually save to the State the valuable lives of many of our sailors and soldiers.

Proviso, in Traffic, is sometimes used for the wages due to a factor. See Factorage.

Provisions, Park of. See Park.

Provion, in the Canon Law, the title or instrument, by virtue of which an incumbent holds, or is provided of, a benefice, bishopric, or the like.

Ordinary collators give provision in case of vacancy by death, pure and simple demission, and permutation. See Collation.

The court of Rome grants provisions by resignation, devolement, and prevention.

Provions by Prevention, are also called gratia expecitate, and mandata de providendo; of the great abuses of which throughout England, frequent complaint was made in our ancient statutes, and a remedy was provided for the fame by the statutes of premunire. See Expectative Grace.

Provions of small benefices, in the court of Rome, are only simple signatures, which are, as it were, minutes of the bull; because the bulls themselves, dispatched on parchment, would be too expensive. The signature is no more than the petition of the impotent answered by the pope in these words: “Conceelum uti petitur in praefentia D. N. papae,” wrote in the hand of the primate who prefixed over the signatures.

Extraordinary provisions are signed by the pope himself in these words, “Frat ut petitur;” with the first letter of his name.

PROVISO, in Law, a condition inserted in a deed, upon the observance of which the validity of the deed depends.

PROVISO, in Judicial Matters, is where the plaintiff defers from prosecuting an action, by bringing it to trial in a due time; in which case the defendant may take out a venire facias to the sheriff, having it in these words; Provito quod, &c. to the end that, if the plaintiff take out any writ to that purpose, the sheriff shall summon but one jury upon them both. In which case it is called going to trial by proviso. See Jury.

But this practice hath been to be diffused, since the statute 14 Geo. II. c. 17, which enacts, that if, after issue joined, the cause is not carried down to be tried according to the course of the court, the plaintiff shall be esteemed to be non-suited, and judgment shall be given for the defendant as in case of a non-suit. In case the plaintiff intends to try the cause, he is bound to give the defendant (if he lives within forty miles of London) eight days notice of trial; and if he lives at a greater distance, then fourteen days notice, in order to prevent surprize: and if the plaintiff then changes his mind, and does not countermand the notice six days before the trial, he shall be liable to pay the costs to the defendant for not proceeding to trial, by the same last-mentioned statute. The defendant, however, or plaintiff, may, upon good cause shown to the court above, as upon abstinence or hucksters of a material witness, obtain leave upon motion to defer the trial of the cause till the next assizes.

PROVISO is also a sea term. A ship is said to moor a proviso, when she has an anchor out, and also a hawser afore; and so is moored with her head to the shore with two cables at least.

PROVISO is generally taken for him who hath the care of providing things necessary; in which sense it coincides with purveyor.

PROVISO MONTIERRIUS is used for the steward or treasurer of a religious house.

PROVISO, in our Statutes, also denotes a person who is to the court of Rome for a provision, or expectative grace. See PREMUNIRE.

PROVISO are dicuntur, qui vel episcopatum, vel ecclesiasticam aliam dignitatem in Romana curia fibi amiantem de futuro, quod ex gratia expectativa nuncupatur, quia, ulque dum vacat, exspectandum effet.” Spelm.

PROVISO, in Statutes against. See PREMUNIRE.

PROULACH, in Geography, a town of the duchy of Carinthia; 11 miles S.W. of Clagenfurt.

PROVOCATIVE, in Physic, a medicine which strengthens nature, and simulates the incites to venery. Such are cantharides, fatyron, &c.

PROVOCATORIUS, in Antiquity, a class of gladiators, supported by Liptius to be generally matched with the Samnites.

PROVOST, Præpositus, an officer, of whom there are divers kinds; civil, military, &c.
PRO

Provost of the City, or of the Merchants, is the chief municipal magistrate in several considerable trading cities; particularly Edinburgh, Paris, and Lyons; much the same with the mayor in other places.

The provost presides at the city courts, and, together with the sheriffs, or bailiffs, decides all differences relating to trade and merchandize; he takes cognizance of the affairs of officers of policy of the city, with regard to their functions; of the delinquencies of merchants, commisioners, and factors; inspects the ports, rivers, duties, impoits, &c.

Authors attribute the institution of provost of the merchants of Paris to Philip Augustus. Du Haillan refers its epocha to the year 1190.

The provost of Edinburgh has the title of lord; the bailiffs are his deputies. He calls conventions of the boroughs by his own wills.

Provost, or Provoet Royal, also denotes a sort of inferior judge establisht throughout France, for the taking cognizance of all civil, personal, real, and mixt causes, among the people; but without any jurisdiction in the causes of nobles.

These, in the Bourbonnois, Auvergne, &c. are called chatelains; in Normandy, vicomptes; in Languedoc and Provence, vigniers.

Grand Provost of France, or of the Huysebold, an officer who, in the old regime, had jurisdiction in the king's house, and over the officers in it; he looks to the policy and regulation of it, the rates of provisions following the court, &c. He was anciently called roi des ribauds.

Grand Provost of the Confulable, a judge of the sword, who managed processe against the soldiers in the army, who had committed any crime.

He had four lieutenants, distributed throughout the armies, called provosts of the army; and particularly provosts in the several regiments.

Provost Guard. See Guard.

Provost-Marshal of an Army, is an officer appointed to seize and secure defectors, marauders, soldiers frugally beyond the limits of the camp, and all other criminals.

The provost-marshall is to go often abroad round the army to hinder the soldiers from pillaging. It is his office to indict offenders, and to see the sentences passed upon them executed.

He likewise regulates the weights and measures, and the price of all provisions, &c. in the army, when in the field. For the discharge of his office, he has a lieutenant, a clerk, and a troop of provosts of marchals men on horfeback; a serjeants guard, and sometimes a subaltern's guard; as also an executioner. The provost-marshall, or chief provost of the army, seems to have been formerly an office of much greater rank and authority than it is now. At present, the office of provost-marshall is executed by the adjutant, whose duty it is to see all sentences of regimental courts martial inflicted.

There is also a provost-marshall in the navy, who hath charge of the prisoners taken at sea.

The French have a provost-general of the marines, who is to prosecute the marines when guilty of any crime, and to make report of it to the council of war; besides a marine provost in every vessel, who is a kind of gaoler, and takes the prisoners into his care, and keeps the vessel clean.

Provosts of the Marchals are a kind of lieutenants of the marshals of France, establisht for the security of the country against rogues, vagabonds, and defectors. They take cognizance of royal caufes; which, for this reason, are called provostal caufes. Such are all crimes committed by ftrollers, or people without any fixed abode; robberies on the highway, infractions of safeguard, burnings, &c. They pronounce en dernier refort, or without appeal.

There are a hundred and eighty seats of these provosts in France; their chief jurisdiction regards highwaymen, footpads, houfetakers, &c. They correspond to the officers established by Augustus and Tiberius, called, as Cujas tells us, latrunculatores; to fiew that their office was to pursue thieves.

Provost of the Mint is a particular judge instituted for the apprehending and prosecuting false coiners.

PROW, PRORA, in Navigation, denotes the head or fore-part of a ship; being that which is opposite to the poop or stern.

In front of it is the beak that cuts the water to make way for thevel.

The prow is lower than the poop, and contains fewer stories or decks. On the beak is usually fome figure or hieroglyphic, which often gives name to the vessel.

Prow, in strictnes, is only that part of the forecastle which is aloof, and not in the hold; particularly that part between the chafe and the loof.

The ancients represented birds in the prows of their ships, whence they were called rostrum.

Prow is also a name given by feamen to the beak or pointed cut-water of a polare, xebec, or galley. The upper part of the prow in these vessels is usually furnished with a grating platform for the convenience of the feamen, who walk out to perform whatever is necessary about the fails or rigging, or the bawpsprit.

PROX, in Natural History, a name given by Aritotle to the cervus platycterus, or broad horned flag.

PROXENETA, or PROXENETES, a kind of broker or agent, who transacts between two perfons. See Broker, and Agent.

The word is Greek, προξενητα, q. d. conciliator or para-
rius, reconciler or mediator. The Latins give them a more honourable appellation, calling them interpreters.

The term proxeneta is chiefly applied to those who negociate offices, marriages, &c.

The Roman law grants the proxeneta an action for recovery of their hire or wages.

Thefe made a kind of office or college in Rome: to them the fathers addressed themselves, to found and examine the inclinations of the young men they intended for their daughters. A commentator on the Digest accounts it a great defect in the modern policy, that there are not now any of these proxenetae, or match-makers, establisht by public authority.

PROXIMITY, PROXIMITAS, denotes the relation or nearness either in repect of place, blood, or alliance.

PROXY, PROCURATOR, a deputy, or person who officiates in the room of another.

Princes are usually married by proxies, or representatives. Peers are allowed to give their votes by proxies.

Proxy, Procuracy, among Civilians, also denotes a commission given to a procifer, by a client, to manage a caufe in his behalf.

PROYART, in Geography, a town of France, in the department of the Soisne; 10 miles W.S.W. of Péronne.

PRASAN, a town of the duchy of Warfaw; 48 miles N. of Warfaw.

PRUAT. See PRUVAT.

PRUCK, a town of the duchy of Sreia, on the left bank of the Muelr; 20 miles N.N.W. of Gratz. N. lat. 47° 27'. E. long. 15° 8'.

Vol. XXVIII.
 Pru. See Bruck.

PRUCREOS, a cape on the coast of New Spain, in the South Sea.

PRUDENCE, in Eheic, may be defined an ability of judging what is best, in the choice both of ends and means. According to the definition of the Roman moralist, (De Officiis, lib. i. cap. 43.) prudence is the knowledge of what is to be desired or avoided. Accordingly, he makes prudentia (De Legibus, lib. i.) to be a contraction of providentia, or forethought. Plato (De Legibus, lib. iii.) calls this the leading virtue; and Juvenal, Sat. x. observes, "Nullum numen abest si sit prudentia."

The idea of prudence includes 

provision, or due consultation, that is, concerning such things as demand consultation, in a right manner, and for a competent time, that the resolution taken up may be neither too precipitate nor too slow; and providentia, or a faculty of discerning proper means when they occur; and to the perfection of prudence, these three things are further required, 

es. prudens, or natural sagacity; 

cupio, or the thorough, sound, or ready turn of thought; and 

providentiae, or experience. The extremes of prudence are craft or cunning on the one hand, which is the pursuit of an ill end by direct and proper though not honest means; and folly on the other, which is either a mistake, both as to the end and means, or professing a good end by foreign and improper means. Grove's Moral Philosophy, vol. ii. chap. 2.

PRUDENCE, in Geography, a small island, lying N. of Cananicut in Narraganset bay, and belonging to the town of Portsmouth, in Newport county, Rhode Island.

PRUDENTIUS, Aurelius, in Biography, a Roman poet, of the fourth century, was born in Spain, probably at Saragossa, about the year 348. He was brought up on the seashore, and became chief magistrate in two considerable cities. He also served in the army, and obtained honourable employment at the court of Honorius. This is all that is known of his personal history. He was a zealous Christian, and his poetical talents were devoted to the service of his religion. His compositions are chiefly valuable as documents of Christian antiquity, for their defects of style and verification exclude them from the list of classics even of a low order. They consist of "Psychomachia," or the soul's combat: "Cathechumenon," or litanies for festivals: "Apotheosis," or on the Deity, against heretics, &c. Of the editions of Prudentius, some of the best are those of Heinius, Lug. Bat. 2 vols. 12mo. 1667; and the Delphin 1687.

PRUDENZA, Ital. in Music, a term of caution at the beginning of a difficult movement, left in playing it at sight, a performer should begin more rapidly than he shall be able to fulfill. Can prudenza, therefore, points out the danger. Al suo comando is of the same import.

PRUNA, in Physiology. See Hare Frost.

PRUM, in Geography, a town of France, and principal place of a district, in the department of the Sarthe; 24 miles N. of Treves. The place contains 1072, and the canton 4699 inhabitants, in 42 communes. Also, a river of France, which rises about four miles from the town of Prum, and runs into the Sour, eight miles N.W. of Treves.

PRUMBACH, a town of Bohemia, in the circle of Saatz; eight miles N. of Eger.

PRUNAY, a town of France, in the department of the Aube; 12 miles N.W. of Troyes.

PRUNE, in Botany. See Prunus.

PRUNE-Tree. See Prunus.

Gen. Ch. Cal. Perianth inferior, of one leaf, two-lipped, shorter than the throat, permanent; upper lip flat, rather wide, truncate, slightly three-toothed; lower lip erect, narrower, acute, cloven half way down. Cor. of one petal, gaping; tube short, cylindrical; throat oblong; upper lip concave, undivided, drooping; lower reflexed, obtuse, cloven into three segments, of which the middle one is broader, emarginate, serrated, concave. Stam. Filaments four, awl-shaped, forked at the top, two of them a little longer than the others; anthers simple, inserted into the filaments below the top, as it were on another branch. Pistil. Germen superior, four-cleft; style thread-shaped, with the filaments incurved by the upper lip; stigma clavunc. Peric. none, except the closed calyx, which encloses four, nearly oval seeds.

Of. The great peculiarity of this genus consists in its having forked filaments like Cranesbys, and the middle segment of its lower lip toothed as in 

Self-heal.

Eff. Ch. Filaments forked, one point bearing the anther. Stigma clavunc.

2. P. grandiflora. Great-flowered Self-heal. Wild. n. 2. Curt. Mag. t. 337. Jacq. Aulfr. t. 377. (P. vulgaris β. Linn. Sp. Pl. 837.)—Lower leaves flaked, oblong-ovate, toothed at the base. Upper lip of the calyx trifid. Stem ascending. Native of the Alps, and various other parts of Europe, flowering in July and Augst. This large and showy species was considered by Linnaeus merely as a variety of the common one, but later authors have determined it to be distinct, its leaves being constantly lower, leaves more tender, and flowers twice as large. Stems about six inches long, erect, slightly angular, hairy. Leaves entire, or slightly toothed, bright green; upper ones almost lamellate. Spike looser, more ovate. Flowers large and handsome, of a rich blue or purplish colour. Mr. Atkin in the first edition of his Hortus Kesw motorcycles Linnaeus in making this species a variety of P. vulgaris, but in the second edition of that work he has made it a distinct species.

inches high. *Leaves* more or less laciniated and hairy. *Flowers* larger than in *P. vulgaris*, but less than those of the last species, of a yellowish-white colour. It is subject to vary in its leaves, and the colour of its flowers. Linnaeus considered this species as differing very little from the common fort.

4. *P. hyssopifolia.* Hyssop-leaved Self-heal. Linn. Sp. Pl. 837. (Brunella angustifolia integrerhifitur; Morif. Hift. v. 3. 364. fift. 11. t. 5. f. 7.)—Leaves sessile, lanceolate, entire, rough. Stem erect.—Native of the north of France, about Monepelle, flowering from July to October.—Stem erect, firm and little branched. *Leaves* narrow, oblong, entire, hairy, on short stalks. *Flowers* large, generally blue, but occasionally white; the keel of the upper lip of the corolla is hairy.

5. *P. pensylvanica.* Pennsylvanian Self-heal. Wild. Hort. Berol. 9. Ait. Hort. Kew. v. 3. 430.—Leaves stalked, ovate-lanceolate, toothed at the base. *Lips* of the calyx equal; the upper one truncated, with three awns. Stem ascendent.—Native of Pennsylvania, received from thence by M. Thouin in 1801. It flowers from July to September.—We adopt this new species on the authority of the above quoted authors, but are not acquainted either with a specimen, figure, or description of it.

**PRUNELLA,** a name given by some physicians to a dryness of the tongue and throat, happening in continued fevers, especially acute ones, accompanied with a heat and redness of the throat, and a scurf covering the tongue; sometimes whitish, and sometimes blackish.

Some also give the name prunella to the quinny, and others to the apline.

**PRUNELLA, Sul,** in *Pharmacy,* is a preparation of purified saltpetre; called also lapis prunella, and crysrall mineral.

It is prepared by separating and absorbing some of the more volatile parts of the saltpetre, which is done by burning upon it, when melted in a crucible over the fire, about a twenty-fourth part of its weight of flowers of brimstone. When the deflagration is over, the melted salt is poured into clean, dry, warm, brais moulds, so as to form it into little cakes.

It is given to cool, and provoke urine, in fevers and quinzy; though some think that saltpetre, purified three or four times, would be a better medicine.

The sal prunella is said to be frequently adulterated with alum; and that the deceit is known by its whiteness and glittering.

**PRUNES, PRUNA,** are plums dried or baked in an oven, or in the sun. See **PRUNUS.**

Three sorts of this fruit are ranked among the articles of the materia medica; they are all met with in our gardens; but the shops are supplied with them, moderately dried, from abroad. These are the Brignole plum, or prunella, brought from Brignole in Provence, of a reddish-yellow colour, and a very grateful, sweet, fucabac taste; the common, or French prunes, called by our gardeners the little black damask plum; and damsons, the larger damask violet plum of Tours, which is seldom kept in the shops, but has been generally supplied by the common prunes. All these fruits posse the same general qualities with the other summer fruits. They are nearly odorous, and contain chiefly mucus, facelarine matter, and malic acid. The prunelles, in which the sweetness has a greater mixture of acidity than in the other sorts, are used as mild refrigerants in fevers and other hot indispositions, and are sometimes kept in the mouth for alleviating thirst in hypodric cafes. The French prunes and damsons are the most emollient, lubricative, and laxative, they are taken by themselves for gently loosening the belly in collique habits, and where there is a tendency to inflammation; deconcoctions of them afford an useful basis for laxative or purging mixtures, and the pulp in substance for electuaries.

**PRUNES, Island of,** in Geography, a small island near the E. coast of Madagascar. S. lat. 18°. E. long. 49°. 48'.

**PRUNES, a river of Louisiana,** which runs into the Mississippi, N. lat. 35° 33'. W. long. 96° 20'.

**PRUNIFEROUS TREES, or Shrubs, the plum-bearing kind,** are those whole fruit are pretty large and soft, with a stone in the middle.

In this kind the flower adheres to the bottom of the base of the fruit.

**PRUNING,** in *Rural Economy,* the lopping or cutting out branches or boughs of trees of the fruit, timber, or other kinds. See **ORCHARD** and **TIMBER.**

It has been observed, that in timber plantations, and most other kinds of woods, it is highly proper and necessary to have an eye to the pruning and taking out the branches of the young trees occasionally as they advance in their growth, in the view of guarding against and preventing their shooting out and increasing in an irregular and improper manner, and thereby becoming too thick, and injuring each other by their rubbing, or by being drawn up weak and in too close a manner. The trees should therefore be now and then carefully looked over every year after the third from the time of their being planted, and such branches or other parts, headed down, taken out, or cut away in such other manner, as may appear suitable and proper for promoting their more perfect and beneficial growth and thereaft. And when this has been well effected, the only thing which remains further to be done, is that of encouraging proper leaders in the different trees, by means of shortening all the other branches which seem to contend with it, to nearly one-third of their length, in the intention of strengthening the main proper item. All that is afterwards required is that of properly pruning out and thinning the more strong top-branches and shoots, as well as those side ones that are improperly situated, which is often done by a light kind of hand-bill; but it may be well accomplished by a small saw, or any other instrument of the strong cutting fort. These modes of pruning are applicable to forest-trees in general; but those of the fir and evergreen fort seldom require any thing more than the proper regulation of their leaders, as that of keeping them single where they throw out double, for the left the side branches are touched the better.

It may be further however noticed, that though the pruning of woods and plantations is in general considered to be much less necessary and essential than that of properly thinning of them, yet that it may notwithstanding in numerous instances be of great utility and advantage. Mr. Loudon has observed, that it equally corrects the extravagancies of the trees, takes off their redundancies, and directs their produce in the most proper methods. And that the trees of the same kind planted out in similar soils and situations, the one pruned, and the other left to nature, though they may produce in an equal length of time the same quantity or weight of timber; yet the tree that was pruned will contain the greater part of that timber in an upright clean bole or item, while the other, which was left to nature, will have a great part of it in the arms and side branches. Hence, where the application or intention was that of ship-building, or any similar purpose, it is most likely the natural one would be preferred; but that where
wainscotting or any similar use was intended, the other
would unquestionably be the most profitable, and of course
preferred. But even the larch, without any pruning, is
supposed the best for the purpose of wainscotting; and
the oak, without any pruning, the most suitable for ship-
timber. These, and other cates which might be added,
would seem to shew that trees, equally in respect to the
quality of their wood, and the modes of their growth,
are fitted by nature for certain particular purposes in the
arts of life; and which again tends to prove that pruning
is sometimes unnatural and often unnecessary. But from
various and different causes and circumstances, it not un-
frequently becomes necessary, and proper to use trees for
purposes, and intentions, which they are not designed for
by nature. Anterior to the larch being introduced into
this country, and in situations where it could not be ob-
tained, it might be necessary to train the oak-tree for wain-
scotting ues; and where the larch alone will grow, and
ship-timber is required, it may be advantageous to prune
or bend it to the forms which will suit these intentions.
Farther, the ash, the elm, and the beech, when planted in
foils and situations which suit their different natures, are,
without pruning or particular cultivation, admirably fitted
for the several useful purposes to which they are applicable.
But their applications and uses being revisited or intermixed,
pruning then becomes necessary and essential.

In the performance of this business there are two points
requisite to be particularly attended to; the first of which
is the general principles of vegetation; and the second,
the purposes for which the wood or timber are to be ap-
plied. In general, however, in artificial plantations, it
may be a good common rule, to consider pruning on the
means of forcing more timber into the trunk or principal
stem, whatever direction that may have assumed by
nature. Pruning, where necessary for these purposes,
ought commence after the trees have been five or six years
planted, and continue until they are nearly full grown.
In common, no tree should be pruned of all its side branches;
as a sufficient number of small ones should always be left
in order to circulate the sap through the tree. And the
branches of spacious trees never attain a timber size, which
shews that their chief use is to serve this particular purpose.
In the fir and pine tribes their number and importance may,
it is supposed, be accounted for, from the sudden ascent of
the sap, and the singular largeness of the albunious veizels
in these trees. Hence in this tribe of trees no side branches,
it is thought, should be removed, until they shew some
evident marks of decay, or of a tendency to be destroyed.

It is conceived that wherever the practice of pruning is
much attended to, it is for the most part carried too
to great a length; and that the timber is thereby very ma-
terially injured, as well as the characteristic beauty of the
trees. The junk and useful medium in this sort of work is
but very seldom had recourse to, the trees being too fre-
quently either wholly left to contend with whatever kinds
of injuries or diseases may come in their way, or so much
mutilated and deformed by the hands and tools of the forest
pruner, as to be unfit to perform their proper and necessi-
tary offices or functions: the consequence of the first of which,
it is supposed, is that of unprofitable timber; and that of the
second, timber of a bad quality, as well as perpetual de-
formity of shape. Better proof of which cannot be afforded
than in the tall, naked elms, pollard oaks, and naked fir
woods, which prevail in many parts of this country, and
not unfrequently disfigure whole districts of it. The timber
of those sorts of trees, as is extremely well known, is,
where they are treated in a proper and suitable manner, the
best and most valuable of any; but that after the above
kind of management has been practised with them, both its
quality and quantity are very greatly injured, impaired, and
lesioned; so that being rendered unfit and improper for every
sort of valuable purpose, it is not unfrequently employed
for use as fire-wood.

From this view of the subject, the great value and utility
of moderate and judicious pruning in forest-woods and
plantations is particularly evident, and the improper and
disaadvantages of carrying it too far fully pointed out and
explained.

In the business of reducing and preferring all sorts of
old woods and plantations, which have suffered from neglect
and inattention, pruning in a proper manner should always
accompany the various other means which are necessary for
these purposes, according to the times of the growths, the
dimensions, and the kinds of the trees, as well as the pur-
poses that they are intended for.

It is supposed by Mr. Loudon, that in the management
of all sorts of wood, in the view of ornament, pruning
serves many important purposes. Where there are indi-
vidual trees upon the lawns, or near to the houses, of heavy
inlegent forms, they may often be lightened, and reduced
to more defirable and agreeable shapes, either by cutting
out branches, or by incisions made in the bark and outer
layers of the wood, in order to force young shoots to spring
out. The limbs of single trees may be thrown to advantage,
or be disguised where they are too formal. Small groups
may also be improved in the same manner. And in connection
with the knife, cords and weights may not unfrequently
be resorted to with good effects; as by these means,
branches may be more gracefully and conveniently bent and
directed, by hanging stones towards their extremities;
or their positions may be altered, by fixing them with cords
either to other branches, or the trunks of the main trees,
or to polls driven into the ground for that purpose.
In this way, awkward and misshapen trees, which could ill
afford or admit of being thinned, may, it is asserted, be
balanced, without cutting off any of their branches. Like-
wise clove formal trees may be rendered irregular, by sepa-
rating their boughs. And the limbs of trees may be formed
and moulded into more pleasing and agreeable bends or
curves, in scenes of beauty and ornament; or be rift, shat-
tered, or broken, in those of the grotesque or romantic
kinds. Farther, the sky line of a plantation, too simipal
from being deficient in variety, may, it is contended, be
rendered interesting; or one which is composed of furs, that
is disiplying from the formality of their conic tops, may
be changed by taking away some trees entirely, and cutting
the tops from others. Even the laft of these operations
may also be applied to conic trees, when they are too pre-
valent upon lawns, or in parks, and where they do not
group well with buildings. It must, however, be allowed,
that this is destroying the natural character of the trees; but
the conical form of the fur is a singuler character in trees,
and in harmonizing scenery, general excellencies are to be
chiefly attended to. It is asserted that many of these op-
ations are executed with excellent eftect at Foxley; and in
some other places likewise, under the direction of the writer,
where the formality of trees not pruned at all, and of others
pruned only to a certain height by cattle, were equally dis-
guised, and rendered imperceptible. See Plantation,
Planting, and Wood.

Pruning of Trees, in Gardening, the operation of oc-
casionally cutting out parts, in order to give them any de-
ferred form, and to retrench or reduce irregular and redundant
or superfluous growths.
PRUNING.

It is particularly necessary to be practised on many sorts of fruit-trees, more especially the dwarf sorts; such as all kinds of wall and espalier fruit-trees. It is also necessary, occasionally, for standard trees, both dwarfs and half and full standards, and for some sorts annually, as all kinds of wall-trees, espaliers, and molt other dwarf or trained fruit-trees; which is done in order to preserve the proper figure, and to keep them within their limited bounds, as well as to promote fruitfulness. But as to common standards, whose heads have full scope of growth every way, they require but very little pruning, except just to retrench any occasional redundancy, ill-growing branches, and dead wood. Wall-trees and espaliers require a general regulation in this way, twice every year: in summer, to retrench the evidently superfluous and ill-placed shoots of the year, and to train in a supply of the most regular ones; and in winter, to give a general regulation both for the supply of young wood left in summer, and to the old branches where necessary.

In pruning these sorts of trees, as they have their branches arranged with regularity to the right and left, one above another, in a parallel manner, four, five, or six inches aunder, and forming a regular spread, so as the branches of each tree completely cover a certain space of wall, &c.; and as the whole spread of branches constantly sends forth every year a great number of unnecessary and useless shoots, each should be limited to a certain space. An annual pruning is consequently necessary to retrench the redundancies, and all irregular and bad shoots, to give the proper bearing branches due room, as well as to confine each tree within its proper limit, consistent with its regular form.

The first pruning for wall fruit-trees, to give the head its first regular formation, is effected by pruning short, or heading down in spring all the shoots produced the first year from budding and grafting; and when a year old, being mostly pruned down in March, within four or five eyes of the bottom, to throw the sap more into the remaining lower buds; and thus, instead of running up to one stem, to push forth several strong shoots from the lower part the ensuing summer, so as to fill the necessary space of walling and espalier regularly from the bottom; which shoots being trained straight and regular in a spreading manner, each at full length all summer. And in the winter or spring following, where a supply of more principal shoots shall seem necessary to form the head more effectually, pruning short also these shoots, each to four or five eyes, when they will throw out the same number of shoots the same year, which, according as they advance in length, should be trained at regular distances at full length, during the summer; for the shoots of wall-trees should not in general be shortened in the summer season, as that would cause them to push forth many superfluous unnecessary lateral shoots; though, sometimes, in order to fill a vacancy as soon as possible, strong young shoots, by being pinched or pruned early in the season, as May or beginning of June, to four or five eyes, will throw out several proper shoots the same summer. The work of pruning short should be occasionally repeated one or two years, either in general or on particular shoots, as may seem necessary, till a proper set of branches are by that means obtained, to give the head of the tree a proper formation; afterwards it may be omitted, except occasionally to any particular shoot to fill a vacant space; but some sorts of wall-trees require almost a general shortening of their supply of shoots, such as peaches, nectarines, apricots, &c. which bear only on the young wood, have that of each year shortened, to force out a supply of shoots for future bearing. Other sorts of wall-trees and espaliers are not, in the general course of pruning, to be shortened, such as pears, apples, plums, and cherries, which continue bearing in the same wood of from two or three to many years' growth. See Espaliers.

When the trees have been thus furnished with a proper spread of branches, trained regularly to the wall and espalier, they every year throw out many more shoots than are wanted, or can be converted to use, by some being too numerous, others ill placed, and others of a bad growth; all of which mult, therefore, be regulated accordingly by proper pruning; as the regular figure of the tree, being well furnished in every part equally from the bottom to the top of the wall or espalier with proper branches, capable of producing good fruit, is the principal object of this operation.

In performing it, the operator should be careful to free the trees of every thing that is superfluous, irregular, or hurtful, both in the summer and winter prunings. These branches are superfluous, which though good and well placed, are more than wanted, or that can be properly laid in; and those irregular, which are ill placed as not to be trained with regularity to the wall or espalier, such as all fore-right shoots, being such as grow immediately from the front or back of the branches in a fore-right direction; and those are hurtful, which are of bad growth, such as all very rank or singularly luxuriant rude shoots. The superfluous or redundant growths should of course be thinned, by pruning out all that seem to cause confusion; and the irregular and hurtful rank shoots be displaced, cutting all those off quite close to the place whence they proceed, only leaving a proper supply of the regular or best placed side shoots where necessary, so as to preserve every part well furnished with bearing wood, trained straight and close to the wall or espalier, at equal distances. Some sorts of wall-trees, &c. however, require a general annual supply of young wood, such as peach, and all other trees which bear only on the shoots of a year old; others require only an occasional supply of wood, such as apples, pears, &c., and all other kinds that bear on the old wood of from two or three to ten or twenty years old, or more; so that the same branches continue in bearing many years, and the trees require only a supply of young shoots now and then, to replace any worn out or dead branches. See Summer and Winter Pruning.

This art chiefly consists in being acquainted with the nature of bearing in the different sorts of trees, and in forming an early judgment of the future event of shoots and branches, as well as other circumstances, for which some rules may be given; but there are particular instances which cannot be judged of but upon the spot, and depend chiefly upon practice and observation.

With regard to the nature or mode of bearing of the different sorts of wall and espalier trees, &c. peaches, nectarines, apricots, &c. all produce their fruit principally upon the young wood of a year old; that is, the shoots produced this year bear fruit the year following, and the fame of every year's shoots; so that in all these trees, a general supply of the best regular shoots of each year should be given every where preferred, both in the summer and winter prunings, at regular distances, quite from the bottom to the extremity of the trees on every side, in such order as to seem coming up regularly one after another, and trained principally at full length during their summer's growth; but in the winter pruning generally shortened, according to the extent of the different shoots, in order to promote their throwing out more effectually a supply of young wood the ensuing summer, from the lateral eyes, in proper places for training in for the next year's bearing; the fruit-buds being
being mostly produced along their sides immediately from the eyes, as they rarely form any considerable fruit-spurs, as in the apple, pear, &c.; the same fruits producing the fruit, and a supply of shoots at the same time for the succeeding year's bearing. All these trees also bear on casual small natural spurs, sometimes arising on the two and three years' wood, one or two inches in length, which are generally well furnished with bloom buds in the proper season, and should be preferred for bearing; always, however, depending on the main young shoots as the principal bearers.

Vines also produce their fruit always upon the young wood, shoots of the same year arising from the eyes of the half year's wood only, and must therefore have a general supply of the best regular shoots of each year trained in, which in the winter pruning should be shortened to a few eyes or joints, in order to force out shoots from their lower parts only, properly situated to lay in for bearing fruit the following year.

Figs bear also only upon the young wood of a year old, a general supply of it is of course necessary every year; but these shoots should at no time be shortened, unless the ends are dead, as they always bear principally towards the extreme part of the shoots, which if shortened would take the bearing or fruitful parts away. And these trees mostly throw out naturally a sufficient supply of shoots every year for future bearing without the precaution of shortening them.

And as to apple, pear, plum, and cherry trees, they bear principally on spurs arising in the general branches, of from two or three to ten or twenty years old, the same branches and spurs continuing bearing a great number of years, as has been seen, so that having once procured a proper set of branches, in the manner already directed, to form a spreading head, no further supply of wood is wanted than only some occasional shoots now and then to supply the place of any casual worn-out or dead branch as before suggested; these spurs or fruit-buds are short, robust shoots, of from about half an inch to one or two inches long, arising naturally in these trees, first towards the once extreme parts of the branches of two or three years old; and as the branch increases in length, the number of fruit-buds increases likewise; this therefore determines, that in the general course of pruning all these kinds of trees, their branches that are trained in for bearing must not be pruned or shortened, but trained at full length, as where shortened it would divest them of the parts where fruit-buds would have first appeared, and, instead thereof, would throw out a number of strong unnecessary wood-shoots from all the remaining eyes; therefore all the shoots or branches of these trees should be trained principally at full length, and as they advance still continue them entire. When however there is a vacancy, and only one shoot, where two or three may be requisite, pruning or shortening is allowable to force out the proper supply. See Dwarf-Trees.

In these trees care is necessary to preserve all the proper fruit-buds or spurs, which are readily distinguished by their short, thick, robust growth, rarely exceeding one or two inches in length.

In the course of pruning all sorts of wall and espaliered trees, all improper and ineffective shoots and branches, necessary to be displaced, must be taken off quite close to the place whence they arise; which in the summer pruning, if attended to early, while the shoots are young and tender, may readily be rubbed off close with the thumb; but when the shoots become older and woody, as they do not readily break, it must be done with a knife, cutting them as close as possible: all winter pruning should however be performed with a knife.

In pruning in summer, the necessary supply of regular shoots that are left for training in, should never be shortened, unless to particular shoots to fill a vacancy, or to reduce within bounds any too long extended shoots; as by a general shortening in this respect, all the shoots treated would soon push again vigorously from every eye, and run the trees into a perfect thicket of useless wood; therefore all forts, whether they require shortening in the winter pruning or not, should in the summer dressing be laid in at full length.

Summer Pruning.—This is a necessary operation, as in spring and summer wall and espalier trees abound with a great number of young shoots that require thinning and other reforms to preserve the requisite regularity and beauty of the trees, and encourage the fruit; and the sooner it is performed the better; it is therefore advisable to begin in May or early in the following month, and disburthen the trees in time of all redundant and superfluous growth, and ill-placed and improper or bad shoots; which may be then performed with more expedition and exactness than when delayed till after the trees have shot a considerable length and run into confusion and disorder; besides, the injury of the fruit is prevented. It is therefore of importance to proceed in this operation early, when the main year's shoots are sufficiently formed to enable you to make a proper choice.

The buffets now is to thin and regulate the unnecessary shoots, by pruning away the superfluous ones, and all such as are ill-placed and of bad growth, retrenching the most irregular-placed, weak, and all such as are evidently not wanted for use, and where two or more shoots any where arise from the same eye, clearing all away but one of the best, referring a sufficiency of the moderately strong and most regular-placed side shoots, and always a leading one at the end of every branch, where it commodiously occurs; all of which should be retained to be regularly trained in to choose from in the winter pruning, leaving more or less in proportion, according to what the trees are, or the mode of bearing, though in all those trees that bear always on the young wood, at least doubly or trebly more shoots should be left in this pruning than what may appear necessary, especially of peaches, nectarines, apricots, vines, figs, &c. as it is highly requisite to retain plenty of regular young wood in summer, to choose from in winter pruning, to lay in for next year's bearers; but as to apples, pears, plums, cherries, &c. which continue bearing many years on the same branches, only here and there some good well-placed shoots need be left towards the lower parts, or in any vacancy between the main branches till winter; and if then not wanted, be early retrenched.

Where, however, a tree is in general inclined to luxuriancy, it is proper to retain as many of the regular shoots as can be commodiously trained in with any regularity, in order to divide and exhaust the too abundant sap, which caueth the luxuriancy; as by humouring somewhat the natural inclination of luxuriant trees by leaving plenty of branches, and these mostly at full length, they may the most readily be reduced to a more moderate rate of growth.

Great attention should always be paid to the lower parts of the trees, as it is frequently the case to find proper shoots arising in places necessary to be trained in, either to supply a present or future vacancy, or as a reserve to replace any decayed or worn-out or other bad branch, so that if moderately strong well-placed shoots arise in such parts, they are to be particularly regarded at this time; and in winter prun-
PRUNING.

ing, such of them as are not wanted may be easily cut out and removed; but all weak trifling shoots should now be taken out.

After having summer-pruned and cleared any tree from all useless shoots, all the remaining proper shoots should be directly, or as soon as they are long enough, trained in straight and close to the wall or espaliers, at full length. When there is any great vacancy in some particular part, it may however be proper to cut or prune one or more contiguous shoots to three, four, or five eyes or buds, in order to promote an emission of laterals accordingly the same season, more effectually to supply the vacant spaces; but all the rest should be trained at full length till winter pruning, when they must undergo another regulation. Those of such trees as require it, as peach, nectarine, &c., should be shortened.

The work of training the shoots in this season, is performed when against walls, both by nailing, by means of proper thongs and nails, and occasionally, by fastening in the smaller shoots, with little licks or twigs stuck between the main branches and the wall; and for espaliers, by tying them with small others, rubes, or hafs stringts.

After having thus summer-dressed and trained the trees, it will be necessary to look them occasionally over, in order to reform such branches or shoots as may have started from their places, or taken a wrong direction, and according as any fresh irregular shoots are produced, they should be disposed; and likewise, as the already trained shoots advance in length or project from the wall or espalier, be trained in close, containing them at full length during their summer’s growth; every thing being kept close and regular, by which the trees will appear beautiful to the eye, and the fruit they itself, and attain its due perfection more effectually.

Winter Pruning.—In this pruning, a general regulation must be produced both in the mother branches, and the supply of young wood laid in the preceding summer. The proper time for this work is, in most wall-trees, any time in open weather, from the fall of the leaf in November until March. And in performing the business, it is proper to unnaul or loosen a great part of the branches, particularly of peaches, nectarines, apricots, vines, and such other trees as require an annual supply of young wood, and considerable regulation in the regular branches.

All the principal or mother branches should first be looked over, and examined, to see if any are worn out or not furnished with parts proper for bearing fruit, and such branches be cut down either to the great branch from which they proceed, or to any lower shoot or good branch they may support toward their bottom part, leaving these to supply its place; likewise examining if any branches are become too long for the allotted space either at the sides or top, and reforming them accordingly, by shortening them down to some lower shoot or branch properly situated to supply the place; being careful that every branch terminates in a young shoot of some sort for a leader, especially in all parts where room to extend them, according as the limited space admits, having the leader either placed naturally at the termination of the branch; or where too long in any particular parts of the tree, pruned conformably to some lower shoot, &c., so as that it may still terminate in a proper leader, and the extended branches not cut to naked stubby or stubbed ends, as is often practiced by inexperienced pruners. And from the principal or larger branches, pass to the young wood of the year; or, in proceeding both in the occasional reform among the principal or older branches, and more general regulation in the young wood of the year, or shoots of the preceding summer, the above intimations relative to the principal branches should be observed in the pruning of the whole, both on the old and young wood, and be carried on regularly together at the same time, cutting out or retaining according to circumstances; as for instance, in older wood observing the above particulars, and as below, and in the general supply of young wood, cutting out close all fore-right and other irregular shoots that may have been omitted in the summer-pruning; likewise all very weak shoots, and those of very luxuriant growth, unless it be necessary to keep some to supply a vacant place; then of the remaining regular shoots, selecting a greater or smaller portion to leave either as a general supply for next year’s bearing, as is requisite for peaches, nectarines, apricots, vines, and figs; or only in others some occasional shoots, such as in full trained apple, pear, plum, and cherry-trees, &c. either to furnish casual vacancies, or to supply the places of any defective or improper branches, or ineffectual bearers, as may casually occur, or that of decayed or dead wood.

But as peaches, nectarines, apricots, vines, and figs, always bear principally on the year-old wood, as already noticed, a general supply of young shoots must be left in every part, from bottom to top, at regular distances; and, at the same time, some proportional part of the most naked old wood, and of the two preceding years past bearers, be pruned out to make proper room for this requisite young supph of future bearers in the following summer, to be now retained in a general manner, both laterally, and as terminals to the general parent branches, which should be pruned accordingly; and mostly all the said supply of the present retained shoots, except the fig, must be more or less shortened, according to their situation and strength, to encourage their furnishing more readily a proper supply of shoots in spring and summer for the succeeding year’s bearing, as noticed before, leaving the strongest shoots always the longest, as is more fully explained under each of their respective genera; but as the figs always bear towards the end of the shoots, they must not be shortened.

With respect to the apples, pears, plums, cherries, &c. as they continue to bear on the same branches of from two or three to many years standing, the said bearers must be continued accordingly; and the trees only require an occasional supply of young wood, according as any of the branches become defective, or unfit for bearing, and want removing; which should now be cut out as may seem necessary, training in here and there, in proper places, some good regular young shoots towards the lower part, and where it may seem necessary, to be coming gradually forward to a bearing state, to be ready to replace worn-out and other useless branches to be cut out, as they may occur; and of the young wood, selecting what may appear necessary of the best well-placed shoots, and the superabundance, or those not wanted for that purpose, together with all irregular-placed shoots, rank luxurians, and other ineffectual growths, should now be cut clean out, close to whence they originate, not leaving any spur or stump, as every one would pull out several strong unnecessary shoots the next spring, to the prejudice of the trees and fruit; particular regard should be paid to preserve the shoots at the termination of all the already trained branches entire, but not more than one to terminate each branch; preserving also carefully all the proper fruit-spurs, taking care that the supply of young wood be occasionally reserved, and the branches in general of these trees be trained in at full length, and continued fo in future, as far as the limited space will admit; and according as any extend above the wall or espalier, or any where beyond their proper
PRUNING.

proper limits, they be pruned down with deference to some convenient bud, or lateral shoot, or lower branch, which should be trimmed entire.

In this pruning, as in the summer dressing, it is of importance to have a strict eye to the lower parts of wall-trees, &c. to see if there is any present vacancy, or any that apparently will soon happen; in which cases, if any good shoot is situated contiguous, it should be trained in either at full length, or shortened to a few eyes, to force out two or more shoots, if they shall seem necessary; for precaution should ever be observed in taking care to have becomes a sufficient stock of young wood coming forward to fill up any casual vacancy, and substituting a new set of branches in place of such as are either decayed, or filled in need of rebranching.

In wall-trees and espaliers there are sometimes many large difagreable barren spurs, confling both of old worn-out fruit-spurs, and of clusters of thumps of shortened shoots projecting considerably from the branches, occasioned by unskillful pruning, when retrenching the superabundant and irregular shoots, which, instead of being cut out close, are thumped off to an inch or two long, and in the course of a few years, form numerous barren thumps, and very little fruit, the trees appearing like a thumped hedge. In this season of pruning, in this case, it is proper to reform them as well as possible, by cutting all the most disgraceful thumps clean out close to the branches, leaving these at full length, especially in apples, pears, &c. and referring an occasional supply of young wood in different parts: thus in two or three years such trees may be reduced to a regular figure and a proper state of bearing.

It is observed that bad pruning ruins many a good tree, as is observable in numerous gardens, where the wall-trees and espaliers appear as just described, pruned every year, yet never producing any tolerable crop of fruit.

Severe injudicious pruning in strong wood is greatly prejudicial to the health of some sorts of fome fruit-trees, by causing them to gum and soon decay. Plums and cherries, in particular, are often greatly-damaged by a too severe discipline of the knife, these being very liable to gum by large amputations: it is therefore of importance to attend to tree trees well in the summer pruning, to retrench all the superfluous and irregular shoots betimes in the summer, while quite young, and pinch others occasionally where wood is wanted to fill vacancies, so as to require but little pruning out of large wood in winter.

A general nailing, &c. must every year be performed, according as the pruning advances, as it is proper that every tree, as soon as pruned, be directly nailed to the wall, or if espaliers, tied or nailed to the trellage, being careful in the winter pruning, as the work of nailing, &c. will require to be performed more or less upon all the branches, to train them with great regularity, nailing them along horizontally, as straight and close as possible; never crossing any of the branches but training them distinctly and parallel from four to five or six inches aunder, or in proportion to the size of the leaves and fruit of the different sorts, making the opposite branches of each side arrange equally in the same manner and position.

Pruning of Standard Trees.—Standard fruit-trees require but very little pruning; for, as their branches have full scope above to extend themselves every way, they must not be shortened; besides, as the standard fruit-trees, confiding principally of apples, pears, plums, and cherries, bear fruit on natural spurs arisitng towards the upper parts of the branches, this determines that they must not be shortened, nor any other pruning be practised, than just to reform any great irregularity, &c. in them. In these trees, the first occasional pruning necessary is the first two years of their growth, in order to form their heads somewhat regular, by retrenching any irregular shoots; and when designed to have them form more regular spreading heads, to prune the first shoots, when a year old, down to or five eyes, in order to force out lateral shoots from these lower buds the following summer, to give the head a proper formation. After this, the branches should be suffered to take their natural growth, except that, if while the trees are young, any very luxuriant shoots ramble away considerably from all the others, and draw most of the nourishment, it is proper to prune them, either by retrenching entirely very irregular ones, or shortening others to some regularity, to branch out conveniently with the requisite form of the head of the tree; but except in such cases of reducing irregularities, the heads of all kinds of STANDARD always should be left to branch away as fast as possible, both in length, and laterally, agreeable to their natural mode of growing; and they will naturally furnish themselves abundantly with bearing wood.

In standard fruit-trees of some years growth, as irregularities and diforders will occasionally happen, they should be regulated a little by pruning out the most conspicuously irregular and redundant growths in the winter season.

For instance; where any considerable branches grow right across others, or in any other awkward direction, to incommode or cause confusion, or much irregularity in the head, they should be retrenched close; likewise any branch that rambles considerably from all the rest, should be reduced to order, by cutting it down to some convenient lower branch, so as to preserve some regularity. Where the head is considerably crowded with wood, let the worst of the redundancy be thinned out as regularly as possible, cutting them close to their origin; and as sometimes very vigorous shoots arise in the heart of the tree, or towards the bottom of the main branches, growing upright, and crowd the middle of the head, they should be contantly retrenched to their very bottom; cutting out also any very cankered parts, and all decayed wood; and clearing off all suckers from the root and stem. The standard trees, thus disburthened from any considerable irregularities and confusion, fo as all the proper branches have full scope to spread free and early in their natural manner, will not fail to repay the trouble in the superior quality of their future fruit. See Orchard Trees.

Pruning of Fruit-trees, &c.—With respect to pruning of forest and ornamental trees, flowering shrubs, &c. it is very inconsiderable. Fruit-trees, &c. must be suffered to run up as fast as possible, so that their heads should not be shortened; all that is necessary is, to prune off the lateral branches occasionally from the limbs; or if, while young, any lateral shoot of the heads, is of a very rude rambling growth; but otherwise suffering the top and general branches of the heads to remain entire, and take their own natural growth; only pruning the stragglers occasionally. It is, however, very improper to trim up the limbs too high, as often practiced to forest-trees, as scarce to leave any upper branches to form a head: never, therefore, trim the limb much higher than the full spread of the principal branches, as a full head is both ornamental and essentially necessary to the prosperity of the tree. See Planting.

And as to the shrub kinds, they should, for the general part, take their own growth at top; and only be pruned occasionally in any lower stragglers, from the inferior part of the limbs, or any very irregular rambling shoot of the heads, and all dead wood. Except in those cases, their heads mustly should be suffered to shoot in their own way, according to their different modes of growth, in which they will
PRU

will appear always the most agreeable. Where, however, it is required to keep shrubs low, they must be regulated, as convenient, with the pruning-knife, as being more proper than the garden-trees, which should never be used for that purpose to shrubs and trees in rural growth.

The particular method to be followed with each sort of tree has been shown under the proper head to which it belongs.

Pruning Implements.—For the purpose of general pruning, several implements are necessary, such as pruning-knives, saws, chisels, hand-bills, hatchets, &c. Two or three different sizes of knives are requisite, in order to prune neatly; a strong one for cutting out larger branches, shoots, &c.; and a small one for the more exact pruning among the smaller branches and shoots of peach and nectarine trees. These knives are generally made curving at the point, and should not be too long, broad, and clumsy, but have rather a shortish narrow blade, and be very moderately hooked at the point, for when too crooked, they are apt to hang in the wood, and not cut clean; it is also proper to be furnished with a strong thick-backed knife, to use by way of a chisel occasionally, in cutting out any hard stubborn stumps, &c., placing the edge on the wood, and with your hammer striking the back of it, and it will readily cut through even and smooth. A long knife with a concave edge, and a pruning-knife with a convex edge, are also recommended by Mr. Fortham.

Hand-pruning saws are likewise proper for cutting out any large branch too thick and stubborn for the knife: these should be of moderate sizes, one being quite small and narrow, in order to introduce it occasionally between the forks of the branches, to cut to exactness.

And as saws generally leave the cut rough, it is proper to smooth it with a knife or a pruning-chisel.

The pruning-chisels are necessary to use occasionally both to cut off any thick hard branches, and large hard knotty parts, or stumps, and to smooth cuts in large branches, &c., after a saw; they should be flat, and from about one to two inches broad: sometimes large strong chisels, fixed on a long pole, are used in pruning or lopping branches from the fles of high standard forest-trees, one man holding the chisel, while another, with a large mallet or beetle, strikes the end of the pole. A hand-bill and hatchet are also necessary to use occasionally among larger kinds of the standard trees.

All these pruning tools, in their proper different sizes, may be had at the cutlery shops, and of the ironmongers, and many of the nursery and seedmen.

PRUNUS, in Geography, a town of Austria; six miles S.S.W. of Vienna.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, deciduous, cloven into five, obtuse, concave segments. Cor. Petals five, roundish, concave, large, spreading, inserted into the calyx by claws. Stam. Filaments from twenty to thirty, awl-shaped, nearly the length of the corolla, inserted into the calyx; anthers twin, short. Pist. German superior, roundish, style thread-shaped, the length of the flaments; stigma orbilicate. Peric. Drupa roundish. Seed. Nut roundish, compressed, even, with rather prominent sutures.

Eff. Ch. Calyx five-cleft, inferior. Petals five. Stone of the drupa even, with slightly prominent seams.

Obf. Of Prunus, which comprises, according to Linnaeus, all the above quoted genera of Tournefort, only fourteen sorts occur in the Species Plantarum. Wildenow and Martyn each enumerate thirty-three species, from which the following are selected. The first five of these are British plants.

P. Padus. Bird Cherry. Linn. Sp. Pl. 677. Engl. Bot. t. 1383. Fl. Dan. t. 205.—Flowers in long pendulous clusters. Leaves deciduous, with two glands on the under side at the base. Not unfrequent in woods and hedges in the north of England, flowering in May. The branches of this shrub, or small tree, are round and smooth. Leaves alternate, flaked, ovate, pointed, serrated, veined, smooth, rather glaucous, smelling like rue. Stipulas linear, slightly fringed, deciduous. Clusters on the newish branches, solitary, pendent, composed of numerous snow-white blossoms. Fruit oval, dark purple or black, bitter, but very grateful to birds. The fruit of the drupa is lightly rugged, not so smooth as in the other species of Prunus, which seems to confirm the opinion of Gartner, that no fold difference exists between this genus and Amygdalus. Every part of P. Padus except its fruit is highly poisons or distasteful.

P. Cerastus. Cherry-tree. Linn. Sp. Pl. 679. Engl. Bot. t. 706.—Umbels nearly fiddle. Leaves ovate-lanceolate, folded when young.—Native of woods and hedges, flowering in May. The branches of this tree are ash-coloured, polished and round. Leaves flaked, pointed, unequally serrated, veined; the younger ones folded, more or less downy beneath. Stipulas toothed, glabrous. Umbels leafless, pendent, composed of but few blossoms, each on a long flake. Calyx reflexed. Fruit red, jolly celebrated for its highly agreeable and acid flavour. Dr. Smith, in his Flora Britannica, notices four varieties of the cherry, two of which have blackish and less acid, approaching to sweet, fruit. They also vary in fles.

P. Domestica. Plum-tree. Linn. Sp. Pl. 680. Engl. Bot. t. 1783. Woodv. Med. Bot. t. 85.—Flower-flaks mostly solitary. Leaves lanceolate-ovate, convolute when young. Branches without spines.—Found frequently in hedges, bearing flowers in April or May.—A middling-sized tree, whole branches are unarmed. Leaves on short flaks, ovate, serrated, smooth; the younger ones downy. Flowers white, generally on solitary flaks. Fruit of a dark blue or purple colour, mostly elliptical or obovate. From this species proceed all the different varieties of plums which abound in our orchards and gardens. Parkinson mentions sixty forts, „all which“, he says, „are to be had of my very good friend Mr. John Tradescant, who hath wonderfully laboured to obtain all the rarest fruits he can hear of in any place of Chirrendome, Turkey, yea, or the whole world.“

from different buds, in pairs, on simple, shortish stalks, large, white. Fruit globular, black with a blue bloom, very four and auffere, scarcely edible in a crude state. Dr. Smith observes that the common white bullace cultivated for the table differs only from this, as the white curant or white elder differ from the common kinds of each.

*P. spinosa.* Sloe-tree. Black-thorn. Limn. Sp. Pl. 681. Engl. Bot. t. 842. Fl. Dan. t. 926. Wood. Med. Bot. t. 84.—Flower-stalks solitary. Leaves lanceolate, smooth. Branches ending in a spine.—One of the most common British plants, flowering early in the spring. A low, bushy shrub, formed of numerous rigid, spreading, thorny branches, covered with a dark but glaucous hair. Leaves on stalks, lanceolate or inversely ovate, serrate, deep green, not appearing till the plant has bloomed. Flowers solitary, each on a short stalk, white. Fruit globular, black, very aureole, and only palatable when prepared with a great quantity of sugar. "Its expressed juice infused over a flow fire, is a substitute for the Egyptian Acacia, and not an unuseful astringent medicine. The recent fruit is one of the many articles used to adulterate port wine in England. The dried leaves are said to be a substitute for tea, and are, perhaps, often mixed with it in this country."

*P. fruticosa.* Dwarf Pink Plum. Billard. Syrinx. f. a. 15. t. 6. Wild. n. 35. Att. n. 19. Sim. Fl. Grac. Sibth. t. 428; unpublished. (P. cirtica montana minima humifusa, flor. laev. rubens; Tourn. Cor. 43. Voyage v. 1. 19.)—Flower-stalks in pairs. Leaves ovate, deeply serrate, or with gland, white and downy beneath. Stem diffuse.—Native of Mount Lebanon, and of the loftiest mountains of Crete, which it enlivens with its copious pink blossoms, soon after the first melting of the snow. Dr. Sibthorp gathered it also on Mount Parnassus. On its native rocks this plant is a spreading procumbent shrub, with a thick woody black stem. In our gardens it riffs to the height of two feet, in a bushy form. The leaves are small, cut, and deeply serrate; bright green above, white beneath. Flowers small, pink, with a smooth tubular calyx. Fruit the size of a pea.

**PRUNUS.** In Gardening, contains plants of the fruit-tree, flowering and evergreen shrubby kind, of which the species cultivated are, the common plum tree (P. domestica); the bullace plum tree (P. insititia); the apricot or apricot tree (P. armeniaca); the common or cultivated cherry tree (P. cerasus); the small-fruiting cherry tree (P. avium); the common bird cherry tree (P. padus); the Cornish bird cherry tree (P. rubra); the common American bird cherry tree (P. virginiana); the Canadian bird cherry tree (P. canadensis); the perfumed cherry tree (P. mahaleb); the evergreen bird cherry tree (P. caroliniana); the common laurel (P. lauro-cerasus); and the Portugal laurel (P. lusitanica).

The varieties of the first sort, or garden and orchard plums, are very numerous, differing in the form, taste, colour, and substance of the fruit; but those mostly cultivated in this country are the following, according to Mr. Forsyth, and the times at which they ripen.

The jamnivate, or white primordian, which is a small plum, of a yellow colour, and mealy; it ripens in the latter end of July, or beginning of August: one tree of this fruit will be sufficient for a garden of the common size. The early damask, which is commonly called the Morocco plum, and which is middle-sized, and the flesh good; it ripens at the beginning of August, or sometimes a little later. The little black damask, which is a rich fruit, a good bearer, and becomes ripe about the latter end of August, or thereabouts. The great damask violet of Tours, which is a fine rich plum of a bluish colour, and becomes ripe in August. The red Orleans, which is large, of a rich juice, and becomes ripe in the latter end of August. The Fotheringham, which is a crimson plum, of a dark red, and the juice rich; there is hardly any plum that excels it, according to the opinion of some. The blue perdrigon, which is of a very good taste, and ripens in August. The white perdrigon, which is a pretty good fruit, and has a sweetish taste, mixed with tartness; it ripens in the beginning of September. The red imperial, or red bonum magnus, which is a great bear, and mostly used for baking; it is ripe about the latter end of September. The white imperial bonum magnus, or egg, white Holland, or Mogul, which is a large fruit, and, like the red, mostly used for baking; it is a great bearer, and ripens about the beginning of October. The la royale, which is a fine plum, equal to the green gage, but a shy bearer; it is of a red colour, and ripens in the latter end of September. The little queen Claudia, or Dauphiny, which is a small rich fruit, becoming ripe in September. The large queen Claudia, or Dauphiny, which is an excellent plum, of a yellowish-green, and ripens about the beginning of October. The green gage, which is of an exquisite taste, and eats like a sweetmeat, it's colour and size sufficiently distinguisht from any other; it ripens in August and September; it has several sub-varieties, all of which are of good qualities. The drap d'or, which is a good plum, and a plentiful bearer; it is ripe about the latter end of September. The Chester, which is rich, and a great bearer; it is ripe about the latter end of September. The apricot, which is large and sweet, is ripe in the beginning of October. The maitre Claud, which is a large round whitish plum; the juice is very brilk, though sweet; it is accounted among the best white plums that we have, and ripens about the beginning of October. The myrobalanum, or cherry plum, which is a middle-sized sweet fruit, and ripens about the beginning of September; this plum is frequently planted for ornament, as it blossoms early. The la Mirabelle, which is of an amber colour, and small, but full of juice, and excellent for sweetmeats; it bears well, and becomes ripe about the beginning of September. The Brignole, which is esteemed the best plum of any for sweetmeats; the flesh is dry, but of a rich flavour; it is ripe about the latter end of September. The red diasper, which is large, and of a very high flavour; it ripens about the beginning of September. The Saint Catharine, which is one of the best, and is much used for confectionary; it is also very good for the table, having a rich sweet juice; and is a good bearer, hanging the longest of any upon the tree. Mr. Forsyth says he has had them in gathering fix weeks; it ripens about the latter end of September. The imperatrice, or empress, which has an agreeable flavour, and ripens about the middle of October; it is one of the last plums, and should not be gathered till it begins to thrivel; it will then eat like a sweetmeat; and make a great addition to the table in the latter end of October and beginning of November. Monieur's, or the Wentworth, which is a large fruit, resembling the bonum magnus; it ripens about the beginning of October, and is good for preserving, but too sharp to be eaten raw. The wine-fower, or Yorkshire, which is one of the best for preserving; it is ripe in October. The damson, of which a fine large fruit from Shropshire, raised from suckers or stones, is an abundant bearer, of a rich flavour, and good for baking or preserving; it ripens in the latter end of September, and continues till near the latter end of October to be good and fit for use.

To these Mr. Forsyth adds the following list: the admirable,
rable, the black damascene, the black pear, the blue match-
lefs, the damas noir de Tours, the Don Carolos, the
double-flowered, the early blue primordial, the early red
primordial, the early amber, the early Tours or precoce de
Tours, the early violet, the early Orleans, the fine early
plum, the jacinthe or hyacinth, the Koas imperial, the
la prune Siifhe, the la prune valeur Valantia, the match-
lefs, the maugerone, the mufeole, the Perlian, the red queen
mother, the royal pea, the royal dauphin, the St Julian,
the femina, the small white damascene, the Spanish damas-
cene, the striped-leafed, the true prune, the vert-de-ock
or verdock, the whitton or nutmeg, the white bullace, the
white Orleans, the white pear, the white prerdigon.

The following forts are recommended by the fame writer
as proper for a small garden; the jaumative, the early da-
malk, the Orleans, the la royale, the green gage in different
forts, the drap d'or, the Saint Catharine, and imperatrece;
the magnum bonum for baking; and the winefor for
preserving.

The second fort varies with black and white, or rather
wax-coloured fruit; and also with a red, bitter, unpleafant
fruit.

There are many varieties of the third fort; but the fol-
lowing are the moft commonly cultivated, according to
Mr. Forfyth: the masculin, which is a small roundifh fruit;
it is the earlieft of all the apricots, ripening about the latter
end of July; and is chiefly eftemned for its tart taste; when
fully ripe, it is of a red colour towards the fun, and of
a greenifh-yellow on the other fide. The orange, which is
pretty large, but rather dry and inipid, and fitter for tarts
than for the table; it is of a deep yellow colour when ripe,
it is about the latter end of Auguft; this is confidered
as the beft for preferring. The Algiers, which is a flatted
oval-shaped fruit, of a fraw colour, juicy, and high-
flavoured; it ripens about the middle of Auguft. The
Roman, which is larger than the Algiers, rounder, of a
deeper colour, and not quite fo juicy; it is ripe about the
middle or latter end of Auguft. The Turkey, which is
larger, and of a deeper colour than the Roman; its shape
more globular, and the fleth firmer and drier; it ripens about
the latter end of Auguft. The Brea, (brought from thence
to England,) which is originally from Africa; it is large,
round, and of a deep yellow colour; the fleth is soft and
juicy; it is an excellent fruit, especially if ripened on a
standard, becoming ripe about the latter end of Auguft.
The Bruifels, which is held in very great esteem, on ac-
count of its bearing fo well on standards, or large dwarfs;
it is of a middling size, red towards the fun, with many
dark spots; and of a greenifh-yellow on the other fide; it
has a brisk flavour, is not liable to be mealy or doughy, and
is preferred by many to the Brea; but when the Brea is
planted as a standard, the fruit is more juicy and of a richer
flavour; it ripens in Auguft on a wall, but not before the
latter end of September on standards. The Moor-park,
called also Anfon's, Temple's, and Dunmore's Brea, which
is a fine fruit, and ripens about the latter end of Auguft.
The fruit of the peach kind, which was introduced from
Paris, by his grace the duke of Northumberland, at Stou-
houfe, in 1767, is the finest and largelft of all apricots, and
is generally thought to be the fame as the Moor-park; but
upon a minute examination, the leaves will be found to
differ; it ripens in Auguft. The black, which has been
very lately introduced by Sir Joseph Banks from France, in
which country it is highly eftemmed. It is obferved, that
the trees that Sir Joseph planted in his gardens at Spring
Grove, near Houfhow, bore fruit laft leafen (1792) for
the firft time in this country; but, in confequence of the
wet and unfavourable weather, it did not arrive at perfection.
It ripens about the second week in Auguft. To the above,
Mr. Forfyth has added the following; the great apricot,
the Holland apricot, the Provence apricot, the albore,
the angoumois, the blotch-leaved, the Nancy apricot,
which has a fine large fruit; the Dutch apricot, the Grover's
Brea, the Perlian, the royal orange, the transparent, the
Portugal apricot, which has a small fruit.

The following are advifed as proper for small gardens, in
order to have regular fuccifions of fruit. The masculin,
the Roman, the orange, the Brea, and the Moor-park.

Of the fourth fort the varieties are numerous; but the
following are the moft in cultivation, according to the
above author; the small May cherry, which is the firft ripe,
and requires a good wall; one or two trees of this kind
may be fufficient for a large garden; it is ripe in June.
The May duke, which comes in about the fame time as the
former, but is larger; it is an excellent cherry, and bears
well againft a wall. The archduke, which, if permitted to
ripen properly, is an excellent cherry; it becomes ripe in
June and July. The Hertfordshire cherry, which is a fort
of heart, but firmer and of a finer flavour than hearts in
general; it does not ripen till the latter end of July or be-
ginning of Auguft, which renders it the more valuable, as it
becomes more early cherries. The bleeding heart, or Ga-
toin's, which is a very large cherry of a long form, and
dark colour; it has a pleafant taste, and ripens in the latter
end of July. The Harrifon's heart, which is a fine cherry;
it was introduced from the East Indies by governor Har-
ifon, and firft cultivated at his feat of Balls in Hertford-
sire; fome of the trees, Mr. Forfyth is informed, he pre-
ented to George I.; and they are at this time in a flourifh-
fling flate, bearing fruit, in Kenfigton gardens; it is ripe
in July and Auguft. The black-heart, which is a fine
cherry, but too well known to require any defcription.
The Morelo, or Milan, which is a very fine fruit when kept
till the month of October, and makes a very great addition
to the defert at that time of the year; it is the black cherry
that we have for preferring, and for making cherry-brandy.
The carnation, which takes its name from its colour, being
red and white; it is a large round cherry, but not fo sweet
as the duke cherry; it ripens in the latter end of July. The
yellow Spanish, which is of an oval shape and amber colour,
and is a fweet pleafant fruit; it is ripe in Auguft and Sep-
tember. The corone, or coroum, which resembles the black-
heart, and which is an excellent fruit, and a good bear-
er, ripening about the beginning of Auguft. The luward,
which comes in foon after the former, and is also a fine ple-
afant fruit, and a good bearer; it ripens in the beginning of
Auguft. The graffion, which is fupposed by many to be
the fame with Harrifon's heart; but, upon a dirty exa-
mination, Mr. Forfyth finds it to be a different cherry; its fleth
is firmer and the fone fatter; it ripens in July and Auguft.
Ronalds's large black-heart, which was introduced into this
country in the year 1794, from Ciccific, is a fine large
cherry, a great bearer, and valuable as a fowing for; it is
well worth cultivating, ripening in the beginning of July.
The Frafer's black tartarian, which is a fine large fruit.
The Frafer's white tartarian, which is white and transparent.
These cherries are excellent bearers, but particularly the
black kind; the fruit is of a fine brisk flavour, and they
ripen early. The lundie gean, cultivated at lord vifcount
Duncan's, near Dundee, which is black, and almoft as
large as a black-heart cherry; Mr. Forfyth fays, it is now
common in the nurseries about Edinburgh; and that Meffrs.
Gray and Wear have had it for fome years in their nursery
at Bromptom park. The transparent gean, which is a small
delicious
delicious fruit. To these the following lift is subjoined; the
to the amber heart; the black maraud; the Churchill's heart;
the double-blossomed; the Flemish heart; the gros goblet;
the Holman's duke; the Jeffrey's royal; the Kenfigh
duke; the large Spanish cherry; the late large Morelo; the
Montmorency; the ox heart; the purple heart; the red
heart; the Swedish black heart; the South's large black;
the Spanish black; the Trade-fruit; the Turkey heart;
the weeping; the Wentworth heart; the white heart.

And the following are recommended as proper for a small
garden. The May duke; the large duke cherry; the arch-
duke cherry; the black heart; the Harrison's heart; the
ox heart; the Turkey heart; and the Kenfigh duke
cherry.

The only varieties raised by seeds from the fifth fort, are
the black coron; and the small wild cherry; of which there
are two or three sub-varieties, differing in the size and colour
of the fruit. It is observed by the editor of Miller's Dicti-
onary, that the wild cherries are proper to plant in parks,
because they grow to a large size and make beautiful trees.
In spring, when they are in flower, they are very ornamental;
the fruit is good food for birds; and the wood is very useful
for turners. These trees thrive in poor land better than
most other forts. The French often plant them for avenues
to their houses, on poor land; they also cultivate them in
their woods, to cut for hoops; and the fruit is generally
sown for raising flocks, to graft or bud other cherries
upon, being of quicker growth and of longer duration. It
is added, that the garden cherry grows only about fifteen or
twenty feet high, whereas this attains forty or fifty feet in
height, with a more erect and lofty head.

The sixth fort is commonly propagated in the nurseries as
an ornamental tree or shrub, growing well in woods, groves,
or fields, but not in a moist soil. It bears blossoms, and suf-
fers the grafts to grow under it. It is sometimes called the
cluffer cherry tree.

Method of Culture in the Plum Kind.—It is obvious that
all the varieties were first obtained by seed, or the flowers
of the fruit; and the approved kinds acquired in this manner
were afterwards multiplied by grafting and budding, as they
do not continue the same farts from seed; for from the seed
of one tree many different farts may be produced, and prob-
ably none like the mother-tree, and very few that afford
fruit worth eating; but when in perfection of any approved
farts, they may be multiplied at pleasure, by ingrafting
shoots or buds of them into any kind of plum-farts. Of
course the mode of increasing these trees is by grafting,
budding, and occasionally by layers; but the two former
are the most usual methods of practice.

The two first modes may be performed upon flocks of
any farts of the plum kind, which have been raised from the
flowers, sown in autumn in beds of good earth, about two
inches deep; and when the plants are a year old, planted
out in nursery rows two feet and a half afunder; when
after having from one to two or three year's growth, they
are in a fit state for grafting or budding with the desired
farts; which is performed in the usual way, either low in
the flock for dwarfs, or at several feet height for standards.

See Grafting and Inoculation.

These trees may be trained either as dwarf wall-trees,
efpaliers, or as standards and half standards.

When the first farts from the graft or bud are one year
old, those of the trees designated as dwarfs for walls, &c.
should be headed down within five or six inches of the bot-
tom, particularly the budded trees, in order to force out
lateral branches from the lower eyes, so as to furnish a proper set of
branches, proceeding regularly from the bottom of the tree,
to cover every part of the wall or espalier. With regard
to the standards, their first shoots may either be suffered to
run and branch in their own way, or headed to a few eyes,
if it seem necessary, to force out lower laterals to give the
head a more regular spreading form, afterwards letting them
take their own natural growth.

When the trees raised in either of these modes are from
one to two or three years old, they are of a proper size for
being finally planted out in the garden, or other proper
place; though trees which are much older may be safely
removed; but the younger they are planted where they are to
remain, the sooner and more firmly they establish themselves,
and form for bearing.

In the layer method, which is only practised occasionally,
the bushes may be performed any time from November till
March, choosing the half summer's shoots, and laying them
down by flat-laying; when in one year they will be rooted,
and must then be separated, and planted in nursery rows,
being trained either for dwarf, or standards, as may be
required.

And the double blossom, the striped varieties, and the
flonekels kind, are all increased by budding or grafting upon
any kinds of plum-farts, either for dwarfs, or half or full
standards.

The bullace kinds are capable of being increased by fol-
ning the berries or ftones an inch deep in a bed of common
earth in autumn; but to continue the different varieties dif-
tinct, they must be increased by budding, grafting, or lay-
ning, as in the other forts.

The proper season for planting all the farts of these
trees is any time, in open weather, from November till March.
And trees of all the varieties will mostly succeed in any
common soil, and open exposure; but some of the best
farts should always be put for walls and espaliers, those for
walls generally having an east or west aspect, or even a south
wall for some of the choice farts, and a few may also be
planted against a north wall, to furnish late fruit: and those
for espaliers may be planted round any of the open quarters,
as also the standards.

The trees designed for walls and espaliers should be planted
out at fifteen or eighteen feet distance; though where the walls,
&c. are rather low, eighteen or twenty feet distance may be
requisite, in order that, in default of a proper height of
walling, there may be more scope to train the branches ho-
izontally. But when the trees thus planted are quite young,
as only of one year's shoot from the grafting or budding,
they should in March be headed down, as above, to four or five
eyes, to force out lower horizontals in the ensuing summer;
which, according as they advance in length, should be trained
horizontally at full length all summer, unless it be necessary
or desirable to forward a further supply of lower branches as fast as pos-
tible; in which case the young shoots should be pinched off
in May down to a few eyes, when each will throw out several
lateral branches the same year, which should also be trained
horizontally at full length during their summer's growth;
and in the winter pruning, cutting out only any fore-right
and back shoots, training in all the regular ones at full length;
as the branches of these trees should be shortened only occa-
sionally to procure wood to fill vacancies, as the branches
always form fruit-laps first towards their extreme parts,
which would be destroyed by shortening; so that, after
having shortened the first and second year's shoots occasion-
ally, as above, and thereby procured a proper set of lower
horizontals, to give the head its first form; the whole may
then be trained in entire about four, five, or six inches
afunder; and accordingly as the trees shoot, every summer
training in a necessary supply of the regular shoots to fill
the
the wall, &c. at the same time retrenching superfluities, and irregular and very rank luxuriant growths, training the supply of regular wood till at full length at the above distances; by which the trees will soon cover a large space, and the faine unshortened branches continue bearing many years. See Pruning.

The necessity of this sort of training is obvious from all the forts bearing principally upon spurs, half an inch or an inch long, arising from the sides of the branches, of from one to two many years old, which, if shortened, would throw out a multiplication of useless wood, and hardly any fruit-spurs.

All the forts of wall and espalier trees of this sort should be pruned twice every year, as in summer and winter, in order to retrench the superfluities of each year, and all fore-right and other irregular shoots, and bad wood, and to train in a neccessary portion of young wood where wanted to fill vacancies, or to supply the place of decayed, worn-out, and other bad branches.

The standard trees should be trained as full standards and half standards, budding or grafting the former six feet high, and the latter only three or four; both kinds being worked low in the flocks, training the first shoots to those heights for items, then fuffering them to branch and form heads: these may be planted out at from twenty to thirty feet distance, letting heads form naturally.

Mr. Foryth advises, in choosing the trees the fame directions should be observed as for apricots. Clean straight plants, with single items, should be employed, as those with two never make handsome trees on walls or standards, and the border should be managed as directed for apricots; digging the holes the fame width and depth, and loosen- ing the bottom: then fill up the holes with fine fresh loam, or the mould that was used the preceding year for melon and cucumber beds; being careful to keep the mould a proper height above the border, and the roots of the trees as near the surface as possible, spreading them horizontally. When there are any tap-roots, they should always, he says, be cut off, as should also the fine hairy roots, as they are liable to get mouldy and rot, and thereby bring on a putrefaction of the mould about the root of the tree. When the roots are not spread near the surface of the ground, it will, he says, prevent the sun and air from penetrating to them; and the fruit, of course, will not have its full flavour. He further advises that the items of young plum-trees should never be cut when first planted, but be left till the buds begin to break, when they may be headed down to five or more eyes, always observing to leave an odd one for the leading shoot; always cutting sloping towards the wall, and as near to an eye as possible. Thus managed, the shoots will soon fill the wall with fine wood. When it is found that some of the shoots are too luxuriant, they may have the tops pinched off with the finger and thumb, as above, about the beginning of June in the first year after planting; by doing which plenty of wood may be obtained to fill the bottom of the wall. He adds, that a great deal depends on the first and second year's management of the trees.

With respect to the distance from each other at which plum-trees should be planted against a wall, it depends on the height of the wall. If the wall be ten feet high, which is the common height, they may be planted at eight yards distance from tree to tree; but if the wall be twelve feet high, or more, seven yards will be sufficient. For his part, he prefers a wall of ten or twelve feet, which will, he thinks, be found high enough, if the branches are trained horizontally; by which means the tree will be much more fruitful, and not grow so luxuriantly. He further adds, that by training an upright shoot on the plums, as directed for pears, fine kind shoots may be gotten from the fides. The leading shoot should be shortened, leaving it from one to two feet long, according to its strength. If the leading shoot be very strong, it may, he thinks, be topped twice in the summer, as for pears, and at the same time repeating the fame every year till the wall is filled to the top. He would always recommend, where it is convenient, to allot one wall for plums and another for cherries, as they always thrive better by themselves, or when distinct.

As there will be plum-trees to spares, that were planted between pear-trees, when they begin to meet, these should be planted against another wall, or as dwarf standards. Those intended for standards should be prepared in the following manner. The year before they are to be planted they should be cut in the side-shoots at different lengths from one foot to three, according to the fize of the trees; fuffering them to grow rude all the summer, neither nailing in nor cutting the fides and fore-right shoots. And some time during the winter the ground round their roots should be opened, cutting in the strong ones, which will cause them to put forth fine young fibre; then filling in the earth. In the following autumn, or during the winter, the sooner the better, they should be transplanted out as standards. And in transplanting of the trees, especially large ones, he considers it to be of great conquence that they be placed in the fame position (that is, having the fame parts facing the fame points of the compass) as formerly. If notice be taken when a tree is cut down, it will, he says, be found that three parts in four of the growth are on the north side. When it is intended to plant them against a wall, they should never be cut in the side-shoots, but only the roots; by this method the trees will, he says, bear fruit the first year after transplanting, and there will be a great saving of time and money. He has often transplanted old plum-trees that have been headed down that have made very fine roots, which he has divided, and thereby obtained four or five trees from one, cutting them of to form them into heads. "Some that were transplanted in 1798 were in full bloom in 1799, producing some fruit, and in 1800 bearing a full crop."

It is recommended further by the same author, that, the ground in the borders and quarters where fresh trees are to be planted should be well trenched, two spits deep at leal, to give the roots room to run into the fresh-hiired ground." And he says, that when the trees are planted without filuring the mould they seldom thrive well.

He advises, that "when plum-trees are planted for standards in an orchard which is to be kept for grapes, they should be in rows at the distance of twenty yards from each other. If in the kitchen garden for standards, he would always recommend the planting of dwarfs." The tree may be trained up to have a stem of about three feet high, at the distance of seventeen yards. If the garden is laid out with cross-walks, or foot-paths, about three feet wide, the borders should be made fix feet broad, planting the trees in the middle of them. "In the royal gardens at Kensington, which are very long and narrow, and where the winds are very hurtful, he has," he says, "planted two rows of apple-trees, intermixed with other fruit-trees, alternately, one row on each side of the middle walk (which runs the whole length of the garden), at the distance of seventeen yards from each other. He has also made cross-walks of three feet broad at the distance of twenty yards, with borders on each side fix feet wide, having two rows of trees in each border, about twelve or fourteen feet inder.

These
These dwarf-trees are very useful in breaking the force of high winds, and are at the same time of such a height, that a man standing on the ground may gather the fruit. As plum-trees may be planted in the same manner and for the same purpose as the above, he can have the quarters clear for crops for the kitchen, and a free air be admitted, which can never be had where espaliers are planted. Dwarf standards can," he says, "be kept to what size you please; they look much handomer than espaliers, and produce a greater quantity of fruit."

In regard to the method of managing and refloaring old decayed trees of this fort, he remarks, that he has reftored "some of them which were far decayed as to have only from one to two or three inches of bark left; they are now completely filled up with sound wood, with large heads, which at four years' growth filled a wall fifteen feet high, and are at this time full of fine fruit; some of the items are several inches in circumference, bearing treble the crops produced by young trees that have been planted three times as long as they have been headed down. Where the trunks are become hollow, he always cuts out all the loose rotten parts, and also examines the roots, cutting off what is rotten, injured, or decayed. This method should," he says, "be pursed with all low and decayed trees; and, if properly executed, they may be so completely filled up, as fearlessly to leave a mark behind, even where the wood is totally decayed. He has had shoots from trees of this fort which have been headed, that have grown upwards of seven feet long, and as large as a walking-stick, in one summer: this should never be suffered; but they should be pinched off with the finger and thumb, in the beginning of June, close to an eye or a bud, unless the wall be filled to the top; in which case they should never be cut out while they continue to bear handsome fruit. Before they begin to cease from bearing, you must always," he says, "begin with shortening every other shoot, leaving them only from six inches to a foot long, and nail them in till the second year, taking care to rub off the superfluous and strong fore-right shoots: by that time they will begin to bear; then cut out the others that have done bearing: by this method you will," he thinks, "keep the trees in a flourishing state. When the branches are thus managed, they will frequently throw out small shoots, or fore-right shoots, about an inch or two long, which will flower next year. They should never be shortent till after the fruit is set, and become about the size of a large pea; by that time the leaves will have covered the fruit, and be able to protect it from the inclemency of the weather. You may now shorten these shoots close to the fruit, which will leave them from one to two inches long. This method he has practised with great success for several years. By leaving these short fore-right shoots, the fruit is," he says, "protected till it is out of danger of being killed by the frost, or fliotted by the cold north and north-west winds that happen about the latter end of March and the beginning of April. The cold chilling rain and snow, which are also very injurious to the fruit, will be thrown off by the branches standing out from the trees. He by no means likes to see great fliours standing out from the wall; for they are always sure to be injured by the frost and cold winds. When the shoots are left naked, he has often seen the plums turn yellow, and drop after they have grown to a considerable size, from their being exposed to the cold frosty winds and rain. They should, therefore," he thinks, "in cold and frosty weather, be covered in the same manner as apricots. Plums are," he remarks, "more tender than any other fort of flone-fruit, owing to the flower-cup dropping sooner than that of peaches, nectarines, &e. And they are very liable to decay after cutting off large limbs or branches, which always brings on the gum and canker, if it be left to nature to perform the cure. He would, therefore, recommend the application of the composition (in the same manner as directed for other forts of fruit-trees,) to every shoot where the knife touches; as soon as the trees are cut and nailed."

And with the intention of having the fruit large and fine, care must be taken to thin it where too thick; but that must not be done too soon, lest it should be pinched by the cold. The fruit ought to be of the size of a small marble, and well sheltered by the leaves, before any attempt is made to do this. He advices never to pull off the leaves that shelter the fruit, till it is full-grown and begins to turn. See AMYGDALUS.

In conclusion it is also observed, that "he has taken up several old trees from the walls, when they have grown too near each other, and planted them out as standards, at the same time shortening their branches to form handomc heads, which are now full of fine fruit." These hints and directions are highly deserving of attention, as being the refult of much practical experience.

**Method of Culture in the Apricot Kind.**—These trees are increased by budding them upon any kind of plum-focks, for which purpose they are reeled from the fiones of the fruit, fown in autumn in beds of light earth two inches deep; when they will come up the following spring, and in autumn or spring after being set in nurfery-rows; when in a year or two they will be fit to be put for dwarfs for walls, &c; but for half standards and full standards they must be three, four, or five years' growth, and be trained up with items from three or four to fix feet high; though sometimes the budding for standards is performed low in the fock, and the firft shoot trained up for a flem.

The operation of budding should be performed in August, being careful to procure shoots from which to take the buds from trees of the best forts, performing the operation in the usual way. See INOCULATION.

The buds should be set the following spring; at which time, before they begin to push, the fock should be headed down a little above the intetion of the bud; soon after which the buds will flor and advance rapidly, and by autumn form a large shoot, and the trees are then proper for planting out for good, especially the dwarfs intended for wall-trees; or some may remain a year or two longer in the nurfery, and be trained in a proper manner for planting against walls; and others for standards. But whether they remain in the nurfery, or are planted out into the borders, the firft shoot from the bud should, in the March following, be headed down to four or five eyes, to procure lower horizontal branches, as in the plum.

When those intended for wall-trees are of one year's growth with their firft shoots or head entire, they are of a proper size for planting out finally where they are to remain. They may be planted out any time in open weather, from October until the beginning of March, choosing a south wall for the early and sunny other kinds, to come in forward, but as those exposed to the full south sun are apt to become soon mealy, it is proper to plant a principal suppiy against cast and west walls.

Mr. Forsyth, however, thinks "the best time for planting apricots is in autumn, as soon as the leaf begins to fall. The person who goes to the nurfery for the plants should," he says, "make choice of those which have the strongest and cleanefl items; and if he can procure such as have been headed down, (to use the phrase of the nurferymen,) of two
or three years' growth, they will bear and fill the walls much sooner than those which have not been so treated. He should make his choice of trees with one item; or, if they have two, one of them should be cut off; for by planting those with two items the middle of the tree is left naked, and of course one-third of the wall remains uncovered."

And though it is a practice with many to make choice of those with the smallest items, he thinks they always make weaker shoots than the others.

These trees succeed in any common soil; they are usually planted in a range close along the wall, at eighteen feet distance, with their heads entire, which should be felled either to the wall or to float stakes, one to each tree, to preserve them ready until spring, when they must have their first pruning, &c.

Mr. Forsyth, however, directs, that "if the borders wherein the trees are to be planted be new, they should be made two feet and a half or three feet deep, of good light fresh loam," and that, "if the trees are to be planted in old borders, where the earth has been injured by the roots of the former trees, it will be necessary to take out the old mould at least three feet deep, and four feet wide, filling up the hole with fresh loam, taking care to plant the trees about eight inches higher than the level of the old border, to allow for the sinking of the earth, that they may not be too deep in the ground."

After being planted, if the trees are only one year old with their first head from the bud entire, they should be headed down in the spring to four or five eyes, to force out branches below; after which the trees should have water in dry weather, and the shoots from all the remaining eyes should in summer be nailed up "regularly to the wall at their full length; and if any fore-right or back shoots come out, they should be rubbed off, being careful to cut the regular shoots to the wall all summer and the following winter; and in spring each shoot should be shortened to about eight, ten, or twelve inches, according to their strength, leaving the lower ones on each side rather the longest; this pruning shoot being fill necessary, in order to procure a further supply of lower branches, that every part of the wall may be occupied quite from the bottom; having particular attention to preserve nearly an equal number of branches arrangement on each side of the tree, nailing them close to the wall horizontally, four, five, or six inches asunder. In the summer following, each horizontal branch will push out three or four, or more, new shoots, of which, if any move fore-right and behind the branches, they should be rubbed off earlier, in the season, nailing in all the regular side-shoots at full length during the summer, except it is necessary to pinch any particular shoot early to fill a vacancy. In the winter pruning, if there be any superfluities, or irregular growths left in summer, they should be cut off, and all the regular-placed necessary shoots be shortened, though they should not now be pruned so short as in the two first years, only cutting each shoot according to its strength, from about eight or ten to fifteen or eighteen inches long; as the head of the tree is now tolerably well-formed, therefore pruning only so as to obtain a further supply of wood, and a production of fruit; for as these trees bear principally upon the year-old wood, it is proper to train in a general supply of young shoots, of each year, in every part; the same shoots producing at the same time both a crop of fruit and a supply of wood for next year's bearing. The annual supply of wood must always, however, be shortened in the winter pruning; for if left entire it would produce only some shoots near to the top, and leave the bottom naked, so as in a few years the whole tree would become very thin of bearing wood below, and bear only a little towards the extreme part of the branches. And as these trees bear also upon short spurs, arising upon the two-year-old branches, it is proper to preserve them wherever they appear, only retrenching such as project considerably fore-right; leaving all those of one or two inches long, as the young shoots of one year's growth are the principal bearers: those produced one year bear fruit the next, and a general supply must be every year retained, and not shortened in summer, which would force out laterals from every eye, and spoil the shoots for next year's bearing; but in the winter pruning, a general shortening is necessary, according to the strength of the tree, and the situation and strength of the respective shoots, and the whole tree should then be regularly nailed to the wall.

Mr. Forsyth says, that "when the trees are planted, they should by no means be headed down till the month of April or May; when they begin to throw out fresh shoots: strong trees should be cut a foot from the ground; and those that are weak, about half that length. But in backward seasons, they should not be headed down so early; never until the buds are fairly broken: always observing to cut sloping towards the wall, and as near to an eye as possible, that the young leading shoots may cover the cut; which operation should be again performed in the next March or April: the shoots that are then thrown out must be trained horizontally, to cover the wall; the number of these to be left ought to be from three to fix on each side, according to the strength of the main shoot; taking care to rub off with the finger and thumb the fore-right shoots all over the tree, except a few which may be desired to fill up the wall, near the body of it; and in the second year the horizontal shoots must be shortened in the same manner, according to their growth; and so on every year, till the wall shall be completely covered from top to bottom."

He adds, that "it is a frequent practice with some gardeners, to head down the trees at the time of planting; which often proves fatal to them."

These trees must be pruned twice a year, as in summer and winter.

In the summer pruning, the irregularity of the numerous shoots should be reformed, beginning in May or early in June, and rubbing or cutting off close all fore-right and back shoots, and all superfluities or very rude growths; retaining, however, in every part a full supply of the regular side-shoots, as succession-wood for the next year's bearing, training them in at full length, as above, to remain till the winter pruning; as it is of importance to leave more than a sufficiency of the well-placed shoots at this season, to have plenty in every part to choose from in the general winter pruning. See PRUNING.

In the winter pruning a general re-form should be made in all the branches and shoots, retrenching all worn-out and old naked branches ill-furnished with bearing wood; at the same time felling and retaining, in every part, the best shoots for the next summer's bearing, cutting out close all the superfluous or unnecessary and ill-placed shoots, and reducing part of the former year's bearers and unfruitful old branches in every part of the tree, to make due room to train the necessary supply of young wood at proper distances; being careful in retrenching the old wood occasionally, to prune it down either to a young shoot, or to some convenient branch it supports, which is furnished with one or more such shoots, so as every branch may also terminate in a young shoot for its leader, cutting off all small shoots arising from the sides of the main ones, and letting the general supply
supply of young wood in every part be now shortened moderately, according to their strength: the smaller shoots may be cut to about eight or ten inches, the middling ones to twelve or fifteen, and the strong shoots to eighteen inches or two feet long, pruning them generally to a wood-bud, in order to obtain a shoot at the end for a leader. All dead wood, cankered parts, decayed spurs, and limbs should be cut out; and as soon as one tree is pruned, let it be directly nailed, which should be performed with great regularity, training all the branches, &c. horizontally, as straight and close to the wall as possible, at equal distances. See PRUNING.

When the tree is at a young vigorous growth, the shoots should be left thicker or more abundant than in moderate shooting trees, shortening them less in proportion, that by dividing the amp among many and a greater extent of branches, the luxuriancy may be restrained, as the more the young wood in a luxuriant tree is pruned, or the shoots shortened, the more vigorous the tree shoots, and produces little fruit. See AMYGDALUS.

The old trees should be well attended to in pruning, to continue them in a good fruitful state, by encouraging young wood in proper abundance; as by this care there is not only more certainly produce crops, but the fruit generally ripens earlier, and has a peculiar richer vinous flavour. As these old trees are apt to run up naked below in the main branches, care should be taken, when young wood advances in these parts, as well as in all vacant spaces, to preserve it so as to continue all the parts of the tree, from bottom upwards, regularly furnished with bearing wood.

In respect to old decayed trees, Mr. Forthys fays, "it has been the general practice to train wall-trees in the form of a fan, which occasions the sap to rise too freely to the top, leaving the lower part almost naked; so that scarcely one quarter of the wall is covered with bearing wood." He fays, that, "in that cafe, it will be necessary to cut down the whole of the tree as near to the place where it was budded as possible, always cutting it at an eye or a joint: if there should be any young shoots on the lower part of the tree, it will be proper to leave them, training them horizontally, which will check the flow of the sap, and thereby render them much more fruitful." He adds, that, "very frequently, when large branches have been cut off in a careless manner, and the wounds left to nature, the whole tree is infected with the gum and canker; which, if not checked, will in a short time totally ruin it: the best remedy in this cafe is," he thinks, "carefully to pare off the cankered part of the bark with a draw-knife, or other convenient instrument. You will frequently find the white inner bark infected, which must also be cut away, till no appearance of infection remains; this may be easily known by the brown or black spots, like dots made with a pen, of which not one must be suffered to remain: all the branches so cut and pared should," he fays, "be immediately covered with the composition in a liquid state." And "as we sometimes see walls with all the trees infected, it will in that cafe be most prudent to cut every other tree, leaving the rest for a supply of fruit till those which are cut begin to bear; this will be in the second or third year. When trees are in a very bad condition, they should," he thinks, "be cut in a partial manner, taking off the worst branches firft, particularly those in the middle of the tree, always cutting as near to the graft as possible; or every other branch may at firft be taken out, leaving the rest to bear; by which means there will be a supply of fruit, while the other parts of the tree are renovating: it should be remembered, however, that all the cankered bark may be cut off without los of time; otherwise the new wood will be infected. Old trees thus headed down will," he fays, "sometimes throw out very strong and vigorous shoots, which it may be necessary to top, as it will cause them to throw out side shoots, and soon fill up the wall with fine bearing wood; but they should never be suffered to have any fore-right spurs, except little dugs: the topping should be done in the beginning of June, which will cause the tree to produce fine bearing wood for the next year: these shoots must be pruned in March following, shortening the shoots from fifteen to six inches, but according to their strength, always leaving the strongest shoots long. And wherever the knife has been used, the composition must," he fays, "be immediately applied." It is also observed, that "after the full of the leaf, it will be proper to unall the young shoots, leaving only a few to prevent the tree from being broken by the wind. By this method they will be more exposed to the sun and air, which will ripen and harden the wood much more speedily than if they be left nailed." He adds, that "he has a great dislike to annual pruning of fruit-trees, of all kinds of stone-fruit in particular: for by pruning at that season you seldom fail to bring on the canker; and no fruit-trees are more liable to this disease than the apricot: the reason is obvious,—the great acidity in these trees, the exposure of the wounds, and the dormant state of the sap, predispose to mortification; whereas, in spring, when the sap is beginning to flow, and will follow the knife, the lips will quickly grow: if the branches are small, the fresh bark and fresh wood will in one season completely cover the wound; but if large, a time proportionate to their size will be occupied: this process, however, is manifestly much accelerated by the application of the composition, which excludes the air and wet from the air and sap-refidues of the tree." To regard to the standard trees, they sometimes in favourable seasons bear plentifully, particularly the Breda and Bruffels apricot, either in half or full standards; the half standards are more out of the power of the winds and cold air.

These should be planted in a sheltered warm situation in the full sun, that they may have a greater chance of setting a good crop of fruit, and of ripening more effectually with a rich flavour: their culture is nearly the same as that of other standard fruit-trees: they require but little pruning, only just to reduce or retrace any very irregular growth or out-growing ramblers, or occasionally to regulate confufed crowding branches, and to cut out decayed wood; all which should be performed generally in winter.

Covering and protecting the Bliifions and young Fruit.—As trees of this kind planted against walls bloom very early, both bloom and young fruit are very liable to be injured by frosts and cutting blasts: it is therefore useful to afford occasional protection, in unfavourable seasons, to some of the forwardest and most valuable kinds, either with mats fastened over the trees, or twigs of evergreens stuck between the branches, beginning the covering as soon as the blossom begins to expand, and continuing it till the fruit is fairly set; the mats to be used only on nights and in bad weather, but the evergreens to remain constantly till all danger is past.

Mr. Forthys remarks, that "in severe weather they ought to be covered before the flowers begin to expand; for he has often seen the blossoms drop off before they opened; and he affirms, that the best covering is old fiftens, which should be put on three-fold; and if a few branches of dry fern are stuck in among the branches before
fore the nets are put on, they will assist greatly in breaking the force of the high winds." The common practice of covering with mats in the night, and taking them off in the day, by frequently expelling the trees to the cutting winds, does, he thinks, more harm than good. And the covering with branches of spruce-fir and yew, by being too close, he supposes, encourages a blight, and causes the leaves of the trees to curl, and the florets to break very weak; whereas the nets admit a free circulation of the air, and at the same time break the force of the wind: when it happens to rain or snow in the fore part of the night, and freeze towards the morning, the drops are, he says, found hanging in icicles on the meshes, while the tree is almost dry: when the florets become pretty long, and the leaves expand to cover the fruit, it will be necessary, he says, to keep the net clear from the tree, by placing forked sticks, from six inches to a foot long, between it and the wall: this will prevent the florets and leaves from growing through the net; the forked end of the sticks should rest against the meshes of the net. See Amygdalus.

Thinning out the Fruit.—In some seafons these trees set many more fruit than can attain perfection; and as they sometimes are placed very close, or often in clutters, and fit close to the branches without any yielding footstalls, as in cherries, &c. they, in their advancing growth, must impoverish and thrust one another off; thinning becomes necessary, which in wall-trees particularly should not be omitted, and it also proper occasionally in standards in some degree. This busines should be begun when about the size of large cherries, &c. and should be done with great regularity, leaving the largest, fairest, and best situated to grow to maturity, mostly all singly, or at least never more than two at the same eye, but most commonly single in the large kinds. The fruit thinned off makes excellent tarts, and should always be saved for that purpose, and for which use they may be thinned by degrees, both in wall-trees and standards; but not in the former, so as to leave the superabundant fruit to grow large in any considerable degree, nor in great quantity, to rob the continuing crop of its proper nourishment; for this use they should always be gathered before they flame, or harden in the heart or middle.

Method of Forcing Apricots.—In this method the fruit is obtained much more early than in the natural way, and is effected by having the trees in hot-houses, or on hot-walls, or in bark hot-beds.

The proper trees for this purpose are the dwarfs, trained as wall or espalier trees, but sometimes as small low standards; they are mostly trained in the full ground till advanced to some degree of bearing, and then planted in the borders of the forcing-houset and hot-wall, and trained in the manner of wall-trees, to a light open trellis; some also, as small dwarf standards, placed forward in the former, or occasionally in pots, and introduced in the same situation; in all of which, the trees, being well fresh-rooted in their places, are forced at the proper season by means either of fire-heat, or bark-bed, or sometimes both occasionally in forcing-houses, but in hot-walls mostly by the former; the forcing-houses and hot-walls have mostly flues for fire-heat, and sometimes the farmer has a pit for a bark-bed; but where this is not the case, the whole bottom space is formed of good earth, and the trees planted in are generally in asemblage with peaches, nectarines, plums, &c. as the fame degree of heat is suitable to the whole.

The proper season to begin the work of forcing is principally in January, or early in the following month; when, or rather a little time before, the glazes are flush close; and at the proper time the fires made in the furnace moderately

Vol. XXVIII.

PRUNUS.

every evening and morning, to heat the flues in a proper degree, to afford a moderate regular heat, to warm the internal air to a proper degree, which forwards the trees to early blooming and fruiting; having fresh air moderately admitted in fine days, and more freely when there is a warm wind; being sometimes watered both in the earth and over the branches after the bloom is past, and the fruit fairly set. See Forcing-Frame, &c.

Culture in the Cherry Kind.—These are all increased by grafting, and budding them upon stocks of any of the cherry kind, raised from the flones of the fruit of any of the forts; but for having larger-growing trees, for standards, walls, and espaliers, the most general flones used are the wild black and red cherry, raised from the flones of the fruit; they, however, grow upon any sort of thes flones, and likewise take upon plums, though these flones are not proper for general use; they are also capable of growing upon laurel-flones; which, however, is only practised for curiosity, suffering a small part of the flock to grow up to shew the singularity of the two forts growing upon the same root. All the varieties likewise take upon the bird-cherry flones; but this should only be practised when it is required to dwarf any of them as much as possible; which, in this way, are proper to train for small dwarf trees, either to plant in pots, or in the open borders, and in pots for forcing, or to plant in the borders of a forcing-frame. See Forcing-Frame.

But for general use, flones either of any of the common cherry varieties; or, to have larger trees, the wild cherry-flones, should be used, as being the freest shooters and of longest duration; though, in raising the flones, it is from the flones of the fruit, which should be found in autumn in beds of light earth, covering them near two inches deep; they come up in the spring, and in the autumn or spring following, if the plants are strong, plant them out in nursery rows two feet and a half in diameter, to remain for grafting, &c. when, about the size of a large goose-quill to that of a person's little finger, or little more, they are fit to work for dwarf trees; but for standards, they must have at least four years' growth, as they must be grafted at five or six feet height. And to have trees of more moderate growth either for walls, small standards, or dwarfs, the Morello and small May cherry flones may be proper.

The grafting and budding of all the forts is performed in the usual way, though the former is most proper for general practice, as they are not so liable to gum in the grafted part as in that of the budded trees. Though both methods may be occasionally used, and may be practised as the flones occur in proper growth, &c. whip-grafting is the most proper, for the moat part, in this method of raising them; the budding is performed in the common way; the grafting should be done in the spring, as February and March, and the budding in summer, as June or July; the dwarfs should be grafted or budded near the ground, and the half and full standards from three to six feet high; the grafted trees shoot the same year, and the budded ones the spring following.

When the first shoots from the graft or bud are a year old, those of the dwarf forts for walls, &c. must be shortened down in March or beginning of April, to five, six, or eight inches long, according to their strength; to procure lateral shoots to form the head, and the standards may be shortened or left entire as the case requires. When wanted to form a spreading head, the first shoots should be shortened to force out lower branches; after this, the branches of the dwarfs and standards remain mostly at their full length; and while the trees continue in the nursery, those designed for walls, &c. should be trained to flaks, in a proper position, occasion-
PRUNUS.

ionally pinching or pruning young shoots of the year early in summer, down to a few eyes or buds where necessary, in order to procure a production of lateral branches the fame season, to train in for a further supply of young wood, to increase the expansion of the branches as soon as possible to continue entire.

When the trees have from one or two to five or six years’ growth they are proper for being finally planted out; though, if planted when their heads are not more than two or three years old, they succeed much better than larger trees. Mr. Forsyth advises the same attention in choosing these trees, as for apricots, peaches, and nectarines, and that they should be headed down the first year.

The leaft for planting them out is any time in open weather, from the end of October or beginning of November till March.

The wall-and espalier trees should be planted eighteen or twenty feet distant; and where the walls are tolerably high, a half, or a full standard may be planted in the spaces between the daws, that while they cover the bottom and middle, the standards may catch the upper part of the wall.

When these planted against walls or espaliers were planted when only one year old from the grafting, &c. with the first shoot from the graft or bud cutting, they should be pruned short in March or beginning of April, to furnish lateral branches; but if they were headed in the nursery, and horizontal branches obtained, the shoot will not be shortened afterwards, except occasionally in particular shoots to fill a vacancy; as the fruit-sprouts first rise towards the upper end of the branches, a general shortening would not only cut away the fruitful part, but force out a great deal of useless wood.

The necessary branches, arising every year after the first heading down, should be trained horizontally at full length, five or six inches asunder; and where wood is wanted some adjacent young shoot may be pinched in May or early in June, or shortened in the spring following, when it will push forth two or three laterals; being careful to retain all right and other irregular-placed shoots, and continue training the regular branches till at full length at equal distances, till they have filled the proper space of walling or espalier.

In these trees the bearing-wood does not want renewing annually, the same branches continuing bearing several years, and only want renewing with young wood occasionally, as any branch becomes barren or an ill bearer, except in the Morelo, which generally bears the most abundantly in the year-old young wood; a general successional supply of each year’s shoots should therefore be retained for successional bearers.

The trees in all the sorts should be pruned twice every year; a summer pruning being given early in the season, to retrain all the superfluous shoots soon after they are produced, likewise all fore-right and other ill-placed shoots, and rank wood, as soon as possible; and to pinch shoots where wood is wanted, so as there may be as little pruning as possible upon the older wood, which is apt to gum by much cutting; retaining, however, a general moderate supply of the regular placed shoots to choose from in the winter pruning, training the whole at full length; and in the winter pruning, examining the general branches, old and young, both in the former trained bearers, and the retained shoots of the preceding summer, retaining all the fruitful and regular placed former trained branches; and if, among these, any irregularity, disorderly or improper growths occur, the whole should be reformed by proper occasional pruning. In old trees, as well as others, it is proper to retrench any worn-out or declined naked branches, which are a detritus of bearing-wood, or fruitful spurs, and to cut out all decayed wood; retaining a plentiful successional of leaf summer’s young wood, in proper places, where necessary, to supple the place of any unfeasible old wood now retrenched; and at the same time cutting out all superfluous, or over-abundant, and other unnecessary shoots reserved last summer, not now wanted, leaving only some well-placed ones, in any vacant spaces, or some in particular parts, to train in between the main branches, to be advancing for bearers, ready to supply any deficiency; and generally a terminal shoot to the general branches in all parts where the allotted space admits, of extending them in proper regularity; accordingly as each tree is thus pruned and regulated, the general branches and shoots should be trained in regularity, and nailed to the wall, &c. about three, four, or five inches asunder, at all their full length, to the extent of their limited space.

Mr. Forsyth advises, in pruning these trees, never to shorten their shoots, as most of them produce the fruit at their extremities, the shortening or cutting off of which very frequently occasions the death of the shoot, at least of a great part of it. The branches, therefore, should be trained at full length. He has often seen the whole tree killed by injudicious pruning. Wherever the knife is applied, it is sure to bring on the gum, and afterwards the canker, which will inevitably kill the tree, he says, if no remedy be applied to the wounds.

The Morelo, in particular, and the small early May cherry, bear both on the young wood of last summer, the fruit-bloom-buds illuming immediately from the eyes of the shoots very abundantly, and upon small natural fruit-sprouts arising on the two and three years’ wood, and continuing on the older branches; but generally bear the most plentifully on the young wood; and, therefore, it is necessary, both in summer and winter pruning, to attend to this, and retain a general supply of the young shoots of each year, trained in plentifully in all parts of the tree in summer, of the most regular placed, as many as can be conveniently admitted with proper regularity; and in the winter pruning, making a general selection of the best well-placed shoots of last summer, to train in for successional bearers the ensuing season, cutting out the superabundant, with part of the naked former bearers occasionally, to make room for the young supply, leaving a terminal one to each mother branch, and thus train in the general branches and shoots horizontally, about three or four inches asunder at their natural length.

The standard cherry-trees should be planted twenty-one feet distance at least; but if for a whole orchard, twenty-four feet, or eight yards distant every way, will be requisite. The first shoots having been previously shortened in the nursery, if thought necessary to promote lower branches to form the head, plant them now with their heads entire, except just reducing any irregular growth, and suffer them to branch every way, and shoot in length as fast as they are able, not shortening any, and all the branches will soon form numerous fruit-sprouts.

Little pruning is required for standard cherries, as too much use of the knife, in the larger wood particularly, causes them to gum and canker; all that is necessary is occasionally to rebranch any very irregular growing branch, and all decayed wood.

In respect to old trees, Mr. Forsyth says, “he has headed down a great many cherry-trees, which were almost past bearing, and so eaten up with the gum and canker, that what few cherries they bore upon old cankered spurs were not fit to be sent to table,” and that “in the years 1790 and 1791 he cut, or headed down, fifty trees. The operation
operation was performed in the months of April and May, in each year. These trees made shoots from three to five feet the same summer, bore fine cherries the next year, and have continued to bear good crops ever since. To the above trees he applied the composition. At the same time he cut down twelve trees in the same row, but did not apply the composition: these twelve trees all died in the second and third years after. They now," he says, "gather more cherries from one tree where the composition was applied, than they did from the whole number formerly; being also much larger and finer fruit. When cherry-trees are very old, and much injured by large limbs having been cut off, (which will," he says, "if fallibly bring on the canker,) and, if no remedy be applied, in a short time kill the trees,) or if there are great Spurs left standing a foot perhaps from the wall, the best way to bring them to have fine heads, and to cover the wall, is to head them down as low as possible; taking care to leave some small shoots, if there be any; if not, leave a bud or two at the ends of some of the shoots. Sometimes you will have a great difficulty to find any buds. If that be the case, in the spring, before you mean to head the trees, make some incisions in the branches. This should be done on different branches, at the most convenient places for filling the wall with good wood. The size of the incisions should be from one to two inches, according to the largeness of the branches; observing to make them just above the joint where the buds should come out. If you cut just below a joint, the shoot will die as far as the next bud or joint, and of course injure the tree, if no remedy be applied." He adds, that "the time for performing this operation is in March, April, or May." But this method of making incisions is only recommended where there are no young shoots or buds, and when the tree is in the leaf stage of the canker. Where you have a few young shoots or buds, he advises to cut down the head as near to them as you can, and to take great care to cut out the canker, till you come to the sound bark. The canker makes its appearance in these trees in the same manner as in peaches and nectarines, and may be easily discovered by an attentive observer. "If any gum remains, it must be cut or scraped off; the best time for doing which is when it is moistened with rain; you can then scrape it off easily, without bruising the bark. This operation is very necessary; and if it be neglected, the disease will increase rapidly." And wherever the bark or branches have been cut off, the edges should be rounded, and the composition applied to them.

It is observed, that the general way of pruning these trees has been to leave great Spurs, which continue to increase till they stand upwards of a foot from the wall, and become as thick as a man's arm; but it must be observed, that cutting off from year to year the shoots that are produced from the Spurs, increases the canker, till large protruberances, like wens, are formed on the branches, becoming very unightly; and these occasion them to produce only small and ill-flavoured fruit, at a great distance from each other. When this is the case, the method he pursues is to head the trees down, as before directed. And if the young shoots are properly trained, they will produce fruit the following year; and in the second year, produce more and finer fruit than a young tree that has been planted ten or twelve years. The same writer remarks, that it has been a general complaint, that heart cherries are bad bearers, when trained up as wall-trees; but by pruning them as duke cherries, he has brought them to bear in the same manner; that is, he leaves a great many fore-right shoots in summer, tucking them in with some small rods run across under the adjoining branches, to keep them close to the wall, and prevent them from being broken by the wind, and from looking unightly. He advises, never to make use of the knife in summer, if it be possible to avoid it, as the shoots die from the place where they are cut, leaving ugly dead flubs, which will infallibly bring on the canker. These shoots may be cut in the spring to about a couple of eyes, as duke cherries, which will form a number of flower buds.

Mr. Forfyth indeed well observes, that as cherries are a very considerable article of traffic in the London markets, and the markets of most towns throughout the kingdom, employing such a great number of people during the summer season in gathering, carrying to market, and selling them, the raising of them is certainly worth any gentleman's while, especially as the trees may be rendered ornamental, as well as profitable, by planting them in shrubberies, &c. Gentlemen of small fortunes, who are at a great expence with their gardens and plantations, may in a great measure reimburse themselves by selling their cherries, and other fruit, (for which there will be plenty of chapmen,) and thus enjoy, at an easy rate, the pleasures of a rational and useful recreation. And he adds, that in all parts of the country, there are persons employed in collecting fruit for the markets, and to hawk it about from place to place; and surely it is much better to sell it to them, than to let it rot on the ground, or be devoured by birds and insects.

It is advised, when cherry-trees begin to produce Spurs, to cut out every other shoot, to make the tree throw out fresh wood. When that comes into a bearing state, which will be in the following year, to cut out the old branches that remain; by that method you will be able to keep the trees in a constant state of bearing, taking the same method as before directed with the fore-right shoots. And great care should be taken to rub off many of them in the month of May, leaving only such a number as you think will fill the tree. By so doing, your trees will continue in a fine healthy state, and not be in the least weakened by bearing a plentiful crop of fruit. The reason is obvious: the great exhalation which would be occasioned by the fun and air, in the common mode of pruning, is prevented, by the composition keeping in the sap which nourishes the branches and fruit. And further: he cut some trees, as directed above, more than twelve years ago, that are now in as good a state of bearing as they were the third year after the operation, and likely to continue so for many years. He states, that a row of dwarf cherry-trees, that stood against an old paling, with an old thorn hedge at the back of it, (which every year to infected them with a blight, accompanied by an immense number of caterpillars and other insects, that, even in a fine year, they could not gather eight bushlets from the whole row,) became so fruitful, after the hedge and paling were removed, that they gathered forty-two pounds a-day for six successive weeks, besides what the birds, wasps, and flies destroyed. He mentions the fact to stimulate market-gardeners and farmers, who have large orchards and gardens, to exert themselves in trying every method, however unimportant it may at first appear, to improve and render them more fruitful; and concludes, that the duke and heart cherries from these trees were as fine as any that were produced from wall-trees. And as they are much more productive, he has been induced to take up many old renovated trees from the walls, and plant them out for dwarf standards, supplying their places with pears, plums, peaches, &c. And further: that in all old gardens and orchards throughout the kingdom, and particularly Kent, whence the London markets are chiefly supplied with
The greater part of the old trees will hardly bear we fruit sufficient to pay the expense of gathering it; but if the above method of pruning, &c. were practiced, the owner would soon find his account in it, and be amply repaid for his trouble: the fruit would be much finer, and he would have five times the quantity that the trees produce in their present condition; the trees would be more lightly, and always keep in a flourishing and bearing state. But when old standard cherry-trees become decayed and hollow, he would recommend heading them down, as directed for wall-trees and dwarfs; to scoop out all the rotten, loofe, and decayed parts of the trunk, till you come to the solid wood, leaving the surface smooth; then use the composition.

**Method of forcing of Cherries.**—This sort of tree may likewise be forced by artificial heat, in houfes, fo as to obtain fruit at an early feaon, as in April and beginning of May. And for this purpose theearleft dukes and May cherries are the proper forts, but principally the former; trained both in standards, of four, five, or six feet films, to elevate the heads near the top-frames of the forcinghoufe, which are generally pruned to a small compass for that purpose; and in dwarf standards, with short films and low heads; both of which, for this ufe, should be fuch as are previously trained in the full ground, till the heads are of three, four, or five years' growth, or till they have commenced bearers in some tolerable degree. The forcing-houfes for this ufe are of different contructions, according to circumftances, and the other purpofes to which they are applied. They have proper flues for fire-heat, and mostly internal borders of good earth, either in the back part for the taller trees, and in the front for lower; or sometimes, where no internal bark-pit is made, for bark-bed heat: the forcing being effected wholly by fire, the whole bottom space is entirely formed into a bed of earth of proper depth, and the trees planted in it in rows from the back to the front, in some regular gradation, according to their height; sometimes with dwarfs planted between the taller standards, and towards the front; and occasionally with dwarf trees in pots. In this fort of forcing, a very light degree of fire-heat is fufficient; therefore, when there are back flues, they need not be employed, only that in the front being used.

The author of the Scotch Forcing Gardener observes, that where the situation is dry, the bottom a kindly sand, gravel, or clay, and the foil a fandy loam to the depth of two feet; the border will require no other preparation than being well enriched with ftable dung, and, if poiffible, a little marl, which ought to be trench'd and well mixed twice or thrice during the summer before planting. But where it is wet, the bottom a cankered gravel or cold clay, and the foil either a poor sand, gravel, or fibblish clay, care must be taken to render them otherwife, by pailing the border to the breadth of twelve or fourteen feet, running a drain in front to carry off the wet, and removing the bad, and bringing in good foil, fo as to confpoce a rich fandy loam to the depth of thirty inches at the wall, and twenty-four in front, allowing three or four inches for fetting. If a new building is erected for cherries, it is immaterial, he thinks, whether the building or border is completed firft, (provided the latter has a fufficient time allowed for the mixing and incorporation of the foil,) as the front wall and flue fland on pillars, whose foundations ought to be at leaff six inches deeper (if the border is not paved) than the foil. He confiders about the firft of January to be a good time for planting; although a month sooner or later at this feaon is of little confquence, as there must be no fire-heat applied the firft year. Having provided the neceffary number of healthy, well-rooted, maidens, or one-year-trained May dukes, (as experience gives that no other cherry deferves a place in a forcinghoufe,) let them be planted against the treills at the distance of eight, nine, or ten feet, according as the length of the houfe will beft divide; filling-in the pits with vegetable mould from decayed tree-leaves, and fettling all with a little water. Riders, with five or fix feet boles, which have been trained two or three years againft a wall, and have produced a crop or two, fhould be provided to fill the upper part of the treills, where they will yield a few crops before the dwarfs require their removal. There will generally produce a few fruit the firft, and be fure to produce a full crop the second year.

The surface of the border fhould be forked over once a year, and a little well rotted dung occasionally worked into it.

In repect to the trees, he observes, that the dwarfs or principals being the only ones intended ultimately to fill the treills, the riders being planted folely for the purpofe of obtaining a crop or two while thofe are making their wood and forming their fruit-spurs, and, by being checked by their removal, may not be expected to put forth much young wood while they remain there, it will be unnecessary in pruning to thin them out much, only let them be dreffed regularly to the treills, and (where not absolutely requisite) divelling them of any fhoots they may make, paying repect to their fruit-spurs only; as when they have ferved this purpofe they will be of no further ufe. He fays, that after planting, the dwarfs, if maiden threes, fhould be headed down to two or three eyes, in order to make them put forth vigorous fhoots, to furnifh the treills from the bottom: and, if they have been one year in training, the bottom branches fhould be laid well down, and the reft drefled in a regular manner to the treills, using fhings of fresh matting to tie with; and be careful to allow sufficient room in the ties, as much milchife is done to fruit, especially cherry-trees, which are fo apt to gum, if not allowed a fufficiency of room in the fized, or tie, fuch as will at leaff admit another of the fame fize along with it.

As these trees are apt to gum, and the branches decay, from the flighted injury, it would be imprudent to train them horizontally; in which cafe, the lefs of a branch is supplied with much more difficulty than when trained in the fan manner. This laft method he therefore recommends. And when the tree has produced its fhoots to the length of five or six inches, they fhould be gone over and thinned, fo as to enable the operator to lay them in at about the diftance of twelve inches; pinching off any that are produced fore-right, and which are, from their appearance, not forming for fruit-spurs; and, as they advance, let them be neatly laid in, and divelled of any laterals—they may produce. If all have gone well, at the end of the firft year they will have produced fhoots from the old threes thirty inches long, which fhould then be thronited to about two-thirds of their length. In the second fefon they will fhoot vigorously, and begin to form many fruit-spurs on the preceeding year’s wood, which must be encouraged, for the production of a few fruit the following year. The trees fhould be kept clear of all fuperfluof and lateral fhoots, laying the leading ones at the diftance of eight or nine inches; and, at the end of the fefon, fhortening a few of the strongeft alternately, fo as to make them break their buds in the fpring in a regular manner; as they will not require to be any more thronited. And in the thrid fefon, they will produce a few fruit, make fine spurs and moderate fhoots; which as they advance to the riders, room SHOULd
should be given by lopping off their branches, or thinning away their foliage, so as to afford a free circulation of air and admission of sun. In the fourth season, they will produce a full crop of fruit; and often make such a progress towards the riders, that their presence becomes unnecessary; in which case, it will be advisable to sacrifice whatever fruit, or appearance thereof, there may be on them, to the encouragement of the principal tree. After the trees have filled their spaces, and have begun to produce plentiful crops of fruit, they will make little or no wood; and will require no further care, on the score of training, than to supply the place of any branch that from accident may die out or be destroyed. These trees, from their nature, bear very little artificial (especially fire) heat, on which account he would not advise the forcing of them too early, especially if there be no more than one compartment for their culture; since, in that case, there would not be a continued succussion for the supply of the table, and furnishing a dessert, till they came in on the open walls. He considers the first or middle of February to be an eligible time for the commencement of the forcing; but, in a new planted house, the third year ought to arrive before fire heat is applied. Were it not for the sake of other articles that may be placed or planted in the cherry-house, it would, he thinks, be better that the glaftes were not put on the first season at all; but this is generally too great a sacrifices: however, if they are put on, a free circulation of fresh air, even in the night, ought to be encouraged.

When, in the third year of planting, the trees have made good progress, plenty of fruit-spurs, and a reasonable hope of success is entertained, the glaftes should be put on about the middle of January, plenty of air being admitted through the day, shutting them at night. On the first of February the fire may be lighted, which must be made so moderate, that, at night, and eight in the morning, Fahrenheit's thermometer may not stand above 45°. In which condition it should be kept as near as possible till about the twentieth of the month; and then increased gradually to 45°: at which point endeavour to keep it till the fruit is fairly set. Afterwards increase the heat to 50°, but not more, till the flowering is over, and the fruit have begun their second swelling. Although, for the sake of the fruit, all danger is then past; yet, if too strong a fire heat is indulged in, it will have the tendency of drying the shrubs too weak: and therefore he would not advise that the air of the house, at the fore-mentioned hours, should ever pass 60°.

With regard to the admission of air, the house ought to be uncovered all the first season after planting: but, if this is not the case; and if, from the nature of what other plants are placed therein, it is imprudent to leave little air in the house in the night, it should be opened by fun-rise in the morning, having a large and free circulation all day, shutting it up at sun-set. However, when the month of May arrives, it ought, he thinks, to be entirely uncovered.

In the second season, he advises, that the glaftes be put on by the first of March, large portions of air being admitted, as directed above, and the glaftes be removed by the first of August. From the commencement of the forcing, this article must be more particularly attended to; the first ten days after which, a very large share of air should be given, to prevent the buds from breaking too suddenly, and of consequence too weakly: besides, vegetation (in forcing) ought always to be brought on, as it were, by health: the juices flow more kindly; and the plant suffers the first impulse of reviving activity with more patience, than when hurried on in a violent manner. But, after the buds begin to appear turgid, a more moderate quantity may be admitted; still having respect to the temperature of the house, and the prevention of frothy winds from hurting the bloom. At all events, advantage should be taken of sun-shine; which will allow a larger portion than at other times. Nevertheless, let no day pass (unless a severe frost) wherein less or more air is not admitted; and, in sun-shine, to the extent that the thermometer may not rise more than ten degrees above the fire-heat medium. After the crop is all gathered, if consent with the welfare of the other articles contained in the house, the glaftes should be removed, and the trees exposed to the weather till the next season.

When planted, the mould should be settled to the roots of the trees by a moderate watering; and if the house remain uncovered the first season, little attention, except in dry weather, will be required. Due attention should be paid the second year to keep the border in a moderately moist state, that the plants may grow freely; and when their growth is stopped for the season, withhold the water, that the wood may ripen perfectly before they are exposed to the weather. From the time the forcing is begun, plentiful waterings should be given to the border, until the bloom begins to open; and then in a moderate degree till the fruit is fairly set. After which, again increase the quantity till the fruit begins to colour; and then diminish the quantity by degrees till you entirely withhold it, which ought to be done sometimes previous to the fruit's being ripe. It is also observed, that washing with the hand-engine should commence with the day the fire is lighted; and, except from the time the bloom begins to appear till the fruit is fairly set, should be repeated thrice a week in the evening, and that with a considerable degree of force, till the fruit begins to ripen. And in the interval of washing (viz. while in bloom, and till the fruit is set,) a little water should be poured on the floor every evening when the fire is at the long, which causes a fine agreeable steam to arise in the house, greatly to the benefit of the flowers and foliage. Soft and tempered water should be used at all times, and on all occasions.

With respect to the insects that infect the cherry-house, they are the aphid, or green fly; the acarus, or red spider; the caterpillar, and the grub. The first, and least hurtful, is easily destroyed by a fumigation of tobacco; the second by the prociss of washing with the engine, which is indifferently necessary to the health and vigour of the trees. Therefore, when they begin to make their appearance at any time, the water, in the ordinary course of washing, should be thrown against the trees with greater force, making a point of beginning at the contrary end of the house each time; whereby, if you happen to miss any part the one way, you may strike it the other. The caterpillar and grub have given him more trouble than the preceding, or indeed any species of insect whatever; and, after trying a variety of prescriptions, being at much trouble and expense, he can venture to allure the reader, and the public, he has at last discovered a cure, which is as follows:

Take of soft soap, two pounds; flowers of sulphur, two pounds; leaf, or roll tobacco, one pound; nux vomicae, two ounces; and oil of turpentine, a gill; boil them all together in eight gallons of soft or river water to fix; and let the liquor stand for use. And any time in winter, at least a considerable time before the trees begin to vegetate, let them be all untied or unnailed from the trellis or wall; brush every part of the branches and buds clean with a soft
soft brush, such as is used for painting; make the liquor milk-warm; and, with a sponge, carefully anoint every part of the tree, trellis, &c. Drench the trees nearly to the trellis again; but use none of the old ties or shreds: and let this operation be repeated every winter. The first summer after anointing, there may be a few appear, whose eggs have, by being concealed, escaped the action of the liquor, which must be picked off, to prevent their breeding; but, if any, there will be very few, as it is of the most penetrating nature. But this liquor must on no account be used in summer, as it instantly destroys the foliage. Fruit-trees of all kinds should be anointed with this liquor every year; as it is equally destructive of every insect and their eggs which infest them.

In cultivating dwarf trees in pots or boxes, it is observed, that where there is an extensive variety of forcing, and a green-house or conservatory, cherries may not only be produced at an early season, but in a long succession, by removing the pots or boxes from one house to another. When there are twenty or thirty trees, they should be divided into four or five equal parts, to make as many successions; and be placed in equal rotation: first (in November or December) in the green-house, where they may remain till they are fairly set; then, in an early peach or vine-house, till they begin to colour; and lastly, in the pine or dry house, to come to maturity. And a very rich compost, such as is used for cucumbers or melons, should be made of, watering them frequently with the drainings of a dung-hill. They should also be washed or watered frequently over head with a hand-fquirt or watering-pan; and be placed in the moit airy situations.

The double-blossomed fruit may likewise be increased by grafting or budding, as in the other varieties, upon any kind of cherry-tsocks, and be trained both as dwarfs, half and full standards, to effect the greater variety in plantations and other places.

And the wild cherry is easily raised from seed, as the flowers of the fruit; and any variety which affords large and fine fruit may be continued by grafting, &c. in which way it will bear sooner, for which a quantity of flowers should be provided in autumn, when the fruit is dead ripe, and be sown in beds of light earth an inch and a half deep, when they will come up in the spring, and after having one or two years' growth may be planted out in nursery-rows, with their tops entire, training them up for standards, with items six feet high, then letting them branch out above every way, to form heads.

They may be planted out as standards in orchards or any open grounds for the fruit, and in ornamental plantations of fruit-trees, where they have a good effect.

The bird-cherry forts may also be increased in the same manner, and likewise by layers, which will readily strike root, and be fit for planting out in one year. They will also grow well by cuttings planted in autumn.

And the last fort is capable of being raised by grafting, and sometimes by layers.

Method of Culture in the Laurel Kind.—These are readily increased by seed and cuttings; but as cuttings are the most expeditious mode, they are most commonly raised in that way.

In the first mode, the seeds should be sown in autumn, when ripe, in beds of light earth, near an inch deep, allowing them some protection in severe frosts in winter, either by hooping and matting the bed, or covering it with dry long litter; but suffering them to remain uncovered in mild weather. The plants come up in the spring, giving occasional waterings in dry weather; and in the autumn or spring following, when the seafon is settled, planting them out in nursey-rows to remain two or three years, or till wanted.

The cuttings should be procured in August or September, in moist weather, from the same years' shoots, cutting them off from about eight, ten, twelve, or fifteen inches long, with about an inch of the old wood to the bottom of each, if possible, though this is not indispensably necessary; then strip off the leaves from the lower parts, and plant them in a shady border, in rows twelve inches asunder, planting each cutting half or two-thirds into the ground, giving water in dry weather, when those planted in August will be rooted the same year; and all in the following summer, that, rooting at top, perhaps a foot long, by the autumn; at which time, or in the spring after, they may be planted or bedded out in wide nursey-rows, to acquire strength, till wanted. In either of these methods the trees may be trained either bushy or of a shrub-like growth, or trimmed up to a single stem for standards.

These plants delight in a light loamy soil, which is not too moit.

The proper seafon for planting them out is in the early autumn, or spring, according to the soil. They are highly ornamental in clumps and plantations, in lawns, parks, or out-grounds.

Hedges are sometimes formed of the common laurel for ornament; but where this is practifed, it should not be trimmed with garden-fhears, which mangle and spoil the beauty of the large leaves; all necessary cutting should be performed with a knife, in order to preserve the leaves entire, so as to make a fine appearance.

PRURIGO, in Medicine, from prurire, to itch, seems to be nearly synonymous with pruritus, and to signify simply an itching sensation.

At present, however, it is commonly appropriated, after the example of Dr. Willan, to a state of difcafe in the skin, of which a fever itch is the principal characteristic, but which is also connected with an eruption of pimples, or papules. These pimples, however, as M. Long long ago remarked, are not numerous and conspicuous in proportion to the severity of the itching, but are sometimes few in number, and scarcely perceptible to the sight, while the itching is almost intolerable. "Pruritus enormis non sempere denso, congeraque papulis afferunt; pauca vix alpea notandae occurris, quae hominem convallavit." (Long, de Morbis Cutaneis, cap. iii. art. 1. p. 2.) The papules are not very conspicuous, because they are of the same colour with the skin, slightly elevated, and somewhat flat; and it is only when much scratching or rubbing has been resorted to, for the relief of the itching, that they appear red and inflamed. They are less noticed, too, by an unpractised observer, on account of the appearance of a number of little dark feabs, which arrest their attention, as the most conspicuous marks of diseafc. These are small concreitions of blood, and of a little ferous fluid upon the points of those papules, which are excoriated by the action of the nails in scratching. These little dark feabs are, in fact, common to every eruption which is accompanied by excessive itching, where there is a papular, or even a small vesicular or pustular eruption; since they are the effect of the common operation of scratching to relieve that sensation; whence they occur in some varieties of lichen, and in scabies, or proper itch. With a view to the diagnosis, therefore, as the latter is a contagious difcafe, and the prurigo is not, an accurate examination of the papula in question will be requisite. In
one form of the itch, which has been called febrile papuliformis, (see SCARIES,) the resemblance of the eruption to prurigo is very considerable: but the pimples in the former are found, if carefully examined, to contain at their apex a minute portion of fluid, being in fact papuliform vesicles; they are also more acuminated, and are inflamed or red, independently of friction; and when recently abraded, they present a little shining point of humidity at their tops. The lichen is also a pimply disease, somewhat approximating to prurigo; but the pimples in lichen are acuminated and inflamed, seldom, if ever, containing any fluid, and terminating in a flight mealy desquamation; and the fensation accompanying it is often a tingling and heat, rather than mere itching: it is likewise more distinctly connected with indigestion than prurigo. See LICEN!

The prurigo has been divided by Dr. Willan, in his classification of cutaneous diseases, into three species, (exclusive of several local forms of the disease,) to which he gave the trivial names mitis, formicans, and fenilis. But the appearances on the skin are much the same in all cases, except as to the extent and quantity of the eruption; and the fessions differ chiefly in the degree of their severity, or in the combination of different species of irritating feelings with the itching. In young subjects of languid habit, the eruptions are less extensive, and the itching less severe, and the disorder is more manageable by medicine, yielding often, indeed, spontaneously with a change of season, or from flight modifications of diet: whence the epithet of mild (mitis) may be appropriated to such cases with sufficient accuracy. In persons advanced in years, universal prurigo, in a violent and unyielding degree, so as to render existence occasionally a burden, has been mentioned by medical writers, from Hippocrates downwards, as a disease of common occurrence; and the epithet fenilis, as indicative of the period of life in which it occurs, and the severity and permanency of the malady, which that age implies, is sufficiently applicable. But, in the middle age, the disease occurs under every degree of violence; and, both in that and in the decline of life, the fenatiation of itching is, in some cases, combined with various other painful fessions, which aggravate the sufferings, diminish the rest, and disturb the functions of the patient. These fessions have been variously described as pricking, burning, creeping, flinging, piercing pains, such as the crawling and biting of insects, the piercing of sharp and heated points, &c. might produce. These fessions, as well as the itching, are greatly aggravated by the erathching and friction which they call for, as well as by the impression of heat, or of cool air, by the warmth of bed, of hot rooms, of the direct rays of the sun, or of a fire, and by violent exercise, and even by the exposure on undressing, or getting out of bed; they are aggravated too by internal fimulation, as by digesting the stomach with food, but still more by the use of high-acifed and strong viands, and of fermented and spirituous liquors. When the peculiar fessions, above described, are present, the epithet formicans is appropriated to the disease; but it may be doubted whether there is any real specific difference in these forms of the complaint.

The causes of prurigo are by no means always obvious. It is certainly often connected with that heated and irritable state of the habit, which is the result of a stimulant diet, especially in hot weather; and sometimes with other rearrangements of the digestive organs. In old age, however, this state of the habit seldom occurs in those affected with prurigo, and it is sometimes seen in middle age in persons of lean form, and unhealthy complexion, and in those who are weakened by an insufficient supply of nourishment, lots of sleep, hard labour, or other sources of exhaustion.

The method of treatment, therefore, adopted for the varieties of the disease, is somewhat empirical, and often very unsuccessful. A continued use of the tepid bath is generally productive of alleviation, under all circumstances; though in the young and plectoric, it is apt to produce some increase of irritation at first. The bath of Harrowgate is deemed still more efficacious, if employed with perseverance for some months, even in the most violent state of prurigo formicans; and sea-bathing has sometimes cured the disease. In the more inflammatory forms of the disease, the use of sulphur, in repeated small doses, combined with nitre or soda, contributes to diminish the cutaneous irritation, and is occasionally adequate to the removal of the disease. The sulphuric acid is also beneficial in some instances under the same circumstances; and the oxygenated muriatic acid, taken in doses of a drachm in a glass of water, is said to have effectd a cure. (See Bateman's Practical Synopsis of Cutaneous Diseases, p. 19.) It is common to resort to a course of active purgation, with the view of evacuating from the habit some supposed morbid humour, which is imagined to make its way to the skin, and produce the eruption; but these purgatives appear to be actually injurious, if they are violent or often repeated. The same observation is still more decidedly applicable to the sudorific medicines that are sometimes recommended in these cases; for they seldom fail to aggravate both the eruption and the distressing fessions accompanying it. Antimonials and medicated and adherent doses of mercury appear to be altogether inefficacious.

Where the eruption is so general, as is usual in these forms of prurigo, the use of local applications, whether lotions or ointments, can scarcely be resorted to; and those generally recommended, containing sulphur, hellock, zinc, mercury, &c. are either afield of little efficacy, or are productive of increased irritation, especially in the young and plethoric. As a temporary alleviation to the itching, in such patients, a lotion containing a considerable portion of the aqua ammoniac acetata, or a little diluted spirit, has sometimes been found very beneficial. See Bateman, loc. cit.

In irritable and sanguine habits, much benefit is to be obtained by cutting off the sources of internal fimation, i.e. by a careful regulation of the diet. The mere omission of wine, spirits, and fermented liquors, will sometimes occasion a cessation of the disease; and the substitution of a light and simple diet, for the strong and high-seasoned viands which are commonly used, affords no less salutary influence. The use of whey, milk, and aqueous fluids, as drink, and of vegetable and farinaceous substances, with a little plain animal food, should be adhered to as the general regimen; and all condiments, spices, vinegar, pickles, and crude or undressed vegetables, should be avoided, as well as salted and dried meats: for all these articles have a tendency to heat the skin by sympathy with the irritated stomach, although the acids and raw vegetables are often recommended as antiscorbutics, in these cases, from a misinterpretation of the term sour.

We have known several examples of the immediate influence of vinegar upon the skin, exciting heat and tingling very soon after it was swallowed; and Dr. Withering considered the fact so common, that he asks, "Who has not observed the full scarlet flush upon the face after eating herrings or vinegar, after drinking acetic acid or cider?" See his Treatise on Scarlet Fever, p. 62.

When the prurigo occurs in persons much advanced in years,
years, or in those who are enfeebled in habit by any of the debilitating causes before-mentioned, the mode of treatment must be somewhat different. The diet, though it must be still unstimulating and void of heating qualities, should be nutritious, consisting of soups, broths, and plain animal food, jellys, and amplyuous substances. And in respect to medicine, the decoctions of farfaparilla, cinchona, ferpentaria, and other tonic vegetables, with or without the carbonate of soda, or the mineral acids, are sometimes serviceable. The warm bath, and especially the warm salt water bath, perferved in for a considerable time, affords considerable relief; and the application of a lotion, containing some active stimulant, as spirit of wine, the oxybromate of mercury, &c. is producive of much alleviation to the distressing itching. These lotions cannot, however, be employed without exciting great irritation, where the surface is exacerbated by the nails. In old people, this form of prurigo is occasionally accompanied with a great indisposition to the propagation of pediculi, or body-louse, and the mercurial lotion is also useful in destroying these insects. (See PHTHI-RIASES.) They sometimes, however, pertinaciously continue to be produced, and aggravate the distress of the patient, notwithstanding the affidious application of the wash. In the cafes, such as we are now referring to, the popular system of purging and sweating, with a view to evacuate morbid humours, is still more unsuccessful than in the other classes, as it conduces to the increase of debility, which is already too great.

Local Prurigo.—The sensation of itching is often very distressing in particular parts of the body, where the papular eruption, before described, does not appear, and it arises from various causes. In the arm-pits and groin, and other parts where there is a frequent affusion of surfaces, or a folding of the skin, it is occasioned by a slight inflammation, called Intertrigo; which see. When it affects the intertrige, it is usually the result of the presence of morpions, pediculi pubis, or crab-lace, which penetrate and adhere tenaciously to the skin, but which are speedily destroyed by a little common mercurial ointment, or by any essential oil or spirit of turpentine. A very troublesome itching sometimes occurs in the urethra, which in men is usually sympathetical of some disease about the neck of the bladder, or of the irritation of stone or gravel in that organ; but Dr. Hunter remarked, that it sometimes takes place in women without any obvious cause, and is curable by the use of a borcige. These, however, are not so frequently the objects of medical treatment as the distressing itching which affects the pudendum in females, and which becomes a serious malady; for the sensation is incessant and scarcely tolerable about the labia and os vagina, so that it is feerely possible to refrain from perpetual attempts to obtain relief by friction, or by refrigerant lotions, or to mix in society; and sometimes even a degree of nymphomania has been the consequence of the local irritation. This formidable affecion is most frequently about the period when the catamenia have finally ceased; but less degrees of it are occasionally connected with the irritation of acarides in the rectum, and sometimes with leucorrhoea. There is generally a certain degree of inflammatory fulness about the labia in these cases, which being alleviated by refrigerant applications, the itching subsides. Simple cold water, or solutions of lead, or of the cooling wells, dulled vinegar, lime water, with calomel, or, which is the most efficacious of all, with red rust of mercury, constitute the lotions which are usually resorted to, and certainly afford relief.

Somewhat analogous to this is the prurigo pedicis, or a teasing itching about the anus, which affects men of advanced age, and especially those of sedentary habits, and that independently of acarides in the bowel or of the piles. It generally arises from a slight inflammatory condition of the part, with some degree of increased and morbid secretion from its glands. It is sometimes also connected with a slight pioriasis of the febrotum, when the itching becomes permanent and severe, disturbing the patient night and day. The lotions, which afford much relief in the preceding affections, are inefficacious in this; but the citrine ointment, properly diluted, or the ointments of the red oxyd and white precipitate of mercury, afford much alleviation. High living and stimulant ingests, are found very prejudicial. See Willan's Treatise on Cutaneous Diseases; and Bateman's Synopsis; also Heberden's Commentaries, cap. 76; Sennert. Pract. lib. v. part iii. 9. cap. 8; and Mercurialis de Morb. Curand. cap. 3.

PRURITUS, a sensation of the skin, which incites the desire of using friction to the part, and is popularly termed itching. It is apparently the result of a slight determination of the blood, not amounting to inflammation, to the vessels of the part affected, as from the bites of small insects, &c.; and sometimes it is so severe as to claim the character of a disease. See PRURIGO.

PRUSA, in Geography. See BURSA.

PRUSA, a town of Lithuania; 36 miles N.E. of Breske.

PRUSATZ, a town of Bohemia; 36 miles S. of Bajalouka.

PRUSKAY. See PROSKAU.

PRUSSIA, a country of Europe, imperfectly known to the ancients, who mention various tribes that polished it, and the amber that formed a considerable article of commerce; derives its name, as some say, from the Prussi, a Slavonic tribe; but according to others, from the name of Ruffia, and the Slavonic word Po, signifying near or adjacent. It is bounded on the N. by Lithuania, the Baltic, Pomerania, and Mecklenburg, on the E. by Lithuania, on the S. by Saxoy and Poland, and on the W. by the Baltic, Mecklenburg, Pomerania, Hildesheim, and several of the German states. But it is not easy to settle the fluctuating boundaries of this kingdom, or to ascertain the dominions which it may permanently comprehend. Besides the acquisition of Silicia, and a third part of Poland, its territories have undergone several alterations in the course of the late war, and now it is terminated, other changes will occur, upon which its extent must necessarily depend. Of the acquisitions made by Prussia, we may enumerate Hildelheim, Paderborn, Munster, Erfurt, Blankenhausen, Untergraben, Eichsfeld, Mullhausen, Northhausen, Quellinburg, Eilen, Werden, Elten and Ilford; and of its cessions we may mention Cleves, Gelders, and Moers, besides mutual cessions, which took place between Bavaria and Prussia in 1803. Exclusive of small detached territories, the kingdom of Prussia, according to the statement of Mr. Phipkerton, now extends from Hornburg and the river Oker in the country of Halberstadt, the farthest western connected district, to the river Memel, or about 600 miles. The breadth, from the southern limit of Silicia to Dantzick, exceeds 300 miles. On the E. and S., he says, Prussia now borders on the dominions of Ruffia and Austria, and the western limits adjoin to the bishopric of Hildelheim. Before the recent acquisitions in Poland, the number of Prussian subjects was only computed at 5,621,500, in a total extent of 56,414 square miles, that is, about 99 to the square mile. At present they probably amount to about eight millions; includ-
The same author, allowing for different territorial arrangements gained by Prussia, and other causes of augmentation that have occurred since the year 1801, reckoned the number of inhabitants at 9,500,000 in 1804. Halfel gives 9,856,000, and Krug 9,700,000. The rapid increase of population in the Prussian dominions must have rendered former accounts of the number of inhabitants in the principal towns very inaccurate. The annexed table exhibits a comparative statement of Mr. Pinkerton's estimates, with those of later German authors.

The margraviate of Anspach and Baireuth, computed at 400,000; and the last acquisitions in Poland at 3,100,000 inhabitants. Prussia, however, has recently ceded the countries of Anspach and Baireuth to the French arrangements in Germany. It has also ceded Neutches and Valdivis, as an independent principality, to marshal Berthier. We have, however, more accurate statements from German writers. Krug (Abriß der Neuen Statistik des Preuß. Staats.) 1805 gives the extent of the Prussian dominions in square miles, and that of the detached territories at 8,800. Halfel (Statistik der Preuß. Staats.) 1805 gives the extent of the Prussian acquisitions in Poland, in 1793 and 1795, at 31,824 square miles. The original population of Prussia appears, from Tacitus and Pliny, to have consisted of the Peucini and Ælissi, Gothic tribes bordering on the Venedi, who were Slavons. The amber of the Ælissi, who seem to have been merely a tribe of the Peucini, continued to be celebrated in the time of Theodoric; but at what precise period these original inhabitants were expelled, or subdued, by the Slavonic tribes on the east, remains uncertain. It is sufficient to observe, that the Slavonic tribes, who extended widely over the north of Germany, after the last Gothic inhabitants migrated towards the fertile regions of the south, in consequence of the decline and fall of the Roman empire, were repelled by the knights of the Teutonic order in the 12th and following centuries, who destroyed great numbers of them, and in some measure restored the original Gothic population. Nevertheless, one-half of the Prussian population, as Pinkerton conceives, must still be considered as Slavonic; and to the former Pomeranians must now be added a numerous accession of Poles. One of the most singular features in the geography of these regions, during the middle ages, is the existence of Jutia, a city of great extent and commerce on the right bank of the Oder in Pomerania, which was destroyed by Waldemar I., king of Denmark, so that the name hardly now exists in a place called Wollin. Farther to the east the Slavonic tribes on the Baltic continued Pagans to a late period; and the country was little known or visited, except by a species of crusaders, who went to assist the Teutonic knights in subduing the Saracens.

As a kingdom, Prussia is of recent origin; and being composed of several ancient states, its historical epochs and antiquities are complex. Without mentioning the smaller detached provinces, Prussia may be considered as comprehending four large divisions, viz. the electorate of Brandenburg, the kingdom of Prussia Proper, the large province of Silesia, and a third part of the ancient kingdom of Poland. The family which now rules these extensive domains was originally the electoral house of Brandenburg, which is derived from Thasillo, count of Holznollern, who lived about the ninth century. Brandenburg had been for some time chiefly peopled by Slavonic nations; but Sigefred, a Saxon count, who was appointed margrave A.D. 927, soon raised it to considerable distinction. In 1373 the emperor Charles IV. allotted Brandenburg to his second son Sigismund, who in 1415, being then emperor of Germany, sold this margraviate and electorate to Frederic, burgrave of Nuremberg, for 400,000 ducats. Frederic, the ancestor of the present race, displayed considerable abilities. Joachim II., elector of Brandenburg, embraced the Lutheran religion in 1539, and this has ever since been the prevailing sect of the state. John Sigismund became duke of Prussia in 1618. Frederic William, furnamed the great elector, succeded his father in 1640; and in 1656 compelled the king of Poland to declare Prussia an independent state, as it had formerly been held of the Polish sovereigns. In 1688 he was suc-
PRUSSIA.

Haffel reckons that of a population of 9,836,000 persons, 5,187,700 are Protestants, 4,325,000 Roman Catholics, the remaining 316,100 being Jews, Greeks, &c. And Krug, who computes the population at 9,700,000, reckons 4,800,000 Lutherans; so that the Lutherans are considerably more numerous, not only than the Catholics, but than all the other sects put together. The Prussian army, according to Hoeffeck, amounts to 178,897 infantry, and 39,867 cavalry; forming, with artillery, &c. a total of 237,609. Another author lays, that the army contains 224,144 men. Hoeffeck reckons the revenue at 36,000,000 dollars, or about 6,000,000l. sterling; and Haffel, who quotes him and many other writers upon the subject, computes it at from 38 to 40,000,000 dollars, or about 63 millions.

The government of Prussia is absolute. Its military force we have already mentioned; at present it does not rank among the maritime powers. The manners of the Prussians are observed to be very different from those of the other Germans. Compared with the Saxons, who are a lively and contented people, they appear dull and gloomy, which some have ascribed in part to their military government. The ruling language of Prussia is the German. The literature of Prussia is of recent origin; nevertheless it may boast of Cherusius, an eminent geographer, Copernicus, so well known as an astronomer, Regiomontanus of Königsberg, Leibnitz, Wolfius, Ramler the poet, Nicolai, an original writer of romances, Butechting, Humboldt, Klaproth, &c. &c. Prussia, however, has not yet produced any artists, painters, sculptors, or architects, of distinguished reputation. This country has several universities, each is of Halle, which in 1682 had 634 students, of Erlangen, which in 1801 had 300 students, of Königsberg, which in 1802 had 300, and that of Frankfort on the Oder, which had 153. There is also a royal school at Posen.

The chief cities and towns of Prussia are Berlin, Königberg, Breslaw, Warsaw, Danzig, Brandenburg, Frankfort on the Oder, Pothdam, Magdeburg, Stettin, Elbing, Glogau, Hirchingberg, and Schweidnitz; which fee respectively. Although inland navigation has not been attended to in the degree which it deserves, and the most important canals are not remarkable for their extent; yet, by joining the Elbe, the Oder, and the Vistula, they form an uninterrupted line of navigation, of fix or seven hundred miles in length; and the traffic upon them, though fettered by the difference of duties in different provinces, by extra-vagant tolls and other impediments, is nevertheless very considerable.

If we except the lines of Sileisia, the manufactures of the Prussian dominions are of small importance. Yet for home consumption they afford glass, iron, brass, paper, and woollen cloth; and Frederic IL introduced a small manufacture of silk. The exports of Danzig consist almost entirely of timber, corn, tallow, and fish articles. Amber constitutes a monopoly of this country; but its commerce is become insignificant. Among the considerable exports may be reckoned excellent timber of all kinds, flax, leather, flax, and hemp; and the linens of Sileisia are sent into Holland, and sold under the name of Dutch manufacture. In return Prussia receives wine, and other products of more southerly and favoured countries. The exportation of amber amounts to near 200 tons annually. Brandenburgh exports timber from Hamburg, to the amount of one million of dollars. In Sileisia (in 1796) 40,603 persons were employed in the linen manufacture, and 13,540 in the woollen. Metz exports much timber to England.

The climate of the Prussian dominions is, upon the whole, cold and moist. That of Brandenburgh, (which fee,) the whole of which is an extensive level of sand, and that of Pomerania (which fee,) may be regarded as less humid than that of Prussia proper, which, as Bürching says, has about eight months of winter, the summers being often deluged with rains. The northern part of Poland, which has fallen under the Prussian sceptre, abounds with forests and marshes, which cannot contribute to the salubrity of the air. The lower parts of Sileisia (which fee,) are regarded as the most healthy and fertile provinces of the monarchy; but the southern and western parts of that duchy, bordering on elevated mountains, being covered with snow, are exposed, even in summer, to severe freezing gales. Prussia proper formerly abounded in woods, and is more fertile than Brandenburg; and this is also the case with respect to the immense plain of Prussian Poland. The soil of this latter territory is loamy and fertile. Prussia proper and the Polish provinces yield every kind of grain and euculent plant that can flourish under such a latitude. The soil of Prussia proper, however, is represented by Mr. Marshall as sandy and ill cultivated; nevertheless the peasants, though oppressed by heavy taxation, being free from the wanton extortions and capricious personal services exacted by the Polish arithocracy, displayed signs of comparative ease and prosperity. The soil being light, two ozen, or sometimes even a small horse and cow, are sufficient to draw the plough. The chief crop, according to this writer, was buck-wheat, which was found to be more profitable than barley; and this grain was generally cultivated, along with a few Swedish turnips, except in the vicinity of Danzig, where abundance of manure assured plentiful crops of wheat.

The chief rivers of the Prussian dominions are the Elbe, the Spree, the Oder, the Vistula, the Prigul, and the Memel, forming, in part, the Prussian boundary on the east. The lakes of Prussia are numerous; especially those of the eastern part; among which may be enumerated the Spalding-fee; and to which class we may refer those inland sheets of water, called "Haff," which are formed at their inlets by the rivers Oder, Vistula, and Memel: such are that of the Oder, Zal expressing Graf Haft; that of the Vistula, or Frich Haft; and that of the Memel, or Kurlitz Haft; which fea respectively. The only mountains in the Prussian dominions are those of Sileisia. (See SUBETIC Chain.) In the N.W. parts of Sileisia are also detached mountains of considerable height, as the Spitzberg, and Grätzberg, the Ruheberg, the Georgenberg, and the Reichenbach. According to Fabrici, the Sileesian mountains yield some silver, tin, copper, and cobalt, with considerable quantities of calamine, lead, and iron; and there are quarries of marble, freestone, alabaster, flate, and potters' clay. Coal abounds near Schweidnitz. Woods and forests abound in Prussia proper, and in the recent Polish acquisitions. Towards Hungary, Sileisia presents a continuation of thick forests, which confine with the elevated mountains to form an insuperable barrier.

The breeds of horses and cattle in Prussia are not differing of particular mention, and few parts are adapted to afford any excellent breeds of sheep. The race of the urus, or large and ferocious wild cattle of Lithuania, which also appeared in Prussia proper, is almost extinct. Among the wild animals may be mentioned the marmot, a species of cat, the lynx, the bear, and the elk. In the Oder is sometimes found the sturgeon of a large size. In the southern districts of Sileisia were formerly mines of gold and silver, and mines of copper and lead still exist; and there are considerable founderies of iron. In the Sileesian mountains are also found chryso-ple, agate, jaspier, and clear crystals of quartz, vulgarly called diamonds; coal occurs in various parts of Sileisia, and the level districts present some good peat-moors. But the moat
most distinguished and peculiar production of Prussian is amber, (which see,) affording yearly to the royal revenue about 5000L. This is chiefly found on the Samland shore of the Baltic, near Pillan, on a neck of land formed by the Frich Haff, which seems to have been the chief seat of this mineral from the earliest ages. Mention is made of an amber mine, in Prussia, 98 feet in depth, where the amber is found between two flabells of carbonated wood, and sometimes adherent. We ought not to omit mentioning salt, which is calculated to afford about 300,000L. yearly to the state. The salt springs at Halé are said to be the most productive in the known world. Silésia presents one spring of hot water at Warnbrun, near Hirschberg; and this is said to be the only mineral water worthy of notice in the Prussian dominions.

**PRUSSIAN BLUE, in Chemistry, a colour used by artists and painters, of a fine blue. It is composed of prussiun iron, and the earth precipitated from alum, or pure aluminate.**

Under the article Prussic Acid we refer to the history of this substance. We shall here give the methods employed in the large way for manufacturing Prussian blue, as practised on the continent and in this country.

The first method employed to obtain Prussian blue, was first to calcine dried bullock's blood with potash, in a crucible at a red heat. The mixture was now poured into a quantity of water. During the heat, the animal substance afforded the prussic acid, which was caused by the potash forming the prussiun of potash. This compound dissolved in the water, constituted what was then called the Prussian lioxium. To this was added a mixture of sulphate of iron and sulphate of aluminate in a state of solution. The prussic acid takes the iron, while the potash combines with the sulphuric acid. The excess of alkali precipitates the aluminate from the alkali, which becomes mixed with the prussiun of iron, and forms the substance which, when separated from the liquid, washed and dried, forms a blue concrete mass, called Prussian blue. When an excess of sulphate of iron is used, the excess of alkali will precipitate the iron in the form of an oxyd, which soon becoming yellow, gives the mass a green colour, which arises from the yellow precipitate being mixed with the blue. In this case the addition of some acid will be necessary to take up the oxyd of iron, in order to produce the change from green to blue. The muriatic acid is generally employed. It is better, however, not to have to add an acid at this stage of the process, since it in common combines with the aluminate which is essential in forming a body for the colour, as well as to dilute the colour.

It is now certain that the black oxyd of iron, which is that combined in green vitriol (sulphate of iron), does not form a perfect blue with prussic acid. The colour is at first green, and does not become blue but by exposure to the air, or by the addition of oxygen in some way or other. The oxysulphate of iron, which in the state of solution is of a reddish-brown colour, contains the red oxyd of iron. When the prussiun of potash is added to this solution, a deep blue precipitate is instantly formed. Some mineral waters in the vicinity of coal-mines contain a great quantity of the oxysulphate of iron, as well as some sulphate of aluminate. Such a situation would be a definable object for the manufacturer of Prussian blue.

A great variety of animal substances may be employed for producing the prussiun acid besides blood. The horns, hoofs, and the refuse of the skins of animals, have all been employed with success for this purpose. The refuse leather of shoemakers and curriers might be used to good purpose.

**PRUSSIAN GREEN. See Green and Prussic Acid.**

**PRUSSIATS, in Chemistry, a class of salts formed by the prussiun acid with the different alkalies, earths, and metallic oxyds. These with the latter are generally insoluble in water. Two of the earths form insoluble salts with the prussiun acid; namely, yttria and zirconia. The only metallic prussiun which appears to be soluble, is that of mercury, exclusive of the metallic bases of the earths and alkalies.**

For combinations of prussiun acid, see the different bases, as potash, soda, iron, &c.

**PRUSSIC ACID, a substance which possesses some of the properties of an acid in its combinations with earths, alkalies, and metallic oxyds, and has been called among the acids.** If, however, the doctrine of Lavoisier be correct, it is not entitled to be classed among these bodies, inasmuch as it has not been proved to contain oxygen.

This acid in its pure state is a liquid as clear as water, and extremely volatile. Its most conspicuous property is that of precipitating metallic oxyds of different colours. With oxyd of iron it forms a beautiful blue precipitate, and with the oxyd of copper it forms a pigment of an intense brown colour.

It was first discovered, in combination with potash, by a colour-maker of Berlin, of the name of Diebsc. He procured some alkali from Dippel, a celebrated chemist, for the purpose of precipitating the colouring matter from cochineal, with which alum and green vitriol were also dissolved. The alkali which he added for that purpose produced a beautiful blue precipitate. Dippel had been heating the alkali with some animal matter, for the purpose of obtaining an animal oil, for which he became celebrated. The prussiun acid was formed and united to the alkali, which caused the blue precipitate in Diebsch's solution. Dippel afterwards made this blue precipitate for sale, which he kept a secret for some time. It was called Prussian blue, from the place of its discovery.

This substance, which became celebrated for its fine blue colour, was sold at a great price, and became a subject of research with other chemists. Dr. Woodward got some information of its preparation from Germany, and published an account of the process in the Philosophical Transactions for 1724. He recommended four ounces each of nitre and tartar to be projected into a red-hot crucible, for the purpose of procuring a tolerably pure potash; to this he added four ounces of dried bullock's blood, mixing them intimately. These were put into a covered crucible, and heated in a moderate red heat, till they ceased to give out smoke, keeping them at a low red heat for some time afterwards. The contents of the crucible were now thrown into four pounds of water, and boiled for some time. The clear liquor was now decanted, and fresh water boiled upon the residuum, for the purpose of extracting all the soluble matter. The separable clear washings being collected, the mass was evaporated to four pounds. He then dissolved one ounce of green vitriol, and eight ounces of alum, in four pounds of boiling water. He then mixed the above liquid with this solution, from which he precipitated a substance of a greenish-blue colour. To this was added muriatic acid, till the precipitate assumed a fine blue colour. This powder, being separated and dried, assumed the form of a hard blue substance, which was called Prussian blue.

It was soon found by other chemists, that almost any animal substance heated with an alkali, afforded a blue precipitate with iron. Geoffroy and Macquer conceived, that the alkali combined with the phlogiston of the animal substance, which it gave up to the iron, reducing it to its metallic form, from which they accounted for the blue colour.
The latter chemist found, that Prussian blue lost its colour by heat, leaving the iron in the flake of red oxyd. He found also, that when Prussian blue was boiled with an alkali, it lost all its blue-colour, and farther found, that the alkali had acquired the property of precipitating iron of a blue colour from a solution of that metal.

Little more was discovered relative to the prussian acid, till the researches made in it by the celebrated Scheele in 1782 and 1783.

The first new fact he observed in the combination of this acid with potash, which till this time had been called the phlogisticated alkali, was its losing the property of precipitating iron of a blue colour, by exposure to the air for some time. He rightly suspected, that the substance which combined with the alkali, giving it the property of producing the blue precipitate, was diffigured from the alkali by the carbonic acid of the atmosphere. To verify this conjecture, he exposted the alkali to carbonic acid gas, and soon found that it deprived the liquid of the property of producing the blue colour with iron. He further confirmed this opinion, by placing in the same vial with the gas, over the liquid, a slip of paper which had been dipped into a solution of iron, and a little alkali dropped on the paper to precipitate some iron without leaving an excess of alkali. No sooner did the carbonic acid diffigure the prussian acid, which becoming volatile, rose into the upper part of the vessel, than the paper began to assume a blue colour, arising from the volatile acid combining with the iron. That this effect was produced by the superior affinity of the carbonic acid for the alkali above the prussian acid, was proved by other acids having the property of diffiguring the colouring matter.

This very ingenious experimenter, with a view to obtain the prussian acid in a separate flake, mixed ten parts of Prussian blue in powder, with five parts of red oxyd of mercury, to which he added thirty parts of water. On boiling the mixture a few minutes, the blue colour disappeared, the liquid at the same time assuming a greenish-yellow colour. This liquid was separated by the filter, the residuum being wafted with boiling water, and the waftings added to the filtered liquid. In this process, the oxyd of mercury separated the iron in the flake of red oxyd, and at the same time combined with the prussian acid, forming a soluble compound. This solution he now poured upon parts of very clean iron filings, adding at the same time one part of strong sulphuric acid. The iron became oxidized by the mercury, and diffused by the sulphuric acid, the mercury being reduced to its metallic form. The colouring matter of the Prussian blue was at the same time set free, and being volatile, was separated from the other substances by distillation with a gentle heat. The prussic acid acid thus obtained in a liquid form. A small portion of sulphuric acid was added over the same time, which he afterwards separated by a second distillation from carbonic acid.

By the distillation of Prussian blue, he was inclined to suppose that the colouring matter was a compound of ammonia and carbon, and that it loses its blue colour by oxidizing. He then pushed to the bottom of the mafs small pieces of sal ammoniac (muriate of ammonia). As soon as the fumes of the salt had escaped, he poured the whole, while red-hot, into water. On examining the solution, he found that the colouring matter had been formed.

We are particularly indebted to Berthollet, for the true analysis of prussian acid; he found that it was composed of hydrogen, azote, and carbon, forming a peculiar substinance, so that although Scheele had reason to conclude it a compound of carbon and ammonia, Berthollet drew a very different conclusion, yet both agreed in its being formed of the same constituents.

The latter chemist found, that when oxybromuric acid is mixed with prussian acid, the former loses its oxygen, assuming the form of common muriatic acid. The prussic acid, which takes the oxygen, becomes more odorous and volatile, and acquires the property of precipitating iron, not of a blue, but of a green colour. This he has denominated oxyprussic acid.

Scheele obtained the prussian acid in the form of colourless liquid. It had a strong smell, resembling peach blossom and bitter almonds. It has a sweeter acid taste, having an irritating effect upon the tongue and throat. It is said to be very poisonous. The deleterious effects of the bitter almond, and the kernels of several fruits, are said to arise from the presence of this acid.

The prussic acid has been obtained in a flake of greater purity than that obtained by Scheele. For this discovery we are indebted to Gay Lussac. An account of his experiments is given in the Annal. de Chim. vol. lxxvii. p. 128.

He put the prussiat of mercury into a retort, and separated it in a similar way to that used by Scheele. He provided several receivers, with two necks each. The first, which was connected with the retort by one of its necks, contained a mixture of carbonic acid of lime and dry muriate of lime. The first was to take up any sulphuric acid which might come over, and the latter to arrest the progress of the water which might come over with the acid. The first receiver was connected with the second, that with a third, and so on to four. Each receiver was surrounded with a freezing mixture. A gentle heat being applied, the acid came over into the first receiver, where it became deprived of its water. The pure acid, which was highly volatile, was carried forwards to the next receiver, where it became condened. When the freezing mixture was removed from the receiver containing the prussic acid, and a gentle heat applied, it passed over to the next receiver. The latter receiver, being similarly treated, caused it to pass to the next in succession, and so on to the last. By this means acid is obtained in a flake of complete purity, and possesses the following properties.

It appears in the form of liquid, perfectly colourless. Its taste is at first cooling, but afterwards acid and irritating; it boils at 79.7° Fahrenheit. Its density at 44.6° Fahrenheit is 70553, water being 1. At 56° it supports 14 inches of mercury. At 68°, if it be exposed under any given volume of air, it increases the elastic volume five times, provided a sufficient quantity of the liquid be present. It becomes solid at 50°. If a drop of it be exposed at the end of a glass rod, the evaporation is so rapid that the drop freezes.

The prussic acid in its simple form is applied to no use. Its greater volatility may present some advantages in producing great cold. Combined with lime, and with potash and iron, it is employed as a sensible re-agent in detecting the presence of iron in mineral and other situations. It forms infusible compounds with the metallic oxides, and hence is of importance in chemical analysis. See PRUSSIAN BLUE.

Blood appears to be the most proper sustinance for affording it, from the facility with which it may be obtained. The great nuisance attendant on the drying of blood may be obviated by distilling it, and burning the fetid fumes with the inflammable gas furnished at the same time. In this process a large quantity of carbonate of ammonia may be obtained. The residuum in
in the retort is a shining black coal, which, when calcined with potash, will furnish the same quantity of pruffic acid, which the blood would have furnished in any other state less dried.

This carbonaceous matter is pretty much the same, whether furnished from the blood or other parts of animals, perhaps with the exception of the bones.

In the large way, one hundred pounds of potash are put into a thick iron vessel, capable of bearing a brisk red heat for a length of time. The fire is to be raised till the potash is fuséd. Twenty-five pounds of the powdered coal residue above-mentioned, are now to be rapidly stirred into the fuséd potash. In half an hour twenty-five pounds more carbon must be added, treated as before, and at the end of a similar space of time, another twenty-five pounds. The mafs is now to be constantly stirred, the heat being all the time sufficient to keep it in a soft and plastic state for several hours.

During the formation of the pruffic acid, a reddish colored flame appears upon the surface of the melted mafs. The finishing of the process is marked by the flame changing from a red to a pale blueish tinge. At this period the mafs is to be removed as speedily as possible into a large vessel of boiling water, and stirred, to promote the solution of the pruffat of potash. Let the dregs settle, and decant off the clear liquor. Add fresh water, and apply a boiling heat to dissolve what may remain, and decant the second liquor, and so on till the water ceases to have any considerable taste. The several decantations are now mixed together. If the liquor is not sufficiently clear, it must be filtered through flannel or linen.

The alum and green vitriol, which are now added to form the blue precipitate, are in very different proportions, from equal parts, to the proportions of two to one. The quantity of these mixed facts for the above quantity of pruffat of potash is about two hundred pounds. They are first dissolved in water and then added.

The precipitate of Prussian blue is immediately formed, and when it subsides the liquor is to be poured off. Boiling water is added from time to time, for the purpose of washing off the sulphate of potash. The pulp mafs of Prussian blue is now to be put into bags, and pressed. The mafs is then exposed to the air to dry, and it assumes at the same time a deeper colour, and acquires a hard confection, exhibiting a bright glossy fracture of a bronzy hue, but when ground for the use of painting, is a superb blue.

Lime and alkalies decompose Prussian acid, and hence destroy its colour, producing a dirty red. Soap which contains alkali has the same effect. See Prussian Blue, under Iron.

PRURAL, in Geography, a river of Poland, which rises in the S.W. part of the new kingdom of Galicia, on the borders of Hungary, passes through Moldavia, and joins the Danube near Renay in Beffarabia. In the year 1711, Peter the Great, in a war with the Turks, encamped his army on the banks of this river, not far from Jaffy, in a situation so disadvantageous, that he seemed to have no hope but that of cutting his way through the enemy; with this resolution he retired to his tent, in an agony of despair, absolutely prohibiting any person from entering it under pain of death. At this important juncture, the principal officers, and the vice-chancellor Shafirroth, assembled in the presence of Catharine, and drew up certain preliminaries, in order to obtain a truce from the grand vizier. In consequence of this determination, plenipotentiaries were immediately dispatched, without the knowledge of Peter, to the grand vizier; and a peace obtained upon more reasonable terms than could have been expected. This is called the "peace of Pruth."

PRYM. See Prum.

PRUYSSEN DROOGTE, a rocky islet at the east entrance of the straits of Sunda. S. lat. 5° 20'. E. long. 106° 48'.

PRYCK-Spur, in Military Antiquities, a fort of spurs, which came into use about the time of the conquest, having only a single point, like the gaffle of a fighting cock. The knights of the three or four reigns succeeding the conquest used this kind of spur, after which the rouelle, or wheel-fur, came in fashion.

PRYGGEE, in Geography, a town of Pegu; 38 miles N.E. of Perfaim.

PRYK, a kind of service or tenure, and, according to Blount, signifies an old fashioned spur with one point only, which the tenant holding land by this tenure, was to find for the king. "Per servitium inveniendi unum equum, unum faccum, et unum pryk in Guerra Wallis." 1 Ric. II. And in the time of king Henry VIII. light horsemen in war were called prickers, because they used such spurs or pryks, to make their horses go with speed.

PRYMISL, or Prussian-law, in Geography, a town of Bohemia, in the circle of Czallau; three miles E. of Deutch Brod.

PRYNNE, William, in Biography, a learned lawyer and antiquarian, celebrated as a leader among the Puritans in the reign of Charles I., was born at Swanwick, in Somerfetshire, in the year 1600. He was educated in grammar learning at Bath, and afterwards entered at Oriel college in Oxford, where he remained till he had taken his bachelor's degree at about the age of 20. He then was entered at Lincoln's Inn for the study of the law, which he pursued with great avidity, and became in process of time barrister, bencher, and reader of the society. By his attendance in early life on the lectures of Dr. John Preston, he became attached to the principles of Puritanism, and in 1627 he appeared as a writer. It was not, however, till the close of 1632, that he published an elaborate work, entitled "Hilfrio-matrix," in which he inveighed very bitterly against theatrical exhibitions and public spectacles of all kinds. The book was regularly licensed; nevertheless, on account of some reflections against women actors, which were supposed to be levelled against the queen, who had taken a part in a pastoral performed at Somerfet-house, he was prosecuted in the Star-chamber, and sentenced to a fine of 500l.; to be expelled the university of Oxford, and Lincoln's Inn; to be degraded and disabled to pursue the profession of the law; to stand twice in the pillory, loosing an ear each time; and to remain a prisoner for life. This savage sentence, which may be taken as a sample of those cruel oppressions, that in a few years excited the people to overthrow the government which dealt in such barbarities, and brought the king himself to the block, was executed in all its rigour, chiefly at the instigation of Laud, who could never forgive Prynne's previous attacks on episcopacy, and who was steeled against every feeling of humanity. Prynne bore his sufferings like a man, supported by the con-
The sentence was put in execution in 1637, and he was sent for his imprisonment first to Caernarvon castle, and afterwards to the isle of Jersey. His spirit was not to be subdued by suffering; there was that elasticity in his mind, which was equal to the force of every blow, and it almost instantly recovered from the pressure. He continued to write till the meeting of the parliament of 1640, when he was chosen representative for Newport, in Cornwall, and by order of the house of commons was released. He entered London, with many other sufferers in the same cause, in a sort of triumphal procession, and presented a petition to the commons for damages against his persecutors. He now became distinguished by his speeches and writings as an opposer of episcopacy, and when the impeachment of Laud was undertaken, he was appointed the chief manager. After the parliament had become victorious in the civil wars, he was appointed one of the visitors to the university of Oxford, and displayed great zeal for the establishment of Presbyterianism, but to his honour be it spoken, he used all his influence to promote an accommodation with the king. It was in his speech, in behalf of his majesty, that he affirmed, that in all his own services and sufferings in the cause, he had neither received redress nor reward, but that he had continued, at his own expense, to maintain his writings the justice of the parliament’s proceedings, to the convenience of great numbers at home and abroad. It is well known, by those who are acquainted with the history of that period, in what manner the army interfered to prevent an agreement with the king, and for his interference in behalf of his majesty, Prynne was with other members excluded and imprisoned. He afterwards became a bitter enemy of Cromwell and his party, the infant he saw in them enemies to the public liberties of his country; on this account he was, in 1650, thrown into prison without any particular cause being alleged in the warrant. He appealed to Magna Charta, and was liberated, and in the following year imprisoned at Taunton and Pendennis. He was still the industrious and ardent writer in the cause of liberty, civil and religious, and published between the years 1655 and 1660, no fewer than forty-six tracts. In the year 1659 he refused his place in the house of commons, and weared out by the tyranny of the protectorate, he became one of the most eager for the restoration of Charles II., hoping, no doubt, that he might be bound by such rules of action, as should render him a patriotic monarch. In 1660 he sat in the parliament, as it was called, and was appointed to the office of chief keeper of the records in the Tower, for which he was undoubtedly well qualified. In the following year he printed a pamphlet on a bill then depending in parliament, which drew upon him the cenfure of the house of commons, and he was probably convinced of his error, for he submitted to ask pardon for the offence which he had done. His latter years he occupied in writings connected with his office in the Tower. He died in 1660. He was unquestionably a man of great learning, and the most indefatigable industry. It has been said he lived solely for the purposes of writing, and Wood supposes he must have written a sheet a day from his coming to man’s estate till his death. His writings, however, were the effects of his public spirit and patriotism, and he lived, not to write, but to oppose tyranny wherever he found it, and writing was the instrument he made use of to effect his purposes. He was by his contemporaries, the moderate men of his time, as well as by the governments which he opposed, looked upon as a schismatic and libeller; but without such men, all that is excellent in our constitution would long since have been lost. Prynne, therefore, merits the regards of posterity, and ought to be treated with the reverence to which every ardent friend of the liberties of the country has a claim. His works amounted to forty volumes folio or quarto. The most valuable are, his “Collection of Records,” three vols. folio. His edition of “Sir Robert Cotton’s Abridgment of the Tower Records,” and his “Observations on the Fourth Part of Coke’s Institutes.” Biog. Brit. Hume.

PRYTANEUM, πρύτανειον, in Antiquity, a considerable building in Athens, where the council of Prytanes assembled, and where those who had rendered any signal services to the commonwealth, were maintained at the public expense. See Athens.

PRYTANIS, or Prytanes, the first magistrate in most of the cities of Greece.

At Athens there were fifty Prytanes, at Corinth there was but one, who was the same with what the archon was at Athens.

The Prytanes of Athens were the senators who composed the grand council that governed the state; and correspond to what we now call the “flutes general of the United Provinces.”

Fifty of these were chosen each year out of each tribe; and to these were nominated fifty more, to supply the places of the former, in cases of death, or mal-administration.

The tribes took the government by turns, each after the other, for the space of thirty-five days. This was an establishment of Solon. Scaliger is mistaken, when he says the tribes took their turns every day.

All the fifty Prytanes of the tribe did not govern together during these five weeks; but in companies, ten at a time, chosen by lot; seven days each company; after which another tribe came into office, and had its five weeks after the same manner.

PRTANITIDES, a name given to those widows who at Athens, and throughout all Greece, had the sacred fire of Vesta committed to their care. The cult of the Greeks, in this respect, differed very much from that of the Romans; who allowed none but virgins to tend this sacred fire, whence they were called Vestals.

They had the appellation Pyrnanides from πρύτανειον, a common name to all places sacred to Vesta.

PRZEBORS, in Geography, a town of Poland, in the paltinate of Zambor; 20 miles N.N.W. of Malogocz.

PRZEBAUTSCH, a town of Bohemia, in the circle of Chrudim, on the Elbe; 12 miles N.W. of Chrudim. N. lat. 49° 58’. E. long. 15° 30’.

PRZEMER, a town of Lithuania; 22 miles N.N.W. of Grodno.

PRZEMENTZ, a town of the duchy of Welsh; 32 miles S.W. of Pofen.

PRZEMILLO, a town of Bohemia, in the circle of Chrudim; 6 miles S. of Chrudim.

PRZEMISLAU, a town of Austrian Poland, in Galicia; 20 miles E.S.E. of Lemberg.

PRZEMYS, a town of Poland, in Austrian Galicia, defended by a castle, the seat of a Greek and Roman bishop; 4 miles W. of Lemberg. N. lat. 49° 36’. E. long. 22° 45’.

PRZEROLID, a town of Lithuania; 8 miles W.S.W. of Troki.

PRZEROW. See PRZEM.

PRZESTITZ, a town of Bohemia, in the circle of Pilzen; 6 miles S. of Pilzen. N. lat. 49° 33’. E. long. 13° 26’.

PRZINDA. See FRANENBURG.

PRZICOVOVUS. See FRAUBEL.

PRZICOVOUS, Sambul, in Biography, an eminent Polish knight, was born about the year 1592. He was initiated in the elements of learning in his native country, and commenced his academical course of studies at the university of Altdorf. Here he probably embraced the Unitarian doctrine, which obliged him to retire to Holland, and he purified his studies at the university of Leyden. When he was only eighteen years of age he published anonymously "Differatio de Pace et Concordia Ecclesi," which was so ably written, as to be ascribed to the pen of Epictocus. Having spent some years at Leyden, in the cultivation of science and learning, he returned to Poland, where his talents recommended him to the notice and confidence of king Jadwiga Sigismund. He was appointed to fill different posts of honour and authority; rendering his name illustrious by his valour in the field, and his wisdom in the cabinet; by his persuasive eloquence and invincible fortitude, and at the same time he was eminent for his distinguiished virtues. In his leisure moments he drew up a panegyric on Jadwiga Sigismund, king of Poland, in which he extolled that prince's clemency to the Diffidants, and pointed out the important advantages which the country derived from it. Under his administration, the followers of Socinus met with wonderful success in propagating their opinions, and establishing churches in the Polish territories. Their flourishing state induced Przicovius to compose "A History of the Unitarian Churches in Poland," but the work was lost during the form of persecution in which they were afterwards involved.

In 1648 he experienced a sad reverse of fortune, on the breaking out of the war with the Ccphacks, who plundered and laid waste the country, particularly the districts bordering on the Borysthenes or Dnieper, where the possessions of Przicovius were chiefly situated. This was soon followed by the calamities in which the Unitarians partook, in common with the rest of their countrymen, during the civil wars which overspread Poland, in which the Austrians, Muscovites, and Swedes took part, as auxiliaries, with the conflicting factions. After peace was restored to the country, our author and his Unitarian brethren were harassed by the incessant persecutions of the popish party, till at length, in the year 1658, a general proscription was passed against them. By this act they were, for ever, banished from their country, being allowed a year in which they might dispose of their property. Means were, however, found to deprive them of the benefit of this pretended indulgence, and the greater part of them were entirely stripped of their honours and estates, in which number was Przicovius. After he had become an exile from his country, the reputation of his virtues and learning procured him an asylum with the elector of Brandenburg, who gave him the honourable appointment of privy-counsellor. With the salary which he derived from this office he maintained some families of his fellow sufferers in his own house, cheerfully submitting to privations, that he might be able to afford more relief to his persecuted brethren, and making no provision for the widow of his only son, and his two grand-children by her, but trusting that a kind Providence would raise them up protectors and friends. On account of his acquaintance with theological subjects, his skill and long experience in the management of business, and because his name was in great repute among foreigners, a synod of Unitarians, held in Silesia in 1663, devolved on him the office of maintaining a correspondence with their brethren in other nations, with a view of promoting the interests and increase of the whole community. He died in 1670, at the age of 78. Besides the pieces already noticed, Przicovius was author of "Cognitiones sacrè de initiatìis Matthaei et Epiistolae Apostolicæ," "Vita Pauli Socini Senenis," "Demonstratio quod neque Pater Domini nostri Iesu Christi per Metaphorem Pater, neque Filius ejus unigenitus per eandem Metaphorem Filius, dicit quæ aut debet," with other pieces. It may be right to mention here that the collection entitled "Bibliotheca Fraenum Polonorum," is not complete without the works of Przicovius.

PSADURIA, in Mineralogy, a genus of rough stones of a plain uniform structure, not laminated, but splitting equally in all directions.

PSAGDA. See SAGDA.

PSALM, from ἕλσις, Ising, a divine song or hymn.

The denomination psalm is now appropriated to the one hundred and fifty psalms of David; and the name canticle, or fong, is given to other pieces of the same kind, composed by other prophets and patriarchs.

The ancients, as is observed by St. Augustine, made this difference between a canticle, or fong, and a psalm, that the former was sung by the voice alone, but the latter accompanied with a musical instrument.

The psalms, in the ancient editions, are divided into five books; nor is David's name found at the head of more than seventy-three of them; though some, and among the rest St. Augustine and St. Chryfoftom, attribute all the hundred and fifty to him without exception.

The Jews, however, were always of another opinion; and it is certain there are some few, at least, that are not his. St. Jerome observed, among the number, several that were composed a long time after David. Dupin adds, that it is difficult to ascertain the authors; all we know of the book is, that it is a collection of fongs compiled by Ezra.

Gradual psalms were those anciently sung on the steps of the temple. The penitential psalms were not formerly the same with those now called by that name.

The psalms of David exhibit to every reader the most plain and distinguishing marks of poetical writing; the peculiar character of which has been described under the articles PARALLELISM, Hebrew Poetry, and Prophetic Poetry. The book of psalms contains specimens of the various kinds of poetical composition. To the didactic, we may refer the 119th, the other alphabetical psalm, and some few others; about a seventh part of this book consists of elegies, composed on occasions of distress and mourning; the 42d psalm, in particular, is in the highest degree tender and plaintive; and the reader of it in the original, who adverbs to the division of the periods, and the resolution of them
them into their constituent parts or members, will find that
the periods spontaneously divide into verses of nearly equal
length and measure, exactly similar to those of the four
first chapters of the Lamentations of the Lamentations, which
constitute the established metre of the Hebrew elegy. (See
Lamentations.) The whole of the 19th psalm consists
also of the same kind of verse, except the epode, which
contains two long verses of the same kind, and one shorter,
which last is once repeated. The 43d psalm, too, seems
to be constructed upon similar principles, containing eight
of the same kind of verse, with the same epode, and since it
is written in the same train of sentiment, the same style, and
even apparently in the same metre, it ought not perhaps to be
separatated from the preceding psalm, but to be considered
as a part or continuation of the same composition; and if
this be true, the whole poem consists of three parts, almost
equal and alike, each of which is concluded by the same
intercalary period or stanza. For another most beautiful
poem of the elegiac kind we refer to the lamentation of David
for Saul and Jonathan; 2 Sam. i. 17—27. Moreover, the
whole book of psalms may be considered as a collection of
sacred odes; in which we find the ode exhibited in all the
varieties of its form, and supported with the highest spirit
of lyric poetry; sometimes sprightly, cheerful, and trium-
phant; sometimes solemn and magnificent; sometimes
tender and soft. As the compositions of David are of the
lyric kind, there is a greater variety of style and manner in
his works than in those of Job and Isaiah. The manner in
which David, considered merely as a poet, excels, is the
pleasing, the soft, and the tender. In his psalms, there
are many lofty and sublime passages; but in strength of descrip-
tion he yields to Job; in sublimity, to Isaiah. It is a sort
of temperate grandeur, for which David is chiefly distin-
guished; and to this he always soon returns, when, upon
some occasions, he rises above it. The psalms, in which he
touches us most, are those in which he describes the happi-
ness of the righteous, or the goodnes of God; expresses
the tender breathings of a devout mind, or sends up moving
and affectionate supplications to heaven. For other spe-
cimens, we refer to the article Ode. For other psalms re-
ferred to the class of Idyllions, see Idyllion. Blair's
Lectures, vol. iii. Lowth's Lectures on Heb. Poet. by
Gregory, vol. ii.

PSALMANAZAR, George, in Biography, a literary
impositor who assumed that name, was probably a native
of the south of France, though he never made known
either his country or family. He was supposed to be born
about 1680, and educated partly at a Franciscan seminary,
then at a Jesuits college, and at last at a university. He
seemed to have had an uncommon facility in the attainment
of languages, but was not sufficiently steady to render him-
self tolerably perfect in any. At an early age he left the
college, in order to support himself by private tuition.
But this was not at all agreeable to his disposition, and he
went to Avignon, where he pretended to have left his
father's house on account of ill usage through his attach-
ment to the Roman Catholic religion. He next assumed
the character of a young Irish student of theology, who
had left his country for the sake of religion, and was going
on a pilgrimage to Rome; and having obtained a certificate,
and equipped himself with a suitable garb, he set out on
his rambles. After passing through several scenes he
enlisted for a soldier, and became acquainted with one
Jones, chaplain to a Scotch regiment. This man soon dis-
covered Psalmanazar to be an impostor, but instead of ex-
pelling him, immediately conceived a plan of more extensive
fraud, by which he himself might reap some profit. He
engaged the young man to act the part of a convert from
heathenism, and having written a letter to Dr. Compton,
bishop of London, with a flattering account of his pupil, he
baptized him in a public manner, procured his discharge,
and in consequence of the bishop's invitation, proceeded
with him to London. The learned prelate listened to his story,
while he endeavoured to pass for a native of the island
of Formosa, of which little was known to Europeans.
Innes let him about translating the church catechism into
a pretended Formosan language, which he had framed, and
he next employed him in writing a "History of Formosa." Though
he had no other materials than what his own inven-
tion would furnish, aided by the account of Formosa
by Varenius, he drew up such a work as excited the curi-
osity of the public, and was regarded, at that time, as con-
taining genuine information; though in fact, when examined
with a careful and scrutinizing eye, it was found full of in-
consistencies and improbabilities. A second edition was pre-
paring, when the bishop of London sent Psalmanazar to
Oxford to pursue his studies in that seminary. He re-
mained there six months, and then returned to London, but
his patron discredited him, or failed to put him in any
suitable way of living, for a few years he held his
name to a manufacturer of a kind of white porcelain,
which was to pass as a secret communicated by Psalma-
azar, and was advertised by the name of the "curious
white Formosan work." He next endeavoured to get
some money as a medical empiric, and as a teacher of lan-
guages and fortification; but these resources were inadequate
"to his wants, and he became clerk to a regiment of dra-
agoons, which marched to the north in the year 1715, and
in that character he visited many parts of the kingdom.
Without following him through all the changes of this
part of his life, it may be observed that he acknowledges
himself to have been dilatory, unprincipled, and void of
any fixed purpose. At length he obtained some steady
employment as a translator, and it is said, that Law's Serious
Call, with other devotional works falling into his hands, he
was awakened to a sense of his past misconduct, and formed
resolutions of amendment. He entered deeply into the
study of the scriptures, and of the Hebrew language,
in which he soon acquired such a proficiency that he com-
pounded a dramatic piece in Hebrew verse, entitled "David
and Michael." His reputation for learning caused him to
be engaged as one of the writers in the Universal History,
which was his principal literary labour, and employed much
of his time. The history of the Jews, of the Celts, and
Scythians, of the Greeks at the early periods, the ancient
Spaniards, Gauls, and Germans, were the chief parts
which he contributed to this voluminous work. It does
not appear when he dropt the imposture of being a For-
mosan convert; but in his last will, dated 1752, there is an
explicit and penitential confession of his criminality in
adopting that fraud, and supporting it by his pretended
account of the island. After his death, in 1763, his life,
written by himself, was published, from which farther in-
formation may be obtained. See Memoirs of the Life of
Psalmist commonly known by the name of George Psal-
manazar.

PSALMODIST, in the Church of Rome, one of the lower
ecclesiastical orders, the fame with what among us is called
clerk, precentor, or singer.

PSALMODIER, Fr., is, in the Romish church, re-
citing the psalms in a particular manner, between singing
and speaking; it is singing or chanting, because the voice
is sustained in musical tones; it is speaking, because the
words are almost always uttered in the same tone.

PSALMODY,
PSALMODY, the art of singing psalms.

PSALMODY, Metrical. The metrical psalmody, which John Hus, Jerom of Prague, the Bohemian Brethren, and Martin Luther, published in the German language for the use of the common people, that priests might not be wanted, was soon imitated in other countries. The celebrated poet, Clement Marot, in France, having, about the year 1540, verified and dedicated to Francis I., about thirty of the psalms, from a prose translation by the famous Hebrew professor Vatable, they soon acquired such favour at court, as to be sung, in spite of the cenfures of the Sorbonne, by the king, queen, and chief personages of the kingdom, to the tunes of the most favourite songs of the times. Marot, who had long been suspected by the Catholics of heresy, and once thrown into prison for his religious opinions, fearing new persecution, fled to Geneva, where he put into French verse twenty of the psalms. These, with the thirty that had been published at Paris, were printed at Geneva in 1543, with a preface by Calvin himself, but without music. Marot dying the next year, Theodore Beza verified the rest of the psalms in the same manner, and the whole hundred and fifty were published at Strasbourg in 1545. Bayle says, that during the whole sixteenth century there was no French poetry, that approached the fift and natural grace of that with which Marot furnished it. And Menage says, that the French owe the rondeau, the madrigal, and modern form of the fomar, to this poet, who first confined himself to the mixture of masculine and feminine rhymes, though he did not always strictly adhere to their alternate use, as a law. The fale of his fifty psalms was so rapid, that they could not be printed fast enough to supply the public demand for them; more than ten thousand copies having been sold in a very short time. When those of Beza were added to them, their favour still continued, and they were sung not only by the Lutherans and Calvinists, but the Roman Catholics. As yet, indeed, they had never been used in the conventicles of the sectaries, but in private, merely as moral and spiritual songs, to facultate tunes, such as were easy to learn, and play on viola, and other instruments.

It was not till the year 1553, when these psalms appeared in the same book as the catechism of Calvin, and the Genevan Liturgy, that the Catholics took the alarm, and prohibited the further publication and use of them. After which, to sting a psalm in France was a declaration of heretical principles, and Psalmodius became another name for Reformer, Huguenot, and Calvinist. Indeed, the purposes to which this lamentable music was often applied, during the struggles and growth of Calvinism, seems to have been worse than the music itself, as, according to writers of the opposite party, it was made the signal of tumult, sedition, faction, and rebellion.

The chronology of Calvinistical psalmody seems to be this: Zwinglius, the chief of the Protestants in Switzerland, before the arrival of Calvin at Geneva, had introduced among them the same kind of metrical psalmody as John Hus and the Bohemian brethren had recommended to their followers in Germany; and this seems to have continued till the year 1543, when the psalms of Clement Marot, with a preface by Calvin himself, were first published at Geneva, with the single melodies of Guillaume Franck, an obscure musician, if such he may be called, whose name has never had admission in any catalogue of books, or been prefixed to any musical publication, that we have been able to discover.

Among the most celebrated composers of music to Calvinistical psalms, and spiritual songs, must be ranked Claude Goudimel, a musician of Franche-Comté, who seems to have lost his life at Lyons on the day of the massacre of Paris. See Goudimel, and Claude le Jeune, of whose psalms we have three different editions of the music, in three different forms, and in different countries: for though, according to Bayle, they have never been sung in the church of Geneva, yet, in Holland, and in France, before the revocation of the edict of Nantes, as they were universally sung in Calvinistical churches and conventicles, except at Geneva, they went through more editions perhaps than any musical work since the invention of printing.

Claude le Jeune was doubtless a great master of harmony. The manner in which he first set twelve of the psalms of Clement Marot's French translation, in four and five parts, that were dedicated to the duke de Bouillon in 1556, at that time head of the French Huguenots, very much resembled the style in which our old masters used to write upon a plain fong: as one of the parts is continually singing an ancient melody, or well-known psalm-tune, while the rest are declating, or singing in florid counterpoint. In some of these there is great merit of composition in the ingenuity and contrivance of the several parts. See Claude le Jeune.

The establifhing metrical psalmody in England, was the consequence of the reformation, and our communication with foreign Protestants.

Several of the psalms were translated into English metre during the latter end of the reign of Henry VIII. by Sir Thomas Wyatt, and printed in 1549. The earl of Surrey wrote a sonnet to their praise, and translated others himself, but both his version and that of Wyatt are lost. Indeed almost all our poets, good and bad, have attempted to translate, or rather verify, the psalms; but for want of success in this, as well as in writing original hymns, or facred songs, Dr. Johnson has admirably accounted in his Life of Waller.

The first edition of Sternhold's fifty-one psalms, was likewise printed in 1549, and the second in 1553, but both imitations without musical notes; and in all probability, those that were not in possession of the tunes used by the German Protestants, applied to them such ballad airs as would bell suit the metre; as had been done in France, when the version of Clement Marot was in favour at the court of Francis I. Sternhold lived to write a dedication, for the first edition of his psalms, to king Edward VI. following in this the example of Marot, who had dedicated his first thirty psalms to the king of France.

The entire version of the psalms, however, was not published till 1562, when it was tackled for the first time to the Common Prayer, under the following title: "The whole Book of Psalms collected into English metre by J. Sternhold, J. Hopkins, and others, translated with the Ebrue, with apt notes to sing them better." Imprinted by John Day.

There was no base or other part, but the mere tunes, in this edition; which tunes are chiefly German, and fill used on the continent by Lutherans and Calvinists, as appears by collation: particularly the melodies set to the 12th, 14th, 13th, 15th, 16th, 17th, and 15th psalms.

PSALMODY ISLAND. The Roman Catholics, in the first ages of Christlihity, had their paraphrases of psalm-singing as well as the Protestant. St. Ambrose is not only said by St. Augustine to have brought from Greece the manner of singing the hymns, and chanting the psalms, which he established at Milan, and which was afterwards called the Ambrosian chant, but Eusebius tells us, that a regular choic and method of singing the service were first established, and
and hymns used in the church, at Antioch, the capital of Syria, during the time of Constantine; and that St. Ambrose, who had long resided there, had his melodies thence. An order of monks was established there at a very early period of the Christian era, whose discipline obliged them to preserve in their monastery a perpetual psalmody, equally perennial with the vital fire, or perpetual lamps of antiquity. Psalmody flourished in the diocese of Nimes, had its name from a monastery founded by Corbilla, a Syrian monk of this order, about the end of the fourth century. This kind of psalmody is known in the monkish writers by the name of laus perennis; Gregory de Tours calls it psalterium perpetuum.

Psalmody, Parochial. Singing of this kind among the reformers and schismatics, seems in all ages of our religion to have been the favourite mode of addressing the Divinity: for not only the Arians practiced it in their proceedings, but the Albigenses, who may be called the first Protestant martyrs; and who, according to ecclesiastical writers, when Simon Montford, their persecutor, in 1210, had lighted a pile of wood for their destruction, precipitated themselves in the flames, to the number of a hundred and forty, finging psalms.

The disciples of Wickliffe, in England, during the fourteenth century, and those of John Huds and Jerom of Prague, in the fifteenth, were psalm-singers; and the hymn-book of the Picards, and Bohemian brethren, printed with musical notes at Ulm, 1538, shews that the melodies used by these sects, originated from the chants to which the ancient Latin hymns of the Romish church were sung. For in this book there are translations and imitations in German metre of most of the hymns and psalms still used in the Romish church: such as the "Stabat Mater dolorosa," "Te Deum laudamus," "O lux beata Trinitatis," "Pange lingua gloriosi," &c. Some of these melodies, indeed, are in triple time, which never is the case in canto fermo, or cathedral psalmody. But "Stabat Mater," and "O lux," in this book, are set to old Romish chants, and "Te Deum" to the same that is inserted in the preface of Membomius to the ancient Greek musical writers, as the most ancient melody which the church has preferred.

Among the first reformers who interested themelves about the manner of performing the psalms, we have not only Wickliffe, Huds, Jerom of Prague, and Zuingle, but Luther, Cranmer, Calvin, Beza, Buchanan, and John Knox; who, though each of them had different ideas on the subject of sacred music, yet they agreed in stripping it of all the energy and embellishments of measure and melody, as indeed the Calvinists did likewise of harmony. Nor were the original institutes of psalmody more favourable to poetry than music; for by giving to each syllable, whether long or short, a note of the same length, all profody, rhythm, and numerical cadence, are destroyed. And however beautiful the poetical measures may be to read, when sung in this dawdling and ifochronous manner, they not only afford the ear no pleasure, but become unintelligible.

That metrical psalmody, in flow notes of equal length, had its origin in Germany, and was brought thence by reformers to other parts of Europe, is demonstrable: for the 28th psalm, "Beati omnes qui timunt Dominum," had been translated into German verse, in order to be sung in this manner, by John Huds, in the beginning of the fifteenth century; which translation was afterwards modernized in the same measure, and to the same tune by Luther. And the same melody, which we sing to the 100th psalm, is not only given to the 134th in all the Lutheran psalm-books; but by Goudimel and Claude le Jeune, in those of the Calvinists; which nearly amounts to a proof that this favourite melody was not produced in England. It is said to have been the opinion of Handel, that Luther himself was its author; but of this we have been able to procure no authentic proof. Tradition, however, gives to this celebrated herearch, as he is called by the Roman Catholics, several of the ancient melodies, which are still used in Germany.

Psalter, the book or collection of psalms, ascribed to David. See Psalm.

There is a multitude of editions of the psalter. Augustine Juxthian, a Dominican and bishop of Nebo, published a Polyglot psalter at Genoa, 1516. And Contarius published the psalter in Hebrew, Greek, Chaldee, and Arabic, with Latin notes and glosses.

Psalter is also used among religious for a large chaplet or rosary, consisting of one hundred and fifty beads; the number of the psalms in the psalter.

St. Dominic is said to have been the inventor of this psalter.

Psalterium, in Anatomy, or corpus psallioiades; a part of the brain, between the two posterior crura of the fornix. See Brain.

Psalteries, Psalterion, also denotes a musical instrument much in use among the ancient Hebrews, who called it nebel.

We know but little of the precise form of the ancient psalter. Kircher has taken pains to prove, that it was of a square form; and from an old book in the Vatican library he has exhibited a figure of it.

That now in use is a flat instrument; in form of a trapezium, or a triangle truncated at top.

It is strung with thirteen wire cords, set to unison or octave, and mounted on two bridges on the two fides. It is struck with a plectrum, or little iron rod, at sometimes with a crooked stick, whence it is usually ranked among the instruments of percussion.

Its chief, or body, is like that of a spinet. It has its name à psallendo; some call it nabolum, or nabulum.

Papius also gives the name psaltery to a kind of flute, used in churches to accompany the singing; called in Latin farnues.

Psammismus, from ψαμμίς, sand, in Medicine, a term sometimes used for a bath of dry and warm sand, to set the feet of dropical perons upon.

Psammiticus, in Biography, a king of Egypt, was the son of Eicus, who was put to death by Sabbaco on the conquest of Egypt. He avoided his father's fate by flying into Syria; and after the death of King Sathon, was one of the twelve lords who assumed the government of the country, and divided it between them. His part was the sea-coast, which being the least valuable, he was induced to cultivate commerce with the Phanicians, Greeks, and other nations, by which he acquired wealth and foreign connections. His prosperity excited the envy of his colleagues, who made war upon him, but by the affillence of foreign mercenaries or allies, he proved superior to, and finally subdued them, and then made himself sole monarch of Egypt. This event is dated B. C. 670. He rewarded his allies with lands upon the Nile, and from this era a Grecian colony subsisted in Egypt, which maintained an intercourse with their countrymen, and rendered the transactions of that kingdom a part of genuine history. Psammiticus carried on war in Syria, where he besieged the city of Azotus, which refitted his arms for the space of twenty-nine years. The preference which he gave to foreign soldiers caufed a defection of a great body of his own subjects, who marched away to the confines of Ethiopia, where
where they formed a settlement. To repair this loss, he attended still more assiduously to the advancement of commerce, and opened his ports to all strangers. He also renewed his alliances with the Athenians and other Greeks. After a long and prosperous reign of 54 years Plamuniticus died, and was interred in the temple of Buballis at Sais. He was founder of several magnificent edifices, and is said to have introduced the culture of the vine in Egypt, and to have sent an expedition for discovering the sources of the Nile. Univer. Hilt.

PSATYRIANS, Psatyrians, in Ecclesiastical History, a sect of Arians, who, in the council of Antioch, held in the year 360, maintained that the Son was not like the Father, as to will; that he was taken from nothing, or made of nothing; and that in God, generation was not to be distinguished from creation.

PSEDDERSHEIM, in Geography, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the district of Spire. The place contains 1238, and the canton 13,666 inhabitants, in 24 communes.

PSEGLMA, a name given by some of the ancients to the flos aris, or flowers of braas.

PSELAPHIA, a word used by the ancient medical writers to express friction with the hands, in cases where the disintempered parts require it. This was also esteemed a part of the business of a physician, and was done with his own hand.

PSELLISMUS, in Medicine, from ἑλλησμός, a hammer, comprehends not only that species of faulty articulation which is commonly called hammering, but every other defect in the pronunciation of words. Dr. Cullen has enumerated seven species of pellismus, and Savages a still greater number. Those of the former are, 1. Pellismus hesitans, when there is a difficulty in pronouncing the first syllable or word; the battarismus and issophonmon of authors. 2. Pellismus ringens, in which the letter R is erroneously pronounced, being always aspirated, and as it was doubled; the rotacismus and blafistas of authors. 3. Pellismus llanum, or lamacismus, when the letter L is improperly founded, or used in the place of R. 4. Pellismus emoliens, when the harder letters are pronounced too soft, and the letter S is too much used; the traubotes of authors. 5. Pellismus balbutians, when, in consequence of a large or tumid tongue, the labial letters are too much heard, and are often found instead of others. 6. Pellismus achoelos, when the labial letters are founded with difficulty, or cannot be pronounced at all; the P. maglinda of Sauvages. 7. Pellismus lagofomaturn, when, from a division in the palate, the guttural letters are not well pronounced; the cactaismus of authors. None of these species of pellismus is ever the object of medical practice; pronunciation carefully, under the direction of a nice ear, affords the only means of relief. See Cullen, Nofoal. Method. gen. 113.

PSELLUS, Michael, in Biography, a Greek writer, was preceptor to Michael, the son of the emperor Constan- tine Ducas. He was a very voluminous author in a variety of branches, theological, mathematical, legal, medical, political, &c. His works are frequently quoted by the Byzantine writers, and Anna Comnena has given a handfome encomium of him. He occupied an honourable station under Michael, his pupil, on whose dethronement by Nicephorus Botoniates, in 1078, he was stript of his property, and sent to a monastery, where he died in the same year. Among his printed works are, "Compendium quatuor Aristae, de quatuor Mathematicis Scientiis;" "De Santifz-" 

PSE, the name given by naturalists to the fig-gnut, a small species of gnut bred in figs while growing on the tree, and always remaining on the leaves of the same tree, and feeding on its juice. See Carphification.

PSENITZA, in Geography, a town of Bosnia; 12 miles S. of Seraio.

PSEPHISMA, ψηφήζομαι, among the Athenians, a decree of the senate; the same with probulæuma.

PSEPHOMANTIA, ψηφομαντία, in Antiquity, a species of divination, the same with cleromancy.

PSEPHOPHORIA, the art of using the paphi, ἱερο realloc, or counters. This was the first arithmetic taught children of every condition. Capitolinus, in his life of Pertinax, says, "Puer litteris, elementarius & calculi imbutis."

PSEPHOS, ψηφός, a name given to several things, as small stones, shells, and beans, used among the Greeks in giving their suffrages, and in their computations. Their origin is, by Mr. Mahudel, ascribed to the sons of Noah, who used this kind of calculation to affix their memory in numbering their flocks. Josephus affirms us, that the Egyptians borrowed this method of counting from Abraham; and Herodotus relates, that these small stones were used both by the Egyptians and Greeks, only with this difference, that the latter placed them and cyphers from left to right, and the former from right to left. The art of using them in calculations was called ψηφοφορία.

Plephri were in use too among the Romans, who called them calculi. Whatever materials they confided of, they were all of the same colour when used in calculations; whereas those used in giving suffrages were partly black and partly white. Lucky days were denoted by white, and unlucky by black ones. See Calculus.

PSETA, in Ichthyology, a name given by Athenæus to the fish we call the plaice, the gaffier leviz and platea of authors. See Pleuronectes Platea.

PSETITES, in Natural History, a name given by authors to a stone, having in it the figure of a turbot. There are stones found in some parts of Germany having the impressions of several kinds of fish as perfect as if drawn by a pencil, and it is not to be doubted, but that they in reality owe them to the fish themselves; which were received into beds of the matter of stone, yet unhardened, which taking its confluence while they were in its must crush them, and retain the marks of their bodies. They are usually found in a whitish flaky stone.

PSEUDO, a term or particle, used in the composition of divers Latin and English words; in the sense of false or spurious.

The word is formed from ἑλλησμός, lie, falsehood, of ἑλλησ, I deceive.

We say a pseudo-martyr, q. d. a false witness, pseudo-prophet, pseudo-apologist, pseudo-churl, &c.

PSEUDO-ACACIA, in Botany. See Robinia.

PSEUDO-ACORUS. See Iris.

PSEUDO-APIOS, a name given by some authors to the roots of bulbocaulataum, or earth-nut.

The peafants in Burgundy, and other parts of France, turn up these in great quantities with the plough, and eat them. They call them arnottas, and some of the writers of the adjacent places not distinguishing what they truly were, have avoided the common name, by giving them this of pseudo-apos, formed of the name of a root to which they have no alliance, and taking away a name by which they would have been much better known; arnota being only a corruption of the Dutch name crasne, or earth-nut, a name by which they are called almost everywhere. See Buxium.
PSEUDO-ARGYRON, in Mineralogy, a word used by the ancients in two very different senses; some make it the name of what Virgil calls orichalcum album, white brass; and others of a mineral with which the common brass was made.

It is very evident, from the joint testimony of the old Greeks and Romans both, that they had in use a kind of white metal made of copper, and they esteemed it greatly above the yellow, or brass.

Aristotle tells us of this white metal, and gives it great encomiums; he says it was very white and very bright; and that it was made by melting copper together with a certain earth; but this he does not describe, so that we are left in the dark as to what it was.

Thus, this shining white metal might very naturally be called pseudo-argyron, or half-pike silver.

PSEUDO-CAPSICUM. See Solanum.

PSEUDO-CARPASUM, a name given by some authors to the plant called by the generality of writers libanitis.

This is a plant of a very strong smell; and the carfophas, or carphophilum of the ancients, being a poisonous gum, and the smell of the libanitis approaching to the same odour, occasion its being called the halfard carphophilum.

PSEUDO-CYPERUS. See Carex.

PSEUDO-DICTAMNUS. See Marrubium.

PSEUDO-DIGITALIS. See Digitalis.

PSEUDO-DIPTERE. See Apis.

PSEUDO-FUMARIA, in Botany, a name used by some for a species of fumitory.

PSEUDO-GELEDINUM, a name given by Rivi-nus to a genus of plants, the fame with the bignonia of authors.

PSEUDO-IPACUANHA, the name by which some authors have called a poisonous kind of American apocynum, the root of which resembles the true ipacuana, and has sometimes been unfortunately collected and used in its place.

PSEUDO-LOTUS, a name by which some call the cauliferae of Tournefort. See Indian Date Plum.

PSEUDONYMOUS, Jovialis, formed from Jove, i.e., and unus, name, a name given by the critics to those authors who publish books under false or signed names. As the name cryptomous is given to those who publish under secret and disguised names; and anonymous, to those who publish without any names at all.

The Apostolical Constitutions, the greater epistles of St. Ignatius, &c., are usually supposed to be pseu-donymus.

PSEUDO-OPTERUS, in Ichthyology, a name given by Klein to the Scorpaena Voleata; which see.

PSEUDO-PELLEX ARBOREUS, in Entomology, the name of a genus of insects described by M. Reaumur, and somewhat approaching in their form to the plexus arboreus; but having their wings covered with a squamoso, which those creatures have not, and having broader and flatter bodies. These principally live upon the fig-tree and the box; they pass through a sort of metamorphosis into a hopping fly, supposing by some of the nature of a gnat-hopper; but erroneously, for that animal has a cafe for its wings, and the other not.

PSEUDO-STELLA, in Astronomy, any kind of meteor or phenomenon appearing in the heavens, and resembling a star.

PSEUDO-SYPHILIS, from syphe, saphis, and saphis, the venereal disease, in Surgery, a name given to a variety of diseases which resemble lues venerea, but are in reality of a different nature.

Sore on the glass penis, prepuce, &c., in the form of cancer, as Mr. Hunter notices, may and do arise without any venereal infection, although in general they are a consequence of former venereal forces which have been cured.

The symptoms produced by the venereal poison in the constitution, are such as are common to many other diseases. For instance, as Mr. Hunter has ably explained, blotsches on the skin are common to what is called a locobaslic habit; pains are common to rheumatism; swellings of the bones, peristem, felinea, &c., to many bad habits, perhaps, of the fealous and rheumatic kind. Thus, says this valuable observer, most of the symptoms of the venereal disease, in all its forms, are to be found in many other diseases.

Hence the original cause, and many leading circumstances, such as dates, effects of the disorder upon others, from connexion, when only local, the previous and present symptoms, &c., must be considered, before we can determine absolutely what the disease truly is. All the circumstances and symptoms, taken together, may be such as will attend no other disease. However, Mr. Hunter confesses, that, with all our knowledge, and with all the application of that knowledge to suspicious symptoms of this disease, we are often mistaken, calling distempers venereal which are not, and sometimes supposing really syphilitic affections to be of another nature.

Mr. Hunter takes notice, that in some constitutions rheumatism, in many of its symptoms, resembles the lues venerea. The nocturnal pains, swelling of the tendons, ligaments, and peristem, and pain in those swellings, are symptoms both of the rheumatism, and also the venereal disease, when it attacks those parts. Mr. Hunter, however, did not know that he ever saw the lues venerea attack the joints, though many rheumatic complaints of such parts are cured by mercury, and therefore supposed to be venereal.

Mercury, given without caution, often produces the same symptoms as rheumatism. Mr. Hunter has seen such complaints supposing to be venereal, and the medicine continued.

This interesting author also explains, that some diseases not only resemble the venereal in appearance, but, in the mode of contamination, proving themselves to be poisons, by affecting the part of contact; then producing immediate consequences similar to buboes; and also remote consequences similar to the lues venerea.

Mr. Hunter observes, that it is nearly as dangerous, in some constitutions, to give mercury, when the disease is not venereal, as to omit it in other cases which are really syphilitic. Many of the consequences which put on some of the venereal symptoms, when the disease is not really present, are those with which mercury seldom agrees, and commonly does harm. Mr. Hunter has seen mercury, which was exhibited for a supposed venereal ulcer of the tonsils, produce a mortification of those glands, and the patient was nearly destroyed.

PSEUDO-THECA, in Entomology, the name of a species of two-winged fly, approaching to the nature of a common wasp, but having no sting.

This is, according to the later distinctions in the history of insects, properly called a wasp-fly. There are bee-flies, as much resembling the bees as this does the wasp.
PSEUDO-TINEA, the name of a very remarkable species of insect described by M. Reaumur, approaching to the nature of the tinea, or cloth-moth, while in the worm-flate; but not making themselves coats of the fulblance of leaves, cloth, &c. though they form a sort of cafes for their defence against a very terrible enemy.

These creatures are truly of the caterpillar kind, and have in the manner of many of these insects, sixteen legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, though at the expense of their habitations and the cells of their refineries of honey: so that it is no uncommon thing for a swarm of bees to be forced to change their place of habitation, and make new combes elsewhere; leaving the old ones to their contemptible victor, whom they know not how to drive out or dissipate.

Virgil and Aristotle, and all the authors who have written on bees, have complained of this destructive animal: I never eat the honey, but feeds only on the wax; attacking principally those wax cells where the female bee deposits her eggs for the future progeny.

The bees, who are a match for most other creatures, by means of their filings, would easily destroy these weak creatures, were it not for the impervious armour they are covered with. They form themselves a coat of armour of a double matter; the first, which immediately covers the body, is a kind of milk of their own spinning; and the outer covering over this is of the bees-wax; this is laid considerably thick, and the creature just thrusting out its head to feed, goes on devouring the cells undisturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their filings.

When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nymphaate; whence, after a proper time, it comes forth in form of a moth, with granulated horns and crooked proboscis.

The bees have cunning enough to know their destructive enemy in this new form, and as this is a weak and defenceless state, they attack and destroy all the moths of this species they can meet with. They seldom are so fortunate, however, as to kill the whole race as soon as produced; and if only one escapes, it is able to lay a foundation of revenge for the death of its brethren.

The moth produced by this caterpillar flies but little, yet is very nimble in avoiding danger by running, which it does with great swiftness.

There are species of these pseudo-tineae, or wax-eating caterpillars, which infest the subterranean hives of wasps, and other creatures which make wax; the manner of living, feeding, and defending themselves from their enemies, is the same in all the species.

The accurate author of these observations describes also a kind of pseudo-tineae, which feed on wool, and another that eats leather; both making themselves houes also on the materials they feed on. All these creatures, whatever be their food or habitation, finally become phalanx, or moths; and may be distinguished, even in this state, from the other species, by having granulated horns of a remarkable structure, and all of them a probocis, or trunk, more or less incurvate.

PSEUDO-VIBURNUM, in Botany, the name given by Ruminus to a species of lantana.

POLADJA, so named by Jacquin, from ħīz, ħadīz, a drop of dew, because of the glutinous exudation of its leaves, which often fluids in drops upon their surface.—Jacq. Hort. Schonbr. v. 2. 13. Willd. Sp. Pl. v. 3. 2384.

Gen. Ch. Common calyx imbricated, nearly ovate, of about ten lanceolate, bluntish, concave, unequal, erect scales, with a few smaller acute ones at their base. Cor. compound, radiated; florets of the disk numerous, male, tubular, funnel-shaped, with a five-cleft spreading border; those of the radius female, very numerous, in several rows, ligulate, scarcely longer than the others, each with one or two teeth. Stam. in the florets of the disk, filaments five, capillary, very short; anthers combined in a cylindrical tube. Pip. Germen only a rudiment in those florets, without style or stigma; in the others oblong; style thread-shaped; stigma divided, reflexed. Peric. none, except the scarcely altered calyx. Seeds, in the radius only, solitary, linear; down felike, simple. Recept. flatish, naked, except where clothed in the centre with the firmly-fixed rudiments of germens of the male florets.

1. Pf. glutinofa. Jacq. Hort. Schonbr. v. 2. 13. t. 152. (Solidago vicifolia; Schrad. Sert. Hanov. 12. t. 6.)—Native of the island of Mauritius. It was sent to Kew by Baron Hake, from Gottingen, in 1796, and flowers there from June to August, requiring the protection of a green-house in winter. A few amateurs indeed would allow it a place there, the whole plant being far less ornamental than the meanest American Solidago. The stem is shrubby. Leaves alternate, thalcked, ovate, acute, serrated, two or three inches long, dark green, very vilcid. Flowers corystome, terminal, small, pale yellow, without smell.

Gen. Ch. Cal. Perianth superior, of one leaf, bell-shaped, permaent, cloven into five, ovate, rather deep segments. Cor. Petals five, ovate, connate, spreading, inserted into the calyx. Stam. Filaments numerous, shorter than the corolla, inserted into the calyx; anthers small. Pip. Germen inferior, roundish; style awl-shaped, very long; stigma simple. Peric. Berry ovate, very large, crowned with the calyx, of one or occasionally more cells. Seeds numerous, small, kidney-shaped, imbedded in pulp.

Obs. This genus feems but ill distinguished from Myrtus.

1. P. pýsirfum. White Guava. Linn. Sp. Pl. 672. P. fruticofum; Brown Jam. 238. (Guajava foliogram anus germinulangulifer, fructu oblongo; Trew. Ehret. t. 43. Merian Surin. t. 19.)—Leaves elliptical, downy beneath. Stalks single-flowered.—Very common in Jamaica and others of the West Indian islands, also in Cochinchina and the southern provinces of China. It flowers at Kew in June and July. This handsome tree varies from about six to twelve feet in height; its trunk being about a foot and half in diameter. Bark yellowish-brown, with large ash-coloured dots. Leaves opposite, on short stalks, blunt, entire, smoothish. Flower-stalks solitary, short, each supporting
porting a white, sweet-smelling blossom. Fruit smooth, roundish, whitish or yellow on the outside. Seeds enveloped by a firm, flesh-coloured, sweet, aromatic pulp. The fruit of the White Guava is much esteemed both by the natives and Europeans either in its crude state, or when made into jellies. The wood is very tough, frequently used for bows and yokes.

2. P. punicum. Dwarf Guava. Willd. n. 2. Vahl. Symb. v. 2. 56. (Cujavilla; Rushm. Amboin. v. 1. 145. t. 49.)—Leaves lanceolate, acute, downy beneath. Stalks single-flowered. Native of Ceylon. In habit and appearance this is exactly similar to the first species, but only a fifth of the size in all its parts, being a shrub about two feet high, whose branches are covered with a villous, ashy-coloured bark. Leaves opposite, entire, smooth above, hairy beneath. Fruit the size of a hazel-nut, villous.

3. P. aromatcum. Aromatic Guava. Willd. n. 3. Aubl. Guian. 485. t. 191.—Leaves ovate, pointed, smooth. Stalks single-flowered. Native of woods in Cayenne and Guiana, flowering in October and bearing fruit in February. This tree is about five feet in height, branched at the summit in a scattered manner. Leaves opposite, on short stalks, entire; when bruised smelling like Balm. Flowers white, occasionally with only four petals. Berry globose, like a cherry, yellow, succulent.

5. P. decasperum. Linn. Suppl. 252. Willd. n. 5. (Decasperum fruticosum; Forl. Gen. 57.)—Leaves ovate, pointed, downy. Stalks single-flowered, with bracteas. Native of Otaheite, and the other Society Isles. This shrub is for the most part smooth. Leaves on stalks, small, entire, veined, not marked with lines. Flowers small, white, on short, silky stalks. Fruit small, globose, rugose. Seeds placed in a double row, oblong, convex on one side, compressed on the other. Jullien well observes that the seeds of this plant are solitary, in each of the ten cells of the berry, the genus of Forster ought perhaps to be retained.

6. P. pisonadiform. Red Guava. Linn. Sp. Pl. 672. (Malacca pelta; Rheed. Hort. Malabar. v. 3. 33. t. 35.)—Leaves oblong-lanceolate, downy beneath. Stalks three-flowered. Native of the Well Indies, and introduced at Kew in 1692, where it flowers in June and July. The stem or trunk of this species is thick, about twenty feet high, much branched at its summit. Leaves on short stalks, with a strong midrib, and much veined, of a light green colour. Flowers showy, large, and white. Fruit resembling a pomegranate, having an agreeable fragrance.

Jacquin remarks that the Red Guava is nearly allied to the first species, but not so common, and scarcely ever eaten. In Martinico the shrub is called Goyavier de Cayenne; the latter Goyavier du pays. P. poissonadiforme of Loureiro appears to be a much smaller shrub, for he describes it as only four feet in height.

Flowers three together, the middle one sessile, the others on stalks, often deciduous. Fruit small, roundish, tawny without, of a deep red within, having a most grateful and exquisite sweet taste.

8. P. montanum. Mountain Guava. Willd. n. 8. Swartz Prodr. 77. Ind. Occ. v. 2. 879. (P. arboreum, folium odoratissimum, nigro fulvo, fibris undulatis; Brown Jun. 239.)—Leaves oblong, pointed, crenulated, shining. Stalks many-flowered. Native of woods in Jamaica. This is one of the largest trees in the island, frequently reaching to sixty, seventy, or even a hundred feet, and of a proportionate thickness, covered with smooth, spreading branches. Leaves opposite, flaked, undulated at the margin. Flowers white, fragrant, resembling those of the White Guava. Fruit acid. —Brown tells us "it is an excellent timber-wood, of a dark colour and curled grain; works easily, and takes a fine polish. It makes very beautiful walking-sticks."

9. P. canum. Loureir. Cochin. v. 1. 310.—Leaves slightly serrated, downy on both sides. Stalks many-flowered, axillary, and terminal. Found in fields near Canton. This shrub is about two feet high, much branched, diffuse. Leaves alternate, on short stalks, veined. Flowers white, in small oblong clusters. Loureiro called this species cumin, because "the dogs frisk round it with the same delight as cats do about Valerian." Willdenow supposes this not to be different from P. punicum, n. 2.

11. P. rubrum. Loureir. Cochin. v. 1. 311.—Leaves oblong, entire. Flowers sessile, crowded together, axillary. Found with the leaf, being, like that, a tree, of a middling size, with spreading branches. Leaves obtuse, smooth. Flowers white, axillary. Fruit small, oblong, red, succulent, having a sharpish yet sweet flavour.

Loureiro properly retains this species in Psidium, although its calyx and corolla have only four instead of five parts.

Psidium, in Gardening, contains plants of the exotic tree kind, of which the species cultivated are the white guava (P. pyriferum), and the red guava (P. pisonadiform). Although its fruits are somewhat bitter, yet they are much esteemed for their agreeable and sweet flavour.
in the flowe. During the winter, they should have moderate warmth, and not too much water; and in summer, have plenty of moisture, and in hot weather a great share of air.

They afford ornament among other flowe-plants.

PSILOTCHRISTA, among the Ancients, one who plays on the cithara, without singing in concert to it.

PSILOTHERON, |spore, formed from |spore, deglabro, I make bold, or bare, and |spor, hair, in Medicine, depilatory; an external form of medicine proper to take off the hair.

Such are the strong lichivium, quick-lime, ants’ eggs, gendarac, orpinent, and arsenic.

Eff. Ch. Capsules of two or three cells, and two or three valves, conicous, opaque, with many seeds. Brown.

1. Pf. triquetrum. Triangular Naked-fern. Swartz n. 1. Brown n. 1. Ait. n. 1. (Lycopodium nudum; Linn. Sp. Pl. 1564. Lycopodioides frutecens, Sp. laxis nudis; Dill. Mucf. 468. t. 64. f. 4.)—Branches triangular in every part. —Native of the West Indies, the isles of Mauritius and Bourbon, and New South Wales. —Stem about a foot high, repeatedly forked, slender, spreading, triangular, smooth, green. Leaves minute, so as scarcely to be detected, acute, entire, feathery, sessile; the floral ones divided. Structure of the flowers, and mode of impregnation, not yet detected. Capsules numerous, feathery, solitary, at the division of each floral leaf, appearing rolled up under a magnifier, three-lobed, the size of a large pin’s head.

2. Pf. complanatum. Flat Naked-fern. Swartz n. 2. t. 4. f. 5. (Bernhardia complanata; Willd. Sp. Pl. v. 5. 57.)—Branches two-edged, compressed. —Native of Jamaica, on the trunk and branches of trees. Like the foregoing in habit, but flat, and bearing much fewer capsules, situated at the very summits of the branches.

3. Pf. truncatum. Abrupt-leaved Naked-fern. Brown n. 2. (Tine-fipteris tenni; Bernhardi in Schrad. Journ. for 1800. part 2. t. 131. t. 2. f. 5. Billard. Nov. Holl. v. 2. 105. t. 252.)—Leaves dilated, abrupt, with a slightly pointed, dilated, two-celled. Capsule of two cells. —Found by Forster in the island of Tanna. Mr. Brown and M. Labillardiere have observed it in various parts of New Holland. We have specimens from Port Jackson. This is a leafy fern, about a span high, unbranched. Leaves imperfectly two-ranked, alternate, somewhat flaked, oblong, oblique, abrupt, fiddle-ribbed, smooth, about an inch long, each tipped with a small bristle; the floral ones divided to the very base. Capsules oblong, of two horizontally divaricated acute lobes.

Mr. Brown has made a very curious observation on the seeds of this genus; or at least on what are supposed such. These are oval bodies, appearing white in a mass, but semi-transparent when separate, each exploding by a very minute orifice when put into water.

PSINIA, in Geography, a river of European Turkey, which runs into the Vardar, four miles S. of Krupulik.

PSITTACULA, in Ornithology, a species of Alca.

PSITTACUS, the Parrot, a genus of birds of the order Picae, of which the generic character is, bill hooked; upper mandible moveable, and mostly covered with a cere; the nostrils are rounded, and placed in the base of the bill; the tongue is feathery, obtuse, entire; feet formed for climbing.

This splendid and numerous genus is chiefly confined to the warmer regions of the ancient and new continent, or within the limits of the tropics; none being natives of Europe. Some few are found in latitudes far beyond what was supposed by Buffon, and even as far as 40° or 45° on each side of the equator. They are remarkable for their active and imitative disposition. From the peculiar form of their tongue, which, in most species, is thick, flat-tish, rounded, and feathery, they are enabled to articulate with greater distinctness than other birds. The upper mandible is, as we have seen, moveable; and the feet formed for climbing, with a power of bringing forward at pleasure one of the hind toes. They are frugivorous and monogamous, depositing their eggs, which are generally two, sometimes three, in the holes of decayed trees. Though usually observed in pairs, they sometimes assemble in vast flocks. The whole genus, which, according to Gmelin, comprehends about 170 species, is divided into two sections, according to the shape of their tails.

A. Tail long, and wedge-shaped.

Species.

MACAO; Red and Blue Macaw. Red; quill-feathers above blue, beneath rufous; feathers of the shoulders variegated blue and green; cheeks naked, wrinkled. This being by far the most magnificent of the whole parrot tribe, we shall give a pretty full description of it. It is a native of South America, where it resides chiefly in the palm woods, and feeds, like the rest of the birds of this genus, on various kinds of fruit. It has been more accurately described and figured by Edwards than by any other naturalist. He says, "it is undoubtedly the first of the parrot kind, if we consider either its magnitude, or the great variety and beauty of the colours with which its plumage is adorned. It is the biggest of all the kinds I have met with: when the tail is perfect, I have found none of them to measure more than three feet from bill-point to tail-end. The arch of the upper mandible, from the forehead to the point of the bill, is nearly three inches; the leg, from the knee downwards, is not an inch and half long; the least toe, with the claw, is two and a half; the upper mandible of the bill is bluish, except on each side next the head, where it is dusky; the lower mandible is black or dusky; it has no bare skin covering the bill; the nostrils are placed in the upper part of the bill, just within the feathers; the bill is great and strong; the tongue roundish and soft; the sides of the head, from the bill backwards, for a good broad space, are bare of feathers, and covered with a whitish, wrinkled, rough skin; in the upper parts of these spaces are placed the eyes, whose irides are yellow; the head, neck, breast, belly, thighs, upper part of the back, and outer covert-feathers of the wings, are of a fine bright red or scarlet colour; the quill-feathers of the wings are of a very fine blue on their outsides, and a faint red on their under-sides; the first feathers next above the quills are of a fine yellow colour, some of the feathers being tipped with green; the blue quills which fall next the back are tinged with
with green; the hinder part of the thigh has some green intermixed with the red; the lower part of the belly, and covert under the tail, as also the lower part of the back, and covert on the upper side of the tail, are of a very fine blue colour; the tail-feathers gradually shorten towards the sides; some of the longest or middle feathers are wholly red; the shorter or side feathers are partly red, and partly blue, their tips being blue, and their bottoms red; the legs and feet are covered with blackish or dusky scales; the toes are distanced two forwards and two backwards, as in other parrots; they are all armed with strong claws." This noble bird, says Dr. Shaw, at its first introduction into Europe, was considered as a present fit for royal personages, and was one of the principal ornaments in the halls of palaces. In a state of nature, these, of all the species of parrots, fly the belt; and they always perch on the summits of trees, or on the highest branch. During the day they wander to the distance of two or three miles from their favourite spot, or home, but always return in the evening. They build in the holes of trees, which they enlarge when too narrow, and line the inside with feathers. They have two hatches annually, like all American parrots, and each consists of two eggs. The males and females sit alternately on the eggs, or cherish the young, and both equally carry the food: they never desert their charge so long as their assistance is required, and always perch near their nest. The young are fed to be easily tamed; and in many parts of South America these birds are never taken but in the nest, the grown birds being educated with great difficulty. In a state of captivity, like many other birds, they are subject to epileptic fits, which, however, do not prevent them from arriving at a very considerable age, sometimes not less than thirty years.

**Aracango;** Red and yellow Maccaw. Pale scarlet; scapular feathers yellow, tippet with green; quill-feathers above blue, beneath rufous; cheeks naked, wrinkled. It inhabits Guiana, Brazil, and Jamaica, and is the size of the last. The tail-feathers above are scarlet, mixed with violet, beneath dusky red, two middle ones both sides dusky red on the upper half.

**Militaris;** Military Maccaw. Green; wings blue; front and tail red; cheeks mottled naked, with feathered lines. The bill is black; the rump, and tips of the tail-feathers blue.

**Ararauna;** Blue and yellow Maccaw. Above blue, beneath yellow; cheeks naked, with feathered lines. There is a variety of this species, which has a long tail and naked cheeks. It is found in Jamaica, Guiana, Brazil, and Surinam. The tail of the female is yellow, that of the male red.

**Hyacinthinus;** Hyacinthine Maccaw. Violet blue; head and neck paler; chin and orbits yellow, naked.

**Makawanna;** Parrot Maccaw. Above dusky green; head green mixed with blue; chin, throat, and upper part of the breast, reddish; lower part of the breast and belly green; rump red-brown. It inhabits Cayenne and Guiana; is eighteen inches long, and migrates.

**Ator;** Black Maccaw. Black, with a green tinge; bill and eyes red; legs yellow. It inhabits the interior parts of Guiana, on the fertile tops of rocks and dry mountains.

**Obscurus;** Obscure Parrot. Brown; cheeks red, naked; crown varied with blackish and ash; tail cinereous. It inhabits Africa, and is about the size of a magpie.

**Nobilis;** Noble Parrot. Green; cheeks naked; shoulders scarlet. It inhabits Surinam, and is the size of a turtle dove.

**Severus;** Brafil green Maccaw. Green, cheeks naked; quill and tail-feathers blue, beneath purplish. A variety is of a dusky green; with the front brown, and the crown greenish-blue. It is found in Jamaica, Guiana, and Brazil.

**Eupatria;** Gingi Parrot. Green; cheeks naked; shoulders scarlet; bill purplish. It inhabits Gingi in India.

**Japonicus;** Japonefe Parrot. Green; beneath and lateral tail-feathers red; quill-feathers blue. It is found in the southern parts of Japan.

**Amboinensis;** Amboina Parrot. Scarlet; back blue; wings with a green spot. It is about fifteen or sixteen inches long.

**Cyanoccephalus;** Blue-headed Parrot. Head green, chin blue. It is about a foot long, and inhabits India.

**Hematotus;** Red-breasted Parrot. Body above green; throat and breast orange; the feathers edged with blue, belly and tail green. There are three other varieties of this species, viz. 1. Breast red, varied with blue; head, chin, and middle of the belly, blue. 2. This resembles the last, except that the whole belly is blue. 3. Scapulars spotted with red and yellow. Found in New Holland and Amboina.

**Atricapillus;** Black-crowned Parrot. Above blue; chin, throat, and breast red; belly and vent green; crown black; collar green and red. It inhabits the Molucca isles, and is fourteen inches long.

**Tabuenus;** Tabuan Parrot. Head, neck, breast, and belly, purple; back and wing-coverts green; crown terminated by a lunular blue mark; first quill-feathers and greater part of the tail blue. It inhabits the Friendly isles. There is a variety of this species, which is green, head, neck, breast, and belly scarlet; neck terminated by a lunular blue mark; wings green; rump blue; tail deep blue. This is found in New South Wales.

**Papuensis;** Papuan Parrot. Head, neck, and breast red; hind head with a blue spot and two black crescents; wings and part of the back green; rest of the back, belly, and tip of the tail, red; three varieties are, 1. Belly crossed by a black stripe edged with green, breast purplish. 2. Scarlet; tail shorter, hinder part of the back blueish-black; a yellow spot between the wings. 3. Middle of the belly green. It inhabits Papua, and is sixteen inches long.

**Borneus;** Borneo Parrot. Red; quill and tail-feathers green at the tips; wings with a blue spot; orbits brown. It is an Indian parrot, and nine inches and a half long.

**Indicus;** Indian Parrot. Scarlet varied with brown and violet; upper part of the head and neck, breast and stripe behind the eyes, violet; greater quill-feathers tippet with pale brown; lesser and tail-feathers violet brown. It is a native of Amboina, and nearly a foot in length.

**Elegans;** Beautiful Parrot. Head, neck, and body beneath red, above brown; intercarpals pale blue, mixed with red; tail greenish-brown, tippet with white. A variety has its wings, tail and body above green. It inhabits the Molucca isles; the first is about fifteen inches long, and the second twelve; in the former the bill is of a yellowish-brown; in the latter it is a lead-colour, and yellow at the tip.

**Guereписus;** Gueby Parrot. Bright red; quill-feathers black, with a transverse red band; tail brownish-red. It is about nine or ten inches long.

**Janthinus;** Violet Parrot. Head and body above brown, beneath violet; shoulders blue; tail and wings green and red. It is found near the river Amazons.

**Variegenatus;** Variegated Parrot. Scarlet; nape, beginning of the back, breast and belly, purple or blue; wings above
PSITTACUS.

above red, beneath yellow; tail green. It inhabits India, and is from ten to eleven inches long.

Pennant; Pennant's Parrot. Scarlet; fore part of the back black, waved with scarlet, sides and throat blue; quill-feathers each with a white spot. It is fifteen inches long, and inhabits New South Wales. There is a variety, having the middle of each wing with a pale band.

Eximus; Nonpareil Parrot. Head, throat, breast, and vent crimson; back black, waved with yellow-green; wings and tail blue. It inhabits New Holland.

Glorious; Splendid Parrot. Bright blood-red; back-feathers edged with black; chin, wings, and tail blue. It is a native of New Holland, and is fifteen inches long.

Novo Guinea; New Guinea Parrot. Black, with a bright blue tinge; tail beneath red; orbits naked, brown.

Javaicus; Javan Parrot. Scarlet; orbits naked, silver; head crested, chin grey; throat and breast rosy; shoulders and wings mixed red and green; two middle tail-feathers scarlet, the rest rosy, mixed with green, tippet with blue. It is about the size of a lark, and is a native of Java.

Jandaya; Yellow-headed Parrot. Above green, beneath yellow; head and neck yellow. It is a native of Brazil.

Solstitialis; Angola Parrot. Yellow; wing-coverts green; orbits red; lateral tail-feathers blue without. It inhabits Angola, and is nearly a foot long.

Pallidus; Pale Parrakeet. Yellow; wings whitish, slightly tinged, and a c aus of greenish, according to the direction of the light. It inhabits Andalusia, and is about seven inches long.

Guanoua; Brafil Yellow Parrot. Yellow; greater quill-feathers green. It is found in Brazil, and is eleven inches long. There is a variety that is yellow; head reddish; neck orange; wings green. It inhabits New Spain.

Carolinus; Carolina Parrot. Green; head, neck, and knees yellow. It is a native of Guiana, and migrates into Carolina in the mulberry season; it is very destructive to orchards; builds in hollow trees in swampy places; does not easily learn to speak.

Alexandri; Alexandrine Parrot. Green; collar and crest red; chin black. There are of this species the following varieties. 1. Collar rosy; hind-head violet; legs ash. 2. Collar purple, throat and breast pale rosy. 3. Collar double. 4. Head, chin, and tail blue. 5. Head mixed blue and yellow; temples black; throat and breast reddish; tail yellowish.

Pertinax; Yellow-faced Parrakeet. Green; cheeks tawny; quill and tail-feathers rather hoary. This species is a native of America, and it migrates in flocks to the North; it feeds on seeds and fruits, and builds in large ant-hills, and is about thirteen inches long.

Leverianus; Leverian Parrot. Pale green; head and neck yellow; quill-feathers, and tips of the tail-feathers, blue; rump crimson. It is found in the southern parts of Asia.

Smaragdinus; Emerald Parrot. Shining green; hind part of the belly, rump, and tail rusty chestnut. Habits near the Straits of Magellan, and is thirteen inches long.

Canicularis; Red-fronted Parrot. Green, with a red front; hind-head and outer quill-feathers blue; orbits tawny. It inhabits South America.

Aeruginosus; Brown-throated Parrakeet. Green; crown and first quill-feathers blue; orbits ash. It is a native of America, and is ten inches long.

Rufirostris; Red-billed Parrot. Green; bill and legs red; tail-feathers blue at the tips; the orbits are of a flesh colour. There is a variety whose bill, legs, and claws are white-identified; the orbits are cinereous. It inhabits South America, is twelve inches long, and is easily taught to speak.

Ornatus; Orange-billed Parrot. Yellow-green, hindhead, chin, and breast red; crown and auricles blue; orbits cinereous. This is a native of India.

Jacula; Green; quill-feathers brown at the tip; orbits tawny. It inhabits Chili, lives in flocks, and feeds on buds of trees and plants; the flesh is very savoury.

Guananus; Piquouane Parrot. Green; cheeks spotted with red; the lesser wing-coverts are scarlet, the greater are yellow; quill-feathers beneath pale yellow, with a blackish margin towards the tip. It is found in Guiana and the Caribbean islands.

Marginatus; Varied-winged Parrot. Green; wing-coverts black; the lesser edged with yellowish-brown, the greater with blue. Found in Luzonia, as is the next.

Sonnerati; Blue-collared Parrakeet. Green; collar blue; spot on the origin of the wings red.

Pondicerianus; Multichroa Parrakeet. Green; front and stripe from the mandible each side to the chin black; face white and blueish; breast purplish-blue; tail beneath straw-colour. A variety has its head from the base of the bill to the eyes chestnut; a brown line from the nostrils to the eyes; chin black, extending back like a beard; the nape is red. This species is found in Pondicherry.

Erythrocephalus; Blossom-headed Parrakeet. Green; head red mixed with blue; chin black; collar black and pale green. There are three other varieties; 1. Crown and cheeks rosy; hind-head and two middle quill-feathers blue above, the rest blue at the edge. 2. Head, chin, throat, breast, and fore-part of the belly, peach-blossom and hind head rosy. This species is a native of India.

Bimaculatus; Spot-necked Parrot. Green, with two oblong black spots on the neck, and a large sulphur-coloured spot on each wing.

Plumbeus; Brown-fronted Parrakeet. Green; bill, legs, and orbits of a head-colour; front, cheeks, and chin brown; edges and tips of the tail-feathers blue. This is nearly a foot long, and inhabits the tropical regions of America.

Dubicus; Dubious Parrot. Green; neck reddish; orbits yellow, naked.

Chrysogaster; Orange-bellied Parrakeet. Green, belly orange, bill greenish.

Olivaceus; Lace-winged Parrakeet. Olive; hind-head with a blueish spot; wings varying with blue, green, and orange. It is found in Luzonia, and is eleven inches long.

Dubius; Dubious Parrot. Green; neck reddish; orbits yellow, naked.

Virens; Olive-winged Parrakeet. Greenish; lesser wing-coverts at the base, and within, white; without, and at the tip, yellow; the first seven quill-feathers within black, edged with white; the next seven are white, edged and tipped with yellow. This is a native of Cayenne, and it is eight inches long. It is a very numerous species, docile, and not shy; it feeds on the flowers of the erythrina corallodendron.

Versicolor; Waved Parrakeet. Green; head and chin brown, the latter waved with tawny; wings blue, with a flame-coloured bar; belly pale blueish-purple, with brown waved lines. It inhabits Cayenne and Surinam.

Squammosus; Scaly Parrakeet. Green; feathers of the head, neck, and breast, edged with orange. A native of
of Cayenne, and is only about eight inches and a half long.

Incarnatus; Red-winged Parrakeet. Green; bill, legs, and claws, carnation; cere and orbits whitish; chin and wing-coverts red. It inhabits India.

Murinus; Grey-breasted Parrakeet. Olive; face, chin, and breast mouse-colour; quill-feathers green. Inhabits Montevideo; it is about ten inches long, and is easily tamed.

Cornutus; Horned Parrot. Green; head scarlet, with two long feathers standing out like horns; the collar and rump are fraw-colour; the outer edge of the quill and tail-feathers blue. It inhabits New Caledonia, as does the next.

Caledonius; Caledonian Parrot. Olive; crown greenish-yellow; tail-feathers white; at the tip, the outer edges of the four outermost pale blue.

Novæ-Selandiae; Red-rumped Parrot. Green; front purple; crown greenish-tawny; a red stripe from the base of the bill through the eyes; tail-feathers blueish, the two middle ones edged with green; the rump is red. It inhabits New Zealand, and is 15 inches long.

Novæ Hollandiæ; Crested Parrakeet. Olive; crested head and chin yellow; behind the eyes there is a red spot, and an oblique band across the wings. It is a native of New Holland, and is a foot long.

Formosus; New Wales Parrot; and sometimes it isdenominated the black-spotted parrakeet of Van Diemen’s Land. This species is green; the four middle tail-feathers barred with green and black, the rest with black and yellow; the bill and legs are black, and the tail much wedged. This is a most beautiful and elegant species, about a foot long, inhabiting New South Wales, and other parts of New Holland. It is rarely seen, except on the ground, particularly in moist places. It is not known to perch on trees like other parrots, but flies from among the grapes, and immediately alights in it again. The legs and toes are more slender than usual in this genus, and the claws more straight.

Uletitanus; Society Parrot. Olive; head black-brown; rump dusky-red; wings and tail dusky. It inhabits Uletea, and is 10 or 11 inches long.

Multicolor; White-collared Parrot. Green; head, chin, and belly blue; fore-part of the red breast, hind-part and tail beneath yellow; collar white. It inhabits India; the bill is red, and the head is ornamented with a white crest.

Aureus; Golden-crowned Parrakeet. Green; cere and oribets blueish-carnation; crown golden; wing-coverts with an oblique blue stripe. It is a native of Brazil.

Linearus; Green; quill-feathers beneath brown, the inner edge pale. This is about the size of a turtle-dove.

Concinus; Crimmon-fronted Parrakeet. Green; spot behind the eyes and front crimson; the crown is blueish. It inhabits New Holland, and is the size of a turtle-dove.

Pacificus; Pacific Parrakeet. Green; spot behind the eyes and each fide of the rump red; front red; outer edge of the wings blue; tail beneath ash. There are five other varieties; 1. No spots. 2. No. 1. 3. Rump and temples red. 5. Crown yellow. 4. Hind. The spot below the eyes, and sides of the belly, scarlet. 5. Crown blue; hind-head spotted with yellowish-green, the shoulders are edged with yellow. This species, in all its varieties, inhabits the islands in the Pacific ocean.

Palmarum; Palm Parrot. Green; bill and legs red; quill-feathers tipt and edged with black. It is found among the palm trees in Tanna island.

Australis; Blue-crested Parrakeet. Green; crown blue, crested with long feathers; chin and middle of the belly red, thighs purple. It is found in the Sandwich islands, and is 5 or 6 inches long.

Peregrinus; Peregrine Parrakeet. Green; on each wing there is a longitudinal brown spot. It inhabits the islands in the Pacific ocean, and is about eight inches long.

Taïtanus; Otaheite Parrakeet. Blue; feathers of the head long; chin and throat white, bill and legs red. This is a native of Otaheite; it is five inches long; feeds on the fruits of the banana; the tongue is fringed at the end; the body is often white beneath.

Cyanus; Blue Parrakeet. Body entirely of splendid full blue. This also is found in Otaheite, and has been thought to be a variety of the last.

Psittillus; Timid Parrakeet. Olive brown; frontlet scarlet; tail-feathers within, near the base, scarlet. It inhabits New South Wales, and is seven inches long.

Pygmeus; Pigmy Parakeet. Green; feathers tipt with greenish-yellow; quill-feathers within dusky. It inhabits the islands in the Pacific ocean, and is six inches long.

Agilis; Agile Parrot. Green; primary quill-feathers blueish, with tawny coverts; tail hardly lengthened, beneath red; orbits cinereous. It inhabits America, and is 9 or 11 inches long.

Sanguinolentus; Red-shouldered Parrot. Green; green behind; frontlet crimson; crown, and outer edge of the wings, deep blue; shoulders, and wings beneath, blood-red. This is found in New South Wales.

B. Tails fbra, equal at the end.

Coronatus; Crowned Cockatoo. Green; crest plicatil, red, tipt with blue. This is about 18 inches long, and inhabits Guiana and Surinam.

Asterinus; Black Cockatoo. Black; crest large, paler; cheeks red, naked. This is three feet long, and found in New Holland.

Funereus; Funereal Cockatoo. Black; middle of the tail fraw-colour freckled with black. This likewise is a native of New Holland, and is nearly as large as the last.

Banksi; Bankfian Cockatoo. Splendid black; crest small; head and wing-coverts dotted with buff; outer tail-feathers scarlet in the middle, barred and tipt with black. This is about three feet long, and found in New Holland. There are two varieties: 1. Sides of the neck, chin, and throat yellow; this is about 22 inches long. 2. Dusky-brown inclining to olive; tail, except the two middle feathers, crozled with a broad red bar. The size of the former.

Sulphurus; White Cockatoo. White; creft folding, and with the spot beneath, the eyes sulphur-yellow. It is about 10 or 15 inches long, and inhabits the Molucca islands.

Galeratus; New Wales Cockatoo. White; creft long, folding, pointed, sulphur; base of the tail sulphur. It inhabits New South Wales, and is twenty-seven inches long.

Philippinarum; Red-vented Cockatoo. White; creft folding, sulphurous, white at the tip; orbits yellowish-red; the lower tail-coverts are red, dotted with white. This is a native of the Philippine islands.

Moluccensis; Molucca Cockatoo. White, inclining to pale rosy; crest beneath red; lateral feathers within from the base to the middle sulphurous. This species and the next inhabit the Molucca islands, and are about seventeen inches long.

Cristatus; Great white, or yellow-crested Cockato. White; creft folding and yellow; the feathers of the neck are lofty flowing; the creft is five inches long, and capable of being erected. It is about eighteen inches in length, and the size of a domestick ordinary fowl. This and several
few others of the species frequently repeat the word cockate.

ERYTHROLEUSUS; Red and white Parrot. Cinereous; rump, quill and tail-feathers scarlet.

ERYTHROUS; Hoary Parrot. Hoary; temples naked, white; tail coochineal or scarlet. There are three varieties: viz. 1. Wings red. 2. Variegated with red. 3. Red; head cinereous; cheeks naked; primary quill-feathers brown-asf. They all are natives of Africa, and about twenty inches long. This species is very loquacious, modulating its voice in various tones, and easily repeating whatever it hears. It is sometimes called Jaco, from one of its most frequent founds.

CINEREOUS; Cinereous Parrot. This is entirely of a blueish-asf colour. It inhabits Guinea, and is larger than the last species.

MERYDONALIS; Southern Parrot. Above greenish-asf, beneath bright bay; orbits, crown, hind-head, and neck cinereous; the feathers are tipp with brown. It inhabits New Zealand, and is about sixteen inches long.

MACARINUS; Mascarinus Parrot. Cinereous; frontlet beneath black; orbits naked, reddish; lateral tail-feathers whitish at the base.

FUSCUS; Brown Parrot. This is entirely of a brown-asf, and thirteen inches long.

GARRULUS; Ceram Lory, or Ceram purple Parrot. Red; orbits asf; cheeks and wings green; latter half of the tail-feathers blue. There are three varieties: 1. Scarlet coloured; wings green and black; tail-feathers yellow, the latter half greenish. 2. Shoulders spotted with yellow. 3. Most of the wing-coverts dotted with blue. It inhabits the Molucan isles.

DOMICILLA; Blue-cap Lory. Red; cap violet; wings green; shoulders and cheeks black; orbits brown. There is a variety with a blue cap, black orbits, and yellow collar; but, according to some writers, these are male and female. They inhabit the East Indies, and are remarkable for speaking distinctly, and very quickly learning their lessons. They are very scarce birds, and fetch a high price.

LORY; Violet-cap Lory. Purple; cap violet; wings green, breast, cheeks, and tail blue; the orbits are of a pale flesh colour. It is a native of the Philippine isles.

PONICUS; Crimson Lory. This is of a deep scarlet colour, but beneath it is violet; lefser and under wing-coverts, quill-feathers within and underneath, blackish-brown. It inhabits Ambon and.

RUBER; Molucca Lory. Red; area of the eyes and quill-feathers black; spot on the wing and under tail-coverts blue; tail crested at the tip. A variety has its shoulders, belly, vent, tips of the secondary quill-feathers, and greater wing-coverts, blue. It inhabits the Molucca isles and New Guinea.

GRANDIS; Grand Lory. Red; beneath mixed red, blue, violet, and green; nape violet; wings blue; tail tipp with yellow. A variety is varied above with brown and green; beneath it is blue; the edge of the wings and their under-coverts blue; the tail is chestnut colour. It inhabits Ceylon.

COCCHININUS; Cocchinchina Parrot. Blue; front, nape, lower part of the neck, breast, and middle of the belly, scarlet. It inhabits, as its name imports, Cochinchina.

GUIEENSIS; Yellow-breasted Lory. Head and neck scarlet; eye-brows and breast yellowish; wings yellowish-green, tipp with blue; belly, vent, and under part of the tail, hoary, tipp with scarlet. It inhabits Guinea.

PARAGUANUS; Paraguayan Lory. Scarlet; head, neck, vent, tail, shoulders, and wings, black. It is thought to be a native of Brazil.

NIGER; Black Parrot. Tail long and equal; the body is of a blueish-black; the bill and orbits are white. It inhabits Madagascar, and is thirteen inches and a half long.

CARLUS; Blue-headed Parrot. Blue; belly, rump, and tail green; crown yellow; quill and tail-feathers red. It inhabits Guinea.

VARIS; Variegated Parrot. This species is varied with brown and blue; cheeks, chin, and throat whitish; quill and tail-feathers dusky-brown, the outer webs blue. It inhabits South America.

VOLACEUS; Ruff-necked Parrot. This is of a violet colour, varied with mixed black and green; back dusky-green; greater quill-feathers black, the rest varied with yellow-green and red, with a rosy spot on their coverts. It is a native of America, and the size of a hen.

FRINGILLACEUS; Finch Parrot. Green; head blue; cheeks, chin, throat, and spot on the belly white, with a fort of bloody hue; the belly is of a violet colour. It is a native of South America, and is rather more than fix inches long.

CHORUS; Chili Parrot. Green; beneath asf; orbits, carnation. It inhabits Chili.

SINENSIS; Chinefe Parrot. Green; under wing-coverts red, some of the greater and edge blue; tail beneath brown. It inhabits the southern parts of China, Amboina, and New Guinea, and is of the size of a hen.

MACORHYNCHOS; Great-billed Parrot. Green; beneath inclining to yellow; wings mixed blue and green, with black coverts. It inhabits New Guinea, and is fourteen inches long.

NASUTUS; Grilled Parrot. Green; head and breast greenish-grey; wing-coverts yellow. It is a native of China, and is twelve inches long.

GRAMINEUS; Grafs-green Parrot. Green; beneath olive; front and crown blue; tail beneath yellow. It is sixteen inches long, and a native of Amboina.

LEUCOCOFAUS; White-fronted Parrot. Green; quill-feathers blue; front white; orbits snowy. There are the following varieties: 1. Throat red; the feathers edged with white; belly purple; quill-feathers blue on the outer webs. 2. Head from the front to the neck white, the rest pale blue; orbits and spurious wings red. 3. Crown blueish-asf; belly spotted with red. These are found in Martinico, Jamaica, and New Spain.

GERINUS; Gerin's Parrot. Green; head white; shoulders, some of the middle quill-feathers, and tail-feathers within at the base, red. This is a native of Brazil.

OCHROPTERUS; Yellow-winged Parrot. Green; front and orbits whitish; crown, cheeks, chin, throat, and rector wing-coverts, yellow. It is thirteen inches long, and is found in South America. A friend of Buffon posed one of this species, which shewed a strong attachment to his master, but was yet of a very capricious temper, expecting a full return for every demonstration of its civility. It would, in play, sometimes bite a little too hard, and laugh heartily at the act; but if chaffed, it became refractory, and could only be reclaimed by gentle and kind treatment. It took much delight in tearing everything to pieces; was dull and silent, if confined in its cage; but when set at liberty, it chattered incessantly, and repeated every thing that was said. It was very fond of children, which is contrary to the usual disposition of parrots. During the moultiing season, it appeared dejected and uneasy for three months together. It inhabited chiefly on hemp-feed, nuts, fruits of all kinds, and bread, soaked in wine, but preferred flesh.
flesh, when it could get at it; when, however, it was indulged much in this latter article, it became dull and heavy, and shortly after began to lose its feathers. It was also observed to make use of a fort of rumination.

Ochrocephalus; Yellow-headed Parrot. Green; crown yellow; wing-coverts red; quill-feathers variegated with green, black, violet, and red; the two outer tail-feathers within red at the base. There are two varieties of this species: 1. Crown with a yellow spot; bill ruddy. 2. Upper mandible blueish-green, with yellow sides, and a black spot at the tip; lower of a lead-colour, yellow in the middle. This species is from sixteen to eighteen inches long. It inhabits South America.

Barbadensis; Ash-fronted Parrot. Green; orbits and front cinereous; crown, cheeks, chin, throat, and lesser wing-coverts yellow, the greater blue; many of the primary quill-feathers without violet, the rest from the base to the middle red, and afterwards blue. Inhabits Barbadoes, and is the size of a pigeon.

Lucionensis; Manilla Parrot. Green; hind-head and rump blue; wings marked with black, blue, and red. It is found in Luzonia, and is more than a foot long.

Estivus; Amazon Parrot. Green, slightly spotted with yellow; the front is blue; shoulders blood-red; orbits carnation. There are eight varieties of this species, viz. 1. Head and breast yellow; front and chin blueish; edges of the wings and vent red. 2. Leiffer wing-coverts red. 3. Cap blue, variegated with black; a yellow spot on the crown, and each side below the eyes; chin blue. 4. Crown, cheeks, and chin yellow. 5. Pale green; front pale yellow; temples tawny. 6. Green; front blue; crown, cheeks, chin, and middle of the belly, yellow. 7. Green; head and neck yellow; shoulders red. 8. Green, variegated with yellow; front blue; shoulders red. These are all natives of South America, excepting the first variety, which is a Jamaica bird.

Lutus; Yellow-shouldered Parrot. Green; crown blue; shoulders yellow; great wing-coverts with an orange spot. It inhabits South America.

Pulverulentus; Meal Parrot. Green; above meal, spot on the head yellow, on the wings red. It is found in Cayenne, is very large, and speaks distinently.

Havanensis; Blue-fronted Parrot. Green; the front, the chin, and throat, are of an ashy-blue; on the breast is a large red spot; the orbits are cinereous. It inhabits Havanah, and is a foot long.

Paradisi; Paradise Parrot. Yellow; chin, belly, and base of the tail-feathers red. This is rather longer than the last, and inhabits Cuba.

Aurora; Aurora Parrot. Yellow; arm-pits, edges of the wings, and greater quill feathers without in the middle red. It inhabits Brasil.

Passerinus; Passerine Parrot, or blue and green Parakeet. Yellowish-green; spot on the wings, and wings beneath blue. It inhabits Brasil and Guiana, and is about the size of a common house-sparrow.

Cyanolichos; Blue-collared Parrot. Yellowish-green; collar blue; rump red. This species is something larger than a pigeon. It inhabits Chili, where it is called thecan, and where it does a deal of mischief to the corn, flying always in flocks. When the troop is about to settle, one of them acts as sentinel on a tree, and gives the alarm if any peril approaches, on which account it is very difficult to shoot them. This species breeds in the holes of rocks, laying two white eggs in the most inaccessible and craggy parts. From the tops of the cliffs the inhabitants in pursuit of them let themselves down by ropes. Both the eggs and young birds are reckoned very delicate eating. If robbed of its young, this bird will lay a second time, and sometimes even a third. It is easily tam'd, and learns to speak well.

Sordidus; Dusty Parrot. Brownish; chin blue; wings and tail green; bill and vent red. It is about the size of a pigeon, and inhabits New Spain.

Dominicensis; Red-banded Pigeon. Green; band on the forehead red; lunules on the neck and back black; quill-feathers blue. It is a native of St. Domingo.

Erythropterus; Crimson-winged Parrot. Green; or bits blackish; middle of the back black, lower part blue; wing-coverts red. It inhabits New South Wales.

Estivus; Fellive Parrot. Front purplish, eye-brows and chin blue; back blood-red. It inhabits Guiana; is eleven inches long, very active, but fierce and untractable.

Robustus; Robust Parrot. Green; head somewhat ash; wing-coverts dirty black, edged with green; spot on the wings red. It is the size of a pigeon.

Ornithinales; Eastern Parrot. Green; outer edge of the wings and primary quill-feathers blue sick; tail yellow at the tip. It inhabits India.

Adscitus; Blue-checked Parrot. Green; checks and wings blue; back on the fore-part black, with yellow streaks, hind-part yellowish.

Batavensis; Batavian Parrot. Green, with yellow streaks; hinder part and nape blackish; face and thighs scarlet. It is a native of Batavia.

Tarahumara; Tarare Parrot. Green; head, chin, throat, breast, and lesser wing-coverts red. It inhabits Brasil, and is ten inches long.

Brasilensis; Brafil green Parrot. Green; face red; temples blue; orbits ash. This also is a native of Brasil, and is thought to be a variety of the next.

Autumnalis; Autumnal Parrot. Green; front and spot on the quill-feathers scarlet; crown and primary quill-feathers blue. There are two varieties: 1. Front and chin blue. 2. Head variegated with red and white. It inhabits Guiana, and is the size of the last.

Coccinecephalus; Scarlet-headed Parrot. Green; crown and front scarlet; rump greenish-yellow; quill and tail-feathers blue without. Size of the millet thrush.

Acephalus; Hawk-headed Parrot. Green; head grey; neck and breast varied with blueish; quill and tail-feathers tipt with blue. There is a variety, of which the feathers of the head are white, long, and narrow, streaked with black. The former is a native of India; the latter of Guiana, where it is domesticated. When angry it crests its crest.

Menstruus; Blue-headed Parrot. Green; head bluish; vent red. This species is found in Guiana; it is not very docile, and has the voice of a jack-daw. It is the size of a turtle dove.

Purpureus; Purple-bellied Parrot. Above black-brown, beneath purple; crown and cheeks black; orbits blue; collar with dirty spots; quill and tail feathers blue. It inhabits Surinam.

Melanoccephalus; White-breasted Parrot. Green, yellow beneath; cap black; breast white, orbits flesh-colour. Its length is nine inches and a half. It inhabits Mexico, Guiana, and the Caraccas in South America. It frequents woods, and is rarely seen in inhabited districts. Its call is a shrill whistle, which it often repeats in its flight, and it does not learn to talk like other birds of this genus. According
to Mr. Latham, the white-breasted parrots fly in small numbers together, but are perpetually quarrelling with one another; and if any one is taken, it refusés all food, till at length it is starved to death. Parrots of the most robust nature are often subdued by means of the smoke of tobacco; but this bird is only put into bad humour by the attempt. Buffon has observed that "it is thicker and shorter necked than most parrots; that its feathers are more stiffly set on, and that it is of a more dull and sluggish disposition."

Pileatus; Hood Parrot. Green; head black; orbits white; spot on the shoulders blue; tail tip with blue. It inhabits Cayenne, is about eight or nine inches long, and migrates.

Ludovicanus; Orange-headed Parrot. Sea-green; head tawny, inclining to red towards the bill. This species inhabits Louisiana; it feeds on the seeds of the Bromelia and Literudron, which feces; it flies in large flocks, making a great noise; is not easily taught to speak, and is about thirteen inches long.

Collarius; Red-throated Parrot. Green; chin reddish; throat red. It is a native of Jamaica, and about the size of a pigeon.

Senegallus; Senegal Parrot. Green; beneath yellow; head cinéreous; orbits black and naked. This, as its name imports, is found on the sandy shores of Senegal; its voice is harsh and unpleasant; it flies in flocks of six or seven, and roosts on the top branches of trees.

Trypana; Red-fronted Parrot. Pale-green; lunule on the front red; spot on the middle of the wings yellow. It inhabits Brasil.

Chrysopterus; Golden-winged Parrot. Green; spot on the wings blue and tawny; orbits naked and white. It inhabits India.

Pullarius; Ethiopian Parrot. Green; front red; tail tawny, with a black band; the orbits are cinéreous. This is not six inches long. It inhabits Guiana, Ethiopia, India, and Java; it imitates the manners of other birds, but does not easily learn to speak, and is fond of its own tribe.

Malacensis; Malacca Parrot. Green; front and rump blue; under wing-coverts red.

Cervicalis; Red-naped Parrot. Green; front and febrilinar spot on the nape, under part of the throat, and breast scarlet.

Indicus; Indian Parrot. Green; orbits pale flesh-colour; crown red or orange; hind part of the rump red; quill-feathers within and tail without blue-green. It is a native of India, and about the size of a lark.

Vernalis; Vernal Parrot. Bright green; wings paler; throat, rump, and tail blood-red.

Galagus; Sapphire Parrot. Green; rump and breast scarlet; the crown of the male bird is blue. There is a variety that has a yellowish-blue head, with a transverse orange bar behind; the front, the under part of the throat, and tail-coverts red. This species is about five inches long, and inhabits the Philippine islands. It sleeps suspended by one foot, and is very fond of the fresh juice of the cocoa-nut tree. If this is confined in a cage it futilities whistles, and grows füllen. It suspends itself by its feet, so that the back is turned towards the earth, and seldom changes this situation. Its favourite food is boiled rice. The nuts are remarkable for the fineness of their texture. "If," says a traveller, "they had a different construction, the monks would be very mischievous to them; but now, before they can get to the opening, the lowest part, being the weakest, breaks in pieces, and the depredator falls to the ground, without in the least annoying the birds."

Anaca; Chefsant Parrot. Green; beneath tawny-brown; crown bay; spot on the back and tail pale-brown; wings edged with red. It inhabits Brazil, and is the size of a lark.

Purpuratus; Purple-tailed Parrot. Green; crown and neck cinéreous; rump, edge of the wings, and tips of the quill-feathers black; the secondary yellowish, dotted with blue. It inhabits Java and Luzonia, and is six inches long.

Capensis; Cape Parrot. Green; some of the quill-feathers blue; bill and legs reddish. Inhabit the Cape, and is four and one half inches long.

Torquatius; Green; hind-head with a yellow transverse band streaked with black. This species inhabits the Philippine isles, and is five and one half inches long, and does not talk.

Minor; Lesser Parrot. Green; crown scarlet; breast blue; greater quill-feathers black. It inhabits Luzonia, and is smaller than the last.

Tovii; Green; throat with a pale-orange spot; wings with a broad cinéreous band, of a gold-green hue; about seven inches long, and is supposed to inhabit America.

Tirica; Green; bill flesh-colour; legs and claws blueish. It is a native of Brazil and Jamaica, and the size of a lark.

Sospes; Cayenne Parrakeet. Green; a pale yellow spot on the wings and tail-coverts. This is a native of Guiana; is easily tamed, and is very talkative.

Tui; Gold-headed Parrakeet. Green; front orange; orbits yellow. It inhabits Brazil, and is the size of a parakeet.

Erythrochlorus; Red-tailed Parrot. Green; head crested; wings and tail red. It is the size of a black-bird; the crest of this bird consists of six feathers, three of which are longer and moveable at pleasure.

Mexicanus; Mexican Parrot. Green; front crested; wing-coverts and tail purple; orists blue; chin yellow; neck red. This is a native of New Spain, and is about seven inches long.

Among the many parrots that have been imported into this country, the one whose imitative talent was reckoned most extraordinary, belonged to Colonel O'Kelly, which he purchased for 100 guineas. This bird not only repeated a great number of sentences, and answered questions, but was able to whistle many tunes. It appeared to have an accurate ear for music, and would beat time while it whistled; and if by chance it millred a note, it would revert to the bar where the mistake occurred, and finish the tune with great accuracy. The writer of this article is at the moment within hearing of a bird, that will imitate the whistling of a black-bird and thrush, with a vail degree of accuracy. Colonel O'Kelly's parrot could express her wants articulate, and give her orders in a manner nearly approaching to rationality; she could dig a number of fongs in perfect time and tune.

Pskov, or Pleskow, in Geography, a city of Russia, capital of a government, situated on the river Velika, where it discharges itself into the Tchudikoe lake; the see of an archbishop,
archbishop, and an university; 136 miles S.S.W. of Petersburg. N. lat. 57° 50'. E. long. 28° 14'.

PSKOVSKO, a government of Russia, so called from its capital Pskov; bounded on the N. by the governments of Petersburg and Novgorod, on the E. by the government of Tver, on the S. E. by that of Smolensk, on the S.W. by that of Polotsk, and on the W. by that of Riga; about 200 miles long, and 96 broad. N. lat. 54° 40' to 57° 12'. E. long. 27° 24' to 32° 34'.

PSOAS, in Anatomy, the name of two muscles situated in the lumbar region.

The psosas major (prelombo-trocanterien) is placed at the lateral and inferior part of the vertebral column, at the side of the upper aperture of the pelvis, and in the upper part of the thigh. It extends from the side and lower part of the lumbodorsal vertebra to the apex of the trochanter minor. It is elongated, and larger in the middle than at the two extremities; so that it resembles two triangular pyramids joined at their bases. The external surface of the psosas plant backwards; it is covered above by the diaphragm, lower down by the kidney, the peritoneum, and the psosas parvis; still lower it becomes anterior, and is covered by the artery of the lower extremity. The posterior surface covers the quadratus lumborum, from which it is separated by the anterior branches of the lumbar nerves and the anterior layer of the aponuroses of the transversus; it also covers the transverse processes of the lumbar vertebra, to the basis of which it is attached, excepting the fifth. About the middle of the psosas its posterior surface covers the ilio-lumbar ligament, and the iliacus internus muscle; it is at first separated from the latter by cellular tissue, by the lumbar nerves, and the ilio-lumbar vessels; the two muscles then become inseparably united. The tendon of the psosas, with the fleshy fibres of the iliacus internus coming to join it, covers the excavation on the front of the os innominatum from the anterior superior spine of the ilium to the linea iliopectinea. Lower down it covers the orbicular ligament of the hip-joint. Between the latter and the os innominatum on one side, and the tendon on the other, a burza mucosa is placed, which communicates sometimes with the cavity of the joint. The internal surface of the muscle covers the side of the bodies of the lumbar vertebrae, and of their fibro-cartilages, to which parts it is attached, but only at the upper and lower part; for, at the middle of the bodies, it is separated from them by the lumbar vessels, and by the communicating filaments between the lumbar nerves and the great sympathetic. Between this internal surface, and the lumbodorsal vertebra, there is an interval filled by cellular substance: the surface then becomes narrower, and descends along the side of the upper aperture of the pelvis, covered by the external iliac vein and the tendon of the psosas parvis. Below the crural arch, the internal surface of the psosas grows still narrower, and is converted into an edge, which is parallel to the pectinalis, and separated from it by the internal circumflex vessels.

The upper extremity of the psosas is thin and pointed, and attached to the inferior and lateral part of the last lumbar vertebra, and sometimes to the posterior extremity of the last rib. Thence it descends along the side of the vertebral column, growing larger. It runs along the upper aperture of the pelvis, diminishing again in bulk, and directed a little outwards. Conflounded with the iliacus internus, it passes out of the pelvis behind the crural arch, then descends on the upper and front part of the thigh, directed obliquely backwards and outwards, to the trochanter minor, in the apex and anterior part of which it terminates.

The inferior extremity of the psosas magnus is formed by a strong tendon, common to it with the iliacus internus, and continued into the body of the muscle, as far as its middle, increasing in breadth. The fleshy fibres arise by short aponeuroses from the bodies of the last dorsal, and the four upper lumbar vertebrae, their fibro-cartilages, and the transverse processes of the first lumbodorsal vertebra; they terminate on all sides of the tendon, which they accompany very low, particularly on the inside.

The psosas magnus carries the thigh forwards on the pelvis, and rotates it outwards. If the thigh is fixed, it will bring the pelvis forwards on it, as in flopping to bring the hand to the ground. It may also bring the loins forwards on the pelvis. When the trunk is inclined backwards, it will restore it to the erect attitude; in the latter posture, it maintains the pelvis in equilibrio on the thigh, and prevents it from yielding backwards. It is much employed both in standing and walking.

The psosas parvis (prelombo-pubien), which does not always exist, is a long, thin, and flat muscle, situated on the outer and anterior part of the psosas magnus, and extending from the body of the last lumbar vertebra to the ilio-pectinea eminence. It is covered on the outside by the diaphragm, the renal artery and vein, the peritoneum, and the external iliac artery. Its internal surface covers the psosas magnus, and is united to it by loose cellular tissue.

The upper extremity is fixed to the lower and lateral part of the body of the last dorsal vertebra, and to the fibro-cartilage between it and the first lumbodar. It passes obliquely downwards and outwards, and soon forms a flattened tendon, which increases in breadth as it descends, covers the lower and anterior part of the psosas magnus, and terminates by an infection in which the ileo-pectinea eminence, and in the crita of the pubes. This tendon is continued, on the outside, into a fascia, which covers the iliacus internus, and joins the fascia lata (see FASCIA): the upper third of the psosas is fleshy; the two lower are tendinous. It will bend the pelvis on the loins, or the loins on the pelvis, according as the one or other of these is the fixed point.

Psaas Abscess, in the language of Surgery, denotes a collection of purulent matter, which sometimes takes place in the course of the psosas muscle, and is a disease that is frequently attended with considerable danger. It is often called a lumbar abscess. It is occasionally the consequence of an acute inflammation of the cellular substance which lies about the psosas muscle; but, in the majority of cases, the inflammation which precedes it is entirely chronic. The inflammation of this kind is merely accompanied with a pain about the loins, extending up the back, and down towards the thigh. Such pain is increased when the thigh is raised, or extended backwards, or when the patient holds himself quite erect. Hence it is observable, that the patient, whether standing or walking, is obliged to incline his trunk forwards. When the inflammation is acute, the pain is severe; but when it is chronic, the uae abscesses which the patient experiences are duller, and alternately subside and recur, and may easily be mistaken for sciatica, the pain arising from interloboids, or that proceeding from disease of the kidney. The acute inflammation is usually attended with evident febrile symptoms; the chronic is seldom accompanied with them. The first falls into a state of suppuration with all the ordinary symptoms; the second suppurates for the most part slowly and imperceptibly, and often not till after a period of several months.
Psoas Abscess.

The inflammation may be produced by a variety of causes. It may arise from a violent strain of the psoas muscle in leaping, raising a heavy weight, or in some other forcible bodily exertion. Sometimes it is brought on by exposure to cold, or by a blow or fall on the lower part of the back. In the latter case, it often does not occur till long after the occurrence of the injury, so that its cause is already quite forgotten. In numerous examples, the psoas abscess appears also to originate from internal causes; at least, it is remarked, that the disease happens with particular frequency in unhealthy subjects. In such cases, the commencement of the disorder is in general very obscure and imperceptible. All experienced surgeons have noticed how many of the patients with psoas abscesses are manifestly of a scrofulous habit. It has been supposed that the disease is commonly occasioned by a caries of the vertebrae, which are situated close to the origin of the psoas muscle. (Ford on Diseases of the Hip-joint.) Possibly this may sometimes be the real case; but it is not invariably so; for in psoas abscesses it often happens that no caries whatever exists; and when it does, it may, with equal probability, be regarded as an effect of the abscess.

Richter's Anfangsgr. der Wundarzneykunft, band 5. kap. 5.

The original situation of the abscess is generally in front of the psoas muscle, and very near to it; but it is also, in many instances, behind this part. By degrees the matter makes its way outward, though a long period often elapses ere this happens. Abscesses which follow acute inflammation usually point much earlier than those which are the consequence of chronic inflammation. In the former cases the cellular subsidence is apt to be extensively affected, and it falls into a state of suppuration; besides, acute inflammations much more quickly suppurate than those of the chronic kind.

While the abscesses do not present itself externally, the diagnosis is attended with considerable difficulty and uncertainty. After the usual symptoms of inflammation, the patient is indeed conscious of several particular local sensations. For instance, he is sensible of weakness in the loins, which are also exquisitely tender on being touched, or when the thigh is moved, and the lower extremity is remarkably weak. Frequently some general signs of suppuration likewise occur, such as hectic fever, nocturnal sweats, diarrhoea, cough, &c. But all the local symptoms may be confounded by the surgeon as proceeding from rheumatism, diseased kidney, or hemorrhoidal complaints. In the early stage of the psoas abscess, the general symptoms of suppuration are hardly ever very obvious. The previous signs of inflammation are mostly so mild, and precede the formation of matter so long, that they often pass unnoticed. Besides, all conjectures respecting the nature of the disorder avail nothing, as the practitioner can adopt no effectual measures before the abscess presents itself externally.

The psoas, or lumbar abscess, presents itself in a variety of situations. In common cases, the matter descends, by its own weight, in the course of the psoas muscle, passes under Poupart's ligament, and occasions a fluctuating tumour in the soft part of the abdomen. The tumour is free from pain and inflammation; a circumstance which indicates that the matter is not formed in the situation of the swelling itself. The diminution of the local complaints about the lumbar region after the swelling has occurred; the manner in which the tumour is increased when the patient holds his breath or coughs; its sub-
devi'd. The source of the matter lies so deeply, that no effect can reasonably be expected from the employment of external emollient applications.

Experience has clearly proved, however, that when the abscess is opened in the common manner, death generally takes place sooner than if no opening at all were made. A fever, accompanied with auricular sweats and diarrhoea, commonly soon comes on after the abscess has been punctured; the matter becomes thin, fetid, and acrid, and is incessantly discharged in large quantity; so that the patient at length dies debilitated and exhausted. This fatal event has been ascribed by surgical writers to a variety of causes; some dwell upon the entrance of the external atmospheric air into the cavity of the abscess; some build conjectures on the great distance of the source of the matter from the surface of the body, and from the reach of the practioner; while others take more into consideration the ample extent of the cyst of the abscess.

The following circumstances seem to prove, says Richter, that the external air which enters the cavity of the abscess after the operation, has a material share in producing the bad and fatal symptoms. The fever and pain always become more violent after the opening has been made than they were previously. The whole cavity of the abscess appears to be in an inflamed state, in consequence of the irritation arising from the atmospheric air. When the abscess is first opened, the matter is usually observed to be of a tolerably good quality; but, very soon afterwards, it becomes fetid, thin, and acrid. This sudden change in the matter is also imputed to the effect of the air. It is remarked, likewise, that the larger the opening is which the surgeon makes, the greater is the degree in which the preceding circumstances occur; while, on the contrary, the smaller the aperture is, the milder they are, and the result of the operation is in proportion more successful. Hence, it is better to let the abscess break of itself, than to make a large opening; for the aperture which is formed by ulceration is mostly a small one. Such lumbar abscesses make their way through the abdominal muscles, and preface themselves at the belly, are found to be less dangerous than others, perhaps (adds Richter) because the passage of the matter through the muscles towards the surface of the body is so crooked, that the opening of the tumour does not readily give admittance to the air into the original cavity of the abscess, so as to excite inflammation and other bad consequences. Lastly, the observations of Mr. Abernethy prove, that the operation may be frequently repeated with the greatest success, provided it be done so as not to let the air enter the cyst of the abscess.

But, notwithstanding the preceding observations, it is now the opinion of the most accurate surgeons, that the bad effects of the air on abscesses have been exaggerated beyond all moderation. In the first place, it is almost certain that when a lumbar abscess is opened, no air at all can infininate itself into the cyst, which is so strongly compressed by all the surrounding parts, that its capacity is diminished immediately the matter escapes from it. Secondly, even if air were injected into it, the consequences would not be so terrible as has been commonly represented. It is more probable that the irritation which a large opening itself produces in the extensive cyst, and the consequent inflammation of the whole of its surface, are the real cause of the violent fever which is so apt to arise, and of the changes in the quality of the matter afterwards secreted. We can believe with Hunter, that, were it possible to make a large opening in a lumbar abscess, even in a vacuum, the same dangerous conserquences would be just as likely to follow, as when such an opening is made while the surface of the body is exposed to the air.

The apprehension entertained by many practitioners in regard to mischief caused by the entrance of the air into the cysts of lumbar abscesses, has led to the almost universal advice to take the precaution of making the opening in such a way, that no opportunity will be afforded for the air to enter into the cavity from which the matter is discharged. It has also been the usual aim of practitioners to lessen the cyst of the matter, and bring it to near the surface of the body, that the case may be opened and treated like other abscesses, without any risk of dangerous consequences. Both these indications are fulfilled in the mode of treatment recommended by Mr. Abernethy, who opens the collection of matter with an abscess lancet, and as soon as the pus is discharged, brings the sides of the puncture together with sticking plaster, and heals the aperture by the first intention. Immediately the tumour rises again, it is emptied again in the same manner, and the operation may be repeated, if necessary, three, or four several times, or even still more frequently.

In this plan of treatment, regularly as the matter is formed again after each operation, it defends, by its own weight, to the lower part of the cyst of the abscess under Poupart's ligament, where it occasions a return of the swelling. But before the upper part of the cyst is filled with matter again, the surgeon takes a proper opportunity of repeating the operation. Thus the highest portion of the cyst is continually kept empty, and, consequently, by degrees contracts itself, and is obliterated. The lower external part of the cyst, situated under Poupart's ligament, is all that remains, and an immense piaios abscess is in this manner converted into a small superficial abscess, which may now be safely opened, and treated like any ordinary case.

But in order to succeed in effecting this desirable alteration of the cyst of the abscess, the surgeon should not defer the second operation too long. Immediately the swelling is sufficiently prominent to admit of being opened with safety, the operation ought to be repeated. We may conclude, that the upper and deeper part of the cyst is obliterated, and that the piaios abscess is changed into one of a superficial kind, when, in the last operation, the quantity of matter discharged is small; when no more can be got out either by preflure, or making the patient stand up and cough; when no material impulse is communicated to the tumour by coughing; and when the swelling is no longer capable of being leffened by preflure, or the horizontal position. As soon as these changes are remarked, the radical operation may be undertaken, which consists in making an incision into the tumour, and draining it like any common abscess.

It is advantageous in puncturing a piaios abscess to let the opening have a perpendicular direction; for a transverse wound may easily be forced open again from violent coughing, or forcible extension of the thigh. When the external swelling is small, care must be taken not to injure the large curial vessels with the lancet. On this account, the opening ought to be made as much as possible towards the side of the tumour. During the operation the patient should stand up, and be directed to hold his breath, and cough frequently, so that all the matter may be discharged. When the surgeon entertains the slightest doubt concerning the nature of the swelling, he acts prudently in making the opening cautiously, with a bitfloury, and not of too large a size. After the contents of the abscess have been let out, the opening ought always to be accurately closed with sticking plaster. The patient,
patient, throughout the treatment, must abstain from all exercise, and especially avoid moving the thigh, taking care, however, to be as much as he conveniently can in an erect posture.

In general, it will be proper to make the second puncture about a fortnight after the first. But if the swelling becomes very prominent earlier, and, particularly, if the first puncture put on an inflamed appearance, the second opening ought to be made sooner. In every repetition of the operation, the quantity of matter will be found to be diminished, a sufficient proof that the cavity of the abscess is lefsered. For instance, if in the first operation three pints of matter are discharged; in the second the surgeon will let out only about twelve ounces; in the third, six; in the fourth, four; and so on. After the abscess has been emptied three or four times, the upper portion of the cavity is usually obliterated, so that the radical operation for the cure of the lower and superficial remains of the abscess may now be attempted.

Candour urges us to confess, however, that there are cases in which the preceding mode of treatment proves ineffectual. Such are the examples, in which, notwithstanding every precaution, the cyst of the abscess inflames; the puncture ulcerates; where the disfigure has originated from internal causses, which yet continue to influence and keep up the disfigure; where caries exits; and where the abscess has been the consequence of acute inflammation. It is particularly to chronic abscesses that the foregoing plan of treatment is adapted. When this treatment fails, two things may happen; the discharge may continue to be so profuse, that the patient is exhausted; or the abscess may end in a fistula, with which the patient may live a great while. The surgeon, however, is not to abandon all hope in the above description of abscesses. When the puncture inflames, the bad consequences may often be averted by speedily letting out the newly collected matter through another puncture, at some distance from the other, the antiphlogistic treatment being strictly observed. When some internal cause has a share in keeping up the disfigure, its removal is obviously indicated. Lastly, experience proves, that, though caries may exist, the termination of mott abscesses is favourable. When the bones are suspected of being diseased, it is not, in the vicinity of them a measure which should never be neglected.

Some writers and practitioners prefer opening lumbar abscesses with a fenton; while others are advocates for the bold practice of letting out the matter with a trocar, the cannula of which they recommend to be left in the part, and clozed with a stopper, which may be taken out as often as necessary, for the purpose of discharging the matter.

PSOL, in Geography, a river of Ruffia, which rises near Obaud, in the government of Kurik, and runs into the Dnieper, near Kremenzyg, in the government of Ekaterinoglave.

PSOPHIA, Trumpeter, in Ornithology, a genus of birds of the order Grallae: the generic character is, bill cylindrical, conic, convex, somewhat pointed, the upper mandible the longer; nostrils are oval, perrious; tongue cartilaginous, flat, fringed at the tip; feet four-toed, cleft. There are two

Species.

CREPITANS; Gold-breasted Trumpeter. Black; back grey; breast shining blue-green; orbits naked and red. The bill is yellowish-green; legs strong, tall, brownish-ash or green; beneath the back-toe is a round protuberance, at a little distance from the ground; the tail is very short; feathers of the head downy, of the lower part of the neck squamiform, of the shoulders ferrugineous, lax, pendulous, silky; scapulars long, pendant. This is the agami mentioned by voyagers; it is nearly twenty-two inches long, and about the size of a full-grown domestic fowl. It inhabits South America, particularly the interior parts of Guiana, in considerable troops. In its native haunts, it is not diftruftful, and is susceptible of domestication in an eminent degree, acquiring many of the social habits of the dog. It emits from the lungs a harsh and uncommon noise, not unlike that of a child's trumpet, hence its trivial name. It stands on one leg, and sleeps with its neck drawn in between the shoulders; the eggs are blue-green.

UNDULATA; Undulated or African Trumpeter. Crest of the hind-head short and whitish; of the breast long, black, pendent. It is a native of Africa, and is the size of a goose.

PSORAE, in Botany, 4 μη, scurf of any kind, and among others that of trees. Hence the name is employed to designate a supposd genus of Lichenes, established by Hoffmann, whose habit is crustaceous or fcurfy. See Lichenes and LICHENES.

The appellation, Psora, was universally employed by the Greek physicians to designate a scaly or fcurfy disorder of the skin, and not the veicular, or partial itch. Occasionally, indeed, they conjoined the epithet ξυρα, ulcerating, with the term psora; thus obviously distinguishing the ulcerating or partial difcase (which appears to have been improperly), from the psora simply, which always signifies the dry, scaly, or fcurfy matter, mentioned below under the appellation of psoriasis. Hippocrates claffes the psora with lepra, alphas, and lichenes, considering them as blennitures, rather than difcases. And the Greek writers, who followed him, looked upon the prurigo, lichen, psora, and lepra, as progresive degrees of the fame affection—the prurigo being a simple itch, the lichen, itching combined with roughnefs of the skin, the psora, itching with astringency, and the lepra, itching with aeral feafts. (See Aetiusarius, Math. Med. lib. ii. cap. 11.) The misapplication of the term itch, seems to have originated with some of the early translators of the Greek writings, who considered feabies (quasi sebarities) as fynonimous with psora, or a roughnefs of the skin; whence the true seabies, or itch, was fubfrequently confounded with psora. (See Ireton.) Sir John Fringle remarks, that the general opinion, that the psora mentioned by the Greeks is the itch, is far from being evident from their writings, that he is rather difposed to conclude, that the itch was either altogether unknown, or at least uncommon among the ancients. On Difeases of the Army, p. iii. chap. 8. See also Bateman's Pract. Synopsis of Cudan. Difeases. pp. 6 and 186, notes.

Gen. Ch. Cal. Perianth inferior, of one leaf, dotted with tubercles, in five acute, permanent, equal segments, the lowermost only twice as long as the reft. Cor. 5, papillo- naceous, of five petal, with coloured veins; standard roundish, emarginate, directed upwards; wings crescent-shaped, obtuse, small; keel crescent-shaped, obtuse, of two petals.
psoralea

psoralea

Petals. Stam. Filaments in two distinct sets, one simple and petalaceous, nine combined, all ascending; others roundish. Fig. Germen superior, linear; style awl-shaped, ascending, the length of the flanks; stigma obtuse. Peric. Legume the length of the calyx, without valves, compressed, ascending, pointed. Seed one, kidney-shaped.

Eff. Ch. Calyx the length of the legume. Stamens in two distinct sets. Legume single-seeded, somewhat beaked, without valves.

The plants of this genus are chiefly shrubby, and the greater part natives of the Cape of Good Hope. A few are found in the south of Europe, and still fewer in America. The former are either pinnate, ternate, or simple. Flowers spike or solitary, of a dull blue or dirty white. Linnaeus has fourteen P. floraleae in Sp. Pl. two of which now enter the restored genus of Dolae. Willdenow has twenty-nine. Nineteen are mentioned in the new edition of Hortus Kewensis, all green-house plants, except the left, Coryphylia, which is an East Indian biennial species.

P. coryphylia. Hazel-leaved P. floraleae. Linn. Sp. Pl. 1075. Wildd. n. 27. Ait. n. 19. Curt. Mag. t. 655. Burm. Ind. t. 49. f. 2.—Leaves simple, ovate, somewhat toothed. Spikes ovate. Native of the coast of Coromandel, hence it requires to be treated as a tender annual, or biennial, flowering in summer, and readily ripening seed. The habit is herbaceous. Leaves two or three inches broad. Flowers small and inconspicuous, with a pale purplish standard, and darker wings, as well as keel, forming small, long-flaked, axillary heads or spikes. Dr. Sims, in Curt. Mag., judiciously indicates the great generic affinity of this plant and Trifolium carumum, or Blue Melilot.

P. floraleae, in Gardening, comprises plants of the shrubby exotic kind for the greenhouse and house, of which the species cultivated are, the winged-leaved P. floraleae (P. pinnata); the prickly P. floraleae (P. aculeata); the oval-spiked P. floraleae (P. bracteata); the hairy P. floraleae (P. hirta); the bituminous P. floraleae (P. bituminosum); the American P. floraleae (P. americana); the hazel-nut-leaved P. floraleae (P. coryphylia); and the annual P. floraleae (P. daelea).

Method of Culture.—These plants are increased by fowing the seeds in the early spring months, on a moderate hot-bed, or in pots, plunging them in it. When the plants have attained three or four inches in growth, they should be planted out into small pots separately, gradually hardening them to the open air, so as to be placed out in it in the beginning of the summer. They are likewise capable of being increased by planting cuttings of the young shoots in the summer months, in pots filled with light earth, plunging them in a moderate hot-bed and covering them close with glass, watering and shading them well till they have fricken root.

They afford variety among other potted green-house plants.

P. floraleae, in Ethnology, a name by which some authors have called a fish of the turbot kind, remarkable for the variety and beauty of its spots, and more usually known by the name lepers.

P. floraleae, in Medicine, Scaly Tetter, a term used by the ancients to express a scaliens and roughness of the eyelids and corners of the eyes, and also a rough and scaly state of the seromum, attended with great itching. (See Galen of Oeulo, cap. 7, and Definit. Med.) Dr. Willan, however, in his clafification of cutaneous diseases, thought proper to extend the signification of the word to the more general eruptions of a scaly nature, namely, to the dry or scaly tetter, (the p. of the fame writers,) for the purpose of avoiding the confusion, which the double signification of this term among the ancients, and the misapplication of it to scabies by the moderns, was likely to produce. (See P. floraleae.) Whence, in the nomenclature of our contemporaries, the

P. floraleae, or Scaly Tetter, is a disease of the skin, prefixed to a rough and scaly state of the cuticle, sometimes continuous, sometines in separate patches of various sizes, but of an irregular figure, and for the most part accompanied with rhagades, or fissures in the skin. (Willan on Cutan. Difeaes, p. 149.) This tetter is, therefore, very analogous to lepra, and in some cafes, indeed, the two diseases run into each other. The lepra differs, however, in general, by its oval or circular figure, its elevated border, and large scales; whilst the p. has no regularity of form, is more scurfy, is often intermixed with chaps, and usually attended with some disorder of the conflation. Similar definitions were pointed out by the Greek writers between the lepra and p. Paul of Ægina says, "Lepra affects the skin deeply, in circular patches (eckorrapheis), and throws off scales like those of fives; but p. is more superficial, and variously figured, and throws off bran-like substan-
ces." (Lib. iv. cap. 2.) Aëtius gives a similar statement of the characteristics of the two diseases. The older writers among the moderns have comprised the p. under
under the apppellations of psora ficas, facies ficas, and impetigo. See Etmmuller, Hoffmann, Mercurialis, &c.

In the first edition of his work, Dr. Willan described eight varieties of the psoriasis, which, in his second edition, he extended to eleven, by the addition of some local varieties, affecting the prepuce, eye-lids, &c.

1. The psoriasis guttata, in which the eruption appears in very small, separate patches, of an irregular form, seldom exceeding two or three lines in diameter, may be deemed a fort of connecting link between this genus and lepra. The little patches have not the regular oval or circular margin of lepra, nor the elevated border of that disease, and the scales which form upon them are thinner, and separate in smaller fragments, and, when detached, they leave a lefs inflammatory, though somewhat red and polished, face. There is scarcely any part of the body on which the patches do not appear, not excepting even the face, which is rarely the seat of lepra; but in the latter situation, they exhibit only a redness and roughness, without any actual scales. In children, the eruption sometimes appears suddenly, accompanied by some degree of febile irritation, and spreads rapidly over the body; but in adults its progress is gradual and slow, and it is apt to return in the spring season for several successive years, preceded by head-ache, and pains in the loins and limbs.

2. The psoriasis diffusa presents a considerable variety of appearances. In moist cafes it consists of large patches, which are irregularly circumcised, and exhibit a rough, red, and chapped superfcie, with very slight fcaliefs interperfed. This surface is often exceedingtly tender and irritable, and is attended with a fensation of burning and intense itching, both of which are much augmented by approaching a fire, on becoming warm in bed, or even on exposure to the direct rays of the sun; but they are relieved by the imprefion of cool air. As the disorder proceeds, the redness increafes, and the skin appears thickened and elevated, with deep interfeting lines or furrows, which contain a powdery fubflance, or very minute fur. The heat and painful fentations are much aggravated by the leaf ftriction, which also produces exoration, and multiplies the fore and painful rhagades. This form of the disease is most frequent about the face and ears, and the back of the hands; but occasionally occurs on other parts of the body, either at the fame time or in fucceffion, as in the forehead and scalp, the shoulders, back, loins, and abdomen, on the fleshy parts of the lower extremities, the outside of the fore-arm, and the mtfep. When the fcales are removed by frequent waving, or by the application of ointments, the surface, though rafed or uneven, appears smooth and fhining, and croffed with deep furrows. Should any portion of the defcised surface be forcibly excoriated, a thin lymph illues out, mixed with fome drops of blood, which fhightly stalls and fliffens the linen, but foon concretes into a thin dry fcb: this is again exceeded by a white fcaliefs, gradually increafing, and spreading in various directions. As the eruption declines, the roughnefs, chaps, fcales, &c. disappear, and a new cuticle is formed, at firft red, dry, and shrivelled, but which, in two or three weeks, acquires the proper texture. The whole duration of the complaint is from one to four months, and in fome cafes much longer.

On the firft appearance of psoriasis diffufa, the constitution is usually somewhat difordered; there is a felling of universal languor and debility, with flos of appetite, head-ache, pain or fcknefs at the loomach, and pains in the limbs. During the progress of the eruption these symptoms are diminished, or ceafe altogether; but the eruption is apt to return at particular feaons, and each return is usually preceded by the fame symptoms. The disease is often confined to a solitary patch, of an irregular form, red, fcaly, shrivelled, and itching, ftationed on the face, the breall, calf of the legs, about the wrif or elbow, and particularly about the lower part of the thigh behind. In any of these situations, it continues several months with little alteration. The eruption called the baker's itch, which occurs on the back of the hand in bread-bakers, is the psoriasis diffufa, and confifts at firft of one or two small, rough, fcaly patches, which extend and coalesce, reaching from the knuckles to the wrift. Waferwomen are also subject to a peculiarly severe form of this psoriasis, on the hands, wrists, and fore-arms, apparently from the irrtation of soap. From the whole of the surface, which is highly inflamed, the fcaly and brittle cuticle separates in large irregular flakes in rapid fucceffion.

3. Psoriasis gyrate. In this form of the disease, the tatters are distributed in narrow patches or stripes, of various figures; some of them are nearly ftraight, fome circular, or femicircular, with worm-like extremities, and fome are tortuous or ferpentine, reftembling earth-worms or bees. The arrangement of these patches is singular, often regularly corresponding on both fides of the cheek or fpine. A lighter variety of this tatter affects delicate young women and children, in small fcaly circles, flightly discoloured, on the cheeks, neck, and upper part of the breast, which are fometimes called ringworms.

4. The psoriasis palmata, a very oblongate species of tatters, is nearly confined to the palm of the hand. It commences with a fmall, hard, or fcaly patch, which gradually spreads over the whole palm, and fometimes appears in a lighter degree on the aff of the finger and wrift. Its colour often changes to a dirty hue, which the molt diligent washing does not alter. The cuticular furrows are deep, and cleft at the bottom in various places, fo as to bleed on fretching the fingers. There is usually a fentation of heat, pain, and iffnefs in the motion of the hands, and often a troublesome itching, efpecially on the returns or aggravations of the eruption. It is most troublesome in the winter and fpring; in summer and autumn it fometimes disappears, leaving a fofk dark red cuticle; but many perfons have it for a feries of years, with only very flight remifions. Shoe-makers are fubjeft to this complaint from the irrtation of the wax which they constantiy employ; and braziers, tin-men, filver-smiths, &c. feem to suffer by it from handling cold metals. But it is often produced without any very obvious irrtation; and fcaliefs of the foles of the feet, but without chaps, occafionally conurs with the affection of the hands.

5. Psoriasis labialis. The lips are sometimes affected with fcaliefs, intermixed with chaps and iffnefs of the cuticle, when the other parts of the body are free from psoriasis. The fcales that form on the lips are of a confiderable magnitude, fo that their edges are often loofe while the central points are attached: a new cuticle gradually forms beneath the fcales, but it is not durable; in the course of a few hours it becomes dry, shrivelled, and broken, and while it exfoliates, gives way to another layer of tender cuticle, which foon, in like manner, perifhes. These appearances should be diftinguished from the flhing chaps and roughnefs of the lips, produced by very cold or frotty weather, and which are eaily removed. The psoriasis labialis may be a little aggrrated by froft or fharp winds, yet it receives no material alleviation in warm weather: it continues in many cafes, indeed, through all feaons. The under lip always fuffers more than the upper; and the disease especifally affects perfons whose whole lips are full and prominent.

6. Psoriasis ophthalmica. This affection begins about the external
external angles of the eyes, producing a bright redness of the skin, with a smooth, shining, and somewhat moist surface; and the edges of the eyelids near the angles become thickened and rigid, and somewhat inflamed, with considerable itching.

7. The psoriasis preputii often accompanies the psoriasis palmareas. It is characterized by a calcinosis, with painful fissures and thickening of the prepuce. These symptoms, being usually attended with a phymosis, render coitual intercourse difficult, or even impracticable. In some cases, both internal medicines and external applications disappoint our expectations, and the patient can only be relieved by circumcision. This complaint should be carefully distinguished from the venereal phymosis, in which scales and fissures of the skin do not occur.

8. Psoriasis festinata. Sometimes the skin of the scrotum is affected with roughness and calceilas, together with much heat, itching, tension, and redness, independently of any similar affection in other parts of the body. The symptoms are succeeded by a hard, thickened, brittle texture of the skin, and by painful chaps or excoriations, which are not easily healed. The itching and irritation are much increased by changes of temperature, especially on undressing, or getting into bed. The disease sometimes appears to be the sequel of the prurigo festinat.

9. Although the nails are generally affected only in conjunction with the tetter of the hands and arms, yet occasionally a psoriasis unguinum occurs alone, when the nails are bent either upwards or downwards at their extremities, and are either rough and ragged, or thickened and deeply furrowed, and of a brown or yellowish hue.

10. The psoriasis infantilis, which occurs under the age of two years, does not differ materially in its appearances from the psoriasis diffusa, but Dr. Willan marked it as a variety, because it is sometimes succeeded by inflamed and suppurating pustules, and because it is not easily distinguishable from the scaly disease which occurs in infants from venereal infection. The nature of it can only be determined by taking into consideration the collateral circumstances.

11. The last variety described by Dr. Willan is the psoriasis inveterata, the most severe modification of the complaint, beginning in separate irregular patches, which multiply and become confluent, until they extend over all the surface of the body, except a part of the face, or sometimes the palms of the hands and soles of the feet, producing at length an almost universal calceilas, intermixed with deep furrows, and a harsh and thickened state of the skin, which is red, stiff, and rigid, impeding the motion of the joints. The production and separation of scales is so rapid, that large quantities are found in the bed in which the patient has slept. Sometimes the eruption becomes extensively inflamed, and even excoriated, discharging lymph, after which a dry, hard, and horny cuticle is formed, which separates, not in scales, but in large pieces. The nails, both of the fingers and toes, become thickened, convex, and opaque, and are at intervals renewed, but the new ones soon assume the same morbid form. The disease often continues, with indeterminate remissions and exacerbations, for a long period of time, especially in old people, but sometimes even occurs in the young. It results occasionally from repeated attacks of the psoriasis diffusa; and has sometimes followed the prurigo festi.

The causes of psoriasis are by no means obvious in general. It is not contagious, as asserted by some of the older writers, unless the appearance of the small circles in children of the same family or school, can be considered as a proof of contagion in these cases. The other forms of the disease were never seen to spread by contagion. A strong hereditary disposition to it is certainly manifest in some individuals. Dr. Falconer, in his paper on the lepra graecorum, in which he includes also the fea!y tetter (see Memoirs of the Med. Society of London, vol. ii.), ascribes it, in many instances, to sudden chill, from drinking cold water after being violently heated by exercise, or a cause to which many other eruptive diseases have been imputed. Women, and especially those of a fanguineo-melancholic temperament, are most liable to it, having a dry skin and languid circulation; and it affects them more particularly after parturition, or during a state of chlorosis. Dr. Willan had observed it occasionally in both sexes, connected or alternating with gouty rheumatic affections; and we have sometimes seen it occur under a state of great mental anxiety, grief, or apprehension. In those who are constitutionally predisposed to this eruption, indeed, slight occasional caules seem to be capable of producing it; such as being overheated by exercise, the unfeasable use of the cold-bath, a copious use of acid fruits, vinegar, or crude vegetables, and some incongruous mixtures of food.

Treatment of Psoriasis.—The same general mode of treatment is applicable to the different modifications of the disease, but especially to the three first species, which are not limited to particular parts. The popular practice, which is much the same as that which was recommended by Willis above a century ago, is founded upon the old humoral pathology, and confuts chiefly in attempts to expel imaginary humours by evacuants, or to correct them by what are called antiscorbutics. But experience has proved, that a fystem of blood-letting and of repeated purging is injurious, and that the vegetable juices and acids are not merely void of all efficacy, but absolutely prejudicial. In fact, the erroneous notion, that these tettors, and most other cutaneous affections, are of a scorbutic nature, seems alone to have led to the use of these medicines. A more recent empiricism, which refers to mercury in all diseases of a chronic nature, and of some obscurity of character, is not more successful; for from the time of Willis (de Med. Operat. p. 292.) the inefficacy of a mercurial course, whether internal or by external friction, has been acknowledged by all observing practitioners. Dr. Willan says, that, from many experiments cautiously made, he was well assured that strong mercurial preparations are of no advantage in the scaly tetter, but eventually rather aggravate the complaint. Chalybeate waters, such as those of Scarborough and Tunbridge, and chalybeate medicines generally, appear to have no direct remedial operation in this disease, but are sometimes fecondarily useful by improving the constitution.

In the commencement of psoriasis, especially under the three first varieties, and when it appears suddenly in connection with febrile symptoms, a moderate antiphlogistic treatment must be purged. A gentle purgative should be administered, and the diet made light, by abstaining every thing stimulant. This regimen is, indeed, necessary throughout the course of the disease, which is immediately aggravated in sympathy with irritation of the stomach, whether by spices, fermented and vinous liquors, pickles, &c. But when the constitutional disturbance has subsided, the use of the fixed alkali, with sulphur lotum, together with tepid washing with simple water, or milk and water, will be beneficial. If the scaly patches have extended over a considerable part of the body, or the disease have assumed the inveterate form, it must be considered in a similar light with the lepra vulgaris, and treated by the medicines recommended for that disease. (See Leprosy of the Greeks.) It is very difficult by any local applications to give the patient relief from the shooting and burning pain and itching, which anxiously looks
looks for: he is mortified to find that even the mildest substances often prove irritants, and aggravate his disharmonies. A decoction of bran, a little cream, or oil of almonds, sometimes produce ease.

But the more local and less inflammatory eruptions of psoriasis not only bear, but require local expediencies. In the psoriasis palmaris, the same internal medicines are proper, as in the other forms of the disease: but the heat, dryness, and itching of the palms, are relieved by holding them for some time every night in the vapour of hot water, and afterwards putting on gloves made of oiled silk, and by applying the unguentum hydrargyri nitriti, diluted with some mild ointment, according to the degree of irritation in the skin. Sea-bathing, continued for many weeks, is generally an effectual remedy.

In the psoriasis labialis, the same temperate regimen is particularly necessary, and remedies for the correction of disordered stomatch should likewise be prescribed. All acrid applications should be avoided, as uniformly detrimental to the lips, which should be kept almost constantly covered with some mild ointment or plaster, that they may not be influenced either by heat or cold. To the psoriasis ophthalmica and ferotalis, the diluted ointment jut mentioned may be applied with advantage; but in the latter complaint, besides this application and the use of general remedies, great care is requisite to keep the parts clean by frequent ablution with warm water, gruel, &c., and to prevent attrition by the constant use of the ointment. In the psoriasis sanguis, the nails may be immersed from time to time in warm water, and cut smooth. The complaint, however, is more likely to be removed by sea-bathing, and other remedies which act on the constitution, than by any local application. See Willan on Cutaneous Diseaifes, p. 149, &c.; Bateman's Practical Synopsis of Cutan. Diseaifes, p. 36.

Psorica, ψορίς, medicines good against the itch, scabs, and other cutaneous eruptions, especially those of the eye-lids.

Psorica, or Psorica Poa, a name given by the botanical writers among the ancient Greeks to the plant we call scabiosa, or scabious.

Psorophthalmia, ψοροφάθμαλον, from ψορίς and φάθμαλον; scabies oculi; lapitudo scabrosa; oculi psoriatrici. Pso- rophthalmia, in Surgery, means a disease of the eye-lids, which consists of an inflammation and ulceration of their internal membrane near their edges, attended with a discharge of acrid purulent matter. In order to have an accurate idea of psorophthalmia, one must recollect, that both the tears have on their inner surfaces several perpendicular rows of sebaceous glands, the excretory ducts of which terminate just within the internal margin of each cartilage, where they pour out an unctuous kind of secretion, commonly known by the name of the humour of Melombus. It is these glands which are particularly affected in psorophthalmia; the matter which they are accremented to secrete, instead of being soft and bland, becomes acrid and adhesive, producing a substance which is usually called gum, and which irritates the eye and eye-lids, causes ulceration of the edges of the latter parts, and thus keeps up the disease for a very long time. Monument St. Yves, in treating of the ophthalmia, which is occasioned by the small-pox, has drawn up one of the most correct descriptions of psorophthalmia, which is any where extant.

Psorophthalmia frequently follows inflammation of the eye, and sometimes accompanies all its states. This is very common in scrofulous subjects, and patients troubled with herpetic disorders. But, occasionally, psorophthalmia is the consequence of that purulent affection of the eye-lids, to which the Greeks have given the name of παιν. In psorophthalmia, the ulceration is ordinarily confined to the edge of the eye-lids; but, in particular instances, it extends much further over their outer surface, and even over the cheeks, which are excoriated, and have an erythematous appearance. It is also sometimes accompanied with an eruption, or true ecchymosis of the lower eye-lid, in which circumstance the face proves exceedingly obtrusive. The ancients, and even several of the moderns, have detailed different affections, which bear considerable resemblance to those which have just now been mentioned; but they have regarded them as depending upon some constitutional disease, which requires removal, and which, being cured, is always followed by the relief of the symptomatic complaint of the eyes.

Where other symptoms exist, showing a foundation for the suspected disease of the habit, the previous doctrine may be really true; but when no symptoms of this kind prevail, it may lead to very erroneous practice. The ulceration of the ciliary glands in psorophthalmia, may be seen not only with a magnifying glass, but even with the unaided eye, when the eye-lids are everted. The matter poured out from them is of an irritating quality, and, when dry, forms gumy incrustations, which glue the eye-lids together. When psorophthalmia is accompanied with symptoms, evincing that the disorder is combined with disorder of the system, the first indication is to endeavour to amend the state of the constitution.

Scrofula is the disease with which psorophthalmia is most apt to be conjoined, and, in this case, it is necessary to prescribe such general remedies as are found to be most effectual for scrofula, at the same time that topical applications are employed. Baron Stork spoke highly of the extract of cietia; in confirmation of its efficacy, he relates twenty cases, in which this medicine was at first exhibited in the dose of two grains twice a-day, which dose was afterwards increased to three grains, administered three times very twenty-four hours. In the third volume of The Medical Observations and Inquiries, Dr. Fothergill published some remarks on the effects of cietia, which, while it is described as being an useful medicine, is acknowledged to be sometimes unavailing. This practitioner had already extolled the efficacy of bark in cases of inveterate ophthalmia, and he has betrayed a partiality to it; for it was his common practice invariably to prescribe it, in conjunction with calomel pills. In certain cases, mercurials and purgatives bring the constitution into a state, in which the disease of the eye-lids may readily be cured by means of suitable applications.

Before the true character of psorophthalmia was well understood, the generality of oculists applied emollient substances, as mucilage of quince-leafs, cream, fresh butter, &c., or mildly acridgent ointments, which were put on the edges of the eye-lids, in order to prevent them from becoming adherent together. In this manner, they succeeded in softening the scabs and making them fall off; but others soon formed, and thus the disorder went on. Some of the old practitioners, however, ventured to make use of stronger applications. Rhazes recommends a stimulating collyrium to be applied to the ulcerated eye-lids; and the celebrated oculist, St. Yves, was an advocate for touching the fore part of the eye-lids with the lapis infernalis. "J'ai trouvé (says he) qu'en touchant ces ulcères avec la pierre infernale, ils se cicatrisent aisément. Il faut en ôter l'ardeur auflitôt qu'elle les a touché en faisant baiger l'œil plusieurs fois dans un petit verre d'eau; et il faut furtout prendre garde que l'endroit de la paupière fur lequel on a appliqué la pierre se pose point fur le globe de l'œil, que la cuifion qu'elle
qu'elle a cauées, n'en foit paffée. On les touchera une ou deux fois la féminis, jusqu'au ce qu'on juge que ce foit affez, et on met furs ces endroits foif et matin de la tuehie en poudre très fine, qui achenera de les cicatrirer.

The application of cative, in the manner advised by St. Yves, is liable to objections, and the practice, when inconsiderately adopted, has done mischief. A safer topical application, for fulfilling the same indication, consists of an ointment, composed of twenty-four grains of red precipitate, incorporated with two drachms of white wine. Some of this is to be tenderly put on the edges of the defaced eye- lids.

But of all the topical remedies for phorophthalmy, none have gained so much repute as the unguentum hydrargyri nitratum, which was brought into notice in this cafe by the eminent Mr. Ware. He directs a little of this ointment to be melted, and rubbed with the end of the fore-finger, or the point of a small camel's hair brush, into the edges of the affected eye-lids, every night, at bed-time. A pillar of ceratium album is then to be put over the eye-lids, in order to prevent them from sticking together. If, notwithstanding this method, they should yet be found to adhere to each other in the morning, Mr. Ware advises cleansing them with milk and butter well mixed together. In a few cases, where the small-pox has affected ulcers on the edges of the eye-lids, it is necessary to have recourse to the argentum nitratum. When the inflammation extends to the globe of the eye, the thebaic tincture is to be employed as a topical application, as mentioned in the article OPHTHALMY.

Phorophthalmy is a complaint that is particularly apt to recur; and hence it is frequently indispensible to observe, for some time after the cure, a proper regimen, and to continue a course of alternative medicines. See L'Encyclopédie Medicale, Partie Chirurgicale, art. Phorophthalmy; Ware on Ophthalmies, &c. &c.

PSACHAGOGICA, formed from Ἴκς, anima, and ἀγος, ἄγος, a word used by the ancients to express such medicines as were used in apoplexies and faintings, to recall life.

PSUCHROTROPHON, in the Materia Medica of the Ancients, a name given to a plant often recommended, but not perfectly understood as to what species it means. It is the same plant called σώματος from the Greeks, and has this name only because of its growing in moif places; the word being formed of the Greek Ἴκς, ις, meif, and ἄγος, to nourify, or cause to grow.

PSYCHOLOGY, Ἰς ἤ Ἱς, Ἰς, Ἰς of the Ancients, from Ἴκς ἤ Ἰς, σωλ, and ἱς, ἱς, ἱς, discussing the doctrine of the soul.

Anthropology, or the science which considers man, consists of two parts: the first treating of the body, and the parts belonging to it, called anatomy; and the second of the soul, called psychology.

PSYCHOMANCY, formed from Ἴκς, σολ, and μακς, divination, a kind of magic or divination, performed by raising the souls of persons deceased.

Gen. Ch. Cal. Perianth superior, very small, five-toothed, permanent. Cor. of one petal, faper-hedged; tube long; limb short, in five, nearly ovate, acute segments.

Stam. Filaments five, capillary; anthers linear, erect, not rising above the mouth of the tube. Pfl. German inferior, roundish; style thread-shaped; stigma in two rather thick blunt segments. Peric. Berry globular, of two cells, crowned with the calyx. Seeds solitary in each cell, hemispherical; flat on the inner side; convex, with five furrows, on the outer.

An extensive genus of, chiefly West Indian, shrubby plants, with simple opposite leaves, sheathing infaftrofusaceous membranous stipulas, and copious, small, whitif, panicked or corymboles, axillary or terminal, flowers. They are generally smooth, growing in dry bushy hilly places. Their qualities have not been much investigated, though the very remote affinity of the genus to Cinchona, and its nearer approach to Coffea, might induce a supposition of their not being altogether unimportant. Only two species, the affatica and herbacea, are mentioned in the Species Plantarum of Linnaeus, but the discoveries of Aublet and Swartz have greatly enriched this genus, so that thirty-nine species occur in Willdenow. Four of them are cultivated at Kew, but scarcely known in other collections. The following examples may suffice.

Pfl. citrina. Citron-leaved Psychotria. Swartz Ind. Occ. 398. Willd. n. 8. Ait. n. 1.—Stipulas ovate, permanent. Leaves elliptical, pointed, somewhat coriaceous, very smooth. Panicles shorter than the adjoining leaves. Berries oblong, ribbed.—Found by Mr. Alexander Anderson, in the West Indies; introduced at Kew by Capt. Bligh in 1793. It is kept in the lrove, but has not yet flowered. A small tree, with a smooth bark; the branches opposite, slightly compressed. Leaves forked, contracted at the base, from three to fix inches long, ribbed, veiny, of a fine shining green. Stipulas ovate, pointed, rigid, permanent. Flowers rather large, whitif, in repeatedly threefold forked panicles. Segments of the corolla villous. Berry furrowed, crowned with the small obtuse calyx. Seeds enveloped in a tunic.

Pfl. nitida. Wild-cows Psychotria. Willd. n. 9. (Mapouria guianensis; Aubl. Guian. t. 1. 175. t. 67.)—Stipulas roundish-ovate, deciduous. Leaves broadly elliptical, pointed. Panicle terminal. Limb of the corolla longer than its tube.—Found by Aublet about rivers in Guiana, flowering in September. The stems are shrubby, brittle, full of pith, seven or eight feet high. Leaves sometimes eight inches long and four broad, of a shining green, plicable, with large deciduous stipulas. Flowers small, white, in terminal panicles. The inhabitants call the plant Mapouria-crabi, because the Mapoura, or Wild Cows, are very fond of feeding on its leaves and branches. Hence Aublet, who thought it a new genus, constructed the name of Mapouria.

Pfl. paraskleia. Paraftical Psychotria. Swartz Ind. Occ. 408. Willd. n. 16. Ait. n. 2. (Vifcoide pendulum; Jacq. Amer. 73. t. 51. f. 1.)—Stipulas abrupt, clasping the stem. Leaves ovate, pointed, veinlets, rather fuculent. Clusters compound; terminal and axillary. Native of mountainous woods, in several of the West Indian islands, where it grows for the most part parafically, on the trunks of aged trees. The stem climbs, throwing out several pendulous leafy branches. Leaves forked, about an inch and a half long, rather curved, bright green, smooth; paler beneath. Flowers few, small, white. Corolla downy at the orifice.

Pfl. involucrata. Althana Psychotria. Swartz Ind. Occ. 413. Willd. n. 20. (Nonatelia officinalis; Aubl. Guian.)
PSY

Guan. 182. t. 70. f. 1.)—Stipulas with two teeth. Leaves ovato-lanceolate, polished. Clusters terminal, corymbose; their partial flanks three-flowered. Bracteas of three linear leaves. Native of barren places, by way sides, in Guiana and Cayenne, flowering and fruiting in August. Aublet. It is said also to be found in Jamaica. The shrubby stem is two or three feet high, with smooth knotty branches. Leaves about two inches long, tapering at each end. Stipulas with a pair of awl-shaped teeth at each side. Flowers small, white. Berry black, the size of a red currant, with ten furrows. Aublet says it has five cells, with a seed in each, and hence he established his genus Nonatelia; but Schwartz, from an examination of original specimens, affirms us this is a mistake, the Nonatelia of Aublet being true Pachystoe.

The species of which we are speaking is said to be in some degree aromatic, when dried or bruised. An infusion of the leaves is esteemed useful in the asthma.

Pf. herbacea. Herbaceous Pachystoe. Linn. Sp. Pl. 245. Willd. n. 29. Ait. n. 4. Jacq. Amer. 66. t. 46.—Stem herbaceous, creeping. Leaves roundish-heart-shaped, falked, obtuse.—Native of the West Indies; said to blosfom in the stone at Kew, from April to June. The stem is thread-shaped, creeping close to the ground, sending down many tufts of fibrous radicles, and throwing up, here and there, a simple, erect, herbaceous stem, three or four inches high, bearing two pair of opposite long-flaked leaves, and a few terminal, corymbose, bracteated, white flowers. Berries globose, even, red.—Jacquin says this species grows abundantly in moist shady parts of Martinico, bearing flowers, as well as plenty of ripe fruit, in December.

Pf. emetica. Emetic Pachystoe. Linn. Suppl. 144. Willd. n. 130. (Ipecacuahua; Pf. Braf. 101? Maregr. Braf. 17?) Stem herbaceous, procumbent. Leaves lanceolate, smooth. Stipulas awl-shaped, extrafoliaceous. Heads axillary, falked, of few flowers.—Native of the province of Grona, in the hottest part of North America, by the governor of which it was sent to Mutis, who communicated a description, but as far as we can discover, no specimen, of the plant to Linnaeus, supposing it one kind at leaf of Ipecacuahua. The root is perpendicularly, roundish, somewhat branched. Leaves crowded. Stipulas deciduous. Flowers axillary, white, falked, from two to five on each flake. Berry nearly ovate. We have never seen this species.

PSYCHOTROPHUM, Browne Jan. 160. t. 13. f. 1. See PSYCHOTRIA.

PSYCHROLUSIA, formed from ῶμος, cold, and σκι, 1 ωθύ, a word used by medical writers to express cold bathing.

PSYCHROMETER, formed from ῶμος, cold, and μέτρον, measure, an instrument for measuring the degree of coldness of the air; more usually called a thermometer.

PSYCTICA, formed of ῶμος, I cool, a term used by medical writers to express cooling remedies.

PSYDRACIA, in Medicines, ψυδράκεια, vpuftules mentioned by the ancient writers, which, according to Gorrazus, were of a cold nature, "quam ῶμος ἄθροισι γίνεται, id est, frigida seiu frigidaque guttula." Whence Dr. Willan, in the definitions prefixed to his treatise on "Cutaneous Diseaues," adopted the term in opposition to phlyzscia, or hot vpuftules, to designate the minute vpuftules, which produce but a slight elevation of the cuticle, and have little inflammation at their base. The psydracia were enumerated among the eruptions peculiar to the head by Alexander and Paul, and some other Greek physicians; but Galen and others mention them as common to other parts of the body. See Gorrazus, Definit. Med.; and Bateman's Synopsis of Cutan. Diseaues, p. 21.

PSYGMATA, derived from ψγμα, I cool, a name given by physicians to all refrigerating medicines, external and internal.

PSYLLI, in Ancient Geography, inhabitants of Cyrene, and other parts of Cyrenaica (which see), situated between the Nafanomes and the Catulli. Their territory abounded with serpents, against the bite of which they were provided, according to Strabo, with a secret antidote, by the use of which, as well as by eating the serpents, they amused the credulity of observers. Savery (Letters in Egypt, vol. i.) informs us, that these serpent-eaters still exist in our days. In a procession at Rofetta, which drew together a large concourse of people, the. cheiks, or priests of the country, were followed by a band of seething madmen, with their arms bare, and a wild look, holding in their hands enormous serpents, which were twined round their bodies, and were endeavouring to make their escape. These Pfylli gripping them forcibly by the neck, avoided their bite, and notwithstanding their hissing, tore them with their teeth, and ate them up alive, the blood streaming down from their polluted mouths. Others of the Pfylli were striving to tear from them their prey; so that it seemed to be a struggle among them who should devour a serpent. The populace followed them with amazement, and believed their performance to be miraculous. Accordingly they pala for persons inspired, and possessed by a spirit who destroys the effect of the serpent.

PSYLLIUM, or PSYLLA, a town of Afa Minor, in Bitbinia, on the northern coast, according to Ptolemy, between Heraeia Ponte and Tion.

PSYLLIUM, in Botany, ταψις της of the ancient Greeks, so denominated from ταψις, a spand, in allusion to the appearance of its little brown, thinning, and slippery seeds. See PLANTAGO.

PSYLON, in Ichthyology, a name given by Ariflotle, and many others of the old Greek writers, to the tench, or cyprinus nigreus.

PSYRA, in Ancient Geography, an island of the Ægean sea; N.W. of and near the promontory Melana, in the ile of Chios.

PSYRA, in Geography, a small island in the Grecian Archipelago, situated W.N.W. of the island of Scio. N. lat. 28° 50'. E. long. 25° 39'.

PSYTLALIA, in Ancient Geography, an island of the Saronic gulf, S.E. of Salamine. After the battle of Salamine the Greeks made a deacon on this island, and massacred several bodies of Persian troops. In the time of Paufanias, this island contained several statues of Pan.

PTARMICA, ἐνταρμία, formed of ταρμός, freezing, medicines proper to promote freezing; more usually called erybrines and frigorariatus.

PTARMICA, in Botany, ταρμία of the Greeks, so called from ταρμός, freezing, because of its effects. (See ACHILEA.) Both A. Ptarmica, and the much more common A. Milletum, have a power of causing freezing, by means of the minute prickles which border their leaves, and which irritate the nostrils when introduced therein with a slight degree of violence. If a blow be given externally while the nostril is thus stung, these prickles are found sufficient to wound the small blood-vessels, and to cause a bleeding at the nose.

PTARMIGAN, the lagopus of Pliny, and the tetra lagopus of Linnaeus, in Ornithology, is also called the white game, and erroneously the white partridge. This bird is of a pale brown or ash-colour, elegantly crossed or mottled with
with small dusky spots, and bars, the head and neck with broad bars of black, rufi-colour, and white; the wings are white, but the shafts of the greater quill-feathers black; and the belly white. In the male, the grey colour predominates, except on the head and neck, where there is a great mixture of red, with bars of white. The females and young birds have a great deal of rufi-colour. Both agree in their winter-dres, being entirely white: except that in the male a black line occurs between the bill and the eyes: the shaft of the seven first quill-feathers is black; the tail consists of sixteen feathers; the black feathers being covered by two upper ones, which in summer are brown, and in winter white.

These birds are called by Pliny lagopus, because their feet are clothed with feathers to the claws, as the hare's are with fur, which serves to guard them from the rigour of the winter: the nails are long, broad and hollow, focooed off at the end exactly like a writing-pen, without the slit, which enables them to form a lodgment under the snow, where they lie in heaps to protect themselves from the cold. Their length is near fifteen inches, the extent twenty-three; and the weight nineteen ounces. They are found in the kingdoms only on the summits of the highest hills of the Highlands of Scotland and of the Hebrides; and some few are found on the lofty hills near Kefwick, in Cumberland. They resemble the grous in taffe, and, like them, keep in small packs, but never, like those birds, take shelter in the heath, but beneath loose stones.

In Hudson's Bay, this bird is called the willow parasid; they gather together in large flocks in the beginning of October, harbouring among the willows, the tops of which are their principal food. They then change to their winter dres; change again in March; and have their complete summer dres by the latter end of June. They make their nests in the ground in dry ridges, and are so plentiful, that ten thousand have been killed in the three forts in one winter. Pennant's Brit. Zool. vol. i. p. 272, c&. Phil. Trans. vol. lxiii. part ii. art. 28. See Goscock.

Obf. Linnaeus originally confounded with this genus what he afterwards called Dodonaeus. His son referred to it Forster's Blackburnia. Some curious observers in Germany, having found the filaments imperfect on one tree and the pith in another, removed Ptela to Dioecia; but Willdenow more correctly says the genus is polygamous, being merely liable to occasional imperfection in one or other of the organs of impregnation, the rudiments, at least, of both sexes being found in every flower. One species only is now admitted.

P. trifoliate. Shrubby Trefoil. Linn. Sp. Pl. 175. Mill. Ec. t. 211. (Dodonaea trifoliate; Trew Ray. 12. t. 9. Frutex virginianus trifolius, ulmi samariis; Dill. Ell. 147. t. 122. f. 148.)—Native of shady moitl hedges, and the edges of woods among rocks, from New York to Carolina, according to Mr. Pursh; flowering in June. It appears to have been known in the beginning of the last century to the British cultivators of curious shrubs, and still keeps its place in shrubberies, rather for the sake of variety than beauty, flowering about Midsummer and afterwards. It often forms a small tree, with spreading branches. The leaves are deciduous, alternate, stalked, each of three, rarely five, ovate irregularly serrated leaflets, about two inches long. Flowers terminal, small, corymbose, copious, of a greenish-white. They are often five-cleft and pendant.

Blackburnia, Forst. Gen. t. 6, is supposed to differ generically in having a simple stigma, as well as a single-federed berry. Its ripe fruit however has not been observed.

PTLEA, in Gardening, contains a plant of the shrubby kind, of which the species is the three-leaved ptala, or shrubby trefoil (P. trifoliatia.)

There is a variety of this with five leaves.

Method of Culture.—This plant may be increased by seeds, cuttings, and layers.

The seeds should be sown in the early spring months, as March, in pots filled with light rich mould, plunging them in a moderate hot-bed to bring up the plants, giving them occasional waterings during the summer season, and protecting them during the winter from severe frost, planting them out in the following spring in nursery-rows, to get strong for being finally planted out.

The cuttings should be made from the young shoots, and planted in pots filled with light earth in March, plunging them in a hot-bed to strike them, but they should not have much heat, due shade being given. They readily strike root, and may be planted out the following autumn.

The layers may be laid down in the autumn, choosing the young shoots for the purpose, giving them a slit underneath, and then placing them in the soil. They are mostly rooted in the course of a twelvemonth.

These plants are proper for shrubberies, and other places in pleasure-grounds, where they have a very ornamental effect.

PTELEUM, in Ancient Geography, a town of Thessaly, in the Phthiattide, at the entrance of the Pelagic gulf, and very near it. Homer says that the territory of this town abounded with peltarum. It existed in the time of the war of Perseus. At the approach of the confoul P. Licinius, 171 years B. C., the inhabitants fled and abandoned their town, which the confoul took possession of and totally destroyed.

PETERANTHUS, in Botany, so called by Forskall, from πτελα, a wing, and ανθος, a flower, because, either of the dilated calyx-lobes, or of the broad compressed flower-stalks. See LOUICEA, and CAMPHOROSMA.

PTERARIA, in Natural History, a class of insects, according to the distribution of Dr. Hill.

PTERIA, in Ancient Geography, a province of Asia Minor, situated, according to Herodotus, in Cappadocia, near Sinope.

PTERIDION, in Botany, a name used by some authors for
for a small kind of fern common in damp places. Ger. Emac. Ind. 2.

PTERIGYNANDRUM. See Pterogonium.

PTERIS, a name borrowed from the ancient Greeks, whose σπερι appears to have been some kind of fern, so called on account of its wing-like figure.—Linna. Gen. 559.

Eff. Che. Fructification in an uninterrupted marginal line. Involute from the inflexed margin of the frond, burfting inwardly.

The original type of this genus is the common English Brake, or Felis fémina of old writers. Linnaeus founded its character on the continued line of capules, running along the edge of the leaf beneath. The writer of the present article, in his Essay on the Genera of Dicrimum Ferns, first adverted to the involucrum, and particularly to its direction, or the manner in which it finally separates. In many species that membrane becomes reflexed or revolute, being pushed back, and usually quite concealed by the abundant capules. See Filices.

Linnaeus describes but nineteen species of Pteris in his Sp. Plantarum. Willdenow, our latest guide, has 108, to which Mr. Brown has added five or fix from New Holland. Mention of others, not yet sufficiently ascertained, may be found at the end of the genus, in Swartz's Synopsis Filicum 167, from Thunberg, Loureiro and others. The genus is divided into numerous sections, according to the division of the frond. The habit of the whole is firm and rather coriaceous; the form and aspect agreeable. In some the flaky is pale and opaque; in others blackish and highly polished.

Section 1. Frond simplex. Six species in Willdenow.

P. piliferifolium. Linn. Sp. Pl. 1539. Willd. n. 1. Banks & C. Kempt. f. 31. Swartz n. 1. t. 2. f. 3.—Barren fronds ruflish or obovate; fertile ones linear, elongated, obtuse. Common flank creeping.—Native of Africa and the East Indies.—The long, branched, fleshy flank flaky creeps to a great extent over the fronds and branches of trees, throwing up numerous, alternate, flaked, simple, blunt, entire leaves, or rather fronds, of a thick leathery texture; convex and smooth above; concave, paler, and opaque beneath. Of these the barren ones are hardly an inch long; the rost twice that length, but not so broad as the former, bordered with a broad, dense, hairy line of tawny-brown capules.

The five remaining species have much the same habit and appearance.

Section 2. Frond palmatum. Three species.

P. pedata. Linn. Sp. Pl. 1532. Willd. n. 8. Swartz n. 76. (Hemionitis; Plum. Fil. t. 152.)—Fronds very deeply palmate, five-lobed, pinnatifid; their segments linear-lanceolate, acute, partly unequally pinnatifid.—Native of the West Indies and of Virginia.—The whole frond is a foot or more in height, erect, with a dark-coloured polished flank. The upper surface is deep green; the under paler, but not powdery as in the following species.

Section 3. Frond ternatum. Four species.

P. argentea. Swartz Syn. n. 73. t. 105, and 301. Willd. n. 11. Gmel. in Nov. Comm. Petrop. v. 12. 519. t. 12. f. 1. (P. pedata varia et Sibircia; Linn. Sp. Pl. 1533.)—Fronds white and powdery beneath; the barren ones twice-lobed; fertile ones ternate, pinnatifid, crenate.—Native of Siberia, in rocky places. An elegant fern three or four inches high, with a dark purplish polished flank, and a pentagonal frond, whose under side is clothed with fine denfe white powder, not easily rubbed off. Nothing can be more distinct than this and the pedate, which lack is a much larger fern.

Section 4. Frond quinata. One species.

P. pentaphylla. Willd. n. 14.—Frond of five nearly sessile, lanceolate, pointed, sharply serrated leaves.—Native of rocks in the Isle of Bourbon.—Stalk six inches high, square, channelled, green, Leaflets five; the central one or four inches long, nearly sessile, with very fine parallel veins; the two next about two inches in length, and the two outermost only one inch. Willdenow, from whose account alone we know anything of this species, never saw the fructification; but he describes the confluence, colour, and appearance, of the barren fronds, as exactly like P. cretica.

Section 5. Frond pinnatifid. One species.

P. pilosa. Lamarck Dicr. v. 5. 717. Swartz n. 60. Willd. n. 15.—"Frond pinnatifid, coriaceous; segments dotted with white, undivided or bluntly lobed. Stalk, as well as the ribs beneath, hairy."—Native of the Island of Mauritis. Lamarck.

Section 6. Frond pinnata. Twenty species.

P. trichomanoides. Linn. Sp. Pl. 1532. Willd. n. 17. Swartz n. 49. (Trichomanes majus, pinnis finatis subtus niveis; Sloane Jam. v. 1. 80. t. 35. f. 1. T. argenteum, ad oras nigrum; Plum. Fil. 57. t. 75.)—Frond pinnata. Leaflets ovate-oblong, obtuse, wavy; hairy at the edge; white and powdery beneath.—Not uncommon in dry rocky places in the West Indies. The numerous fronds form a tuft, and are each about a foot high, composed of many short, crowded, bluntish, undulated, sessile leaflets; of a fine green above; white and mealy beneath, having a marginal line of dark capules, interfered with golden hairs, such as clothe the common flank. We see no reason to doubt the identity of Sloane's and Plumier's plants.

P. longifolia. Long-leaved Brake. Linn. Sp. Pl. 1531. Willd. n. 31. Ait. n. 1. Swartz n. 8. Jacq. Hort. Schoenbr. v. 3. 78. t. 399, 400. (Longchites non ramosa, longis angulis et ad bainum calcarius foliis; Plum. Fil. 52. t. 69.)—Frond pinnata. Leaflets linear, acute, finely serrated; somewhat auricled and heart-shaped at the base. Stalk and main rib rough with scales.—Native of the West Indies. Supposed to have been first introduced into the English gardens by Mr. James Gordon, the celebrated botanist of Mile End, about the year 1770.—The fronds grow in tufts, and are, when at their full size, three or four feet high. Leaflets numerous, parallel, narrow, smooth, of a fine green, with three ribs and numerous transverse veins; the largest near a span long; all are more or less elongated at the base, into a pair of lobes or auricles. Line of fructification pale brown, very dense. Although Jacquin, in his splendid work above cited, devotes two plates to this species, nothing is there shown in detail of the capules or involucrum, which in such expensive plates ought not to be omitted.

Section 7. Frond either pinnatifid or pinnata; the lower divisions compound. Sixteen species.

P. cretica. Linn. Mant. 170; excluding all the synonyms, except that of Tournfort. Willd. n. 54. Swartz n. 14. (Lingua cervina, foliis color inificentibus; Tourn. Infl. 545. t. 321.)—Frond pinnata. Leaflets lanceolate, pointed, on short flarks; contracted and serrated at the base; the lowermost in two or three deep divisions.—A native of various parts of the south of Europe, rarely bearing fructification further north than Naples. The
PTERIS.

root bears several pale fronds about eighteen inches high, whose leaflets are of a rigid, but delicate and transparent texture, with fine parallel veins; the edges more or less partially, and rather acutely, ferrated. Capsules of a light brown.

P. atropurpurea. Purple Brake. Linn. Sp. Pl. 1534. Willd. n. 46. Ait. n. 4. Swartz n. 76. Schkuhri Crypt. 93. t. 101. (Filiula laxifolia, of mundae facie, folia varius margin non ferratis; Pluck. Mant. 81. t. 349. f. 2. 3.)—Frond pinnate. Lower leaflets tenuate or pinnate, lanceolate, obtuse; abrupt or somewhat heart-shaped at the base.

—Found in various parts of North America, from whence living plants were brought to Kew garden in 1770. The dark purplish-black of the polished frond, as well as the deep green of the leaflets, give this species the habit of an Asphanthus; but the elongated figure of each leaflet, as well as of the whole frond, agrees with Pteris, as does the fructification entirely.

Section 8. Frond doubly pinnatifid. Fifteen species.

P. thalictroides. Swartz n. 43. Willd. n. 49. (Acrorhizium thalictroides; Linn. Sp. Pl. 1527. A. n. 377; Fl. Zeyl. 179. t. 4. A. n. 17. Ameon. Acad. v. i. 275. A. filifolium; Sp. Pl. 1527. A. n. 376; Fl. Zeyl. 179. A. n. 7. Ameon. Acad. v. i. 270. t. 12. f. 3. Millefolium aquaticum; Rumph. Amboin. v. 6. 176. t. 74. f. 1.)—Fronds doubly pinnatifid; segments of the barren ones dilated, irregularly dilated, obtuse; those of the fertile ones linear, acute, often deeply divided. Native of Ceylon, Amboyna, and Tranquebar. Rumphius informs us of what the people call lucuban habit of this singular fern might well lead us to suppose, that it grows in stagnant waters and flow rivulets, flourishing in the dry season, when the water is low. The root confits of a dense tuft of very long, mottled, pale fibres. Stalks thick, succulent, weak and tender. Barren fronds broad, very succulent, falcate when dry, of numerous, irregularly dilated and dilated, obtuse leaflets; fertile ones more compound, with very numerous, narrow, awl-shaped, pale segments, about an inch long, under whose reflected margins are situated the large, pale-yellowish, rather sparingly defurring leaflets, partly imbedded in the falcate frond, which they seem to entirely to cover, that we cannot wonder at Lineanu for having refered the plant to his genus Acrorhizium. That he divided it into two species is easily to be accounted for.

P. macroleuca. Willd. n. 56. (Filix latifolia caudata, pinnaul lonicchitidis dentatis; Plum. Fil. 11. t. 13.)—Frond pinnate. Leaflets ovate-oblong, pinnatifid; segments lanceolate, ferrated towards the point; the terminal one very long, tapering, deeply ferrated.—Found near the sides of rivers in Martinico and Hispaniola, by Plumier, the only writer who has given an original account of this species. Willdenow is the only systematic author who has adopted it from him, but it seems a handome well-defined species, very different from all others. The fronds are two feet high, slender, brown, smooth and naked, every one bearing three or four pairs, besides a terminal odd one, of elliptic, or ovate-oblong, leaflets, each deeply and copiously pinnatifid, and ending in a long narrow ferrated point. The segments are also ferrated towards the extremity, bearing a marginal row of chevron-colored capsulas lower down.

Section 9. Frond doubly pinnatifid, doubly or triply pinnate, the lowermost division deeply divided. Eleven species.

P. biannua. Linn. Sp. Pl. 1534. Willd. n. 67. Swartz n. 25. (Filix pinnaul lonicchitidis obtusis nem dentatis, ad oras pulvulcentis; Plum. Fil. 13. t. 15.)—Frond pinnate. Leaflets pinnatifid; their segments linear, obtuse, toothed at the end; the lowest leaflets deeply divided.—Found in various parts of the West Indies. The fronds are two or three feet high, of a bright green, and very conspicuous for the deep division of each of their two lowed branches or leaflets, which are, in a manner, a pair of twin leaflets at each side.

Section 10. Frond doubly or triply pinnate. Twenty-three species.

P. crispa. Curled Stone Fern, or Rock Brake. Linn. Mss. in Sp. Pl. 1522. Sm. Fl. Brit. 1137. Engl. Bot. t. 1100. Willd. n. 89. Swartz n. 101. Ait. n. 6. (Of- munda crispia; Linn. Sp. Pl. 1522. Bolt. Fil. 10. t. 7. Fl. Dan. t. 496. Adiantum album floridum; Pluck. Phyt. 3. f. 2.)—Fronds repeatedly compound. Leaflets of the barren ones wedge-shaped; cut at the extremity; these of the fertile ones elliptical, obtuse, convex.—This pretty species is found on the mountains of Lapland, Norway, Germany, Switzerland, and the Pyrenees, as well as in Britain. In Weil'merland it occurs plentifully on dry flinty open ground, about the sides of lofty hills, being in perfection from June to September.—The fronds grow many together, in tufts, from six to twelve inches high, of pale but pleasant green. Each confits of a long smooth frond, supporting an ovate, or somewhat triangular leaf, which is twice or thrice compound in an alternate manner. The leaflets of the shorter fronds are barren, dilated, wedge-shaped, sometimes pinnatifid, all cut or toothed at the extremities; those of the taller ones all fertile, longer and narrower than the former, their margins pale, membranous, crenate, so strongly flexed as nearly to meet over the dense lines of tufty capsulas.

P. nigricans. Willd. n. 90. (Filix crenis rotundis, et nigricante limbo praecinctis; Plum. Fil. 32. t. 42. Swartz Fil. 108)—Frond doubly pinnate. Leaflets ovate-oblong, obtuse, strongly crenate. Partial fronds zigzag.—Found by Plumier in abundance by the sides of rivulets, in the mossy woods of Hispamnola. No other botanist appears to have met with this fern, nor did Swartz venture to refer it to any genus, he having merely indicated it as a probable species of Pteris. Willdenow has been less fervent, and perhaps justly. The creeping root throws up many fronds, a foot or more in height; their outline of a broad lanceolate figure; their fronds smooth and slender. Each is doubly, alternately, and copiously pinnate, their partial fronds remarkably zigzag. Leaflets so strongly crenate as to seem almost pinnatifid, but very obtusely; their upper surface of a fine shining green; the lower pale, ribbed, and downy. Fructification in a blackish uninterrupted line, along the obtuse edge of each segment.

P. aculeata. Prickly-leaved Brake. Swartz n. 40. Ind. Occ. v. 3. 1601. Willd. n. 98. Ait. n. 7. (Filix arborescens, ramifica et aculeata; Plum. Fil. 6. 5. 11 and 1.)—Frond doubly pinnate. Leaflets oblong, pointed, pinnatifid; segments lanceolate, acute, ferrated. Stalk arborescent, thorny.—Native of the forests of Martinico, where Plumier observed it in plenty. Swartz says it grows in the rather mountainous woods of Jamaica. Living plants were brought to the Kew garden in 1793, but we know not how they have succeeded there. Plumier describes the main frond as thick as a man's body, but low, and belted with black spines. This frond however appears to be produced in very aged plants only, the generality merely throwing out a number of no less spiny fronds, from one very thick tufted root. Each frond is almost three inches in diameter at its origin, and the whole frond, of a fan-like figure, and subequently twice pinnate, is as tall as a man. The segments of the leaflets, when barren, as in Plumier's t. 11, are ferrated through-
throughout; otherwise at the point only, the siders being each occupied by a dense line of caputures, not continued or united along the sinus at the bottom. *Polypodium fimbriatum*, Linn. Sp. Pl. 1554, figured in Sloane’s Jamaica v. 1. t. 56, though cited by Swartz and Willdenow, is evidently a totally different plant, and perhaps a *Cyathea*. Whether Swartz intended this only as a native of Jamaica, or whether he found there the genuine *Pteris acuta*, we have no certain information.

**Section 11. Frond in three deep divisions, or pedate with doubly pinnate branches. Seven species.**

Perhaps, if we may judge by Plumier’s description, the last-described species ought rather to be placed in this section.

P. *efulentus*. Eatable-rooted Brake. Forl. Prodr. n. 418. Swartz n. 43. Willd. n. 103. Billard. Nov. Holl. v. 2. 95. t. 244.—Frond in three deep divisions. Branches doubly pinnate. Leaflets pinnatifid, with linear, obtuse, decurrent segments; the upper ones elongated and undivided. —Native of the Society islands, and of Van Diemen’s land. The natives feed on the root, which is creeping, thick, knotty and brittle, full of aitch-like pith. The fronds are two or three feet high, much resembling our Common Brake, *P. aquilina*, but more coriaceous, much less uniformly pinna
tid in their ultimate divisions, and remarkable for the simple elongations of the extremities.

P. *aquilina*. Common Brake. Linn. Sp. Pl. 1533. Sm. Fl. Brit. 1176. Engl. Bot. t. 1559. Willd. n. 284. Swartz n. 41. Ait. n. 9. Bolt. Fil. 16. t. 19, h. (Felix femina; Ger. Em. 1128. Matth. Valgr. v. 2. 627.)—Frond in three deep divisions. Branches doubly pinnate. Leaflets crowded, lanceolate, acute; the upper ones confluent. —Native of dry barren woods and heaths in all parts of Europe, as well as the north of Asia and America. With us it is the most common fern, and well known for its uses for packing, firing, and shelter, of various kinds. It is sometimes killed in very hard winters. The fronds are annual, originating from a perennial creeping, lealvy root, and rife to the height of from two to five feet, according to the soil. They are rigid and harsh, cutting the hands if incasedly drawn through them. Their colour is a light green, and they spread in a handsome, partly horizontal, posture, being regularly compounded in an almost perfect manner. The upper part of each branch is simple, as in *P. efulentus*, but not elongated, or enlarged, so conspicuously as in that species.

**Section 12. Frond repeatedly forked. One species.**

P. *cornuta*. Beauvois Oware, 63. t. 37. Willd. n. 108. —Frond repeatedly forked; segments awl-shaped, alternate. Capsules in hurnose rows. —An aquatic species, found by M. Filibet de Beauvois, in salt ditches or pools, near the sea, at Oware on the coast of Guinea. This plant is evidently, as its discoverer remarks, akin to *P. thalctro
todes*, see sect. 8. It bears tufts of a paraflfical plant, perhaps a *Marhslea*, which might easily be taken for barren fronds, or leaflets, of its own.

**PTERIUM**, in Ancient Geography, a town of Asia, in Media. Steph. Byz.

**PTEROCARPUS**, in Botany, so named by Loeiing and Linnaeus, from *PTEROS*, a wing, and *KARPUS*, fruit, the margin of the legume being dilated into a flat wing-like expan
bular bell-shape, with five acute teeth. *Cor.* papilionace
ous; *standard roundish-heartshaped, spreading, convex, with a long claw; wings lanceolate, shorter; keel short. Stam. Filaments ten, all connected; anthers roundish. *Pil.* Ger
men flaked, oblong, composed; *style awl-shaped; stigma simple. Peric. Legume roundish-falcate, compressed, with a leaf-like edge, venous at the sides, woody within, not burli
nig, the cell, or cells, longitudinally disjunct. Seeds foli
tary; kidney-shaped, thickset at the base.

Eff. Cl. Calyx five-toothed. Stamens all united. Legume falcate, leafy, with thuud veins, bordered with a wing, not burliining. Seeds foliary.

1. P. *Draco*. Dragon’s-blood Pterocarpus. Linn. Sp. Pl. 1662. Willd. n. 1. (P. officinalis; Jacq. Amer. 283. t. 183; t. 92. Moutonchi suberosa; Aitbl. Guian. v. 2. 748. t. 200. Draco arbore indica filiflora, populi folio; Connel. Hort. v. 1. 213. t. 109.)—Leaves pinnate, ovate, pointed. Stipulas oblong, obtuse. Legume rounded at the extremity.—Native of South America.—A tree thirty feet high, yielding a red pellucid resin, which had formerly the reputation of stopping hemorrhages, but is now out of ufe. Leaves of two or three pair of shining leaflets, with a larger third one. Flowers yellow, in compound axillary clusters. Legume an inch and a half broad, obtuse, marked with strong elevated lateral veins. Gaertner’s *P. hembrita* seems, notwithstanding his opinion, to be the fame with this. It is a stranger to our gardens, though formerly raised from seed at Amsterdam.

2. P. *indicus*. East Indian Pterocarpus. Willd. n. 2. (Lingoum, anaana; Rumph. Amb. v. 2. 205. t. 70.)—Leaves pinnate, oblong, pointed. Stipulas none. Legume sharp-pointed.—Native of the East Indies. Willdenow has dili
guished it from the foregoing, by the figure of Rump
usius only, but perhaps jully. The wood is said to be valuable for the finer kinds of cabinet work, being beautiful and fragrant. Flowers of a fine deep yellow, shining like Wall-flowers.

3. P. *Marjpgium*. Pouch Pterocarpus. Roxb. Coromand. v. 2. 9. t. 116. Willd. n. 3.—Leaves pinnate, cliptical, emarginate. Stipulas none. Clusters terminal, thrice compound.—Native of the Cearc mountains of Coromand, flowering in the rainy fcean. Dr. Roxburgh describes it as a very large tree, whole wood, of a yellowish-orange colour, and hard, but not heavy, is much esteemed by the natives, and used for various purpoifes. The flowers are copious, white with a tinge of yellow. Legume with an oblique acute wing.

ary. Legume orbicular.—Native of South America.—A tree, with smooth, round, greyish branches. Leaves of three or four pair of ovate-oblong, pointed, smooth, shining leafl^ets, with an odd one. Clusters half the length of the leaves. Flowers drooping. Legume membranous, smooth, nearly orbicular, an inch and a half long. Seed one. Mr. Konig, in Ann. of Bot. v. 1. 358, has corrected Vahl and Willdenow, who cite under this species Aublet’s *Apalata ficata*, Guian. v. 1. 382. t. 147, a plant differing from it in genus.

5. P. *lunatus*. Cresent-podded Pterocarpus. Linn. Suppl. 317. Willd. n. 5. Ait. n. 1. (P. aperta; Ger. v. 2. 231. t. 156. Medicago leguminibus lunatis; Plum. 1c. t. 201. f. 2.)—Leaves pinnate. Stipulas spinous. Legume cresent-shaped, thick-edged.—Native of Surinam, from whence specimens in spirits were sent to Linnaeus by Dalberg. Living plants were introduced at Kew in 1792, by
by Mr. Alexander Anderon, but never flowered there. This is a rigid *frob*, or tree, with a pair of strong hooked spines, at the base of each leaf, in the place of *fipula*. Leaves of from five to seven alternate, oblong, obtuse leaflets, about an inch long, one of them terminal. Panicle terminal, downy, its branches spiky, incurved. Flowers white. **Leueme** full an inch broad, thick, woody, and smooth, curved so completely round that the point folds over the bafe; the edge is thick and even, without any wing. **Seed one, large.**

6. **P. santanunus.** Three-leaved Pterocarpus. Linn. Suppl. 518, excluding the reference to Aublet. Wildl. a. 6. Ait. n. 2. — Leaves vernate, roundish, abrupt, very smooth. Petals crenate, wavy. — Native of mountainous precipices in the East Indies, where it was observed by König and Roxburgh. Sir Joseph Banks procured it for the flowers at Kew in 1800, but the plant has not yet flowered there. A very lofty tree, with a kind like Alder, and alternate branches. Leaves rarely pinnate, mossy, ternate, hoary beneath. *Stipula* none. Clusters axillary: simple or branched. Flowers yellow, flecked with red. **Leueme** curved upwards, with a membranous wing along the lower edge. This was sent to Linnaeus as a kind of *Santalum rubrum*, or Red Sanders Wood, having been ascertained as such by König. It is described as hard and heavy, deep red with black veins, and taking a fine polish. The finely perfumed wood, commonly called Sentaloil wood, and used for fans, necklaces, &c. is very different. **See SIRIUM myrtifolium.**

7. **P. Ecaflatphylum.** Oval-leaved Pterocarpus. Linn. Syll. Nat. ed. 12. v. 2. 439. Swartz Obs. 275. Wildl. n. 7. Ait. n. 3. Bergius in Act. Holm. for 1759. 117. t. 4. (Hedyfarum Ecaflatphylum; Linn. Sp. Pl. 1552. Ecaflatphylum; Browne Jam. 299. t. 32. f. 1.) Sparrium scandens, citri folius, floribus ad nodos conferentibus; Plum. ic. 2. 1844. t. 246. f. 2. — Leaves simple, ovate, pointed; silky beneath. — Native of the West Indies. Found by Browne, in low swampy places, about Kingston in Jamaica. Holowen sent seeds of this species to the gardens, but it seems not to have survived in our gardens. The flower is flabby, spreading obliquely to the extent of six or seven feet. **Leaves** all simple, three or four inches long, and one and a half broad, downy all over when young. *Stipula* oblong. Flowers few together, in short axillary clusters.

**PTEROCEPHALUS.** See *SCABIOSA.*

**PTEROCCOCUS,** from *elgus*, a wing, and *latex,* a berry, a name given by Pallas to the plant which Linnaeus called *Pallasia,* but which was rightly referred by L’Heritier to *Calligonum*; see those articles.

The simple *persimmoniun,* or fringe, distinguishes this genus from *Hypnum* and *Nickeria,* without adverting to the upright hairs of its veil, which, though usual, are not invariably present. Hedwig describes nine certain species in his *Species Mufcorum,* to which four are added by his editor and confractor Dr. Schwagerich, in a Supplement published at Leipfie in 1811. To these 13, are added three others by

the writer of the present article, one of them the Linnean *Hypnum furiosum,* or *Dicranum furiosum,* Brit. Brit. 1215. We shall confine our remarks to the six British species.

**P. gracile.** Slender Wing-mofs. Fl. Brit. n. 1. Engl. Bot. t. 1085. Hedw. Sp. Mufc. Suppl. 1. n. 7. (Pterigynandrum gracile; Hedw. Crypt. v. 4. t. 56. Hypnum gracile; Linn. Munt. 310. H. gracile orthophidioides; Dill. Mufc. 320. t. 41. f. 55.)—Stem creeping. Branches cluttered, cylindrical, recurved. Leaves ovate, finely ferrated. — Native of the trunks of trees, and mountainous rocks, in Britain, Switzerland, Portugal, Carnithia and Carniola, bearing capsules in spring and summer, but rarely with us. This plant forms broad, dense, cussion-like tufts, composed of wiry, creeping, much divided *fleas,* throwing up innumerable recurved, slender, leafy branches, about an inch high. The leaves are every way closely imbricated, deep green; yellowish and hissing in exposed situations; their form broad-ovate, ribles, minutely toothed or ferrated. **Sheaths** lateral, small, pale. Fruit-flakes solitary, hardly an inch long, red. **Capsule** cylindrical, nearly erect. **Lid** conical, bluntish, rather curved. **Veil** pale, slender, clothed with upright deciduous hairs.

**P. filiforme.** Capillary Wing-mofs. Hedw. Sp. Mufc. Suppl. 1. n. 2. Engl. Bot. t. 2207. (Pterigynandrum filiforme; Hedw. Crypt. f. c. 18. t. 7. Hypnum filiforme; Timm. Megapot. 225.) — Stem decumbent, weak, irregularly branched, creeping. Leaves ovate, ferrated, cloely imbricated. Capsules ovate-oblong, erect. — Native of mountainous rather stately rocks, in the middle of Europe, but not common, bearing fruit in summer. This species was detected, since the publication of *Fl. Brit.,* on the end Mr. Geo. Don, and in Ireland, by Mr. J. T. Mackay. The *fleas* and branches are prostrate, in dense entangled patches, and clothed with very small, cloyly imbricated, slightly oblique *leaves,* of a deep, fearely hissing, green, without rib or furrows; their upper half ferrated. **Sheaths** pale, with long, taper-pointed, ferrated fealeb. **Stalks** tawny. **Capsule** shorter, and more ovate, than in the preceding. **Lid** conical, with a blunt point. The *veil* has not been observed.

**P. feiroides.** Squirrel-tail Wing-mofs. Turn. Mufc. Hib. 32. Engl. Bot. t. 1903. (Dicranum feiroides; Fl. Brit. 1215. Swartz Mufc. Suec. 32. Hypnum feiroides; Linn. Sp. Pl. 1566. H. arboricole feiroides; Dill. Mufc. 319. t. 41. f. 54.)—Stems creeping, branched. Branches cylindrical, incurred by drying. Leaves ovato-lanceolate, lirate, entire. Veil smooth. Teeth of the fringe deeply cloven. Found on the trunks of trees abundantly, in most parts of Europe, though rarely bearing capsules in Britain. The habit of the plant is perhaps most akin to *P. gracile,* but the whole is of larger dimensions. The leaves are of a rich green, entire, with three longitudinal plasts, but no ribs. They are sometimes, in Norfolk, accompanied by axillary branching tufted buds. **Sheaths** axillary, long and taper. **Stalks** tawny, hardly thricse as long. **Capsule** erect, ovate, smooth. **Lid** conical, red. **Veil** slender, naked. **Veil** small, tender, pale, its teeth deeply divided, but resembling the internal fringe of *Hypnum* in texture, not the firm teeth of a true *Dicranum.* This circumstance, and especially the lateral situation of the female, as well as males, *flowers,* first induced Mr. D. Turner to remove the plant in question to the genus where we now retain it. The male *flowers* are red.

3. 167.—(Conyza aromatica Pluk. Joseph natives yard for the cylindrical the 3.) Civicran July. of certain leaves 1. flowers 18. Willd. revol—very Willd. leaves when Mr. they flying 68. Ait. the calyx-fcales ftyle leaves in Botany, flowering frudifcatlon poffita branches any green, fimple, tufted, feems Ireland, Engl. and Sacrum Linn. scarcely Mart. fkeii Bot. leaves in winter Italy and Barham. and P. rostrifolium. Round-leaved Wing-mofs. Turn. MSS. Engl. Bot. t. 2525.—Stems ascending, tufted, scarcely branched. Leaves closely imbricated, roundish-ovate, obtuse, entire. Discovered by Mr. Mackay in the south of Ireland, but without fructification, so that it is prepumently only, by its habit, referred to Ptergonium, like the next-described species. The stems are ascending, or nearly erect, hardly an inch high, in dense tufts; each of them generally simple, leafy, swelling upwards, and obtuse. Leaves closely imbricated every way, broad, of a pale but dull green, minutely reticulated, with little or no appearance of any rib.

P. cefifolium. Matted Wing-mofs. Engl. Bot. t. 2526.—Stems branched, entangled, prostrate, slender. Ultimate branches ascending, obtuse. Leaves ovate, concave; revolute at the base; minutely serrated at the summit. Gathered by Mr. W. Borrer, on rocks by the river at Dollie bridge, Scotland. The wiry much-divided stems throw up many short, simple, obtuse, ascending branches, clothed with larger and paler leaves than those on the main stems. As no fructification has been found, we cannot be certain of the genus, though the habit is such as to leave no scruple in our minds on that subjeft.

PTERON, in Ancient Geography, a promontory of Lower Mysia, between the mouth of the Danube, called Sacrum Osium, and the town Itropolis, according to Ptolemy.

Obst. Jullieu says that in some species, if not in all, at least those with opposite leaves, the receptacle is certainly naked; though the seeds, being not only crowned with down, but clothed with villous hairs, give an appearance of a brilfly receptacle. This accoult does not agree with Gertner, nor with what we have observed.

A genus of rather humble rigid shrubs, of which Lin- naeus has only one species, camphorata, in his Sp. Pl. but which the discoveries of Thunberg chiefly have to greatly enriched, that Willdow admits 27, all natives of the Cape of Good Hope, except the laft, a very doubtful Pteronias, from Mexico. We fed a few examples.

P. camphorata. Aromatic Pteronia. Linn. Sp. Pl. 1176. Willd. n. 2. Ait. n. 1. (Coryza aromatica fructeceans mauritiana, camphorata folis, &c.; Pluk. Mant. 56. t. 345. f. 2.)—Leaves scattered or fafficulate, thread-shaped, ciliated. Calyx-scales finely ferrated. Hairs of the receptacle somewhat tufted. Introduced from the Cape by Mr. Maffon in 1774. It blossoms from June to September, and is sheltered in the green-house in winter. Stem much branched, about a yard high. Leaves very narrow, flat, spreading. Flowers terminal, yellow, folidary, larger than those of Santolina maritima. It appears, from Mr. Maffon’s communications to Mr Joseph Banks, that he gathered this species in sandy ground, near Swartland.

P. Porophyllum. Dotted-leaved Pteronia. Cavan. Ic. v. 3. 15. t. 225. Willd. n. 27.—Leaves pinnatifid, obfute, with fringe-like teeth. —Native of Mexico. It flowered in the garden at Madrid in November, being an annual herbaceous plant, about two feet high. Leaves scattered, about two inches long, pinnatifid, lyrate, obtuse, their ferratures tipped with long hairs. Flowers terminal, folitary, yellow, with pinnatifid, almost capillary, braftces.

PTEROPHERICUS INDIARUM, in Ornithology, a name under which Nieremberg has defcribed a bird, which he lays is called by the Spaniards there commendado, remarkable for the redness of the upper part of its wings. It is of the shape and size of the flaring, and not unlike it in colour, but for the singularity of the upper part of its wings, which, in one part of their lives, are of a yellowish or orange colour, and in the reft red. They are kept in cages, and learn to imitate the human voice; they feed on vegetables, principally Indian corn, and are common as well in the colder as in the hotter climates; flying in large flocks, and often doing...
doing great damage to the people. They build in trees and are eaten there; but are not very valuable bird. See ORIOlus Phoecicus.

PTEROPHORES, in Ancient Geography, a country of Scythia, towards the Rhiphean mountains, according to Pliny.

PTEROPHORI, πτερόφοροι, in Antiquity, a name given to such of the Roman couriers as brought tidings of any declaration of war, a battle lost, or any misfortune to the Roman armies.

They were so called, because they bore wings on the points of their pikes; from the Greek πτερός, wing, and ωρ, I bear.

PTEROPHORUS, in Botany. See PTERONIA.

PTEROPUS, in Zoology. See VESPERTILIO.

PTEROSPERMAEANDRON, in Botany. See PENTAPTERETES and PTEROSPERMUM.

Gen. Ch. Cal. Perianth inferior, deeply cloven into five, coriaceous, oblong, reflexed segments. Cor. Petals five, oblong, spreading. Stam. Filaments fifteen, linear, combined at the base into a tube; anthers oblong, erect, twisted. At every third filamen is a long, coloured, erect body, as long as the petals, resembling a barben filament, but without any anther. Pfl. Gemen inferior, roundish, (filkated ?) stylo cylindrical, the length of the filaments; stigma thickish. Peric. Capsule filaked, woody, ovate, five-celled, each cell two-valved. Seeds numerous, oblong, compressed, with a membranous wing.

1. P. fuberosum. Various-leaved Pterospermum. Willd. n. 1. (Pentapteres suberosa; Linn. Sp. Pl. 959. Cavan. Diff. 3. 130. t. 43. f. 2.)—Leaves oblong, pointed; slightly toothed at their tips. Native of the East Indies. It flowers in September and October. The branches of this handsome plant are erect, and covered with a ruffly down. Leaves alternate, on short stalks, thick, green above, whitish beneath, with a strong, longitudinal rib. Flowers axillary, at the summits of the branches, one, two, or three together, white. Linnaeus remarked that the leaves of this plant resembled those of the Ilex, or Holm Oak, in substance; and that its flowers had the appearance of Michelia and Gearwa.

2. P. acerosum. Maple-leaved Pterospermum. Willd. n. 2. Bot. Mag. t. 626. (Pentapteres acerifolium; Linn. Sp. Pl. 959. Cavan. Diff. 3. 131. t. 44.)—Leaves oblong, heart-shaped, obtuse, nearly entire. Native of the East Indies, and introduced by Mediras. Lee and Kennedy about 1790. It flowers from July to September. This very superb species, considerably larger than the preceding in all its parts, but exceedingly similar to that in habit, has its bark covered with a white wool, like the underside of its leaves, which are petalate, and supported on long footstalks thickened at both ends. Flowers terminal, white, fragrant. Calyx like thick buff leather, externally dotted, like the stem, with red and brown.

Gen. Ch. Cal. Perianth superior, ringent, of two lanceolate pointed leaves; the lowermost deeply divided, or rather composed of two, combined in their lower part. Cor. Petals two, oblong, converging with the upper calyx-leaf. Nectary a lanceolate filaked lip, shorter than the petals, with an appendage, or swelling, at the base; its claw connected below with the lower calyx-leaf. Stem. Column united at its base with the petals and upper calyx-leaf; winged on each side at the upper part; anther a terminal, moveable, permanent lid, its cells close together; waftles of pollen powder, compressed, two in each cell. Pfl. Gemen inferior, oblong, with six furrows; style, column as above described; stigma tumid, attached to the middle of the column. Peric. Capsule of one cell and three-valves. Seeds numerous, minute, attached to three longitudinal receptacles.

Of this curious and very distinct genus of New Holland Orchidea, Mr. Brown enumerates nineteen species, in three sections. They all grow on the ground, and are smooth herbs, with a pair of naked, undivided, round bulbs. Leaves sometimes radical, filaked, ribbed, membranous, the flower-flask being, in that cafe, leafless, though furnished with bracteas; sometimes cuneate, alternate, none radical. Flowers solitary, rarely in clusters, of a pale yellowish-white; their size, for the most part, rather considerable.

 Sect. 1. Appendage to the lip divided, and tufted, at the tip. Leaves radical, filaked, leaflets. Stalk bracteate, leaflets. Eight species.

P. concinna. Elegant Pterostylis. — "Leaves radical, filaked. Stalk with one bractea near the middle. Lip emarginate, within the flower, the length of the column."—Gathered by Mr. Brown, and Mr. Caley, near Port Jackson. Leaves three or four, heart-shaped, filaked, reticulated, about half an inch long. Stalk four or five inches high, with one bractea near the base, and another more than half way up. Flower solitary, rather large, with green and white; the lower calyx-leaf with two very long, slender, dilatated points.

P. opinobiflora. Cloven-tongued Pterostylis. Br. n. 2.—"Leaves radical, filaked. Stalk naked in the middle. Lip emarginate, longer than the column, protruding at the summit."—Observed by Mr. Brown about Port Jackson, as well as in the tropical part of New Holland.

 Sect. 2. Appendage divided, mostly tufted. Radial leaves none when the plant is in flower. Stem leafy. Five species.

P. obtusa. Blunt-tipped Pterostylis. Br. n. 9. Ait. n. 1. — "Stem leafy, single-flowered. Lip obtuse, not contracted towards the end; appendage tufted."—Gathered by Mr. Brown near Port Jackson, and sent by Mr. George Caley, in 1800, to Kew, where it is said to be a green-house plant, flowering in July and August.

P. reflexa. Br. n. 10. (Disperis alata; Labill. Nov. Holl. v. 2. 59. t. 210.)—Stem leafy, single-flowered. Lip tapering, acute; appendage tufted. Petals with an angular entire dilatation at their inner margin. Found by Dr. White and Mr. Brown near Port Jackson; by M. Labillardiere at Van Diemen's land. The stem is a span high, straight, erect. Leaves rather dilatant, lanceolate, flocating,
Sheathing, acute, about an inch and half long. *Flower* erect, about the same length, exclusive of the *germen*, white striped with green.

Sec. 3. Appendage obsolet, undivided. Five species.

Sec. 4. Character of foliage uncertain. One species.

P. dubia. Br. n. 19. "Leaves radical...those on the stem...the upper one shorter than the flower-flake. Calyx slightly downy. Lip undivided, with a tufted appendage."—Native, as Mr. Brown informs us, of Van Diemen’s land. It is suspected to be but a variety of *P. cuneata*, his sixth species.

Mr. Brown has shown us another species of this genus, found by Sir Joseph Banks in New Zealand; and he informs us that the late colonel Pateron has discovered two more in the neighbourhood of port Dalrymple, Van Diemen’s land, where he established a colony.

**PTEROTRACHEA**, in *Ichthyology*. Body detached, gelatinous, with a moveable fin at the abdomen or tail; two eyes, placed within the head. There are four species, of which the first has been pretty fully described, as follows:

**Species.**

**CORONATA.** Abdomen and tail furnished with fins; head with a round perpendicular proboscis, and a coroet of ten spines on the front. It inhabits the Mediterranean and Archipelago. The body is sub-cylindrical, about a span long, and an inch in diameter; the head is rounded on the fore-part, and furnished in front with a coroet of ten spines; beneath the coroet is the proboscis, two inches long, with a whitish middle nerve, and thick hyaline tip, and terminal mouth; the eyes are seated on each side the back of the neck internally, and remote; trunk near the fin beneath spotted with white; abdomen rough beneath, with an ovate pendulous pouch before the fin; vent near the ligament of the tail; the tail is vertical, an inch long, and triangular, with four prickly lines on each side; the fin is situated beyond the middle of the body; it is orbicular, comprised, and fixed to the white lamina of the trunk, which are crenate on each side; beneath in the margin is another pinnule, which is bell-shaped, hyaline, and affixed by a middle point.

**HYALINA.** Head elongated, projecting, smooth; the fin is central.

**PULMONATA.** Head oblate, hyaline; intestine respiratory and ciliate, with plumes.

**ACULEATA.** Abdomen without fin; tail longer than the trunk, with prickly lines, and a terminal horizontal fin. This, as well as the first, is found in the Archipelago. The habituation of the others is not known.

**PTERYGIUM, or PTERYGION, dim. of πτερυγ, a wing.** By the term pterygium, surgeons universally imply that preternatural, reddish, ash-coloured, triangular, little membrane, which most frequently grows from the internal angle of the eye, near the caruncula lachrymalis, and gradually extends over the cornea, so as to cause a serious impediment to vision.

Of this disease the celebrated Scarp has recently published a description, which may be regarded as the most perfect one extant, and which we therefore feel it to be our duty to incorporate in this comprehensive dictionary.

Though, says Scarp, the pterygium generally arises from the internal angle of the eye, it is sometimes observed to proceed from the external one, and, in some instances, from the superior or inferior hemisphere of the eye-ball. But whatever be its origin, its figure is invariably that of a triangle, with its base on the white of the eye, and its apex more or less advanced over the cornea, towards the centre of this membrane and of the pupil. Indeed, there are a few cases, in which two or three pterygia of different sizes take place on the same eye, and are arranged round its circumference at interspaces of various breadths. Their points are directed towards the centre of the cornea; and if they should unfortunately conjoin there, the whole of that transparent membrane becomes covered with an opaque veil, and a total loss of sight is the consequence. It seems to Scarp, that the term *pterygium* was applied by the ancients to exactly this sort of complication.

Strictly speaking, chronic varicous ophthalmia, with relaxation, and thickening of the conjunctiva, opacity of the cornea, and the pterygium, only differ in the degree of the disease. In reality, all the three complaints consist of a more or less extensive varicous state of the vessels of the conjunctiva, combined with a degree of preternatural relaxation, and thickening, of that membrane.

In chronic varicous ophthalmia, the extraordinary amplitude and knottnes of the vessels, the faciacy and thickening of the conjunctiva, are limited to the white of the eye. In opacity of the cornea, certain veins even dilate, and become knotty, for some ways, over that delicate layer of the conjunctiva, which is continued over the surface of the cornea. In the pterygium, an extraordinary swelling of this subtle membranous expansion is added to the varix state of its veins. Hence, the pterygium seems at first like a new membrane formed on the cornea, while it is really nothing more than the delicate continuation of the conjunctiva just mentioned, deprived of its transparencies, and degenerated, in consequence of chronic ophthalmia, into a thick, opaque membrane, on which there is a plexus of varicous blood-vessels: consequently, in the case of pterygium, there is no new production on the eye, but only an alteration of one of the thin, transparent membranes, which naturally cover it. The following circumstance, as will be more fully explained presently, illustrates, says Scarp, the variety of the preceding statement. The incipient pterygium may be cured in the same manner as opacity of the cornea, *viz.* by merely cutting off that portion of it, which is situated at the junction of the cornea with the sclerotic, without detaching the whole of it from the surface of the former membrane; just as is practiced in opacity of the cornea, in order to destroy the communication of the varicous veins of the conjunctiva with their trunks, the ramifications of which produce and maintain the disease.

Scarp observes, that the pterygium would be as common a complaint as the varicous chronic ophthalmia, so often occupying the white of the eye, if the delicate continuation of the conjunctiva, over the surface of the cornea, were not naturally of a denser and more compact texture than the rest of the membrane, from which it is produced, and if its vessels were not very minute, and delicate, and not so dilatable as those of the other part of the conjunctiva. This is the reason why the pterygium is comparatively a rare case, in respect to the great frequency of varicous, chronic ophthalmias. But should the vessels of the transparent layer of the conjunctiva once yield to the impulse of the fluid propelled into them; should they once become varicous; the cellular
PTERYGIUM.

cellular texture, in which they are enveloped, never fails to swell gradually, and thus the delicate, diaphanous membrane in question changes into a pulpy, reddish tunic, precisely similar to the pterygium.

That the pterygium is truly nothing else, but the natural, delicate, transparent expansion of the conjunctiva on the cornea, converted, for a certain extent, into a pulp, flaccid, varicous membrane, may be inferred (continues Scarpa) from the folds which the pterygium and conjunctiva form at the same time, when the morbid eye is turned towards the origin of the disease. The same inference is equally deductible from the tension occasioned in both these parts, whenever the eye is moved in the opposite direction. We become still more convinced of the fact on observing, that in the first position of the eye, both the pterygium, and the corresponding portion of the conjunctiva (which is equally relaxed, varicous, and reddish), may be easily taken hold of with a small pair of forceps, and raised together in the form of a fold.

When the pterygium is met with in the dead subject, on carefully cutting off, and detaching that flaccid and thickened portion of the conjunctiva in the white of the eye, which corresponded to the part of the cornea in the state of opacity, from the pterygium, Scarpa has constantly found, that the pterygium might be separated, with equal facility, both on the white of the eye, and the cornea. The latter membrane was evidently denuded at the seat of the disease, being no longer covered with the transparent continuation of the conjunctiva. But Scarpa has never been able to deprive the cornea of its natural covering, beyond the limits of the pterygium. Also, when several pterygia occur on the same eye, with interfaces between them, as many flaccid, varicous, pulpy places appear in the conjunctiva on the bulb, and constitute the basis of the pterygia; while the rest of this membrane, covering the white of the eye, continues smoothly spread over the ball, and no varicous blood-veil is perceptible on the anterior hemisphere of the eye, except where the relaxation of the conjunctiva, and the knotting of the vessels, have implanted, as it were, the diftant roots and rudiments of the pterygium.

The pterygium, whether large or small, and whatever its situation may be in the circumference of the eye-ball, constantly retains its triangular shape, with its base on the white of the eye, and its apex on the cornea. The confiency of this fact seems to Scarpa attributable to the increasing degree of firmness, with which the fubtile, transparent layer of the conjunctiva adheres to the surface of the cornea, as it proceeds from the circumference to the centre of that membrane. The following confquences must necessarily result from this fort of structure, and the different degree of cohesion actually existing in healthy eyes. 1. The progress of the pterygium must be the flower in every instance on the cornea, than on the white of the eye. 2. As the pterygium always meets with augmented reflacitance, in proportion as it endeavours to approach the centre of the cornea, it must from mechanical necessity assume the form of a triangle, with its base on the white of the eye, and its apex directed towards the centre of the cornea. Forelius (Opér. Med.) has accurately noticed the circumstances of this appearance, and, he continues, "non cooperer oculum nisi in formam fagittae."

From this invariable appearance, and figure of the pterygium, one of its principal diagnostic characters results, by which the true disease may be discriminated from false influences, and from every other soft, fungous, reddish excrecence that obscures the cornea. For on this membrane excrecences sometimes form, which, from having the colour and confidence of a soft membrane, bear a very great re-

semblance to the pterygium, though they are really widely different, and, strictly speaking, consist of the texture of the cornea itself, degenerated into a soft, fungous substance. Such pellicles, however, not only almost always create a greater prominence on the cornea, than what accompanies the pterygium, but they are constantly of an irregular tuberous form, and never represent a triangle, with the apex pointing towards the centre of the cornea, like the genuine pterygium.

Another distinguishing character of the pterygium (continues Scarpa) consists in the facility with which the whole of it may be taken hold of with a pair of forceps, and raised into a fold on the cornea. Every other kind of excrecence, attached to this membrane, continues firmly adherent to it, and cannot be folded, and raised from the surface of the cornea, in any manner whatever. This particularity is of the highest importance in the treatment of the disease; for the genuine pterygium may be cured by simple means, while fungous excrecences of the cornea can only be radically removed, and perfectly cicatricised with the utmost difficulty. Plenck very properly observes, on this head: "PTERYGIA, quale filamenta folummodo aderent, facile abinduuntur, difficilimum quae ubique accerta sunt corneae, ac in phleam non pollunt." If this excrecence should adhere firmly to the cornea, be of a deep red colour, easily blotted out being touched, and cause stinging pains in the whole eye and temple, though it be of a triangular figure, and constitute the true pterygium, it now threatens to assume a malignant cancerous nature, or has done so already. Hence, in the treatment, it is necessary only to adopt a palliative plan, or else extirpate the whole eye-ball.

The true benign pterygium, says Scarpa, which has a triangular figure, is alth-coloured, or pale-red, is free from pain, and admits of being raised in the form of a fold on the surface of the cornea, may be cured by cutting the opaque triangular little membrane accurately from the surface of the cornea, which is in part covered by it. But as it appears, from what has been said, that the pterygium is nothing but a portion of the delicate, transparent layer of the conjunctiva, converted by chronic varicous ophthalmia into a thick, opaque tunic, it follows, that the pterygium cannot be removed in any way, without the spot, which it occupies on the cornea, being bereft of its natural external covering. Also, as this demodation of the cornea renders a cicatrix unavoidable at the place, it equally follows, that the knife cannot be employed in the cure of the disease, without the cornea being rendered more or less opaque at the point where the pterygium was before situated. Hence, Scarpa cautions young surgeons not to allow themselves to be deceived by the specious accounts of authors, who assert, that they have removed pterygia with the scalpel, and entirely restored to the cornea its former natural transparency. It is true (he says) that, after the removal, and cure, of the pterygium, the cornea at the point affected becomes less opaque than it was before; but the place always continues dim, and clouded with an indelible, though superficial cicatrix. The amendment derived from the operation cannot but be considerable; by means of the incision, and firm cicatrix, a stop is put to the progress of the complaint, or rather to the increase of the varicous affection, and swelling, of the thin, transparent layer of the conjunctiva, situated on the cornea; the local cause of irritation, and inflammation of the eye, is entirely obviated; and, thus, complete opacity of the cornea is prevented. But should it ever have happened after the reception of a large pterygium, that the patient regained his sight, we are to understand a certain degree of vifion; in that proportion (Scarpa wishes to signify) which exists between
Pterygium.

tween a dense membrane, which entirely obstructs the passage of the light, and a light, superficial cicatrix of the cornea, which does not intercept it altogether.

Scarpa's experience enables him to state, however, that the superficial, indelible speck remaining in the cornea after the resection of the pterygium, is always less extensive than the space previously occupied by the disease. This fact, says he, is a constant one, and, in the vast number of pterygia for which he has operated, some had advanced over the cornea two lines, others two and a half, towards its centre. In all, the fear, and opacity of the cornea, diminished after the cure was perfected, and never exceeded a line and a half, or a little more, in cases in which the pterygia had been two lines in length.

The resection of the pterygium is a very easy operation. For this purpose there is no occasion for a needle threaded with silk, which most surgeons recommend to be passed through the little membrane, in order to make a noose for raising the pellicle, which must be divided at its base. The plan is disadvantageous, as it prolongs the operation considerably, and, particularly, as the bleeding from the punctures prevents the operator from distinguishing, with the necessary clearness, the margin of the parts designed for removal. A pair of dissecting forceps, and a pair of sharp scissors, suffice for this operation.

It is customary (continues Scarpa) to remove the pterygium by making the incision on the cornea, and extending it over the white of the eye, as far as the base of the disease reaches on the conjunctiva; so that when the pterygium grows from the internal angle of the eye, most surgeons continue the section as far as the caruncle. This practice is disadvantageous, first, because it denotes too much of the white of the eye; secondly, because, in consequence of the large portion of the conjunctiva removed at the base of the pterygium, and, in consequence of the direction of the wound, the cicatrix in the white of the eye forms an elevated fraxnum, which, like a little cord, keeps the eye-ball approximated to the caruncula lachrymalis, and destroys the freedom of its motions, particularly towards the external angle.

To avoid this inconvenience, Scarpa says, he has found it useful, in the treatment of pterygia with bases extending far in the white of the eye, to detach them at their apex, as far as the junction of the cornea with the sclerotic, and then to separate them at their base by a semi-circular incision, comprehending one line in breadth of the substance of the conjunctiva, and made in a direction concentric with the edge of the cornea. Scarpa has observed, that, in this mode of operating, the subsequent cure takes place sooner than when the common method is adopted; the cicatrix occasions no sort of fraxnum, and the conjunctiva, circularly stretched by the cicatrix, lies smoothly over the white of the eye, and loses that relaxation and varicose state, which are the ground-work of the pterygium. Such attention, however, is not requisite when the pterygium is small, and its base does not extend far in the white of the eye.

Scarpa describes the operation as follows: The patient being seated, an alligator behind him is to elevate the upper eye-lid with the index and middle fingers of one hand, while he depresses the lower eye-lid with the corresponding one of the other. Supposing the right eye, the operator is to stand, or sit down, just as he prefers, in front of the patient; and the former, after directing the latter to move his eye-ball towards the part corresponding to the base of the pterygium, is to seize the morbid membrane with a pair of forceps held in his left hand, and pinch it into a fold, at about one line from its apex. The duplicitage is now to be raised, and drawn out gently, until a sensation of something giving way is felt, which indicates the detachment of the pterygium from the delicate cellular texture, by which it is connected with the subjacent cornea. Next, by means of a pair of scissors in the right hand, the surgeon must detach this fold, as closely as possible, from the cornea, proceeding from the apex towards the base of the pterygium. The section being completed to where the cornea and sclerotic meet, the fold is to be again elevated still more, and, with one stroke of the scissors, the pterygium, and the relaxed portion of the conjunctiva, forming its base, are to be detached, as concentrically and closely to the cornea as possible. This second incision will have a semilunar shape, the horns of which ought to extend two lines beyond the relaxed part of the conjunctiva in following the curvature of the eye-ball.

When the operation is finished, the surgeon must promote the hemorhage, by washing the part with warm water, and then cover the eye that has been operated on, with a pledget of dry lint, or lint moistened in the aqua vegeto-mineralis, supported by a bandage, that does not make too much pressure on the part.

If no particular symptoms arise (continues Scarpa), such as pain, tension of the eye, considerable tumefaction of the eye-lids, it is sufficient to wash the eye, and infuse of the eyelids, three or four times a day with a warm lotion of mallow, and carefully keep these parts from being exposed to the air without compreiling them. If the symptoms just mentioned should afterwards occur, the antiphlogistic treatment must be adopted in its full extent, &c.

On the fifth or sixth day, at last, after the operation, all the surface from which the pterygium was cut appears yellowish, and covered with a fluid, like mucus. This is a mode of suppuration (says Scarpa) peculiar to membranes in general, and particularly to those of the eye. The edges of the wound, and the adjoining part of the conjunctiva, assume a reddish colour. Afterwards the surface of the wound contracts more and more daily, so that at length it completely closes, and the cicatrix forms.

During the whole treatment, subsequent to the operation, there is no occasion to employ any other topical applications, but the warm lotion of mallow, three or four times a day. Numerous cases have convinced Scarpa that astringent collyria, and the boiled powders of the Florentine iris and alum, cause great irritation to the eye operated on, and give rise to tumefaction, and a fungus-like state of the conjunctiva, which are impediments to the cure. What is still more incommodious is, that such means produce fungous excrecences on the middle of the wound itself, which only admit of being repressed and cicatrizted with difficulty. Scarpa has seen all these inconveniences arise from one single unnecessary application of the argentum nitratum. On the other hand, when a mere lotion of mallow is the only remedy employed in the treatment, the cure proceeds regularly; the yellowish surface of the incision diminishes daily, and in three, or, at most, four weeks, the wound is quite healed. The vitriolic collyrium, containing a few drops of camphorated spirit of wine, can only be prudently infilled three or four times a day into the eye, for the purpose of strengthening the conjunctiva and its vessels, after the wound is perfectly cicatrizted.

We have already repeated Scarpa's sentiment, that the incipient pterygium, strictly speaking, is nothing more than an opacity of the cornea, in which the venous vessels of the conjunctiva covering that part of the cornea, which is the seat of the disease, are somewhat more dilated, than in the case to which the term opacity is usually affixed: and, also, that the density and opacity of the delicate layer of the
the conjunctiva are much more considerable at the part affected in the incidence of pterygium, than in that of simple opacity of the cornea.

The incipient pterygium (adds this author) is not a dense, opaque membrane, but a pellicle as fine as a cobweb, interwoven in different places with various blood-vessels, the iris continuing tolerably visible behind it. In this early state of the pterygium, it is unnecessary to deprive the cornea of its natural covering; it is quite enough to cut off a portion of it, in order to intercept all communication between the dilated venous ramifications of the pterygium, and the various trunks in the white of the eye.

The reception, says Scarpa, is accomplished by cutting out, with a pair of forceps and scissors, a filamentous piece of the conjunctiva, at the point where the cornea and sclerotics conjoin, and exactly at the base of the incipient pterygium, just as is practised for opacity of the cornea. The recent pterygium is observed to disappear gradually after the operation, or to change into a slight dimness of the cornea, extending over a part of the space previously occupied by the defect. This opacity is commonly much more trivial than what follows a cicatrix. Acrell, in his surgical observations, mentions having successfully treated an incipient pterygium in this manner. Scarpa has also tried the plan several times with success. Scarpa.Sulle Malattie degli Occhi, cap. 11.

Gen. Ch. Cal. Perianth superius, ringent, of three lanceolate, equal, concave, spreading leaves. Car. Petals two, roundish-ovate, nearly as long as the calyx, spreading, approaching the upper calyx-leaf to as to form a hood. Nectary a lip, various in shape, inserted into the column between the lobes of the anther, reflexed and spreading. Stam. Column erect; short, either blunt or pointed; anther of two roundish separable lobes, one at each side of the column, curving laterally. Pils. Germin inferior, oblong, furrowed; style column as above; stigma convex, solitary, at the base of the back of the anther. Peric. Capsule of one cell, with three valves. Seeds numerous, minute.

Eff. Ch. Lip inserted into the middle of the column, between the lobes of the anther. Petals rounded. Two lower calyx-leaves disarticulated, concave. Stigma posterior.

Willdenow, after Swartz, reckons up six species.

1. P. alatum. Winged Pterygodium. (Ophrys alata; Linn. Suppl. 404.)—"Stem leafy. Leaves lanceolate. Lip in three segments; the middle one very short."—Found by Thunberg at the Cape of Good Hope. A small plant, three or four inches high.

2. P. catholicae. Inflated Pterygodium. (Ophrys catholicae; Linn. Sp. Pl. 1344. O. alaris; Linn. Suppl. 404. Orchidæ affinis, Bore luteo; Buxb. Cest. 13. 13. t. 21.)—"Stem with two or three oblong pointed leaves. Lip papulate, pointed, wavy." Native of the Cape. A span, or more, in height, with a few large, concave, yellow flowers.

3. P. fulvicolor. Arrow-lipped Pterygodium. (Ophrys Volucris; Linn. Suppl. 403. O. triphylla; Thunb. Prodr. 2.)—"Stem with three ovate leaves. Lip hallowe."—Gathered by Sparrmann and Thunberg at the Cape. Introduced at Kew in 1797, by Sir Joseph Banks. It flowered in the green-house in June and July. This species is a foot high. Leaves three on the stem, ovate or oblong, pointed, ribbed. Spike of many, dilated, rather small flowers.

5. P. inversum. Cloven-fringed Pterygodium. (Ophrys inversa; Thunb. Prodr. 2.)—"Stem clothed with fringed, two-ranked leaves. Lip lanceolate, divided at the base."—From the same country. Spike dense, of many flowers.

6. P. atratum. Blackened Pterygodium. (Ophrys atrata; Linn. Mant. 121.)—"Stem with several linear-spatulate leaves. Lip papulate, somewhat heart-shaped." Native of sandy ground at the Cape. Stem three or four inches high. Leaves numerous, dilated; the lowestmost broadest; the upper longest and narrowest. Spike lax, of several dilated flowers. The whole plant when dried turns as black as ink, whence the name; but this circumstance is common to many of the Orchis family.

PTERYGODIUM, in Anatomy, the name of a process and of a foramen of the sphenoid bone, and of some other parts situated near them. See CRANIUM.

The pterygoid nerve is a branch of the superior maxillary going through the pterygoid foramen. See NERVE.

PTERYGOIDEUS, Externus, and Pterygoideus Internus, two muscles of the lower jaw, arising from the pterygoid processes of the sphenoid bone. See DÉGLOTTISATION.

PTERYGO-PHALYNGEUS, a name given to some of the fibres of the constrictor pharyngis superior.

PTERYGO-STAPHYLINUS, Internus, the levator palati muscle.

PTERYGO-STAPHYLINUS, Externus, the circumflexus palati.

PTILOSIS, from πτιλος, bald, a lops of the eye-lashes, from the fess of the eye-lids.

Eff. Ch. Calyx in five deep lanceolate segments. Stamens connected at their base, without teeth. Anthers of two cells. Stigma capitatus. Capsule without valves, single-seeded, included in the three inner segments of the calyx, which are connected by wool half way up, and naked and spreading above.

This genus consists of annual smooth herbs, with narrow alternate leaves. The flowers are terminal, somewhat capitate, accompanied by three membranous shining bractaea, which remain after the calyx is gone. It is said by its learned author to be very nearly akin to his TRICHINIUM; see that article hereafter.

Both species were gathered by Mr. Brown in the tropical part of New Holland.

PTINUS, in Entomology, a genus of insects of the order Coleoptera: antennae filiform, the last joints larger; thorax nearly
nearly round, not margined, receiving the head. There are thirty-nine species, divided into two sections, depending upon the form of the feelers and lip.

The genus *Ptinus*, like that of *Dermeles* (which see), consists of small insects, which, in general, have similar habits, living both in their larva and complete state among dry animal substances, and some species of dry wood, committing much havoc among the older articles of furniture, which they pierce with innumerable holes, thus causing a slow but gradual destruction.

### A. Feelers elevated.

#### Species.

* **Tessellatus.** Brown; thorax even; shells faintly testaceous. It is a native of England.

* **Striatus.** Brown; thorax uneven, with two ferruginous dots at the base. It is a native of Kiel.

* **Rufipes.** Black; thorax roundish; shells faintly ferruginous. This is found in different parts of Germany.

* **Castaneus.** Downy, chestnut; shells faint. It inhabits France.

* **Pertinax.** Brown, immaculate; thorax compressed. This is found in divers parts of Europe, and is very destructive to wood furniture and books. When caught it contracts itself and counterfeits death, nor can it be put into motion again by any stimulating means but by the application of great heat.

* **Boleti.** Brown, opaque; legs testaceous. Inhabit German; is on fungi. The body is rarely ferruginous.

* **Mollis.** Ferruginous; eyes black; shells narked. It is of a brick-colour, with dark-coloured eyes. It is found in this country and various parts of Europe, among rubbish; it is extremely destructive to collections of plants, and not to be got rid of but by the heat of an oven. The larva is white, and capable of enduring great cold.

* **Paniceus.** Downy, ferruginous; shells faint. Found in flake decayed bread.

* **Arietis.** Brown, naked; shells testaceous. It inhabits Germany, and is found in the fir-tree.

* **Planus.** Brown; thorax plain; shells with crenate frize. It is a native of Kiel.

* **Cephalus.** Ferruginous; shells faint, paler. Found at the Cape of Good Hope.

* **Minutus.** Testaceous; thorax rounded; shells sub-ferrugineous and pubescent. Found in dried plants brought from Italy.

* **Micans.** Smooth, brown; shells naked; legs testaceous. Found in some parts of Germany, as is the next.

* **Nitidus.** Naked, black, polished; legs testaceous.

* **Pulicarius, or Death-watch.** Subvilous, duskly, with irregular grey brown spots. There seems a considerable degree of doubt where to place the death-watch; some will have it to be a species of the Termites. Fabricius appears to have supputed it the dermelle testaceous, and Dr. Shaw describes it as the *ptinus fatidicus*: for its curious habits and manners; see our article Death-watch.

* **Fagi.** Black; antennae tawny; shells grooved and punctured. It is a native of Berlin.

* **Ferrugineus.** Ferruginous; eyes black; shells obstrately frigate. A native of some parts of Germany.

* **Testaceus.** Ferruginous, eyes black; shells smooth. A native of Berlin.

* **Fuscus.** Brown; body speckled with grey; scutellum grey; antennae ferruginous. Inhabits divers parts of Europe, as do the four following.

* **Rufus.** Rufous, with a yellow gloss; thorax with a yellow spot on each side behind; the shells are frigate and punctured.
and sometimes fea, to render it laxative. Most of the de-
cotions of physicians are called _pifian_. Feverish patients
are prohibited wine, &c. and reduced to _pifian_.

PTICIANA, _in Ancient Geography_, a town of Africa,
in the interior of Mauritania Tingitana. _Pto-

PTOLEMAIC System, or Hypothetis. See System.

PTOLEMAIS, _in Ancient Geography_, one of the towns
of Phoenicia, situated 32 miles from Tyre, according to
the Itinerary of Antonine. Its ancient name was Acco or
Aco. _See Acre._—Also, a town of Egypt, in the
Thelah, according to Strabo, who says that its government
was formed after the model of the republics of Greece.
Here the Ptolemies called it Hermis, and says that it was the capital
of the Thinite nome. Also, a town of Africa, in Cyre-
nena, according to Strabo, Pliny, and Steph. _Byz._—Also,
a town of Ethiopia, upon the Arabic gulf, according to
Pomponius Mela. Pliny names it Epithera, and places it on
the borders of the lake Monolesus, adding, that it was built
by Philadelphus, at the distance of 420 miles from Beren-
iece, on the coast of the Red sea.—Also, a town of Ada
Minor, in Pamphylia. Strabo.—Also, a port of the
town of Arsinoe, in the Arsinoitic nome, in Egypt, accord-
ing to Ptolemy.

PTOLEMAITAE, _in Echecologica! History_, a branch of
the ancient Gnostics, so called from their leader Ptolemy,
a man of considerable learning, who improved greatly on
the system of the Gnostics his predecessors, and enlarged it
with a number of notions and visions of his own.

The Ptolemaits were properly, a branch of the sect of the
Valentinians, which sprung up towards the close of the
second century, under Ptolemy, who differed in opinion
from his master Valentin, with respect both to the number
and nature of the souls.

St. Epiphanius is very full on the subject of the Pto-
lemaits, and produces a letter of Ptolemy to Flora, in
which that heretic lays down his doctrine. He maintained,
that in the law of Moses there were three things to be con-
sidered, inasmuch as it did not all come from the same
hand; but part of it, said he, from God, part of it from Moses,
and part of it from neither of them, but from the pure
traditions of the ancient doctors: on which last part it was
that he founded his dreams.

PTOLEMY, _furnamed Lagus, and Soter, in Biography,
king of Egypt, was a native of Eordea, in Macedonia;
he was probably a natural son of king Philip, who gave
his mother, Arinoe, when pregnant by him, in marriage to
Lagus, a Macedonian of mean descent. He passed for the
real son of Lagus, from whom that dynasty of Ptolemies
were called Lagides. He was brought up to arms, and be-
came one of the most celebrated officers of Alexander the
Great, whom he accompanied in all his expeditions. He
particularly distinguished himself in the war against the na-
tions on the Indian border, and had a great share in the suc-
cesses of his sovereign. On the division of the Macedonian
empire at the death of Alexander, the government of
Egypt, with part of Arabia and Lybia, were assigned to
Ptolemy. His administration of that province was so wise
and equitable, that many returned to it from Europe and
Asia, and by the honours which he paid to the remains of
Alexander, when conveyed to Egypt for interment, he at-
tached to himself many of the veteran soldiers of that con-
queror. When Perdicas began to manifest his ambitious
designs, Ptolemy joined in a league with Antipater and
Craterus to keep him within bounds; and when Antipater
made a new division of the provinces, Ptolemy was con-

deed could not be taken from him. He afterwards polishe-

ed himself of Syria and Phenicia. He met with very little
opposition in this attempt, except from the Jews, whose re-
sistance obliged him to lay siege to their capital, Jerusalem.
This city he took by storm on the fable-day, the religion
of the inhabitants not permitting them, on that day, to make
use of the means of self-defence. He sent a number of
Jews as captives into Egypt, of whom he selected those
who served his purpose to serve in his garrisons, and placed
the rest in the conquered countries of Libya and Cyrene.
He afterwards, together with Lykeimachus and Caius,
founded a confederacy to support Seleucus against the power
of Antigonus, who took Syria from Ptolemy, and laid
a siege to the Phoenician sea-ports, which he reduced.
Being obliged, however, to carry his arms elsewhere, Ptolemy
marched into Syria, and defeated Demetrius, the son of An-
tigonus, and recovered all that he had lost. A defeat,
given by Demetrius to a general of Ptolemy's, produced
another change of fortune, and Ptolemy retreated to Egypt,
with a great quantity of spoil, and a numerous body of people
who were defirous of living under his protection. Peace
was restored, and soon after broken: Ptolemy now
made inroads into Cilicia, and conquered the greater part of
the island of Cyprus. He then obtained various succecces in
Lelifer Asia and the Archipelago, and attempted to gain
the hand of Cleopatra, the sister of Alexander; but upon
the bare fulfilment of the princess's intentions in his favour,
the was put to death by order of Antigonus. His career
was short by the activity of Demetrius, who defeated him
in a sea-fight, and reduced the isle of Cyprus. On this oc-
casion the conqueror assumed the title of king, and
conferred the name on his son, and his example was followed
by Ptolemy, and the other Macedonian chiefs. This happened
in the year 306. Antigonus and Demetrius now resolved to
attack the entire conquest of Ptolemy's dominions, and
accordingly invaded Egypt with a powerful armament by
sea and land; but Ptolemy was too prudent and skilful to
allow them to carry their plans into effect. They turned
their arms against Rhodes, but the affiance of Ptolemy
was for ever his friends, and the inhabitants, for his servicers,
honoured him with the appellation of _Saviour_. Ptolemy,
in his turn, became the aggressor, and Antigonus was killed
in battle, while Demetrius underwent a formal defeat.
Ptolemy now recovered the isle of Cyprus, and captured in
Salamis the mother and family of Demetrius, whom he dis-
figured with magnificent presents. He regained likewise part
of Syria and Phenicia. At length, having arrived at an
advanced age, he devolved the cares of government upon his
son Ptolemy Philadelphus, allocating him to the throne,
and declaring him his successor, to the prejudice of an elder
son by another wife. He survive two years longer, and
died in the year 283 B.C. in the 8th year of his age,
having reigned more than forty years. Ptolemy Soter,
furnamed the Two, was one of the greatest of Alexander's
successors, and the first prince of the line which he founded.
His reign, on the whole, was highly prosperous, and at his
death his kingdom was very extensive; besides Egypt and its
dependencies, he held Phenicia and Caro-Syria, Lybia,
Pamphylia, Cilicia, Syria, Caria, and some of the Cyclades.
The feast of his kingdom was the new city of Alexandria,
which he rendered populous by inviting inhabitants from
various countries, and bestowing on them great privileges.
He built the famous Pharos, or light-house, at the entrance
of its port, and founded an academy or society of men of
letters, for whose use he began that collection of books,
which afterwards became celebrated through the world as
the Alexandrian library. He was himself a man of un-
questionable
PTOLEMY.

questionable learning, and composed a history of the conquests of Alexander, which was regarded by Arrian as the best authority for the events of that splendid period. While on the throne he retained the simplicity of manners and familiarity which had distinguished him as a follower. His government was mild, prudent, and equitable, so that his dominions were the refuge of numbers who fled from the disorders, and oppressions prevailing in other parts of the Macedonian empire. He had been four times married; his two last wives were Eurydice, the daughter of Antipater, and mother of Ptolemy Ceraunus; and Berenice, by whose charms he was so captivated in advanced life, that he consulted her on all occasions, and made her his heir. Univer. Hist.

Ptolemy Philadelphus, king of Egypt, son of Berenice, began to reign, as we have just observed, during the lifetime of his father, and in 281 B.C. succeeded him as sole monarch. Soon after his succession he banished the philosopher Demetrius Phalereus, a miserable and revengeful man, whom he suspected of having advised his father to nominate as his successor, his eldest son Ptolemy Ceraunus. The name Philadelphus appears to have been assumed by this king in compliment to his brother Ceraunus, after the latter had sent him an embassied expressing his desire to live on friendly terms with him, notwithstanding his disappointment in the succession. Philadelphus had, as has been seen, received a powerful and opulent kingdom, which placed him among the greatest sovereigns of the times. He had married, as his first wife, Arinome, the daughter of Lyfimachus, whom he repudiated, and then married his own sister, who was the widow of their half-brother Ceraunus; such was the custom of the royal families of the Macedonian race. He now formed an alliance with the Romans, the Athenians, and Lacedaemonians, and sent a fleet to the relief of Athens when besieged by Antigonus Gonatus. The general tranquility of his reign was interrupted by the revolt of his maternal brother Magas, whom Ptolemy Soter had made governor of Lybia and Cyrene. Magas, with a numerous army, advanced towards Alexandria with a view to dethrone Ptolemy, but was recalled to his own government by a revolt of the Marmarides. Afterwards, in conjunction with his father-in-law, Antiochus Soter, king of Syria, he renewed his designs; but Ptolemy was before-hand with him, and defeated all his plans. It was chiefly through the policy of Philadelphus that Alexandria became so celebrated for its commerce. He founded a city on the Red Sea, near the frontier of Ethiopia, which he named, after his mother, Berenice, but finding its harbour inconvenient, he removed the trading station to Myos-Hormos, on the same sea. To this port were brought the commodities of the East, whence they were transferred on camels to Coptos on the Nile, and thence to Alexandria; and, in order to facilitate the passage across the desert, he carried a canal into it from the Nile for the supply of water, and built houses of accommodation at proper intervals. He likewise, for the protection of trade, kept two strong fleets, one on the Red sea, the other in the Mediterranean, in the last of which were some vessels of extraordinary magnitude. By these prudent measures, he rendered his kingdom flourishing, his people happy, and he filled the country with a number of populous towns and cities. Upon the death of Magas, his widow excited a war between her brother Antiochus Theos and Ptolemy, which produced a formidable invasion of Egypt by the Syrian king.

This war did not prevent Ptolemy from pursuing those plans of liberal munificence which have rendered his name illustrious. He employed learned men to collect books from all quarters for his great library, and it is said to have been in consequence of his literary curiosity that the Septuagint (which see) was made; though the manifold fables with which the narrative of this transaction is mingled, have thrown doubts upon the whole. His generosity as a man and patron of letters, drew to his court many eminent persons in various branches, among whom were seven Greek poets, from their number popularly called the Pleiades. He was also the greatest collector, in his age, of the productions of the fine arts, which he purchased by means of his agents throughout Greece. After the death of his sister-wife, his affliction was unabating, and he perpetuated her memory by giving her name to several cities, and raising sumptuous monuments to her honour, nor did he long survive her loss. Ptolemy died in the year 246 B.C. leaving two sons and a daughter by the first wife. He was not of an amiable temper or character, though splendid in all his acts as a public man. He was indolent, luxurious, and effeminate; though he adopted the surname of Philadelphus, he put to death two of his brothers on suspicion of conspiracies, whence some writers have supposed the application of the name to be ironical. His reign forms a kind of era in letters and the arts, and few monarchs have established a more lasting reputation arising from their encouragement. Univer. Hist.

Ptolemy Euergetes, son of the preceding, succeeded to the throne of Egypt in the year B.C. 246. Soon after his accession, his sister Berenice, widow of Antiochus Theos, king of Syria, being, with her infant son, reduced to the most imminent danger by Laodice, the first wife of that king, Ptolemy marched with an army to her succour, but before his arrival, they were taken and put to death. In revenge, he not only feized and put to death Laodice, but made himself master of Syria, Cilicia, and all the country to the Euphrates. He then passed that river, and reduced Mesopotamia, Babylonia, and it is said, the whole tract as far as Bactria and the confines of India. Being called by a revolt in Egypt, he brought back an immense booty in gold and silver, and also a vast number of Egyptian idols which had been carried away by Cambyses. These he replaced in their temples, and hence he acquired, among his superlative subjects, the surname of Euergetes, or the Benefactor. When Ptolemy set out on this expedition, his queen Berenice made a vow to consecrate her beautiful hair to the gods in case he should be returned to her in safety. She fulfilled her vow, but through the negligence of the priests it was soon lost. To avert the king's wrath, Conon, the celebrated mathematician, feigned that the locks had been transported into the heavens, and formed a group of stars near the tail of the lion. To this new constellation, as it was called, he gave the name of Berenice's Hair, by which it is still known. After this Ptolemy made an expedition southwards, which in the end gave him possession of all the coasts of the Red sea on the Arabian and Ethiopic sides, down to the straits of Babelmandel. He died in the year 221 B.C. This king, says the historian, inherited the love of learning which distinguished his progenitors, and employed much care and expense in augmenting the Alexandrian library. He entertained men of literary eminence at his court, and having been a pupil of the celebrated Arikarchus, was himself eminent in letters, particularly in historical composition. Univer. Hist.

Ptolemy Philopator, king of Egypt, succeeded his father Euergetes, assuming his name, lover of his father, for reasons that cannot now be ascertained. He was a vicious, dilute, and cruel prince: one of his first acts, after his accession, was to put his brother Magas to death, because he was supposed to be too much loved by the army. Ptolemy was soon involved in a war with Antiochus the Great, king of
of Syria, who attempted, but unsuccessfully, to recover the provinces of Coelo-Syria and Palestine, which had been detached from the Syrian crown by Euergetes. A peace soon followed, in which the contested provinces devoted to Ptolemy, and on this important occasion he visited all their principal cities, and among the rest Jerusalem, where he offered sacrifices, and made rich presents to the temple. Being refit by the priests in his attempt to enter the Holy of Holies, he returned to Alexandria so much exasperated against the Jewish nation, that he determined to deprive them of their privileges. A rebellion which broke out in Egypt was the cause of the destruction of a number of Jews, which Eusebius records about this period, representing them as fighting on the royal side. Philopator, in the ninth year of his reign, made an alliance between Egypt and Rome: his queen brought a son, after having been childless a great number of years. In joy for this event he gave himself up to all sorts of debaucheries; his queen remonstrated, and to prevent her interference, he caused her to be affianced. He is also represented as having put his own mother to death; and according to history, he was unquestionably a most detestable sovereign. He was not, however, without some good qualities; the love of learning, which was hereditary in his house, was eminently displayed in his character, and he gave some meritorious instances of munificence. He died in the year 204 B.C., after a reign of about seventeen years.

Ptolemy Epiphanes, king of Egypt, son of the preceding, was only in his fifth year when he succeeded to the throne. During his minority, Antiochus the Great having formed an alliance with Philip, king of Macedon, for the partition of the Egyptian dominions, invaded and took Coelo-Syria and Palestine. Ptolemy's guardians thereupon sent an embassy to Rome, imploring the protection of the republic, and M. Lepidus was deputed by the senate to go to Egypt, and assume the direction of affairs. When the young king assumed the reins of government, he fell under the government of courtiers, who ministered to his vicious inclinations, and subverted the influence of Ariamenes, who had been in the habit of giving him faithful advice. This he continued, which Ptolemy so much resented, that he caused him to be put to death. His administration became so odious and tyrannical, that a conspiracy was formed among his subjects, which had nearly effectuated his deposition. By means of another able minister, Polyкратes, he was extricated from the danger, but he manifested his treacherous disposition, by cruelly executing the conspirators, after they had capitulated upon the promise of a pardon. He cultivated a strict friendship with the Romans, to whom he offered succours in their war with Antiochus, although he had married Cleopatra, the daughter of that king. He also maintained a strict connection with the Achaean republic, and one of his last acts was to send an embassy, inviting it to a league, offensive and defensive. As he was preparing to make war against Seleucus, king of Syria, he was poisoned by his nobles and principal officers, who suspected that he meant to defray the expenses of the war with their fortunes. This occurred in the year B.C. 180, in the 24th year of his reign. Univ. Hist.

Ptolemy Philometer, and Ptolemy Physon, kings of Egypt, sons of the preceding, both minors at their father's decease. Philometer, at the age of six, was declared successor to the crown, under the guardianship of his mother Cleopatra. She had the conduct of the regency during eight years, but after her death the young king was de- throned, and his brother Physon was declared sovereign. Physon, who assumed the name of Euergetes II., was expelled by Antiochus, who replaced Philometer on the throne. The two brothers were then persuaded to reign in conjunction. They did not, however, live in concord, and Physon dethroned his brother. The latter proceeded to Rome in a mean garb, and with a few attendants, in order to excite compassion; and representing his wrongs before the senate, they deputed two of their body to conduct him back and restore him. They accommodated the difference by decreeing the possession of Egypt to Philometer, and that of Libya and Cyrene to Physon. The latter, afterwards, by a journey to Rome, obtained a decree for the addition of Cyprus to his share, which island had before been common to the brothers. Philometer, not choosing to acquiesce in the decree which deprived him of his share of Cyprus, opposed his brother with an armed force in the island, and took him prisoner: in this case he displayed a truly fraternal spirit, and not only pardoned the hostility, but restored to him Libya and Cyrene, which he had lost, and added some territories in lieu of Cyprus. After this, Philometer was engaged in a contest with Alexander Balas, (see his article,) in which he lost his life, in the year B.C. 145. He is highly extolled by historians, as well for his benevolence as for his munificence. By his wife and sister Cleopatra, he left a son and two daughters. Upon the death of Philometer, Physon prepared to assert his claim to the succession. By the mediation of the Roman ambassador, an accommodation was effected, on condition that Physon should marry Cleopatra, and reign jointly with her, while her son should be considered as heir to the throne. Physon, however, murdered the son on the very day of the nuptials, and the remainder of his reign is reprented by historians as one of the most sanguinary that ever afflicted the human race. He fo depopulated Alexandria by his bloody executions, that he was obliged to invite strangers from all parts to re-people it. It would disquiet the reader to mention but a small portion of the cruel acts which he perpetrated. He lived the scourge of the human race, and the curse of his own people, till the year 171 B.C. Tyrant as he was, he had the reputation of being a great patron and promoter of learning, and even such a proficient in letters, as to have obtained the title of Ptolemy the Philologus. He enriched the Alexandrian library with a great number of books, collected at a vast expense, which he himself presented, and himself composed historical works, regarded as a commentary on Homer. There were other Ptolemies of Egypt, but they do not seem worthy of record. Univ. Hist. — We shall, however, on account of his attachment to music, mention

Ptolemy Auletes, the father of Cleopatra, and the last of the Ptolemies who reigned over Egypt. This musical prince derived his cognomen of Auletes, from his exquisite attachment to that instrument. Strabo (lib. xvi.) says of him, that besides his debaucheries, he applied himself in a particular manner to playing the flute. He had such an opinion of his own abilities, as to infringe musical contests at his palaces, and had there the courage to dispute the prize, publicly, with the first musicians of his time; and as the dress of players on the flute among the ancients was peculiar to that profession, this prince submitted to wear the robe, the buckles, the crown, and even the bandage and veil of a tibicen, as may be seen on a beautiful amphora in the king of France's possession, of inestimable value, which is supposed to have been engraved by command of this prince, and worn by him to gratify his vanity on account of his musical excellence. Indeed the surname of Auletes is seriously given to him by Cicero, and by Strabo. The first in his defence of Rabirius Polthimus; and the second, who was likewise his contemporary, never mentions him but by the title of Auletes. He had likewise an opprobrious appellation given to him, by his own subjects, in
in the Egyptian language, of the same import, being called Phothingios, or Pothingius, from Phothis, Monolos, or single flute. His violent passion for music, and for the company of musicians, gained him the name of NEOS DIIONTOS, the new Bachus.

A melancholy truth forces itself upon the mind in reading the history of this prince, and that of the emperor Nero, whom he very much resembled, which is, that, if the heart is deprived, music has not the power to correct it. And though these musical princes obtained prizes in the public games, they acquired no honour to themselves, nor did they reflect any upon the profession of music. A musician is so diligent in character and dignity from a sovereign prince, that the one must ittoo low low, or the other mount too high, before they can approximate; and the public sufferers with equal impatience, a sovereign who degrades himself, or an artist who aspires at a rank above his station in the community.

An inordinate love of fame, or a rapacious desire of monopolizing all the glory as well as goods of this world to themselves, must have incited these princes to enter the lists in competition with persons so much their inferiors: a passion that should always be distinguished from the love of music, which they might have gratified, either from their own performance, or from that of others, in private, much more commodiously than on a public stage.

PTOLEMY, Claudius, a celebrated Egyptian geographer, astronomer, and mathematician, was born at Pelusium, about the year 70 of the Christian era. He taught astronomy at Alexandria, where he flourished under the reigns of the emperors Marcus Antoninus and Adrian. Many of his observations were made between the years 152 and 140. He has always been regarded as the prince of astronomers among the ancients, and in his works he has left us an entire body of science. We are indebted to him for preferring and transmitting to us the observations and principal discoveries of the ancients, enriched and augmented by his own. He corrected Hipparchus' catalogue of the fixed stars, and he formed tables, by which the motions of the sun, moon, and planets might be calculated and regulated. He digested the observations of the ancients into a system entitled MYX₂Z₃Z₂, or Great Construction. In this he has adopted and exhibited the ancient system of the world, which placed the earth in the centre of the universe, and this has been called, after him, the Ptolemaic system, to distinguish it from those of Copernicus and Tycho Brahe. By order of the kings of Arabia, in 827 this work was translated into Arabic, in which language it was called Almagellum, and from the Arabic it was translated into Latin about the year 1230, under the patronage of the emperor Frederick II. There were also other versions of it from the Arabic into Latin. The Greek text was first printed at Basil in 1518, and accompanied with eleven books of commentaries by Theon, who flourished at Alexandria in the reign of the elder Theodorus. In 1541 it was reprinted at the same place, and again in 1551, with other works of Ptolemy. An abridgment of it was made by Purbach, and John Muller, with valuable commentaries by the latter, and published at Basil in 1543, in folio. (See Almagest, and Ptolemaic System.) Another important work of Ptolemy was his "Geographie, libri vii." in which he informs us that he followed the geography of Marinus of Tyre, but with numerous additions and corrections, with respect to the longitudes and latitudes of places, as well as the boundaries of countries and provinces in different quarters of the world. Ptolemy was the first who searched out and marked the situations of places according to their latitudes and longitudes: and though, for want of observations, it is far from being perfect, yet it has been found very useful to modern geographers. There are other works of Ptolemy still extant, such as "Quatuor Libri de Apoltelematibus et Judicibus Allorum, frater, frater, frater, frater," or "Frutetus Libro-

Every writer on the subject of music, till the time of Ptolemy, regarded the fourth as the first concord, and dividing all the fifteen modes into tetrachords, regulated the scale in all the genera by that interval. But Ptolemy, about the year one hundred and thirty of the Christian era, and four hundred and fifty years from the time in which Ariftoxenus flourished, proposed a new doctrine and reform in the ancient musical system; in which he reduced the fifteen modes to seven, and made the diapason, or octave, the regulator of his scales, not by abandoning the tetrachords, for he regulated the genera by those intervals in the same manner as his predecessors; but in his reduction of the modes he kept them within the bounds of the octave, and made their number equal to the species of diapason. The ancient names of Dorian, Hypodorian, Lydian, Hypolydian, Phrygian, Hypophrygian, and Mixolydian, he retained, as well as their relative places or distances from each other; but it has been misrepresented as his intention to alter the pitch of all the modes, by raising the proflabemomenos of each a fifth higher. The only ground for this opinion is in the eleventh chapter of his second book, where having occasion to exemplify, in some one octave, the manner in which the mesos of his seven modes would occupy all its notes, he chose that octave between e and E, as he says himself, preferably to any other part of the Greek scale, on account of its convenience; as it was situated in the middle of the scale and voice. But there is not the least reason to conclude that he meant to propose any reform, or to disturb, in this respect, the established doctrine and practice.

Dr. Wallis, who has translated into Latin the Harmonics of Ptolemy, and reduced his modes to modern notation, makes them all conform to transpositions of the Dorian mode, which Ptolemy calls the first, and which Dr. Wallis, after him, has written in the minor key of A natural, placing it in the part of the scale which in practice belonged to the hypodorian.
By this disposition of Ptolemy's modes, it seems as if his
design had been to establish a more easy and obvious relation
and connection between them, than had been hitherto prac-
ticed; for though the modes placed above and below the
five principal ones might have been originally intended as
their adjuncts, yet from the multiplicity and promiscuous
arrangement of the modes at the distance only of a femi-
tone above each other, their intimate relation and union had
not been sufficiently attended to. He therefore included all
his seven modes in the compass of an octave, "making," says
Dr. Wallis, "the Dorian the central or mean; after which he
placed the mixolydian a fourth above the Dorian; the hy-
polydian a fifth below the mixolydian; and the Lydian a
fourth higher than the hypolydian. Then, beginning again
at the Dorian, he placed the hypodorian a fourth below it;
the Phrygian a fifth above the hypodorian, and the hypo-
phrygian a fourth below that." But this round-about
order of the modes is not that of Ptolemy; for in his tenth
book, chap. ii. the title of which is, How to adjust ac-
curately the Distances of the Modes, he gives his method of
taking them by fourths and fifths in the only direct and war-
rantable way in which they can be taken, according to mo-
dern modulation, by beginning at the mixolydian: D, A,
E, E, F, E, G#. Now if each of these modes pro-
duced seven species of diapason or octave, the seven modes
of Ptolemy would furnish seven times seven, or forty-nine
species of octave; not indeed all of different kinds, but of
different pitch in the scale. To each of these modes he af-
signed the compass of a diatonic, or double octave, as it
was the practice in the ancient modes; with this difference,
that the first and characteristic found in the fifteen modes
was prolambanomenos, but in those of Ptolemy mele is made
the key note, and the centre of the scale; which may be sup-
posed to extend an octave above, and an octave below the
found given in the table.

We know not, indeed, what was the success of Ptolemy's
reformation during his life: a reformation, it must be owned,
that had something Calvinistical in it; a zeal for tearing;
and yet, strange to tell! all the traces to be found of it are
in the modes of the Roman church, established long after,
but which resemble those of Ptolemy in nothing except their
number and names. Ptolemy's modes are manifestly tran-
spositions of the scale into different keys: the ecclesiastic, only
different species of octave, in one and the same key.

This great astronomer, geographer, and musician, who
peculiar life of the species of that, and reformation of the
modes which we have just given, appears to have been less
shackled by authority, and a more bold and original thinker
on the subject, than most of his predecessors; indeed he
was not insensible of his own force and superiority, for he
treats all former musical writers and their systems with little
ceremony. Some parts of his disputes and doctrines are
now become unintelligible, notwithstanding all the pains
that our learned countryman Dr. Wallis bestowed on him
near 120 years ago, particularly his third book, which
forms a very striking contrast with the scientific solidity
and precision of the two first. The infant he sets foot
within his beloved circle, the magic of it transforms him
at once from a philosopher to a dotard. He pales suddenly
from accurate reasoning and demonstration, to dreams, an-
alogies, and all the fanciful resemblances of the Pythagorean
and Platonic schools: discovers music in the human soul,
and the celestial motions: compares the rational, irascible,
and concupiscent parts of the soul, to the 8th, 5th, and 4th:
makes the sciences, and the virtues, some diatonic, some
chromatic, and some enharmonic: turns the zodiac into a
lyre, making the equinoctial the key-note of the Doric
mode: sends the mixolydian to Greenland, and the hy-
polydian to the Hottentots!

He seems to have been poffesed with an unbounded rage
for constructing new scales, and correcting those of former
times. He gives us no less than eight different forms of
the diatonic scale, three of which were his own; the other
five went under the names of more ancient musicians of
great renown; such as Archytas of Tarentum, Aritoxenus,
Eratothenes, and Didymus. Most of these scales seem
but to differ in deformity, according to our present ideas of
harmony and temperament. Indeed there is only one of
them which modern ears could suffer, and concerning
that it is necessary to be somewhat explicit.

Each did who first discovered that fix major tones in the
ratio of 4:5 were more than sufficient to fill up the octave,
gave two major tones and a limma to his tetrachord; which
made the major thirds intolerable. Didymus was the first
who discovered that whole tones were of two kinds, major
and minor; and, giving to his minor tone the ratio of 4:5,
divided his tetrachord into major semitone 4/3, minor tone 4/5,
and major tone 5/4, including the whole series in the usual
bounds of a true fourth. This arrangement has been cen-
firmed by Padre Martini, and with reason, if a major key:
and counterpoint had been in question; but, as the abbe
Rouiller justly observes, a minor key, and simple melody,
were alone considered at that time. The minor tone, from
C to D, therefore had this convenience, that it rendered D
a true 5th below mele, the central firing of the lyre, which
regulated the whole system, and to which all the other figures
were tuned, as well as the octave above prolambanomenos,
the fundamental note of every mode. (See Differt. p. 9.)

When the major tone is from C to D, and the minor from
D to E, as in Ptolemy's arrangement, this cannot be the
cafe; for then the 5th from D to a, will contain only two
minor tones, one major, and a major semitone, instead of
two major tones, one minor, and a major semitone, of which
every perfect 5th, in the ratio 4:5, is composed.

Ptolemy, nearly two centuries after Didymus had fugg-
geled the major semitone, and minor tone, adopted them
in one of his divisions of the diatonic 4th, but changed the
place of the minor tone, arranging his intervals, insipide
them to be thele, B C D E, in the following order and pro-
portions: major semitone 4/3, major tone 5/4, minor tone 5/6,
which, together, completed the fourth in the usual, perfect,
confiant, and true ratio of 4:5; and these are the famous
proportions of the intervals proposed in that system of
Ptolemy which is known to theologians by the name of diat-
onic intum, or sharp diatonic; and which, long after his
time, was received in our counterpoint, and is pronounced
by Dr. Wallis, Dr. Smith, and the most eminent writers
on harmonics, to be the best division of the musical scale.
The intervals of our C natural, when made perfect, are in
the following proportions, ascending: 4/3, 4/5, 5/6, 5/4, 4/5,
5/4, 4/3; that is, giving to the octave three perfect, two
minor tones, and two major semitones, arranged in this
order: from the key-note to the 2d of the key, a major
tone; from the 2d to the 3d of the key, a minor tone;
from the 3d to the 4th, a major semitone; from the 4th to
the 5th, a major tone; from the 5th to the 6th, a minor
tone; from the 6th to the 7th, a major tone; and from the
7th to the octave, or 8th, a major semitone. And no sharp
tone can be perfect, but by being tuned in the same name;
and yet, where to place the minor tone has occasioned end-
less disputes among writers on temperament. De Moivre,
in his Doctrine of Chances, gives 210 permutations to these
intervals T, T, T, t, t, H, H.

This arrangement of Ptolemy has been considered by
some writers as a temperament, on account of his departing from the just proportion of some of the 5ths, in order to give perfection to 3rd and 6ths. This temperament, however, if it may be so called, is become to us the standard of perfection, and every deviation from it, in the modern sense of the word, is now called temperament. If temperament implies imperfection, and the alteration of intervals from those proportions which best satisfy the ear; and if those scales are the most, though not the best tempered, which most offend the ear, the word is in that sense chiefly applicable to the old Pythagorean diatonic, adopted by Euclid, and to the other numerous divisions above mentioned.

The scale of the Pythagoreans was indeed founded upon some principle; being, as the abbe Rouffier has shown, produced by a series of perfect 5ths; but the other divisions seem to have been the produce of random experiment, and unmetrical calculation, and were as various and unit for use, as want of principle could make them. Scarce any rule seems to have been observed, but that of keeping the fons flantes, the boundaries of the tetrachords, unmoved from their just ratio of 3. The ancient theorists revered themselves; however, for this confinement by every kind of licenc in the disposition of the two remaining founds; the various tunings of which constituted what they called the ciphers, the colours or shades of the three genera. In these, all kinds of intervals seem to have been admitted, provided they were but rational; that is, expressible by numbers. Ariflothenes did not confine himself even to this rule; for his equal divisions were neither reducible to rational numbers, nor were the vibrations of his intervals, if they could have been put in practice, controllable. Musie, however, was more obliged to him for the invention of a method which it must be allowed left every thing to the guidance of the ear, uncertain as it may be, than to those mathematical speculators who furnished it with so many accurate and demonstrable rules for being infallibly out of tune. Indeed, it is probable, that among the ancients, as well as the moderns, many such untuneful divisions, served more to amuse theorists, than to guide practical musicians.

Ptolemy having a facility, and perhaps a pleasure, in calculating, seems to have sported with the scale, and wantonly to have tried confusions, by displacing and torturing it in all possible ways; and though one of his many fyllems fuits our present practice, it is not to be imagined that it was designedly calculated for the use of counterpoint, which was far from his thoughts. It feems, however, as if musician in parts was first suggested by this arrangement of the intervals; for the 3ds and 6ths, which were before so harf and crude as to be defervely ranked among the discords, were now softened and sweetened into that grateful coincidence with which modern ears are so much delighted. It was impossible, after hearing them, for lovers of musician not to feel the charms arising from the combination and succession of these confonances; and it was from this time that the seeds of that harmony which may be said, in a less mysterious infe as than that of Pythagoras, to be implanted in our nature, began to spring up. They were certainly of slow growth, as no good fruit was produced from them for more than 1000 years after; but arts, like animals to whom great longevity is allowed, have a long infancy and childhood, before adolescence and maturity come on.

Ptolemy of Lucca, an ecclesiastical historian in the fourteenth century, was descended from a noble family, from whom he derived the name of "Bartholomew Fiadoni." He entered young into the order of St. Dominic, and upon his profession he took the name of Ptolemy. He ranked among the most celebrated Italian divines of his time, and was the first of his countrymen who employed his pen on ecclesiastical history. He was superior of the monastery at Lucca, and in 1301 and 1302 he filled the same post at Florence. He was afterwards elected by pope John XXII. as his confessor, and in 1318 he was made bishop of Torcello, under the patriarchate of Venice. This prelate died in the year 1327. He was author of "Annales," extending from the year 1060 to 1303, which was published at Lyons, in 1619. But his largest work was "Historiae Ecclesiasticae," in twenty-four books, commencing with the birth of Jesus Christ, and brought down to the year 1313. This work remained in MS. in the Vatican, Barberini, and other libraries, till it was published at Milan in 1727, by Muratori, in his grand collection, entitled "Rerum Italicarum Scriptores." Moreri.

PTOSIS, from πτώσις, to fall, signifies, in Surgery, a disorder of the upper eye-lid, which the patient either cannot elevate at all, or not in a proper degree. In the first case, sight is entirely impeded, unless the eye-lid be raised with the finger; and in the second, although the patient can see a little when he turns his eye downwards, he soon gets into the habit of inquinting. The dis ease also in this state gives him a particularly drowzy appearance. Of ptosis, surgical authors reckon three species, which originate from three different kinds of causes. The first species proceeds from a preternatural lengthening of the external skin of the eye-lid; the second from weaknesses, or total paralysis of the levator muscle; and the third from a spasmodic contraction of the orbicularis palpebrarum.

The first is the most frequent case. The preternatural elongation of the skin may be known partly by the appearance of the affected eye-lid, and partly by the circumstance of the patient being able to raise his eye-lid immediately the skin of the part is pinched up into a tranverse fold. Sometimes likewise it may be known by adverting to the cau ses from which the disorder had its origin. Tranverse wounds of the lower part of the forehead, or of the eye-lid itself, when their edges are not skilfully brought together, are frequently followed by such elongation of the skin, the consequent cicatrix being very wide. It often happens, too, that no cause whatsoever can be assigned for this lengthening of the skin. In some instances the complaint is transient and of short duration, as when it depends upon an inflamed or edematous state of the eye-lids; a cafe of which we need say nothing more in the present article. Nor need we here dwell upon the example in which the eye-lid is preternaturally diffused by an infected tumour under it, the only indication being that of cutting out the swelling. In the treatment of the first species of ptosis, the object which the surgeon must have in view is to cut away the superfluous portion of the skin of the eye-lid. A tranverse fold of it is to be raised up with the fingers, or a pair of forceps, and removed with scissors. The practitioner must be careful, however, neither to cut away too little nor too much. In the first circumstance, the dis ease is not effectually cured, but merely leffened; and in the second, an opposite complaint is brought on, namely, a preternatural shorten of the eye-lid. If, while the skin is pinched up into a tranverse fold, the patient is capable of raising the eye-lid completely, all is managed rightly, and such fold is to be removed. But if he cannot perfectly raise the eye-lid, a sufficient portion of the skin is not pinched up, and the fold must be larger. Lastly, if he can raise the eye-lid well, but not shut the eye completely, too much of the skin is pinched up, and some of it

5 A.
must be let loose again. As soon as the requisite quantity of the skin has been cut away, the edges of the wound are to be brought together with adhesive plaster, or a future. The cure is generally accomplished in a few days, and the cicatrix is afterwards scarcely discernible.

Sometimes this species of ptosis may be cured without any operation. In one instance, where the usual operation was about to be performed, and the skin had already been pinched up into a fold, the patient, through fear, suddenly drew back his head, by which means the eye-lid was violently pulled and stretched. This happened three times successively, on which account the operation was deferred. The next day the patient had regained the complete power of moving the eye-lid. (See Janin's Observations fur l'Oeil.) The same event has been frequently remarked. Probably, says Richter, the mechanical irritation, and the inflammation thence arising, increased the tone of the levator muscle of the eye-lid, and he takes the opportunity of suggesting that benefit might perhaps be expected (at least in cases in which the eye-lid is not very much lengthened) from cauterizing the eye-lid, or applying to it the tinctura lyttae, cold water, or a weak solution of the lapis infernalis.

The second species of ptosis, or that proceeding from loss of tone, or paralysis of the muscles of the eye, is more uncommon. It is most frequently met with in old persons, when it is very difficult of cure, if it can be cured at all. Sometimes it precedes apoplexy, or is a remaining effect of that alarming disease. It occasionally proceeds from internal causes, and in this circumstance the treatment comes within the province of the physician, who should endeavour to detect and remove these causes. This second species of ptosis has been known to occur as a symptom of chlorosis. (Müller, Diff. de Palpebrarum affectibus, Halle 1742.) Sometimes the complaint is caused by irritation in the stomach, in which case a cure may be effected by emetic medicines. In some cases, worms seem to act as a cause; not to mention several other causes of an analogous description. Sometimes the complaint is altogether local, and it is only then that it is to be clasped with surgical diseases. Although a patient with this kind of ptosis, can lift up the eye-lid with his finger, he cannot do it in any other manner: when the integuments are pinched up into a transverse fold, the levator muscle continues quite incapable of doing its office.

Besides the means already recommended, the following have been referred to: the flower-bath on the hinder part of the head (Cantwell, in Phil. Tranf. N° 449. p. 33. Guerin, des Maladies des Yeux); the external use of cold water (Warner on the Eye); and, at the same time, the internal exhibition of bark (Alix, Observata Chirurgica, fac. 2.); a platter of wax and fused oil of tartar put on the eye-lid (Chandler on the Eye); a false of the tinctura sarni fuica, honey, and camphor. Last ly, it deferves notice, that this species of ptosis is often periodical.

The third case of ptosis originates from a spasmodic contraction of the orbicularis palpebrarum muscle. It is a most rare form of the complaint, and never lasts. The attack occurs at certain or uncertain periods, and varies in its duration. During the paroxysm one can plainly see that the eye-lids are forcibly closed, and that a great and extraordinary reflution is made whenever an attempt is made to separate them. Such spasm of the eye-lids, says Richter, is always the effect of some idiopathic, or sympathetic irritation. In some instances the affection is confined to the eye-lids; in others it extends to the muscle of the face, which distorts the countenance in various directions. The sympathetic irritation, which is productive of the spasm, is of different kinds. The complaint often occurs as a symptom of hystery, hypochondriasis, worms, obstructed menes, &c. and the treatment falls to the duty of the physician. In these examples local means avail little or nothing. The applications recommended, however, are lukewarm milk, in which a small quantity of saffron is mixed; a decoction of white poppy-heads, or of hemlock.

Amongst the local causes which may give rise to this species of ptosis, we have to enumerate such irritating substances as are accidentally introduced under the eye-lid from without. These should be removed, or washed away as soon as possible. Some cases of acute ophthalmia are accompanied with a spasmodic closure of the eye. No cause whatsoever is occasionally assignable for the complaint. In this circumstance, external anodyne applications must be tried, and if they are insufficient, internal medicines of the fame class must also be administered. The warm bath, and bathing the eye with warm water, are mentioned as particularly defering of trial. See Richter's Anfangs gr. der Wundarzneykunft, band ii. cap. 16.

PTYALAGOGA, formed of σύλαμα, spittle, and ἀγωγά, I drive, a word used by physicians to express such medicines as promote a copious discharge of the saliva, such as pelitory-root, and the like. See SIALOGUES.

PTYALISM, PTYSALISMUS, πταλίς, spittle, ἀγογά, I drive, in Medicine, a spitting, or a discharge of saliva by the glands of the mouth; whether it amount to an absolute salivation or not. See SALIVATION.

PTYCHIA, in Ancient Geography, an island of the Ionian sea, near the isle of Conyra. Some have represented it as a town of this island.

PTYSMA, a word used to express whatever is brought up from the lungs by spitting.

PTYSMAGOGA, medicines which promote a copious discharge by spitting.

PUAGORA, in Geography, a town of the island of Sardinia; 15 miles E.N.E. of Saffari.

PUANTE, a river of Canada, which runs into the St. Lawrence, N. lat. 46° 34'. W. long. 72° 21'.

PUARAY, a town of New Mexico; 60 miles S. of Santa Fé.

PUBBLE, in Agriculture, a term provincially signifying plump or full-bodied, when spoken of grain.

PUBEGA, or PIBEGA, in Geography, a town of Italy, in the department of the Mincio; 14 miles W.N.W. of Mantua.

PUBELA, a town of Bengal; 28 miles S.S.E. of Islamabad.

PUBERTY, in Physiology. The Latin word puberty means the growth of the hair about the organs of generation: at the same time that this appears, various important changes occur in the whole economy, which have been included altogether under the term puberty. See GENERATION.

Puberty, Pubertas, in the Civil Law, a natural majority, or the age in which a person is allowed to contract marriage. See MAJORITY.

Boys arrive at puberty at fourteen years of age, maids at twelve. Full puberty is accounted at eighteen. See AGE.

Dr. Kramer observes, that all boys at the time of puberty, between twelve and fourteen years of age, complain of uneafines
uncainines at their breaths, which are swelled and itchy, the nipples and areolae round them inflaming with pain, and sometimes excretion and exudation of some of the laciferous ducts. The best remedy for which, he says, is to press out the white serum then contained in them, after which they are cured with a bit of plaster.

By the law of Scotland, persons under puberty, or under the years of discretion, are capable of committing the higher crimes, which being contrary to the law of nature, are obvious. But they are not chargeable with smaller offences arising from positive law or statute.

Puberty of Plants, the period in which they arrive at their full growth, and are capable of producing blossoms and fruit. It varies very much according to the nature and habits of growth of the particular plants, some arriving early at this state, while others are extremely slow in coming to it.

Pubes, in Anatomy, that part of the abdomen adjoining the generative organs, which is more or less covered with hair in both sexes.

pubescence, pubescentia, in Botany and Vegetable Physiology, comprehends all the various hairy, downy, or wooley clothing of plants, which Linnaeus, under the denomination of pubes, a hair, reckons the seventh and last among their folia, or appendages. He defines the pubes as an excretory duct, of a tapering or brittle-like form. Such it seems to be in numerous plants, whose hairy coats exude a viscid moisture, like the Garden Clary, Salvia helaraea, and some others of that genus; as well as, possibly, in Pilosum and Verbascum, some species of which exhale from their dense wooley covering, when lightly touched, a peculiar odour, depending on an exudation, otherwise hardly perceptible; but which can only be conveyed through their pubescence. Such is the foapy odour of Pilosum fruticoso, and the light tranflient fragrance of various herbs, which vanishes, and is replaced by a different scent, when they are bruised. Odours that reside in glands, or cells, in the surface of the leaf itself, are more durable, if not at first more powerful. — The stinging Nettles, Urticae, of which three species are natives of Britain, are unquestionably furnished with a tubular briskly pubescent, each hair of which is pervious, and has at its base a bag of liquid poison, so contrived that when the perforated point of the hair receives a light touch, the contents of the bag are pressed upwards through the tube, and diffused into any thing, as the human skin, that may be wounded by such minute but formidable weapons. The poison of a viper is conveyed, through its perforated teeth, in the same manner. When that animal is not excited to attack or vengeance, its fangs are recumbent and harmless. So when the pubescence of a nettle is forcibly depressed, by a rude or fearfeal grasp, these delicate points cannot injure themselves so as to take effect.

The hair or pubescence of plants, though generally tubular, is not always pervious, being very frequently found, with the affilience of a flight magnifier, to consist of numerous joints, diversified by tranverse partitions. Fluids cannot readily be sup’posed to pass along a tubular body befet with such impediments. Yet, if we mistake not, such a jointed structure exils in the pubescence of several glutinous plants.

The external configuration of the pubescence of vegetables is very different in different species and tribes. The hairs are sometimes hooked, as on the calyx of Myosotis, and the herbage of some Syngeneous plants. In the genus Hedysarum of Fl. Brit. now adopted in Willdenow and other writers by the name of Apugnia, the hairs of the leaves and other parts vary in having one, or occasionally more, forked terminations. In Cotuna, Salamum, and Lavatera, they often assume an elegant flarty figure, being in the last mentioned genus, and several of its allies, densely entangled, and occasionally endowed with a stinging or pungent, if not venomous, quality. The pubescence of Hippophae, and some species of Cotuna, is partly flarty, but on the whole so depressed as to become fealy, nor does it seem capable of conveying any fluid through its own substance.

The pubescence of some plants is exquisitely delicate, whether it consists of erect or depressed hairs. Of the former kind the Pelargonium odoratissimum, Geranium rotundifolium, and Althea officinalis, are infames, infinitely transcribing the pile of the finest velvets, in softness and minuteun. Of depressed pubescence, no more beautiful example can be found than in the White Willow, the Silver Tree of the Cape, Protea argentea, or the Silver-leaved Ladies’ Mantle, Alchemilla alpina. A more dense, wooley, and impenetra ble covering attracts our notice in various oriental plants, natives of the arid and scorching soil of the Archipelago. These seem to require such a protection against a burning sun, by which all their moisture might otherwise be dried up. It is far more difficult to account for the abundance of such a wooley coating, on the under sides of the leaves in so many Mexican plants, whose smooth upper surfaces are exposed to the hot sun of that climate. Possibly, after all, sonic chemical operations may be performed in the wool itself, where the necessary agents of moisture, air, and exhaled effluvia, are present, as well as the greatest possible quantity of light that the position of the leaves will admit of, the wool being always white, and its substance pellucid.

Whatever other purposes the pubescence of plants may answer, its mechanical life, in abundance of infames, cannot be overlooked. We can at no loss to understand how the appropriate covering of each particular species, or of the several parts of any one herb, may be effectual in repelling or moderating the attacks, or the accidental injuries, of insects, or the atmosphere. It is one, amongst many, means, by which rain, in quantity, is studiously prevented from lodging on the foliage of plants, for any length of time. Leaves require a more continual intercourse with air, and even with light, than with water; by which last, if superabundant, their predominant functions are impeded, and their constitution finally injured; except their nature be such that, like fibres, they cannot exit out of the water.

The envenomed armour of the Stinging Nettles seems so powerful a defence against the attacks of caterpillars, that it is difficult to conceive how any of them can truant their delicate skins within its reach. Yet nothing is more certain than that the plants in question afford nourishment to a greater variety of such insects than most others. Possibly the copious prominent bristles, or tufts of hairs, with which many of them are covered, being longer than the pubescence of the nettle, may sufficiently protect them, and enable them to range with impunity over the leaves, on which they feed.

Few appendages to the herbage of plants are more variable than their pubescence, at least with respect to quantity, and even structure. Young shoots and leaves are often very downy or hairy, though subfrequently they become quite smooth. The purpose of protection against heat and cold, or too much wet, is well answered by such a clothing in their first tender state, and at an unsavourable or unsettled season. It either drops off, or becomes more scattered, by the expansion of their surface. Circumstances, with which we
we are but little acquainted, act in some way or other on the constitution of many plants, so as greatly to influence the quantity of their pubescence. Thus we have seen several mints, hairy or smooth in their native situations, becoming very much if not entirely the reverse, the next season, on being transplanted to a garden. Nor does this change always appear to depend on any sudden transition with regard to moisture. In general, however, it is found, that bog or aquatic herbs, become more hairy on removal into a dry soil or situation; and also that a change from shade and moisture, to an open, airy or sunny exposure, produces the same effect. The rich dense woolly, cottony, or silky clothing, of many rock or alpine plants, becomes flared, mean, and unprofitable, in our gardens, as their whole form and constitution affirms an enfeebled laxity or meagreness. Even in a state of nature, as we have remarked above, the hairs of the same species are occasionally simple or variously forked. The hooks or curvatures of such appendages are usually more permanent in every case; but almost觅t decided or vigorous in proportion as the plant is most healthy.

The direction of the hairs or bristles, composing the pubescence of plants, proves, on a careful examination, to be more invariable than any circumstance attending such appendages. This was first remarked by the writer of the present article, in the progress of his investigation of the British Menthe. The direction of the pubescence, as well indeed as its absence or presence, on the calyx and flowerstalks of these plants, is found to indicate more certain specific distinctions than any other. By attending to its position, their innumerable and ever fluctuating varieties are reducible to a determinate number of certain and well-defined species. Dr. Roth, an able German botanist, has since applied the same test to the genus of Myosotis; in which, on the contrary, several species, readily distinguishable by the pubescence of their calyx, had been huddled together as varieties. (See Mentha and Myosotis.) In Galium the direction of the minute prickles on their leaves, or on the different parts of their leaves, stands us in equal stead, for the determination of some otherwise obscure and difficult species. It would be well if botanists would pursue these observations, and by that means perhaps elucidate the specific characters of other disfigured or intricate plants. We have derived some benefit from this principle in Salix, but we lament its insufficiency, not its failure, in the more perplexing family of Saxifraga. In Ramunculus it confirms rather than leads the character. In the class Tetrandra it solves some difficulties, but does not serve us thoroughly. There is, however, no instance, that has fallen under our observation, of any variation in the direction of the pubescence of any plants, in the same species, that could cause the least perplexity, where it serves at all to distinguish one species from another.

PUBLIC, in Anatomy, the anterior part of the os pubis, by which the pelvis is completed in front. See Extremities.

PUBLIC, Symphytis, the union of the right and left os pubis, by which the pelvis is completed in front. See Extremities.

PUBLIC Accounts. Commissioners are to enquire of the accounts of the sheriffs, custumers, and other the king's officers, after having been paied in the exchequer, and if detected of any fraud they shall pay treble damages, by Stat. 6 Hen. IV. cap. 3. And all the lands, tenements, and hereditaments, which any account hath, shall for the payment of debts to the crown, be liable and put in execution in like manner as if he had stood bound by writing obligatory, having the effect of a statute fable, &c. Stat. 13 Eliz. cap. 4; and there have been several statutes for taking the public accounts of the kingdom, and examining and determining the debts due to the army and navy; also corruptions in the management of the king's treasure, &c. impoverishing commissioners for that purpose, who were to give an account of their proceedings to the king and parliament, Stat. 2 W. & M. 1 Ann. 2 Geo. I. &c. See Public Accounts.

PUBLIC Verdict. See Verdict.

PUBLICAN, Publicans, among the Romans, a person who farmed the impost, taxes, and public revenues. This function was usually exercised by the Roman knights, who constituted an order of great consideration at Rome, and a kind of middle rank between the senators and the people. Their institution was as early as Romulus. They did not attain the great offices, nor enter the senate, as long as they continued in the order of knights; and thus they were the more capable of employing themselves in collecting the revenues of the Roman people.

The publicans are distinguished by Sigeonius into three forts or degrees: the farmers of the revenues, their partners, and their securities; in which he follows Polybius. These are called the Mancipes, Socii, and Praedes, who were all under the Quaiores Erarini, that presided over the finances at Rome. But there were properly only two forts of publicans, the Mancipes and the Socii. The former, called by the Greeks τοσογνωμοι, were much superior to the common publicans in dignity, being mostly of the equestrian order; so they were generally in their moral character. Cicero mentions them with great respect and honour: "flos," says he, "equitum Romanorum, ornamentum civitatis, firmamentum reipublicae, publicanorum ordine continuatur." Orat. pro Plancio, apud Opera, vol. v. sect. 9. p. 544. Oliver edit. He likewise calls them "ordinem mihi commendatissimum." Epist. Fam. lib. xii. epist. 10. Oper. vol. vii. p. 442. epist. 9, and epist. ad Attic. lib. i. ep. 17. vol. viii. p. 8o.

But as for the common publicans, the collectors or receivers, as many of the Socii were, they are spoken of with great contempt, by Heathens as well as Jews; and particularly by Theocritus, who said, that among the beasts of the wilderness, bears and lions are the most cruel; among the beasts of the city, the publican and parasite.

The reason of this general hatred was, without doubt, their rapine and extortion: for having a share in the farm of the tribute, at a certain rate, they were apt to oppress the people with illegal exactations, to raise as large a fortune as they could for themselves. Besides, publicans were particularly odious to the Jews, who looked upon them to be the instruments of their subjection to the Roman emperors; to which they generally held it sinful for them to submit. So that paying tribute to the Roman emperor they looked upon it to be a virtual acknowledgment of his sovereignty. This was, therefore, a peculiar grievance, and created an aversion to the collectors, as the instruments of illegal oppression, apart from all consideration of their rapacious practices. Moreover, the Jews, who accepted the office of publicans, were on that account hated of their own nation equally with heathens: and according to the rabbis it was a maxim; a religious

duras.

PUCARA, a town of Peru, in the diocese of La Plata;
65 miles W. of Caravaya.

PUCCA, in Commerce. See MAUND.

PUCCASERAI, in Geography, a town of Bengal; 25
miles E.S.E. of Bifliumpour.

PUCCOON, in Botany. See Sanguinaria.

PUCCULOE, in Geography, a town of Bengal, capital
of the circur of Attyah; 94 miles E. of Moorshedabad.
N. lat. 24° 10'. E. long. 90° 7'.

Pucelage, in Natural History, a name by which
some authors among the French have called the porcelain-
hells.

Puccellage, Puccellium, in an ancient manu-
script written psuellium, denotes the state of virginity, or
maidenhead.

Puceron, the name given by naturalists to a small
infect of a peculiar nature, frequently found on the young
branches of trees and plants, often in such clusters as wholly
to cover them.

He puceron is a small animal, but very numerous in the
several genera and species; infomuch that Reaumur has ob-
erved that there is fearcely a vegetable to be found, either
in the fields or gardens, that has not its peculiar species of
puceron to feed on its juices. M. de la Hire, of the Paris
Academy, has left many curious particulars in regard to these
animals, in the Memoirs of the year 1703; and M. Lee-
wenhoek, and others since, have given figures and descriptions
of several of the species.

Puceronis are all viviparous animals, and that after a very
ingular manner. It is to be observed, that the name is
fearcely more expressive of the creature, than those of the
other given of late to insects; that of the polype to a crea-
ture which has no legs or feet at all, is very improper; as
that of the puceron hardly lets fo, as it would naturally lead
us to imagine, that the creature thus called was able to hop
like a flea, whereas, in reality, it is very slow in its motion,
and seldom so much as walks.

These creatures fix legs, which are extremely small
and slender; and which, when the animal is at its full
growth, are loaded with a weight so large, that they seem fearcely
able to support it. Some of the species arrive at a tolerable
bigness from common observation; but the greater number are
so small as to be accurately seen without the assistance of
glases. Among these insects there are great numbers that
in their full perfection have wings, and become a sort of
little flies; these are distinguished from the others by the
name of alated puceronis.

These species which never become winged, have nothing
of the appearance of the caterpillar kind; having not long
but short bodies, and much resembing flies whose wings had
been taken off. All the species have antennae or horns;
but these in the several kinds are very different from one
another, some being very short, and others as remarkably
long; and of these last kinds, some carry them straight:
before the head, as is the usual custom, and others carry them
laid along over their backs; in some of these the horns are
longer than the body. But beside these antennae, the
greater number of these creatures have two other horns or
spines placed in a veryingular manner behind them near the
tail. They are placed at some distance at their origin, but
they
they become more distant as they go out from the body. These are much thicker and much shorter than the antennae; and there are among the various kinds of them, some which actually want them, and others which appear to want them, though they have them in reality; and others have in the places of them certain round spots, which stand just where they should, and seem destined to perform their functions.

The several kinds of pucerons differ greatly in colour. The greater number of them are green; but many are brown, some yellow, and some are black. In August the rose-trees afford a vast number of them of a pale red, and some exactly of the colour of the damask rose; in some other months of the year we find green ones on the rose-trees. The fycamore and several other plants afford green ones in the summer, and red ones in November; and there seems no doubt, but that these are the same individual animals which change colour, the leaves and juices of the plants being not capable of affording them the same force of nourishment at some times that they do at others. Some of them also are of a dusky colour, and others bright and shining, as if varnished over. Those of the willow, of the poopy, and some other plants, are of a cloth-like appearance, and some resembel velvet, others, as those of the apricot, and of the catch-fly, are shining, as if covered with the finest laquer. Some appear of the colour of bronze metal, when it has its highest polish; such are those of the tanf York, and some other plants. The largest kind are found on the oak and other trees. The gooseberry-berries afford a species that are of the colour of mother-of-pearl; and, in general, the skin or covering of these species which are bright and shining, is much harder and firmer than that of the others. The most usual species are all over of one colour, but there are some others which are spotted; that of the common wormwood is prettily speckled with black and brown; those of the holm are green in the middle, and black at each extremity; and there are several others, as of the willow, &c. that are variegated with these two colours.

It is not certain, however, that all the species are peculiar to the plants upon which they are found; for it has been observed, that when a plant of the common wormwood has been full of them, by some accident they have all left it to fix themselves upon plants in the neighbourhood, which had juices of a less disagreeable taste. These creatures always live in companies; we never find them singly on plants, and very seldom otherwise than in extremely great numbers. In plants they fallen themselves on every part; and in trees they only feize upon the leaves and young shoots, and they usually cover these entirely, leaving no part to be seen.

The elder is the tree on which they are of all others the most plentifully produced, and on which they are observed in their several stages with the greatest accuracy and ease. They often cover the thick green roots of this tree for many inches together, and sometimes for many feet; and they are always placed so close together, that they touch in every part, and sometimes they lie in two beds, one over another. These are of a greenish-black. If they are observed on the branches undisturbed, they are always found to be perfectly quiet, and seem to pass their whole lives in inaction; but they spend all this time doing the most necessary business of life, that is, sucking in their own nourishment from the juices of the tree. They do this by means of a fine slender trunk, which easily escapes the naked eye; but it is always found by the microscope, and it is by means of this that they pierce the back of the tender parts of the vegetables, and get at their juices. The trunk is usually of two-thirds of the length of the body; but when they are moving on, it is always applied so closely under the belly, that it is not seen.

When there are two series of these insects placed one over another, they are always more loosely placed in the upper series, and these are usually the larger, and the nimbler in all their motions. In this case they have no power of sucking the plant; for besides that it is close covered with the other series, their trunks are not long enough to reach and penetrate it from the height at which they stand above it. These, therefore, are such as have no farther need of nourishment, but are employed in propagating their species. M. Reaumur saw them brought forth; and indeed Mr. Leeuwenhoek long before saw, by the help of microscopes, the young animals perfectly formed, though extremely minute, in the bodies of the full-grown females.

They are a sort of animal which propagates so quickly, that usually there are many females on the same leaf or branch of a plant in labour at the same time; and their fecundity is so great, that when they have once begun to bring forth young ones, they seem to continue it incessantly for a long time together. They will often bring forth fifteen or twenty succulently, and if their bodies be a little squeezed afterwards, there are forced out of them a vast number of others less mature.

These little insects are extremely plentiful on many different trees, and are very easily observed in their several stages and progressions by a curious searcher after them; but if at any time they are not so easily found, the person who seeks after them may be conducted to them by the ants, which he will find moving in great numbers on the trees and plants where they are, and pointing out the way to them.

M. Leeuwenhoek, Hartsoeker, and others, have observed this, and have supposed that the ants fed on them, by their frequenting the places where they are found; but that is far from being the case, the ants, on the contrary, seem to love them as friends. We may easily find out the reason of the ants following the clusters of pucerons, without doing them any injury, when we consider that the ants love sugar and all sweet things, and the places about which the pucerons are, have usually the cavities filled with a thick faccharine matter, and this the ants feed upon.

The most natural opinion would seem, that this was the juice of the tree simply extravasated; but experience shews that it has another origin; it is really the excrement of these pucerons; they receive no solid food into their bodies, all that is conveyed into them coming through their trunk, which is an extremely fine pipe; and as none but a very thin and pure juice can be received through such an organ, it is no wonder that the creature, which lives wholly upon it, should void no solid excrements. The drops of this liquor are not so frequently found on the leaves of plants as might be expected, and that because many of them are immediately devoured by the ants, and many others are dried up by the sun; but they may always be found collected in some quantity in the bladders of the elm, and other trees inhabited by these creatures, as there the liquor is defended from the heat of the sun, and is safe from being devoured.

The puceron, like most other insects, changes its skin three or four times before it arrives at its full growth. These extrude perfectly resemble the animal in its natural state, the legs and other parts being all in their proper places; but whatever is the colour of the species of puceron, these skins which it casts are whitish.

The male and female pucerons, as they are usually sup-

posed
posed to be, differ greatly from one another in form, even in their time of growing, but much more eminently at the time of their maturity, the male having then wings, which the females never have. Lecvenhook and others, who have treated of these animals, have supposed that they all became at length little flies, that is, were winged; but this is a great error.

Notwithstanding, however, the general opinion, that the winged puceroners are all males, and the unwinged ones females, it appears that their manner of generation is yet unknown to us. This opinion was formed too hastily by some from a supposition analogy of these and other insects; but later observations have proved that this is not strictly the case; for that the winged ones, as well as the others, bring forth young ones. Some have supposed, that these winged and naked puceroners were the offspring of different families of several species living together; but the contrary is proved by this, that the winged ones are found to produce some winged and some naked ones; and the naked to produce both kinds in the same manner. Some have imagined, that they found the male puceroners among the others, observing some of a flatter shape, in whose bodies there were never found any young ones, as there always were in the others, even when they were very young; but these have been since found to be only such females as had already brought forth their offspring.

The young puceroners being themselves filled with embryos, and that in every individual, so that all that have been ever examined appear mothers, has given many strange ideas of the manner of their generation: many have imagined them all to be hermaphrodites; and as no copulation has ever been observed among them, they are by some supposed to be able to impregnate each itself. The later opinion, however, is, that when a female is once impregnated by a male, she will bring forth young ones already impregnated with others, and thus to the third or fourth succession; so that copulation is only necessary to these animals once in three or four generations, and the children and children's children of an old puceron that has had congres with a male, will bring forth young ones without having ever had any such congres. Reamur's Hist. Inf. vol. vii. p. 9, &c.

See Woud-Puceron, Oak-Puceron, &c.

PUCERON, Bladder, a sort of puceron that lives in bladders on the leaves of trees. See PUCERON, supra.

We often observe on the leaves of different trees, a sort of roundish bladders, which only adhere to the leaf by a short pedicle; there are a sort of small galls, and their figure varies much in the different kinds; some are less round than others, and many are very rough on the surface, and sometimes they are long, terminating in a point, and being broader at the base than in any other part, and fullained by no pedicle, but fixed immediately to the leaves.

The elm and asp affords us more frequent instances of these than any other trees, and very often on the frill of these they grow to the bigness of a nut, and sometimes much larger; and when they are grown to their full size, they often take up the whole surface of the leaf. When these bladders are opened, they are found to contain a large number of puceroners.

If these bladders are examined at the time when they are but newly riven, which usually is the beginning of June, on opening them there is usually found in them only one puceron, and that always a female big with young; and in others more advanced, the parent insect is found surrounded with different numbers of her young ones. These bladders have all of them at first only one female puceron; but after-

wards they have more, as they become larger; and the largest of all are usually found filled with a prodigious number of young ones. The newly riven bladders are always found close and firm in every part; the aperture, at which the female puceron had entered, being usually neatly and closely flapped up. The question is, how this bladder was formed?

The method of the formation of them seems to be this: as soon as the female puceron is produced, she fixes her trunk into the leaf to suck its juices; the consequence of this in all the puceroners, that the surface of the leaf separates a little from the nervous part. In the common cases, the creature takes no advantage of this, but only continues sucking the juices; but in this kind, the female, as soon as she has had the separation between the parts of the leaf, gets into the cavity that is formed there, by enlarging the orifice first made by the trunk, till it will admit her body. When once in, she works forward in a straight line, and the hole behind her soon closes up, as there was no rupture, but only a stretching open of the parts of the leaf. The female thus finds herself in a secure place, and the elevation she makes in the leaf is scarcely perceivable, only appearing as an oblong small species of gall. The mark of the aperture, at which she made her way in, is always to be seen at some distance behind her, though usually very neatly closed up; thus the whole continues till the creature produces her young. But then the scene is quite altered; the young ones begin to suck as soon as produced, and as they usually seize upon the sides of the small gall, already formed for that purpose, this derives more juices than otherwise would flow into it; and it begins to elevate itself much higher, and forms a tubercle of the shape of a nut or pear.

Its growth, in this case, is entirely analogous to that of the common galls on the branches of trees, &c. and all the difference in the shape of the several bladders is owing to the manner of the young puceron sucking; for if they suck much at its base, that enlarges and becomes the broadest part, as is the case in the common and pointed ones; but if they let this alone, and suck only the sides and upper part, they swell while this does not, and consequently this forms a sort of pedicle to the growing bladder.

PUCERON, Baflard. See Fig.-Infest, and Grub of the Box.

PUCERON, Earth. See Earth.

PUCERON, Grub. See Grub.

PUCERON-ENTER, or LION-PUCERON. See Lion-Puceron.

PUCERON, Oak. See Oak.

PUCERON, Ver. See Ver Puceron.

PUCERON, Wood. See Wood.

PUCATRUI, in Geography, a town of Ruffia, near the sea which separates the continent of Asia from America. N. lat. 65° 50'. E. long. 188° 34'.

PUCHELBAKH, a town of Tyrol; 8 miles S.E. of Reutten.

PUCHENSTAIN, a town of the duchy of Stiria; 6 miles N. of Windisch Gratz.

PUCHIMGONG, a town of Bengal; 48 miles S.E. of Dacca.

PUCHLACHTA, a town of Ruffia, in the government of Archangel, near the White sea; 56 miles N.N.W. of Oneg.

PUCKARPOUR, a town of Hindoostan, in Oude; 8 miles S. of Bahraitch.

PUCKARY, a town of Bengal; 23 miles N. of Goragot.

PUCKASTER COVE, a creek or bay in the English Channel,
PUD

Channel, on the south coast of the Isle of Wight, a little east of Rocken End.

PUCKAUHN BEADY, in Natural History, a name given by the people of the East Indies to a peculiar species of ornamental, which they use in medicine.

They find it on the hills and on the banks of rivers. It is prepared by several tedious processes, and then is given with success in a diabetes.

PUCKBALL, a common name of a species of mushroom, full of dust.

PUCKER, in Geography, a river of Hindoostan, one of the arms of the Indus, which runs into the sea.

PUCKHOLI, a town of Asia, and capital of a district, in the country of Lahore, situated at a considerable distance on the east of the Indus; and therefore it cannot occupy the site of the "Peucelaotis" of Alexander, since that lay on the west bank of the Indus: but as Alexander advanced to this place, from the neighbouring district of Bazira, and the country of the Afsacani, (i.e. Bijore and Affenagur, which was the name of Sewad only a few centuries ago,) major Kennell very much supposes that Peucelaotis was the ancient name of Puckhooli, and that an alteration of boundary, which has frequently taken place in other provinces, may have confined its limits to the east side of the Indus, in the present times; though it might anciently have extended further to the west. The district called Puckhooli, Sewad (or Sowhad), and Bijore, were the scene of Alexander's warfare on the west of the Indus; all of which were subjected to regular authority, during the long and vigorous reign of Achar. Kennell supposes Puckhooli to have been the "Paétya" of Herodotus, (as well as the "Peucelaotis" of Arrian,) from whence Sclavus let out to explore the course of the Indus, under the orders of Darius Hyftapes; for it lies towards the upper part of the navigable course of that river, being the frontier province of Hindoostan, east of the Indus. The Ayin Acaabere gives its dimensions at 35 coffles by 25; and says, that it is bounded on the north by the districts of Attock. Its eastern limit is the river Kifhengonga; and the Indus takes its general course between the provinces of Puckhooli and Sewad. Few particulars are known concerning it, except that the northern, and by far the greater part of it, is mountainous. Puckhooli, its capital, is 85 miles S.W. of Cafmire. N. lat. 33° 45'. E. long 72° 5'.

PUCKLE-NEEDLE, in Agriculture, the common name of a troublesome weed in hard tilled lands, among the wheat, injuring the sample in a high degree. It is with difficulty separated from the grain. It is often known by the names of the plougher's needle and beggar's needle. See Weed.

PUCKO, in Geography. See PAUSK.

PUDAGERI. See Pondicherry.

PUDAGUL, a town of South America, in Chili; 16 miles W. of St. Yago de la Nueva Eftremadura.

PUDPAMOUR, a town of Benga; 37 miles W.N.W. of Ramgur.

PUDASJARVI, a town of Sweden, in the government of Uela; 44 miles N.E. of Uela.

PUPPAMALLY, a town of Hindoostan, in the province of Cattack; 35 miles W.S.W. of Cattack.

PUPPAMOUR, a town of Hindoostan, in the province of Cattack; 8 miles E. of Cattack.

PUPDAMTOIA, a town of Hindoostan, in Orilla; 35 miles S.E. of Boid.

PUPPADANGARDE, a town of Hindoostan, on the coast of Malabar; 10 miles N. of Puntany.

PUPPARD, or PADDAR, a river of Hindoostan, which rises in the country of Agimere, and discharges itself through several openings into the gulf of Cutch, 30 miles S.W. of Janagur. Some have supposed that the word "Pudder" may be merely an appellative, and that the proper name of the river is Butlees. This river periodically overflows a tract of low fenny land, on the west of Ambedabad.

PUDNENING, in a Ship, a thick wreath or circle of cordage, tapering from the middle towards the end, and fastened about the main-mast and fore-mast of a ship, to prevent their yards from falling down, when the ropes by which they are usually suspended are shot away in battle. The puddening is generally formed in the following manner: a small piece of rope, whose length is twice the diameter of the mast, is pliesed together at the two ends; and being thus doubled and extended, a thimble is leaved into each of the extremities. After this a large quantity of parcelling is firmly wound about its surface, in such a manner as to make it gradually larger from the two ends towards the middle. It is afterwards once or twice fewed with spun-yarn throughout the whole length, to bind the parcelling more closely, and render it more compact; and the whole is completed by pointign it on the surface. Being then fitted with the main yard at one of the eyes, it is fixed about the mast by palling the laniard alternately through both eyes or thimbles on the fore side of the mast. Falconer. See DOLPHIN.

Puddnings are also ropes nailed to the arms of the main and fore-yards near the ends, and then three or four at due distances inwards one from another, in order to keep the rigging from falling or wearing asunder upon the yards, when the top-fall fittings are haled home.

They call also those ropes which are wound about the rings of anchors, to fave the chine of the table from being called with the iron, by this name; so that when the ring is so served, it is called the puddening of the anchor.

PUDDING-Fish, in Ichthyology. See SPARUS Radianus.

PUDING-GRAFF, in Botany. See Mentha Pulegium.

PUDING-PIPE-Tree, in Botany. See botanical writers cafia.

PUDING-STONE, in Mineralogy, a term applied by English lapidaries to an aggregate of oblong and rounded pebbles of flint, about the size of almonds, and usually black, imbedded in a hard sileceous cement, of a light yellowish-brown. This mineral subsance is capable of receiving a very high degree of polish, and was formerly much used in inlaying, and other ornamental works. It is chiefly procured from the county of Essex. See Oculatus Lapit.

PUDDE, a small hollow full of water, especially of that which is of the more dirty kind, as in roads or fields.

Puddle also denotes leamy earth mixed up with water, to the confinement of thin mortar, for securing the bottom and sides of a canal or reservoir from leaking.

Puddle-Gutter, or Puddle-Ditch, is a ditch filled up with puddle, so as to form a wall of that substance within any bank that is to retain a head of water; as a efs, Plate I. Canals, fig. 14.

PUDLING-Boots are strong leathern boots, provided for the men who perform the operation of puddling.

PUDDOCK, in Agriculture, a term used to signify a small inclosure. See PADDOCK.

PUDDY, in Commerce, a measure of capacity at Madras. The puddy by which oil, milk, and some other liquids are sold, is the same as that used for grain; and therefore 77 bush puddies are = 125 quarts.

PUDENDA, in Anatomy, the external organs of generation.
tion in both sexes. The singular word pudendum is often applied to the female.

PUDENDAL ARTERY, a branch of the internal iliac distributed principally to the organs of generation. See Artery.

PUDENDUM denotes a thing to be ashamed of. Hence, pudendum virile, and pudendum muliebre. See General.

It is remarkable, that among the fifth-tribe, all that are oviparous have no pudenda, properly speaking; that is, they have no penis or vulva, unless the ovari of the females, and the vescicle feminales of the males, may be called by that name.

The viviparous fish, on the other hand, as the cetaceous fish in particular, and many kinds of the cartilaginous, have the penis and vulva, distinctly and properly so called. Arteried Ichthyolog.

PUDENDUM Regale. See Aphrodisia.

PUDGDARGONG, in Geography, a town of Hindoostan, in Goondwana; 38 miles N. of Nagypour.

PUDGLA, a town of Anterior Pomerania, and island of Ufedom, the principal place of a bailiwick; 6 miles N.E. of Ufedom.

PUDIANO, in Ichthyology, called also pediano, and by others virmelho, spaminixira, and teimixira, a fish of the fize of a middling perch, but not so broad as that fish. Its whole body is of a gold yellow; but that the upper part of its head, and its back, to the end of the back-fin, are of a very beautiful purple; the rim or edge of the belly-fin is also purple, and the rest of a gold yellow. It is a whole-fome and well-tasted fish.

PUDIANO Verde, the name of an American fish of a very remarkable color, and very well-tasted and wholesome. It is of an oblong shape, and its usual fize is about ten fingers long, and three broad in the broadest part; for towards the tail it is but about half that breadth.

PUDICA INTERNA, in Anatomy, the same as the pudendal artery. The pudice externe arteries come from the femoral.

PUDICA Planta, in Botany. See Mimosa.

PUDICOTTA, in Geography, a town of Hindoostan, in Combroore; 12 miles N.W. of Caroor.—Allo, a town of Hindoostan, in Marwar; 10 miles N.E. of Trumian.

PUDIMO, a small island on the east side of the gulf of Bothnia. N. lat. 63° 18'. E. long. 21° 42'.

PUDMAH, a town of Bengal; 20 miles N.E. of Punalov.

PUDMOUL, a town of Hindoostan, in Bahr; 18 miles N.E. of Hajipour.

PUDOGA, a town of Russia, in the government of Olontz, on the east coast of the lake Onezkoe; 108 miles E. of Olontz. N. lat. 61° 30'. E. long. 30° 30'.

PUDOL, a town of Russia, in the province of Uflung; 124 miles N. of Uflung.

PUDSER, a town of Bengal; 13 miles N. of Natore.

PUDSEY, a large township and chapelry, in the parish of Calverley, and wapentake of Morley, west riding of Yorkshire, is situated at the distance of 4 miles E. from the town of Bradford, and 197 N. from London. This township consists of Middle, Nether, and Over Pudsey, which together contain, according to the population returns of 1811, 997 houses and 4697 inhabitants. It is indebted for its origin to a society of Moravians, chiefly emigrants from Germany, who settled here in 1748; and for its progressive improvement to the increase of its manufactures. The Moravians have here a chapel, refectory, dormitory, school, and chair-houses, upon the plans generally adopted by that very peculiar, but sober and industrious, sect of Christians.

PUEBLO, a town of Spain, in Galicia, near the Atlantic; 25 miles S.S.W. of Santiago. N. lat. 42° 32'. W. long. 8° 51'.—Allo, a town of Spain, in the province of Grenada; 5 miles N.E. of Huelva.—Allo, a town of Spain, in Aragon; 16 miles S. of Saragossa.

Pueblo d'Alcober, a town of Spain, in Estremadura; 39 miles E. of Merida.

Pueblo de los Angelos, a town of Mexico, and capital of the province of Tlaxcala. The buildings, generally of stone, are lofty and elegant; the streets are broad, clean, and regular, intersecting one another at right angles; in the centre of the city is a large square, paid to be equal, if not superior, to that of Mexico. On three sides it is adorned with uniform porticoes, occupied by shops full of all kinds of rich commodities; and on the other side is the grand cathedral, with a beautiful front and two lofty towers, all of stone, in the modern taste. It is now the site of a bishop, translated thither from Tlaxcala. It has several churches, besides the cathedral, and also convents, well built and richly adorned: the bell-felts in the country are made in this city, besides which it has also a mint and a glass-house. The number of houses is estimated at sixteen or seventeen hundred. A small river runs through the town, and the adjacent valley produces vines, and all sorts of European fruits. In its vicinity are several firths of mineral waters; 7 miles E.S.E. of Mexico. N. lat. 29° 35'. W. long. 99° 40'.

Pueblo Cordova, a town of South America, in the province of St. Martha, on the coast of the Spanish Main; 20 miles S. of St. Martha.

Pueblo de los Infantes, La, a town of Spain, in the province of Seville; 13 miles N. of Carmona.

Pueblo More, a town of South America, in the province of Chocos; 20 miles E.S.E. of Zitara.

Pueblo Nuevo, a town of Mexico, in the province of Veragua, near the Pacific ocean.—Allo, a bay on the coast of Catalonia. N. lat. 42° 24'. E. long. 3° 6'.—Allo, a town of South America, in the province of St. Martha; 62 miles S. of St. Martha.—Allo, a town of South America, in the province of Caraccas; 10 miles N.W. of Caracas.—Allo, a town of South America, in the government of Caraccas; 20 miles N.E. of Segovia Nucia.

Pueblo de Sanabria, a town of Spain, in the province of Leon; 37 miles S.W. of Alorga.

Pueblo Vigo, a town of Mexico, in the province of Nicaragua; 45 miles N.W. of Leon.

PUECHBERG, a town of Austria; 8 miles S. of Kirchschlag.

PUEGOS, or Siquiror, one of the Philippine islands, small, but well-peopled with brave and warlike inhabitants; 50 miles N. from the W. part of Mindanao.

PUECHES, inhabitants of the mountains of Chili, in South America, now united with the state of Araucana, who are more rude and savage than the others. Their name signifies Eastern men. They are of a tall stature, and fond of the chase, so that they often change their habitations, and even detach colonies to the eastern shores of the Andes, as far as the lake Naguelgapi, and the shores of the Atlantic, in the wide plains of Patagonia. The Araucans highly esteem these mountaineers for their bold services in war, and their taking fidelity to the confederacy.

PUENTE de Arcosipio, a town of Spain, in New Castile, on the Tagus; 50 miles W.S.W. of Toledo.

Puente del Congolier, a town of Spain, in Old Castile; 37 miles W.N.W. of Avila.
The second from correct connection 32 but have which by during first for the if both the returns and put anchor; the thought, also they are well the occurrence of the convulsive paroxysms: but at length some flight twitches are observed about the mouth and eye-lids, which terminate in the complete and universal convulsion of the body.

The paroxysm of puerperal convulsions is commonly considered as in all respects analogous to that of epilepsy, occurring in other circumstances. (See Epilepsy.) And in a great measure this view is correct: both Dr. Denman and Dr. Bland, however, have pointed out a strong analogy to apoplexy, which usually characterizes the puerperal diathesis, and which, therefore, demonstrates the peculiar practice which it requires. This is marked by the presence of hemorr., or hoiring, and a comatose condition, in the intervals, usually deemed peculiar to apoplexy; and together with the frothing of the mouth, which is common to this convulsion and epilepsy, Dr. Denman remarks, "there is also a sharp hitching noise, produced by fixing the teeth, and by the sudden motion of the under lip, as if attempts were made to retract the saliva back into the mouth; and by this noise," he adds, "I have generally been able to discover the state of the patient, though she was in another room." (Introduction to Midwifery, vol. ii. p. 102. See also Bland's Observations on human and comparative Parturition, p. 138.)

Sometimes, however, the comatose state does not continue through the intervals between the paroxysms, but the patient recovers more or less completely the use of her senses.

The fits continue to recur at longer or shorter intervals, if remedies are not employed, according to the state of the child in general, and to the action of the uterus in particular, with which they are much connected; and they will thus return repeatedly, in some cases, until the delivery is accomplished, in which they affect like ordinary pains; and then they generally cease spontaneously, for they rarely occur after delivery. In some cases, the proper remedies have had the effect of preventing a second paroxysm; but in others, the first fit has terminated the life of the patient, or, after repeated paroxysms and recoveries, death has at length occurred in the fit. The prognosis, indeed, is at the best extremely uncertain: for such is the dangerous nature of the paroxysm, that, although the symptoms seem to wear the most favourable aspect, any single accession may produce death. Yet Dr. Denman has justly remarked, that the danger is not exactly to be estimated by the frequency of the returns; since this chiefly depends upon the frequency of the action of the uterus, and not upon an increase of the cause of the convulsions. Mauriac deduces his prognosis more particularly from the condition of the patient in the intervals of the accessions: if the life is in a state of total insensibility between the fits, the danger, he believes, is much greater than when the patient returns to her usual sensibility.

Traité des Maladies des Femmes groffes, lib. ii. p. 335.

Under the state of morbif irritability already noticed, several exciting causes appear to produce the convulsions in different instances. The painful dilatation of the uterine passages, and particularly of the os uteri, which is the seat of much irritability, is the most general source of the convulsive actions; whence these convulsions are much more common in a first labour, than in subsequent labours, when the relaxation is more easily accomplished; and it has been frequently remarked, that any attempt to allay the dilation of the os uteri has brought on, continued, or increased the convulsions. Violent mental emotions have also been observed to produce these attacks. A severe fit of anger,
for instance, has been known to induce them. But the depressible passions appear to be more frequently the origin of them, such as grief, and the apprehension of future misery. "Unmarried women," Dr. Denman observes, "who are unfortunate situations render pregnancy an evil instead of a blessing," are peculiarly liable to be attacked by convulsions during labour, and to become maniacal after it. Sudden terror has also operated as an exciting cause. Blows, falls, and even lees violent corporeal agitations, such as dancing, or other considerable muscular exertions, have occasionally given rise to convulsions about the period of delivery; and internal irritations, such as indigestible, or flatulent congections in the alimentary canal, or even dilatation of the urinary bladder, have proved the cause of puerperal convulsions in those predisposed in the way above-mentioned.

The immediate or proximate cause of these convulsions, however, is, without doubt, an over-excitement of the brain, from a great determination of blood to that organ. Diffusion after death, according to Dr. Denman, has usually exhibited a general turgidity of the vessels of the brain, and of the membranes surrounding it; and Mr. Hewson, in one case, found a small effusion of blood on its surface.

The foregoing view of the symptoms, causes, and nature of the disease, seems to lead, then, distinctly to three indications, with a view to the prevention and cure of puerperal convulsions; viz. 1. To obviate the great determination of blood to the head; 2. To remove all sources of irritation, external and internal, as far as is practicable; and 3. To diminish the morbid irritability of the system.

The first indication, and, indeed, the first great object of practice in this formidable disease, is the removal of the over-diffusion of the vessels of the brain. This end is obtained by blood-letting, which is to be employed freely, according to the obvious marks of determination to the head. It may be performed either in the arm, or from the jugular vein; but, on the whole, the latter is preferable. One copious bleeding has often entirely removed the convulsions, especially from the vessels in the immediate vicinity of the brain; and accident has sometimes effected, what art had been too timid to accomplish. Dr. Denman mentions a case which was related to him by Dr. Bromfield, in which, after a bleeding from the arm had been employed with little benefit, the orifice of the vein was re-opened during a subfequent convulsion, and a considerable quantity of blood lost; from which time the convulsions ceased. This evacuation should, therefore, be repeated, when the first operation has not produced adequate relief, unless some unusual state of the constitution absolutely interdicts it.

The second indication may be fulfilled at the same time, and the means will conjoin in the free ventilation of the room, by which the irritation of heat and foul air will be removed; in the free evacuation of the bowels by purgatives and glyters; in the use of the catheter, where the bladder appears to be distended with urine; in the application of fomentations to the abdomen, or the use of the warm-bath, where there are cramps or pains in the belly; and in the endeavours to tranquillize the mind, by removing all causes of anger, and opposing the tendency to grief, fear, or despondency, by inspiring hope and confidence.

The third indication, with a view to relieve the morbid irritability of the whole frame of the patient, can only be attempted with success, or even with safety, after a sufficient evacuation by blood-letting has been accomplished. The administration of opiates or other anodynes, previous to the reduction of the morbid fullness of the brain, can only be expected to increase the evil, by the stimulation which is combined with their narcotic power. When the first object has been effected, however, a full dose of laudanum, i.e. from twenty-five to forty drops, may be administered with considerable advantage. Perhaps, however, the hyoscymus, which is possessed of less stimulant power, and has no tendency to induce the bowels, would be preferable to the preparations of opium in such cases. Dr. Hamilton, the present professor of midwifery at Edinburgh, is in the habit of giving camphor, or opium, under these circumstances, or of giving camphor alone, which he conceives to be less stimulating and equally soothing. The warm-bath may be resorted to if convenient, for the purpose of calming the general irritability, and warm fomentations are sometimes useful for the same purpose; but in truth, after the immediate source of the convulsions is removed by blood-letting, these secondary expedients are of minor importance.

It may be proper to observe, before we conclude, that some practitioners have ascribed the propriety of allisting the delivery immediately, without waiting till the os uteri is sufficiently dilated by the natural efforts to admit of a ready extraction of the child. But both reason and experience have decided on the propriety of allisting from any attempt to dilate the os uteri, since the very attempt is liable to excite the paroxysms. If the first stage of labour be past, indeed, before the convulsions come on, the paffage will be too much dilated as to admit of turning (especially if the membranes be not broken), or of delivery by the forceps or vectis. The comparative advantages of waiting have been clearly stated by Drs. Bland and Denman, in the works to which we have referred in the course of this article.

Puerperal Fever, in Midwifery, a fever incident to lying-in-women, and attacking them during or soon after labour. For its history and treatment, see Labour, Natural.

The puerperal fever is, in fact, connected with an inflammation of the peritoneum, or membrane lining the abdomen and surrounding the intestines, and differs from ordinary peritoneal inflammation only in the circumstances peculiar to the puerperal state, which increase the danger of the disease. The term puerperal fever should, therefore, be changed for that of puerperal peritonitis, or puerperal puerperum, which conveys a more correct notion of the nature of the disease. See Peritonitis.

Puers, in Geography, a town of France, in the department of the Two Nethes, and chief place of a canton, in the district of Malines. The place contains 3664, and the canton 15,667 inhabitants, on a territory of 85 kilometres, in nine communes.

Puerto de Acapulco, Las, a harbour on the coast of Peru. N. lat. 14°.—P. de los Angeles, a harbour of the Pacific ocean, on the coast of Mexico. N. lat. 15° 30'.—P. del Bayo Bucareli, a large bay on the W. coast of the Prince of Wales's Archipelago, discovered in 1775 by Jigmon Quadra, in which is a great number of small islands. N. lat. 55° 14' to 55° 40'. E. long. 226° 12' to 227° 5'.—P. de Bazan, a bay on the S.W. coast of the Prince of Wales's Archipelago. N. lat. 54° 40'. E. long. 227° 16'.—P. de Cabananos, a harbour on the N. coast of the island of Cuba. N. lat. 23° 4'. W. long. 83° 6'.—P. del Canaveral, a harbour on the S. coast of Pitt's Archipelago, in the Canal of Principe. N. lat. 53° 32'. E. long. 230° 16'.—P. Camilo. See Port Carriacho.—P. Calcico, a harbour on the coast of Brazil. S. lat. 9° 10'. W. long. 34° 50'.—P. Cerrato de Tucapel, a harbour on the coast of Chili. S. lat. 37° 40'.—P. Clar, a bay of the Pacific ocean, on the coast of Darien. N. lat. 6° 52'.—P. del Coral,
PUERTOLAS, a town of Spain, in Aragon; eight miles N. of Ainha.

PUERTOS, Los, a town of South America, in the province of Venezuela, E. of the river, which forms a communication between the gulf of Venezuela and Lake Maracaibo; 15 miles N.N.E. of Maracaibo.

PUFF-BALL, the common English name for the fungus pulvinatus lentus, or lyceoperdon. See Lycoperdon.

The fruit contained within this body, (which, when it is crushed, flies out in an inconceivably fine powder, in form of a cloud of smoke,) when examined by the microscope, appears to be a multitude of regularly figured, though extremely small bodies. These require the most powerful magnifiers to distinguish them, and are found to be little globules of an orange colour, and somewhat transparent; and so small, that the cube of the diameter of a hair would be equal to a hundred and twenty-five thousand of them. In other species of this mushroom, the globules are evidently seen to be so many puff-balls, being of a darker colour, and having each a little stalk or tail; by means of these stalks they penetrate into the ground, when fed from their parent plant.

The fruit of these mushrooms is very hurtful to the eyes, and we have had instances of persons being blinded for a long time by it, with violent pain, swelling and inflammation; and this is probably owing to the sharpness of these almost inconceivably minute stalks or tails. Baker's Microscope, p. 255.

PUFFENDORFF, Samuel, in Biography, a learned historian and jurist, was born in 1631 at Flath, a village of Memia, near Chemnitz, where his father was a Lutheran minister. He received the early part of his education under his father, and was sent to Leipsic to study divinity, which he soon abandoned for the law. After residing some time at this university he removed to Jena, and pursued the mathematics under the celebrated Weigel, and then applied himself to the law of nations, and the politics of the German empire, in which he became thoroughly versed. In 1658 he was appointed governor to the sons of Coyer, ambassador of the court of Sweden to that of Denmark, whom he accompanied first to Leyden, and then to Copenhagen. When war broke out between the two kingdoms, all the household of the Swedish ambassador was put under an arrest. Puffendorf, during the eight months of his confinement, employed himself in commenting on the work of Grotius "On the Rights of War and Peace," and the political writings of Hobbes, and having arranged his observations, he published them in 1660 with the title of "Elements of Univerfal Jurifprudence." By this essay he acquired so much reputation, that the electeur palatine founded, in his favour, a professorship of natural law in the university of Heidelberg.
Heidelberg. In 1670 Charles XI., king of Sweden, conferred upon him the same office in the university of Lund. While he was in that situation, the publication of his great work on the law of nations, brought upon him an attack from professor Beckmann, who printed a libel against him, for which he was banished the kingdom. Enraged at this punishment, he sent Puffendorf a challenge, of which he wisely took no notice. When Schonen became the seat of war, he quitted Lund, and went to Stockholm, where he was appointed royal historiographer and counsellor of State, with the title of baron, and was engaged in writing on Swedish history. He finally accepted the invitation of the elector of Brandenburg to reside at his court as counsellor of State, with the charge of writing the history of the great elector, Frederick-William. Baron Puffendorf died at Berlin in 1694, leaving behind him a character of very great integrity and honour. His historical works are as follow: "An Introduction to the History of the principal States at present in Europe," with a "Continuation," "History of Sweden from the Expedition of Gustavus Adolphus into Germany to the Abduction of Christiana," "History of Charles Gustavus," "History of Frederick-William II., the great Elector of Brandenburg." This was published in two vols. fol. in 1696; it was drawn from the archives of the house of Brandenburg, and contained many retracements in the course of printing, and complete copies are now rarely to be met with. Of his works on law are "Elementorum Jurisprudentiae Universalis," "A Treatise on the Law of Nature and Nations." This work maintains a place among the leading publications on the subject, and it is allowed, that the author has rectified and extended the principles of Grotius. An abridgment of this work was published under the title of "Duties of a Man and a Citizen."

Puffendorf, Israel, brother of the preceding, born in 1628, was educated at Leipsic, where he distinguished himself, and took the degree of M.A. After various changes of fortune, he was made governor of the young count of Koningmark, and was afterwards chancellor of the duchy of Bremen. In 1686 he was appointed ambassador of the king of Denmark to the diet of Ratibon, and died there in 1689. He is the author of a fatirical work, entitled "Anecdotes of Sweden, or Secret History of Charles XI." Moreni.

Puffin, in Ornithology, a name by which some call the Anas arctica Cluii, or the northern duck, or Alca arctica Linnaeus.

This bird weighs about twelve ounces; its length is twelve inches, and the breadth from tip to tip of the wings extended, twenty-one inches; the bill is short, broad at the base, compressed on the sides, and running up to a ridge, triangular, and ending in a sharp point; the base of the upper mandible is strengthened with a white, narrow, prominent rim, full of small holes; the bill near the head is of a blueish-grey, and the lower part red; in the former is one transverse furrow, in the latter three furrows; and the size of the bill varies in different birds; the nostrils are long and narrow; the irides are grey, and the edges of the eyelids of a fine crimson; on the upper eye-lid is a singular callous substance, grey, and of a triangular form; on the lower is another of an oblong form; the crown of the head, whole upper part of the body, tail and covert-feathers of the wing, are black; the quill-feathers are of a dusky hue; the cheeks are white, and full of feathers; the chin of the same colour, bounded on each side by a broad band of grey; from the corner of each eye is a small separation of the feathers, terminating at the back of the head; the neck is encircled with a broad collar of black, but the whole lower part of the body is white; the tail is composed of sixteen feathers, and black; the legs small, of an orange colour, and placed so far behind as to render it incapable of standing otherwise than in an erect position, retting not only on the foot but the whole length of the leg, which circumstance makes the rife of the puffin from the ground very difficult; but when it gets on the wing, few birds fly longer or stronger.

These birds frequent the coast of several parts of Great Britain and Ireland, and are most numerous in Pembrokeshire and Anglesea. They are birds of passage, returning there annually about the first week of May, but some dislodge the rabbits, and make use of their holes. The stork of burrowing falls chiefly to the males, which also affix in incubation. The first young are hatched in the beginning of July, to which the old ones discover a very strong affection, which ceases at the stated time of migration, taking place punctually on the eleventh of August, when they leave such young as cannot fly to the mercy of the peregrine falcon. They lay only one egg, and the eggs are of very different forms. The size of these birds is exceedingly rank, as they feed on weeds and fish, especially sprats; but when picked and preferred in spices, they are admired by those who love high eating. Dr. Caius tells us, that in his time the church allowed them in Lent instead of fish. They are taken by digging them out, or drawing them from their burrows with a hooked stick. Their noise, when taken, is very disagreeable, being like the effort of a dumb person to speak. The winter residence of this genus is but imperfectly known; it is probable they live at sea, in some more temperate climate, remote from land, forming those multitudes of birds which navigators observe in many parts of the ocean; they are always found there at certain seasons, retiring only at breeding time; repairing to the northern latitudes; and during that period are found as near the pole as navigators have penetrated. Pennant.

Puffin Manks, or Shear-water. See Procellaria Puffina.

Puffin's Island, in Geography, a small island near the N. coast of Ireland; 4 miles S. of Brea Head.

Puffinet, in Ornithology, the name of a bird known among authors by that of the Columbia Groenlandica, or the Greenland, or sea turtle-dove. See Columbia.

It is common on the northern coasts, and is black all over, except two small spots on its head; but it is pretended by some, that in winter it turns white.

Pug. the name of a species with dove-tailed or pile-planking; which see.

Puganore, in Geography, a town of Hindooslan, in Myssore; 38 miles N.W. of Arcot.

Puget's Island, a narrow island about five miles in length, discovered by Capt. Vancouver in Columbia river, about 24 miles from its mouth.

Puget's Sound, an inlet of several branches, and containing many islands, S. of Admiralty inlet, within Georgia Sound. N. lat. 47° 10'. E. long. 237° 25'.

Puget's Thieniers, a town of France, and chief place of a district, in the department of the Maritime Alps. The place contains 914, and the canton 2133 inhabitants, on a territory of 142 1/4 kilometres, in 6 communes.

Puggar, a town of Bengal; 30 miles W.N.W. of Ramgur.

Pugil, from pugillus, little hand, among Physicians, c. a measure of flowers, seeds, or the like matters, containing
so much as may be taken up between the thumb and two fore-fingers.

The pupil is esteemed the eighth part of the manipulate (which lee), or handfull; though some confound pupil with manipulus, and use it for a handfull. The French frequently call it pinces, a pinch.

PUGLIENZA, in Geography. See POLLENZA.

PUGNANI, Gaetano, in Biography, chamber musician and first violin to the court of Turin. He was of the Tartini school, and formed many great scholars upon his instrument, among whom we need only mention Fig. Viotti as an illustrious example.

Pugnani went to Paris in 1754, and pleased and astonished extremely at the Concert Spirituel, both as a composer and performer of his own pieces.

In 1755 he published at Amsterdam three quartets, opera prima. In 1765 fix duos for two violins, opera secunda; and fix trios for two violins and a bass, opera terza. A second fet afterwards of fix duets, opera quarta. His opera quinta was fix fanatas for the harpsichord, with a violin accompaniment. Six symphonies, opera sexta. In 1770 fix violin solos, opera septima. Three quintets for two violins, two flutes, and a bass, opera octava. Six solos, opera nona, for the violin, besides a great number of soloconcertos for his own performance, which still remain in manuscript.

In 1768 he came to England, and led some time at the Opera. His manner of playing there is not yet forgotten. He was very near-fighted; but grasped a whole page generally by a single glance, which gave him full leisure to look around him for admiration; and with a nose long enough for a Muflo, he either thought himself or wished others to think him an Adonis. But he had here at this time a most powerful rival in talents and personal appearance in Giardini. It appeared to us in his solos and concertos that Pugnani had not that great and firm command of the finger-board, which Giardini and some other eminent performers on the violin have since manifested. In his shifts he was never sudden nor frequent; but having attained a new position, he never quitted it till he had played all the notes within his reach, which kept his hand stationary sometimes for a whole page.

While at the head of our Opera band, he composed a comic opera called "Manette e Lubino." But though an able professor and writer for his own instrument, he seemed to have begun writing for the voice too late in life to arrive at great excellence in vocal compositions. He since that time has, however, composed several serious operas for different parts of Italy; among the rest "Demofonte" for Turin, in 1788. We have heard nothing of him since the revolution and dethroning of his sovereign.

PUGNAX AVIS, in Ornithology, the name of the bird called in English the ruff, and the female of which is the ruffe. It has its Latin name from its quarrifome disposition, the males being always fighting. See TRINGA PUGNAX.

PUGNO CHIUSO, in Geography, a town of Naples, in the province of Capitanata; 5 miles S. of Viefe.

PUICELEY, a town of France, in the department of the Tarn; 10 miles N.W. of Gaillac.

PUJET, Le, a town of France, in the department of the Var; 9 miles S. of Brignoles.

PUGUILLIEN, a town of France, in the department of the Dordogne; 10 miles S.W. of Bergerac.

PUINORMAND, a town of France, in the department of the Gironde; 12 miles N.E. of Libourne.

PUJOLS, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Libourne; 12 miles N.E. of Libourne. The place contains 1012, and the canton 10,473 inhabitants, on a territory of 122½ kilometres, in 16 communes.—Allo, a town of France in the department of the Lot; 10 miles N. of Agen.

PUL, in Commerce, a general name which the Persians give to all the copper monies current in that empire.

Olearius, who was at Ifpahan in 1637, in the retinue of the ambassadoir of Holstein, affirues us, that each city in Persia has its several copper money, marked with its particular badge, which is only current in that district, and is changed every year. At the beginning of each year, which is at the vernal equinox, all the old money is cried down, and the new appears in its place.

Both the emperor and the state find their interest in this frequent change: the first, in that he only gives at the rate of 17 d. farthing per pound for copper; yet delivers it out coined in kabelqui and demi-kabesqui, at about 2s. per pound: the second, in that the copper money is by this means less abundant, being reduced each year to nearly the same quantity.

PULAH, the name of one of the personages often mentioned in Hindoo sacred writings, as the "ten lords of created beings," sometimes called Bramadikas, or sons of Brahma, and Prajapatii, or lords of creatures. On other occasions seven only are mentioned, and they have been reasonably considered as the same personages as those called Menu, Munis, and Rihis. See Menu, Munis, and Rihis.

PULANS, a county of Kentucky, containing in 1806, 15713 statute acres, 206 miles square, 346 miles from the mouth of the Ohio; 44 miles W. of Radippour.

PULASHI, a county of Kentucky, containing in 1806, 3561,
and an epic romance, probably the first of the kind that appeared in Italy, entitled "Il Cirillo Calvano."

PULE, Le, in Geography, a bay on the W. coast of the island of Jersey.

PULECA, a town of Bengal; 13 miles S. of Kilhen-agh.

PULEGNUM, in Botany. See PENNY-ROYAL.

PULENTE, Ea, a bay on the W. coast of the island of Jersey; 3 miles W. of St. Aubin.

PULEX—L. In Entomology, a genus of insects of the order Apteris, of which there are only two species. The generic character is as follows: Mouth without jaws or feelers, with a long inflected proboscis, covered at the base with two ovate laminae; the sheath is two-valved, five-jointed, and concealing a single brittle lip rounded, and fringed with reflected prickers; antennae projecting, moniliform; it has two eyes; the abdomen is compressed; it has six legs, formed for leaping.

Species.

* IRITANS. Proboscis shorter than the body. For a full account of this insect, see our article FLEA.

PENETRANS; the Chigoe. Proboscis as long as the body. It inhabits South America. This insect is extremely troublesome in the fur and colonies, penetrating into the skin of the inhabitants, where it lodges its eggs, and causes malignant and often fatal ulcers. The body is reddish-brown; abdomen of the female, when gravid, orbicular, and swollen to near a hundred times its usual size.

Pulex Aquaticus. See WATER BEETLE, and MILLEPEDES.

Pulex—Eriot, a name given by naturalists to a sort of worms frequently found on the leaves of trees, where they devour the animals called pulices arboreti.

Of these there are several species, which owe their origin to the eggs of different creatures; for they are none of them in their ultimate state in this their time of feeding. According to the different animals whose eggs they are hatched from, there are of different forms and structure: some are hexapodes, or furnished with fix feet; these belong to the beetle tribe, and finally change into beetles like the parent animals from whose eggs they sprung; others have no legs, and are produced from the eggs of flies of various kinds; and finally, others are genuine caterpillars, though small; but these are the more rare of all. The two general kinds are the hexapodes or beetle-worms, and the apodes, or fly-worms. The fly which gives origin to the last of these is a four-winged one, and takes care always to deposit its eggs in a place where there is plenty of the pulices, usually on the flaks or young branches of a tree in the midst of large families of them. The worm, as soon as hatched, finds itself in the midst of abundance of food, preying at pleasure on these animals, which are wholly defenceless. The flaks of the elder and woodbine are frequently found covered over with these pulices, and among them there may usually be found one or more of these destroyers feeding at will, fucking in the juices from their bodies, and then throwing away the dry skins. Besides the worms of this four-winged fly, there is one of a two-winged fly-fly, very destructive of these animals. Reaumur's Hist. Inf. tom. i.

Pulex—Arboraeus, in Natural History, the name given by M. Reaumur to a very large genus of small animals. They are a kind of half-winged creatures; they have granulated antennæ, and some of them, in their most perfect state, have complete wings. These are distinguished from the others by the name of mufca pules, or the winged pulex.

The several species of these creatures are of different co-

ours;
PULL

joures; some are brown, others yellow; but the most frequent are green. They all feed upon the leaves of trees, which become withered and curled up on their eroding them; and they are so common, that wherever a leaf of a tree is found curled up, or of a different form from the others, it is highly probable these animals are on it, or that it is their work. Among trees, the willow and the rose are most infected by them; and among plants, the bean and the poppy. They live a social life, multitudes of males and females being found together. The females are easily distinguished from the males, by their being thicker in the body, and having larger bellies.

It is very wonderful, that of all the known animals of the winged kind, there are the only ones which are viviparous. This is easily seen beyond a possibility of doubt; for, on examining a cluster of them together, it is a common thing to see, by the help of a small magnifier, a female in the act of parturition; and the author of this account frequently saw the young pulex protruded out, from a paffage near the anus of the female, perfectly formed. He has suspected this from the total want of eggs among so numerous a tribe of animals, and from their remarkably speedy propagation, and was thus convinced of it by ocular demonstration. Reaumur's Hist. Insects, tom. i.

PULGAR, Fernando de, in Biography, secretary, counsellor, and chronicler to Fernando and Isabel. He was a native either of the city or kingdom of Toledo. He wrote the chronicle of the Catholic kings up to 1492. This was published in 1565 as the work of Antonio de Nebrija, by his grandfon, who finding it among his grandfather's papers suppos'd it to be his own work, and that the more readily, as Antonio had published a Latin translation. The Claras Varones of Pulgar have been more frequently printed. Gen. Biog.

PULICA, or PULHA, in Geography, a town of Austria. See BALKAU.

PULISCHIAH, a town of Persia, in the province of Irak; 66 miles S.W. of Hamadan.

PULK, in Rural Economy, a provincial word signifying a puddle.

PULKA, in Geography, a town of Hindoostan, in the cercar of Surgojoa; 65 miles S.W. of Surgojoa.

PULKELA, a town of Sweden, in Eall Bothnia; 88 miles S.E. of Brahefled.

PULLECOIL, a town of Hindoostan, in the Carnatic; eight miles E. of Tanjore.

PULLENDORF, a town of Austria; four miles E. of Michteibach.

PULLEY, in Mechanics, one of the five Mechanical powers (see the article); consisting of a little wheel, or rundle, having a channel around it, and turning on an axis, serving, by means of a rope which slides in its channel, for the raising of weights.

The Latins call it trochlea; and the French, when fitted with a rope, a tackle. An arrangement of several pulleys is called a system of pulleys, or polyspilation: some of which are in a block or cafe, which is fixed; and others in a block which is moveable, and rises with the weight. The moveable wheel or rundle, is called the fiove or fiover; the axis on which it turns, the gudgeon; and the fixed piece of wood or iron, into which it is put, the block.

Pulley, Doctrine of. 1. If the equal weights W and P (Plate XXXVI. Mechanics, fig. 11.) hang by the cord B B upon the pulley A, whose block b is fixed to the beam H J, they will counterpoise each other, just in the fame manner as if the cord were cut in the middle, and its two ends hung upon the hooks fixed in the pulley, at A and A, equally distant from its centre. See Mechanical powers.

Hence a single pulley, if the lines of direction of the power and the weight be tangents to the periphery, neither affords nor impedes the power, but only changes its direction. The use of the pulley, therefore, is, when the vertical direction of a power is to be changed into an horizontal one; or an ascending direction into a descending one; and on the contrary.

This is found a good provision for the safety of the workmen employed in drawing with the pulley.

This change of direction by the means of a pulley has this farther advantage; that, if any power can exert more force in one direction than another, we are here able to employ it in its greatest force. Thus, e. gr. a horse cannot draw in a vertical direction, but draws with all its advantage in a horizontal one. By changing the vertical draught, therefore, into a horizontal one, a horse becomes qualified to raise a weight.

But the grand use of the pulley is, where several of them are combined; thus forming what Vitruvius, and others after him, call polyspilation; the advantages of which are, that the machine takes up little room, is easily removed, and raises a very great weight with a moderate force.

2. If a weight W hangs at the lower end of the moveable block p of the pulley D (fig. 11.), and the cord G F goes under the pulley, it is plain that the half G of the cord bears one half of the weight W, and the half F the other; for they bear the whole between them. Therefore, whatever holds the upper end of either rope, sustains one half of the weight; and if the cord at B be drawn up so as to raise the pulley D to C, the cord will then be extended to its whole length, except that part which goes under the pulley; and consequently, the power that draws the cord will have moved twice as far as the pulley D with its weight W rises; on which account, a power whose intensity is equal to one half of the weight, will be able to support it, because if the power moves (by means of a small addition), its velocity will be double the velocity of the weight; as may be seen by putting the cord over the fixed pulley C (which only changes the direction of the power, without giving any advantage to it), and hanging on the weight P, which is equal only to one half of the weight W; in which case there will be an equilibrium, and a little addition to P will cause it to descend, and raise W through a space equal to one half of that through which P descends. Hence, the advantage gained will be always equal to twice the number of pulleys in the moveable or undermost block. So that, when the upper or fixed block u contains two pulleys, which only turn on their axes, and the lower or moveable block U contains two pulleys, which not only turn upon their axes, but also rise with the block and weight, the advantage gained by this is as four to the working power. Thus, if one end of the rope K M O Q be fixed to a hook at I, and the rope passes over the pulleys N and R, and under the pulleys L and P, and has a weight T of one pound hung to its other end at T, this weight will balance and support a weight W of four pounds, hanging by a hook at the moveable block U, allowing the said block as a part of the weight. And if as much more power be added, as is sufficient to overcome the friction of the pulleys, the power will descend with four times as much velocity as the weight arises, and consequently through four times as much space. The two pulleys in the fixed block X, and the two in the moveable block Y, are in the same cafe with those last mentioned; and those in the lower block give the same advantage to the power. See Polyspaston.
It is necessary to observe, that if the lower pulleys do not rise all together in one block with the weight, as in the cafes just recited, but act upon one another, and the weight is only fastened to the lowest of them, the force of the power is very much increased, each pulley doubling it. 

A power whose increase is equal to 8 lb. applied at a, (fig. 12.) will, by means of the lower pulley A, sustain 16 lb.; a power equal to 4 lb. at B, will, by means of a lower pulley B, sustain the power of 8 lb. acting at a; a third power equal to 2 lb. at C, will, by means of the pulley C, sustain the power of 4 lb. at B; a fourth power of 1 lb. at D, will, by means of the pulley D, sustain the power of 2 lb. at C; and this is not altered by having its rope carried over the upper pulley or roller E. In the former cases, the force of the power is augmented in an arithmetical proportion of the number of ropes or pulleys; but in this, in a geometrical proportion.

3. If a power move a weight by means of several pulleys, the space passed over by the power will be to the space passed over by the weight, as the power to the weight.

Hence, the smaller the force that sustains a weight by means of pulleys is, the flower is the weight raised; so that what is saved in force, is spent in time.

The common methods of arranging pulleys in their blocks, may be reduced to two. The trial consists in placing them one by the side of another, upon the same pin; the other, in placing them directly under one another, upon separate pins. Each of these methods is liable to inconvenience. Mr. Smeeaton, in order to avoid the impediments to which these combinations are subject, proposes to combine these two methods in one. Accordingly, the pulleys are placed in each block in two tiers; several being upon the same pin, as in the first method, and every one having another under it, as in the second; and so that, when the tackle is in use, the two tiers that are remotest from one another, are so much larger in diameter than those that are nearest, as to allow the lines of the former to go over the lines of the latter without rubbing. From this construction arises a new method of receiving the line upon the sheaves; for here, whatever be the number of sheaves, the fall of the tackle will be always upon the middle sheave, or on that next to the middle, according as the number of pulleys in each pin is odd or even. To do this, the line is fixed to some convenient part of the upper block, and brought round the middle sheave of the larger tier of the under block, from thence round one of the same fort next the centre one of the upper block, and so on, till the line comes to the outslide sheave, where the last line of the larger tier falls upon the first sheave of the smaller, and being received round thence, it comes at the opposite side, the line from the last sheave of the smaller tier again rises to the first of the larger, whence it is conducted round, till it ends on the middle sheave of the upper block on the larger tier. See fig. 13. Phil. Trans. vol. xlvii. art. 82. p. 494, 

As a system of pulleys has great weight, and lies in a small compass, it is easily carried about, and can be applied, in a great many cafes, for raising weights, where other engines cannot be used. But they have a great deal of friction on these accounts; 1. Because the diameters of their axes bear a very considerable proportion to their own diameters; 2. Because in working they are apt to rub against one another, or against the sides of the block; 3. Because of the stiffness of the rope that goes over and under them. Ferguson's Mechan. p. 37, 410. See Friction.

PULLICATE, in Geography, a town of Hindoostan, near a large lake to which it gives name. This lake, called by d'Anville Ericans, seems to owe its existence to the fame caufe as the Chikla lake; that is, to the sea's breaking through a low sandy beach, and overflowing the lands within; for its communications with the sea are extremely narrow, like the embouchures of small rivers. This lake is in extent thirty-three British miles, from N. to S., and eleven over, in the broadest part, and contains some large islands within it; one of these is named Irem, in Mr. Bernard's map of the Jafhire, published by Mr. Dalrymple; and as M. d'Anville names this island, as well as the lake, Ericans, Major Kennell concludes it to be a corruption, or misconception, of Irem. In the year 1650 the Dutch established themselves, and built a fort which they called Geldria. After the loss of Negapatam, the chief government on the coast of Coromandel was removed to this town; 22 miles N. of Madras. N. lat. 13° 24'. E. long. 80° 27'.

PULLICH, a town of France, in the department of the Rhone and Mofelle; 6 miles E. of Kaylerech.

PULLING, in Sea Language, denotes the act of rowing with the oars.

PULLING, in Geography, a town of Sweden, in Weft Bothnia, on the Tornea; 48 miles N. of Tornea.

PULLS, in Agriculture, the chaffy pods of rape or cole.

PULLUMNAIRE, in Geography, a town of Hindoostan, in the Carnatic; 94 miles W. of Madras. N. lat. 13° 10'. E. long. 78° 50'.

PULLUS, or Fallon, Robert, in Biography, an English cardinal who flourished in the 13th century, was distinguished as a zealous friend to the interest of literature. He purued his studies at Paris, and about the year 1130 he returned to England, where he had the mortification of seeing the university of Oxford ravaged and nearly ruined by the ignorant and ferocious Danes, under the reign of Harold I. He was one of those able men, to whose indefatigable exertions this feat of learning was indebted for its revival and restoration. To this object he devoted his advice, his fortune, his personal labour, and his learning. For some years he taught daily in the schools: for this and other eminent services, he was rewarded with the archdeaconry of Rochester. After this he returned to Paris, where he filled the chair of professor of divinity. He was, however, recalled by his metropolitan, and the revenues of his benefice sequestered till he obeyed the summons. The archdeacon appealed to the fee of Rome, and sentence was given in his favour. The fame of his learning induced pope Innocent II. to invite him to Rome, where he was received with great marks of honour; and in the year 1144 was created cardinal by Celestine II., and afterwards chancellor of the Roman church, by pope Lucius II. He died in the year 1150. He was author of several works, but the only one of them now extant is his "Sententiarum Liber," which was published at Paris in 1655.

PULLYVELLUM, in Geography, a town of Hindoostan, in the Carnatic; 8 miles S. of Terriore.

PULMAN, Theodore, in Biography, a philologist, born about 1570, at Cranenburg, in the duchy of Cleves, was brought up to mechanical pursuits, and for some years exercised the trade of a fuller at Antwerp. By hard study in the intervals of his business, he became a proficient in classical literature, and an able grammatical critic. He was employed for sixteen years as a corrector of the press, and gave good editions of several Latin writers, from the press of Plantin at Antwerp; for which purpose he revised the text by ancient MSS. He died at Salamanca. He gave editions of Virgil, Horace, Lucan, Juvenal, Ætop, Terence, Suetonius, and several others. Moreri.

PULMO, in Anatomy. See Lungs.

PULMO marinus, Sea-Lungs, among Naturalists, a light spongy
pungous body, of a shining colour, like crystal, intermixed with blue, and usually of a figure resembling the human lungs; whence its name. It is also called *Urtica marina,* (which fce) or the sea-nettle.

It twines on the surface of the water, and is popularly reputed to prefage a florn. It is commonly supphed to be only a vicous excrement of the sea, hardened by the sun; but Sir Robert Sibbald and Dr. Merret rank it among the zoophytes. It thins in the night time, and communicates its luminous property to a flxck rubbed with it. Being applied to the skin, it raises an itching, and takes off the hair.

**PULMONALIS,** in *Anatomy,* pulmonary, a term applied to the artery, veins, and nerves of the lungs. See Lung.

Gen. Ch. Cal. Perianth inferior, of one leaf, with five angles, and five teeth, permanent. Cor. of one petal, funnel-shaped; tube cylindrical, the length of the calyx; limb cut half way down into five obtuse ascending segments; throat pervious. Stam. Filaments five, very short, in the throat; anthers erect, converging. Pfl. Germans four; style thread-shaped, shorter than the calyx; stigma obtuse, notched. Peric. none, the permanent unchanged calyx containing the seeds in its lower part. Seeds four, roundish, obtuse.

Eff. Ch. Corolla funnel-shaped, perennial. Calyx with five acute angles and flat sides.

Section 1. Calyx about the length of the tube of the corolla.

2. *P. officinalis.* Common Lungwort. *Linn. Sp. Pl. 194. Fl. Brit. n. 1. Eng. Bot. t. 118, excluding the coloured leaves, which belong to the frst species. Fl. Dan. t. 482. Woodv. Suppl. t. 212. (P. foliis echii; Ger. Em. 808.)—Calyx nearly as long as the tube. Radical leaves ovate or heart-shaped, rough. Native of shady places in various parts of Europe; rare in England, except in gardens, where it frequently occurs, flowering in May. This differs from the foregoing chiefly in its much broader, shorter, and more spotted leaves, whose surface is bejprinkled with pale, white, round blotches, most remarkable at an early stage of growth.—The flowers are occasionally white in this as well as the anguifolia.

Sec. 2. Calyx but half so long as the tube of the corolla.

3. *P. faurieicola.* Shrubby Lungwort. *Linn. Sp. Pl. 1657. Wildd. n. 3. (Lithospermum anguifolium umbellatum; Bosc. Sic. 77. t. 41. f. 2. Pluk. Phyt. t. 42. f. 7.)—Leaves linear, rough. Segments of the calyx deep, awl-shaped.—Native of mountains in Italy and Sicily. A species but little known, entirely a stranger to our gardens. Its *flora* short, but perennial and rather woolly, clothed with the permanent foliage of the last year. Leaves copious, long and narrow. *Flowers* blue, with more of the character of a *Lithospermum* than of a Pulmonaria.

4. *P. paniculata.* Panicled Lungwort. *Ait. Hort. Kew. ed. 1. v. 1. 1811. ed. 2. v. 1. 293. Wildd. n. 4.—Calyx short, hilpif, with deep segments. Leaves ovate-oblq, pointed, rather hairy.—Native of Hudson's Bay. Dr. Solander is credited as its introducer at Kew, in 1778. This is a very curious species, flowering in May and June, of which no figure has appeared, nor have we seen a specimen.

5. *P. virginica.* Virginian Lungwort. *Linn. Sp. Pl. 194. Ait. n. 4. Curt. Mag. t. 160. Mill. Ic. t. 212. (P. foliis ovatis glabris, laco xaco; Trew Ehret. 11. t. 42. Symphytum, five Pulmonaria non maculata, folis glabris, americana, flore patulo cerasifo; Pluk. Amn. 359. t. 227. f. 6.)—Calyx short, very smooth. Leaves lanceolate, bluntish.—Native of North America; from Pennsylvania to Carolina according to Mr. Purfl, growing on the gravelly shores of rivers, and flowering from March to May. With us it is a hardy perennial, of great beauty, but not so generally cultivated as it deserves. The whole herb is very glaucous, and so nearly smooth as almost to form an objection to the name of its natural order. The flowers are drooping, of a fine sky blue, and shaped like those of an *Onoplia;* their tube and buds purple.

7. *P. maritima.* Sea Lungwort. *Linn. Sp. Pl. 195. Fl. Brit. n. 2. Eng. Bot. t. 368. Curt. Lond. fabe. 6. t. 18. Fl. Dan. t. 25.—(Cerinthe maritima procumbens, foliis et floribus ceraso; Dill. Elth. 75. t. 65.)—Calyx short. Leaves ovate, glaucous. Stem branched, procumbent.—Native of sandy sea-shores in Iceland, Norway, Scotland, and the north of England, flowering in July. This is most akin to the two last, but differs in being smaller, with a procumbent, much branched, and widely spreading stem. The whole herb is very glaucous. Leaves ovate, tapering at the base, rough with minute scattered tubercles. When chewed, in a recent state, their flavour is somewhat like a raw oyster; but by no means the more pleasant on that account, even to oyster-eaters. The flowers are racemose, terminal, of a very beautiful purplish-blue, pink in the bud. This is one of the most strikingly elegant of our native plants, at least in its native situations. The late Mr. John Mackay observed a variety, whose herbage was entirely green, not glaucous.

**PULMONARIA,** in *Gardening,* furnishes plants of the hardy, perennial, fibrous-rooted kind, of which the species cultivated are the common lungwort (*P. officinalis*); the narrow-leaved lungwort (*P. anguifolia*); and the Virginian lungwort (*P. virginica*).

The second species varies with white flowers.
Method of Culture.—These plants are increased by seeds, and paring the roots.

The seeds should be sown in the spring, in a bed or border of common earth, raking them in. They soon come up; and the latter end of summer they should be put out, either where they are to remain, or in nurseries, till October, when they should be planted out finally.

The roots should be parted in the autumn, as about August or September; but the sooner after they have done flowering, the better. They should not be divided too small, and be planted directly; when they flower strongly in the following spring. They afford ornament in shady situations.

PULMONARY CONSUMPTION, in Medicine. Phthisis pulmonaris, or consumption of the lungs. See Consumption.

PULMONES, in Anatomy. See Lungs.

PULMONIC MACHINE. See Pulmo, and Utteria Marina.

PULMONIC MACHINE, is a machine contrived for drawing fresh air, or medicated fumes, into the lungs or throat, &c. Some have recommended for this purpose an inverted funnel: others have contrived machines for in-fusing herbs, &c. and annexed to them tubes for insipiring the fume or volatile parts thus obtained for them. A machine of this kind was contrived some years ago by Mr. Arden of Derby, which is described in the Gentleman's Magazine for 1748, vol. xviii. p. 486. A machine of this kind was contrived by Dr. Hales, for meliorating the air passing through the lungs of miners, &c. and is described in his "Vegetable Statics," vol. i. p. 264, &c. An instrument designed for similar purposes, and called an inhaler, was lately invented by Mr. Mudge. See Inhaler.

PULMONUM ANIMA. See Anima.

PULO AKAT, in Geography. A small island in the East Indian sea, near the N.E. coast of Ceram. S. lat. 3° 6'. E. long. 131° 3'. P. Ampal, a small island in the East Indian sea, on the W. coast of Sumatra. S. lat. 6° 44'. E. long. 99° 29'. P. Anam, a small island in the East Indian sea, near the W. coast of Sumatra. S. lat. 5° 40'. E. long. 99° 27'. P. Annor, a small island in the Pacific ocean, seen by captain Carretet in 1767, who called it Current island. N. lat. 4° 38'. E. long. 131° 46'. P. Avro, a small island in the straits of Malacca. N. lat. 2° 57'. E. long. 100° 24'. P. Avro, a small island in the Chinese sea, near the E. coast of Malacca. N. lat. 2° 30'. E. long. 104° 40'. P. Ayer, a small island near W. coast of Sumatra. S. lat. 1° 11'. E. long. 100° 12'. P. Babai, a small island near W. coast of Sumatra. S. lat. 5° 45'. E. long. 100° 3'. Al-fo, a small island in the straits of Sunda. S. lat. 5° 45'. E. long. 106° 10'. P. Baby, a small island in the East Indian sea, near the N. coast of the island of Nyas. N. lat. 1° 27'. E. long. 97°. P. Battoe, an island in the East Indian sea, near the W. coast of Sumatra, about 40 miles in circumference. N. lat. 0° 20'. E. long. 98° 5'. P. Bawo, a small island in the East Indian sea, near the S. coast of Nyas. N. lat. 0° 52'. E. long. 97° 18'. P. Buittango, a small island near W. coast of Sumatra. S. lat. 0° 58'. E. long. 99° 47'. P. Braff, an island in the East Indian sea, of a triangular form, about 20 miles in circumference, near the N. coast of Sumatra. N. lat. 5° 24'. E. long. 95° 18'. P. Brata, a small island near E. coast of Malacca. N. lat. 5° 55'. E. long. 103° 40'. P. Bringen, a small island near W. coast of Sumatra. S. lat. 1° 58'. E. long. 100° 21'. P. Canton, or Pulau Ratan, an island in the Chinese sea, near the coast of Cochinchina. At some distance it bears the resemblance of two islands, being high at both extremes, and low in the middle. N. lat. 15° 10'.
PULPIT
PUL

lat. 6° 18'. E. long. 98° 35'.—P. Pandan, a small island in the fronds of Malacca, near the N. coast of the island of Sumatra. N. lat. 3° 30'. E. long. 98° 57'.—P. Payang, a small island in the East Indian sea, near the E. coast of the island of Bintang. S. lat. 1° 3'. E. long. 104° 53'.—P. Panjiyar, an island in the fronds of Malacca, near the coast of Sumatra, about 150 miles in circumference. N. lat. 1° 6'. E. long. 102° 28'.—P. Peri, a small island in the fronds of Malacca; about 5 miles W. from the city of Malacca. N. lat. 2° 12'. E. long. 102° 6'.—P. Penneu, or Orange island, a small island near the W. coast of Sumatra. Tjim, a small island near the W. coast of Sumatra. S. lat. 1° 42'. E. long. 100° 15'.—P. Timoen, an island in the East Indian sea, inhabited by Malays, found to be furry and infested by commodore Byron, who touched at the island in 1765. The commodore, notwithstanding their hostile appearance, armed with a long knife in one hand, an iron-headed spear in the other, and a dagger by their side, went on shore, and commencing a treaty with them, could merely obtain about twelve fowls, and a goat and kid. His offers of knives, hatchets, bill-hooks, and similar articles, were contemptuously rejected, and they demanded rupees; but the commodore having none, tendered for payment of what he had purchased, pocket-handkerchiefs, which they condescended to accept, reflecting the beat of them. The nature of these people was small; but they were well made, and of a dark copper colour. The island is mountainous and woody; its productions are rice, and the cabbage and cocoanut tree, in great abundance. N. lat. 3°. E. long. 100° 25'.—P. Timoils, a small island in the fronds of Malacca, near the N.E. coast of Sumatra. N. lat. 4° 27'. E. long. 97° 45'.—P. Tooboygan, a small island in Keyler's bay, on the S. coast of Sumatra. S. lat. 5° 45'. E. long. 104° 42'.—P. Toly, a small island in the East Indian sea. S. lat. 6° 58'. E. long. 105° 50'.—P. Tranjen, a small island near the W. coast of Sumatra. S. lat. 1° 6'. E. long. 99° 55'.—P. Tulung, a small island in the fronds of Malacca, near the N.E. coast of Sumatra. N. lat. 3° 51'. E. long. 98° 42'.—P. Vinel, a small island in the fronds of Malacca, near the N.W. coast of Cambod. N. lat. 8° 33'. E. long. 104° 16'.—P. Vito, a small island in the fronds of Malacca, near the N.W. coast of Cambod. N. lat. 8° 52'. E. long. 103° 53'.—P. Way, a small island in the Gulf of Siam, near the coast of Cambod. N. lat. 10° 8'. E. long. 103°.—Alfo, an island about 30 miles in circumference, near the N. coast of Sumatra; 27 miles N. of Acheen. N. lat. 5° 53'. E. long. 95° 33'.—Alfo, one of the Spice islands, in the East Indian ocean. S. lat. 4° 9'. E. long. 150° 26'.

PULPIT, in fruits, the flesh; or that soft and succulent part between the rind and the nucleus or seed.

The pulp of a tree or plant is the parenchyma, which grows and swells by means of a juice, at first very acrid and disagreeable; at length sweeter, and more delicate.

Pulp, in Pharmacy, denotes the soft part of fruits, roots, or other bodies, extracted by infusion or boiling, and passed through a sieve.

Pulp, in Physiology, denotes the fatter, fuller, and most solid part of the flesh.

Some people apply the word particularly to the upper part of the belly, because flabby; and because it is here that they feel animals, to examine whether they be fat. This part the Latins call pulpa, from pulpare, to feel, handle.

PULPITT, PULPITUM, a term now restrained to an elevation, or apartment in a church, whence sermons are delivered.

Some authors derive the word from pulchrum, because people there exposer to open view.

To the observations on pulpit eloquence, which the reader will find under ELOCTION of the Pulpit, and under other heads to which we shall refer at the close of this article, we shall here introduce some reflections that may not be thought inappropriate to the subject, nor altogether uninteresting and uninteresting.

Pulpit eloquence has its advantages and also its disadvantages. It derives advantages from the dignity and importance of its subjects, which, duly considered, must be acknowledged superior to every other. These are in themselves highly interesting, as addressed both to the understanding and the heart; and they admit, at the same time, both the highest embellishment in describing, and the greatest relevancy and warmth in enforcing them. A preacher likewise, in treating these subjects, has often the advantage of addressing a large assembly, of proceeding without interruption, and of being under no necessity of making any extemporaneous replies. He may also previously chuse the theme of his discourse, and make every kind of necessary preparation. To counterbalance these advantages, the pulpit orator, though he has no adversary with whom he is called upon to contend, is not raised and enlivened by debate: and though he chuses his subjects, which are in themselves important and interesting, they are trite and familiar;
vilar; they have often been discoursed by others; they have
frequently recurred to himself in the exercise of his office;
and they do not admit of much novelty and variety in the
mode of treating them. It should also be considered, that
the preacher is very much restricted to abstract qualities,
such as virtues and vices; whereas other popular speakers
prefert persons as well as characters to the view of their
hearers, and hence derive peculiar advantage for interrelling
their attention. Accordingly Bruyere, in his "Meurs de
Sicile," cloths his comparison of the eloquence of the pul-
pit with that of the bar by observing, "that it is more
easy to preach than to plead; but that it is more difficult
to preach well than to plead well." Nevertheless, though
the art of preaching well is of difficult and rare attainment,
Dr. Campbell (Rhetorie, b. i. c. to.) candidly remarks,
that considering how rare the talent of eloquence is among
men, and considering all the disadvantages under which
preachers labour, particularly from the frequency of this
exercise, joined with the other duties of their office, to
which fixed pastors are obliged, there is more reason to
wonder that we have so many instructive and even eloquent
sermons, than that we hear so few. Some indeed have un-
justly argued, that preaching is no proper subject of the art
de eloquence. But true eloquence, which is the art of
placing truth in the most advantageous point of view for
conviction and persuasion, cannot in any department of
oratory be more suitably employed. A regard to this
object is most intimately connected with the successul
execution of the preacher's office; and if any further
reasoning were necefary in so plain a case, we might refer
to the discourses of the prophets and apostles, as models
of the most sublime and presuasive eloquence, adapted both
to the imagination and passions of men. "With regard to
the pulpit," says Dr. Blair (Leäc. vol. ii.), "it certainly
has been a great disadvantage, that the practice of reading
sermons, instead of repeating them from memory, has pre-
valled in England. This may, indeed, have introduced
accuracy, but it has done great prejudice to eloquence; for
a discourse read is far inferior to an oration spoken. It
leads to a different sort of composition, as well as of de-
ivery; and can never have an equal effect upon any au-
dience." We much doubt, however, whether compositions,
delivered from memory, are likely to be more truly elo-
quently and more impressive on the auditors, than those
that are properly read. Perhaps the most advantageous
mode of preaching, with regard to present effect, though very
few excel in it, is that which is wholly extemporaneous:
the preacher having previously formed the general plan of
his discourse, and trusting for enlargement, on mere hints
committed to paper, to the invention of the moment.
But this is a mode of preaching which one could hardly
venture to recommend to young divines, lest by acquiring
an habitual self-command and a facility of off-hand speak-
ing, they neglect to furnish themselves with ample materials
for judiciously varied discourses. A few subje&ts, recur-
ted to again and again, have usually formed the whole flock
of popular extemporary preachers.

"Another circumstance," Dr. Blair observes, "has been
unfortunate. The fe&ties and fanatics, before the Refo-
ratton, adopted a warm, zealous, and popular manner of
preaching, and those who adhered to them in after-times,
continued to distinguish themselves by somewhat of the same
manner. The odium of these facts drove the established
church from that warmth which they were judged to have
carried too far, into the opposite extreme of a studied cool-
ness and composure of manner. Hence, from the art of
peruation, which preaching ought always to be, it has
palled in England, into mere reasoning and instruction;
which not only has brought down the eloquence of the
pulpit to a lower tone than it might justly altaine; but has
produced this farther effect, that, by accosting the pub-
lic ear to such cool and diffilusive discourses, it has tended
to fashion other kinds of public speaking upon the same
model." See Elution, Elocution, Oration, Preach-
ing, Public Sermon, and Public Speaking.

PULPITUM, among the Romans, was a part of the
toal, called also proeminum, or what we now call the
flage, on which the actors trod. Though some fay it was
properly an eminence on the stage for the mufic, or a fugg-
feflion whence declamations, &c. were spoken.

The French use the word pulpitum, pappire, for a reading-
table in a church, library, or the like; those large ones in
churches they properly called latrins.

PULSE.

all the cognizable variations of the pulse to two, viz. quick and slow. (See Dr. Heberden's excellent paper, entitled "Remarks on the Pulse," in the second volume of the Medical Transactions of the College of Physicians; and Dr. Falconer's "Observations on the Pulse," Lond. 1796.) For in the first place, the uncertainty of the healthy standard in individuals, which induced Dr. Falconer to take the trouble of calculating a long series of tables of comparative rates in different persons, necessarily renders the celerity of the pulse a point of considerable uncertainty; not to mention the numerous sources of variety in this respect, from age, strength, time of day, &c., which we shall presently describe; and in the second place, we think, every attentive practitioner, with a very moderate tact, is able to distinguish several other varieties, which occasionally direct his decision as to the mode of practice which he pursues. The distinctions, for instance, of strong and weak, full and small, hard and soft, equal and unequal, regular and irregular or intermittent, are fully very perceptible in many cases of disease; and not unfrequently serve to modify both the diagnosis and the prognosis, as well as the direction of remedies. The degree of celerity of the pulse is, however, the most obvious quality, and is capable of being measured without any of the tact of experience; and it is moreover the most variable quality under every variation of the condition of the body; it becomes, therefore, the principal object of our consideration.

It is not above a century since the pulse was first counted, or a standard of its natural frequency was attempted to be accurately established. Sir John Floyer appears to have been the first who applied a portable instrument to the purpose, beginning with a minute-glass, (see his work entitled "The Physician's Pulfe Watch," 1707,) and it was only during the present age that the general introduction of such instruments among professional men took place. With respect to the natural standard, to which the comparative terms quick and slow must be referred, there has indeed been considerable difference in the statements of different physicians. This standard has been attempted to be inferred from the examination of the pulse in a number of persons in health, by taking the mean of the numbers collectively. The natural pulse of individuals varies considerably, however, from so many circumstances, that there is some difficulty in adjudging this standard. These circumstances have been methodically detailed by Dr. Falconer, and require to be taken into the consideration of all, who would properly estimate the signs and indications afforded by the pulse: they are as follows.

First, such circumstances as arise from bodily organization; and these are, 1. That of sex. The average number of the pulsations in an adult man, in good health, between 30 and 40 years of age, is estimated at about 75 in a minute; but the pulse of women of the same age and condition is somewhat quicker. Kepler, who estimated the mean pulsations of men at 70 in a minute, estimated those of women at 80, or at one-twelfth more; and Dr. Falconer considers the difference to be in about the same proportion, calculating the ordinary pulse of men at 75, and that of women at 84.

2. The temperament. The pulse cauces which produce a quicker pulse in women than in men, probably operate in different temperaments; for those persons, who bear marks of the fanguine habit (which approximates to the female constitution), namely, who have a fair and florid complexion, light-coloured and soft hair, blue eyes, soft and succulent flesh, with considerable sensibility of mind and disposition, have generally a quicker pulse than persons with dark hair and eyes, pale or sallow complexion, firmness of the muscular parts, and, in the mental qualifications, resolution, and steadiness of temper. 3. The stature. It may be questioned whether the difference of stature occasions so much difference in the velocity of the pulse, as the mechanical physicians maintained, though it probably has some influence. Dr. Bryan Robinson has given a table of pulses, according to stature, taking fix feet as the standard, at which height he found the pulse to be 65, and computing upon this rule, which he says was founded upon a great number of observations, that the mean pulses of well-proportioned bodies were to one another, inversely, as the biquadrate roots of the cubes of the lengths of the bodies. Senac held a similar opinion, but his computation was somewhat different. He states the following proportion; namely, at 2 feet, pulse 90; at 4 feet, pulse 85; at 6 feet, pulse 80; and at 7 feet, pulse 70; the last number of which he says was deduced from observation of one hundred men of the royal guards, who were selected for that office on account of their tallness of stature. Haller, however, pays little regard to this opinion, and brings as instances the Swiss people, who are in general tall in stature, and whose pulses are more numerous than this standard. He himself, tells us, was six feet high, and his own pulse beat 78 in a minute.

Secondly, the pulse is varied by the period of life. The variations of the pulse during the progress of life have been minutely investigated by the late Dr. Heberden, who has stated the following inferences. "The pulse of a healthy infant asleep on the day of its birth is between 130 and 140 in one minute; and the mean rate for the first month is 120; for during this time the liver often beats as frequently as it does the first day, and I have never found it beat slower than 108. During the first year the limit is fixed at 108 and 120. For the second year at 90 and 100. For the third year at 80 and 108. The same will very nearly serve for the fourth, fifth, and sixth years. In the seventh year, the pulsations will be sometimes so few as 72, though generally more." From the twelfth year, then, except that the pulsations are much more easily quickened by illness or any other cause, they differ but little from those of a healthy adult, the range of which Dr. Heberden states to be from a little below 60 to a little above 80 in a minute. From an average of five and twenty boys, observed by Floyer, between the ages of twelve and sixteen, the pulse was about 84; in all of them above 80. In stating the average of the pulse of adults, most authors have taken a less extensive range than Dr. Heberden. Sir John Floyer, who employed confiderable industry in the investigation of this matter, found the average of eight healthy persons, from twenty to forty years of age, to be somewhat more than 73 in a minute; and he observes, (Physician's Pulfe-Watch, p. 40, and 74,) "the most natural pulse will have from 70 to 75 beats in a minute in perfect health." Senac also estimates it at the same rate exactly (see his Traite de Curyr); and Dr. Bryan Robinson found, after an accurate examination of two healthy persons for many weeks together, and at no less than sixteen intervals, of an hour each, daily, that the average number of the pulse of one of them was 73, and of the other 74 in a minute. Dr. Falconer, after comparing all the authorities with his own observations, is inclined to consider 75 as the average of an adult healthy pulse. It is not sufficiently ascertained, whether any material alteration is produced in the pulse by advanced age. Haller thinks that the pulse in old persons is slower than in the middle age; but Dr. Falconer points out some strange mistakes which he has committed, in quoting his authorities. Floyer has given a list of thirteen old persons, in whom the pulse on an average was exactly 70 in a minute. Dr. Fal-
Dr. Falconer is disposed to believe, though not very confident in his opinion, "that the pulse in a healthy person becomes gradually flower from about forty-five years of age to about sixty, after which period it begins again to grow quicker, and to become, as several other circumstances in the system do also, more resembling that of children. But to this," he adds, "there are undoubtedly many exceptions." P. 23.

Thirdly, the pulse is varied by the time of day. The variation of the pulse at different times of the day, even in perfect health, is well known. Whether this variation be the effect of the excitement, produced by the food and drink, exercise, and employment of mind, in the course of the day, or from whatever cause it may arise, it is generally observable, that the pulse is flower in the morning, and somewhat accelerated in the afternoon and evening.

This change is particularly obvious in persons of feeble habit and delicate health, in whom a slight tendency even to feverishness is often present in the afternoon; and, in febrile complaints, notwithstanding the utmost care is taken to prevent the access of every irritating cause, the acceleration of the pulse is very commonly aggravated in the evening. Sir John Floyer observed, that his own pulse in the morning falling beat 76 times in a minute, a little before dinner 77, and after dinner 95 times. Senac, in his Traité du Cœur, has left a few observations on the same subject; according to him, the pulse which was 62 in the morning, rose to 86 after dinner. Haller also found, that the pulse, which in the morning beat 75, in the evening, towards the time of rest, beat 82. (Opera Minora, vol. i. p. 186.)

Dr. Bryan Robinson, after stating some very accurate observations on this subject, drew this inference, "that the pulse is flower in the morning than at any other time of the day; that it grows somewhat quicker before breakfast, and a little more so after it; that it grows flower again before dinner, and quicker immediately after dinner, and that the quickness acquired by this meal continues for about three or four hours, and then abates a little, and continues in that state without any considerable change, in bodies which eat and drink little at night, till they go to rest." Robinson's Animal Economy, p. 148.

Forthwith, this, however, leads us to the consideration of the effects of food and abstinence on the pulse, to which the variations at different times of the day may perhaps be partly attributed. It is universally acknowledged, indeed, that taking food accelerates the pulse, while fasting retards it; and many facts in proof of this are recorded by Floyer, Robinson, Haller, and others; but the degree of acceleration produced, is very different in different individuals, being the greatest in persons of delicate and irritable habits.

Fifty. The pulse is varied by the state of the stomach, with respect to rest or activity. Observations have been sufficiently numerous to prove, that during sleep the pulse is usually flower than when a person is awake, as might indeed have been anticipated from the consideration, that various causes of excitement, both mental and corporeal, cease to operate during that condition. Dr. Falconer says, "I have repeatedly found the pulse at first waking, not to exceed 61, 62, or 63 beats in a minute, which in a short time, without any alteration of posture, rose to 66, 67, or 68." This slowness, however, will not be observed, if a person has taken plentifully of food or stimulating liquor, a little time before going to sleep, or if he sleeps in a close and hot room, or under a great load of bed-clothes; but it will invariably occur, if the stomach is not loaded, the air pure and cool, and the bed-clothes not more than sufficient to preserve a comfortable warmth.

Motion and exertion of every kind is found to quicken the pulse; even the little effort that is made to preserve the body in a standing position is sufficient to produce a very perceptible increase of the pulse above what it was in a sitting or recumbent posture. Dr. Bryan Robinson has given a proportion of relative increase upon change of position and motion, as follows: lying down, pulse 64, sitting 68, standing 78, walking at the rate of two miles an hour 78, at the rate of four miles an hour 100, running rafed it to 140, 150, or more. Speaking is a kind of exercise which has a considerable effect upon the pulse. Every physician must have observed the pulse quickened during his examination of it several beats in a minute by a few words spoken at that time, more especially in a feeble frame; hence they generally recommend silence to their patients during such examination.

Mental agitation of every kind appears to accelerate the pulse, but with this difference, according to the observations of Dr. Falconer, that the depressing passions, as fear, anxiety, and grief, tend at the same time to render it weaker, while the stimulating passions, as joy and anger, make it more full and firm. Floyer mentions an instance of the pulse being excited to 104 beats in a minute by anger, and that it did not return to the natural standard in three or four days.

Lastly. The pulse is varied with the temperature of the body. The application of heat, exceeding the natural temperature of the body, accelerates the pulse. A very hot room, or sitting near a fire, will increase the number of its beats. In physiological experiments, indeed, it has been ascertained that the application of heat will renew the motion of the heart (or punctum falliens) in an egg, after it had ceased for a considerable time. On the other hand, the gradual influence of cold air upon a body that has been over-heated diminishes the number of the pulse. The sudden shock of the cold bath, indeed, quickens the pulse considerably; but in this case the sensation becomes a stimulus to the system, and excites both quickness of pulse and an actual glow or evolution of heat. Sir John Floyer has given a table of the pulses of men in different latitudes, making them 120 in a minute under the equator, and 30 at the north pole; but the data upon which this table is formed appear to be questionable. See his Physicist's Pulse-Watch, vol. i. p. 298.

Before we could derive any information from the pulse, relative to the degrees and nature of distresses, it was absolutely necessary to be acquainted with the foregoing observations in respect to the common standard, and the common causes of variation in health; otherwise we should be liable to many errors in investigating the state of the pulse. Against these ordinary causes of the fluctuation of the pulse, indeed, the physician must be always upon his guard even in disease. The advice of Celsus upon this subject must be followed as long as the pulse is an object of medical attention. After enumerating many causes of its variation, he mentions apprehension, anxiety, and other mental emotions. Therefore, he says, "when the physician first enters the room, if he be a skilful man, he will not immediately apply his fingers to the patient's wrist, but he will first sit down with a cheerful countenance, and make some general inquiries; and if he observes any alarm in the patient, will relieve him by encouraging remarks, and then will proceed to examine the pulse. "Now if the sight of the physician is sufficient to quicken the pulse, how easily may a thousand other circumstances disturb it!" (Celsus, de Medicina, lib. iii. cap. 6.) In feeling the pulse, the two principal qualities to be ascertained are the quickness or frequency (which we deem synonymous), and the strength of the pulsations.
The former, of course, is easily determined by a stop-watch; but the latter requires somewhat of tact and experience; for the degree of strength in the pulse is very different in individuals of different sex, temperament, and vigour, in health. In order to ascertain the force of arterial pulsation, the vessel should first be pressed gently; and, if any doubt arise, it should be strongly compressed by two or three fingers, until no pulsation is felt, and then the fingers should be gradually relaxed until the comparative force with which the pulsation returns may be estimated; the degree of compresibility of the pulse, or the facility with which the pulsation may be entirely stopped, affording a tolerably good comparative notion of its strength. The degree of obesity of a patient should be attended to in estimating the strength of the pulse; for very fat persons have naturally a feeble pulse, and the pulsation is felt less distinctly through a layer of fat. A strong firm pulse is concurrent with high health; for the heart contracts with vigour, when filled with healthy blood; but the strongest pulse, though scarcely compressible under the finger, has some degree of softness, if healthy. If there is a hardness in its beat, if it strikes the finger like a tenent cord or wire, it shews a tendency to inflammatory disease, a phlogistic diathesis, as it has been called, conflating of a morbid fullness and tone of the arterial system. When with this hardness there is increased frequency, and some local pain, inflammatory fever is present. Some writers, indeed, carrying their dread of refinement in the discrimination of pulses too far, make light of all the distinctions, save of frequency; but we are persuaded that those who question the distinction between the soft, fluent, and undulating impression of a healthy pulsation, and the smart stroke, even when feeble, of an inflammatory pulse, must be somewhat deficient in the sensibility of their digital nerves, or in the attention which they bestow upon the subject.

The principal practical use that is made of this distinction between a hard and soft pulse, which is at the same time quick, is its indication of the propriety of blood-letting, or the contrary, in acute diseases. And if those who have denied the existence of the distinction, only intended to afford that such a distinction is not a sufficient guide in practice, they were in a great measure correct. For after all that can be observed of the pulse, we must accede to the statement of Celsus, that it is extremely deceptive, "fallacissima res," and that it is only when taken into consideration in conjunction with the other symptoms of a disease, and with the general state of the constitution of a patient, that it can be relied upon implicitly as a guide in the administration of remedies. But in conjunction with the other symptoms, the continuance or cessation of that smartness and cord-like tension in each pulsation will be an important index, as to the continuance or cessation of inflammatory action in acute disease, and therefore as to the extent to which evacuations ought to be carried.

In all diseases accompanied by pain, and especially when the pain is extremely severe, the state of the pulse is commonly the chief, sometimes the only index, by which the nature of the pain, whether it be inflammatory or spasmodic, is to be ascertained. (See Pain.) This is sometimes of extreme importance; because a large dose of opium, which will speedily remove a spasmodic pain, will not only not alleviate, but will often greatly augment an inflammatory pain, and leave the disease to itself, at the only time when the active remedy, blood-letting, was likely to be beneficial. Hence, pain, however violent, does not always quicken the pulse, and never produces that hardness in its beats which we have above alluded to. An able observer, the late Dr. Heberden, has remarked; "it is often supposed that great pain will quicken the pulse; I am more sure that mere pain will not always do it, than I am, that it ever will. The violent pain occasioned by a stone passing from the kidneys to the bladder is often unattended with any quickness of the pulse; and the excursive and almost intolerable torture produced by a gall-stone passing through the gall-ducts never once quickened the pulse beyond its natural pace, as far as I have ever observed, though it be a disorder which occurs so frequently; and this natural state of the pulse, joined with the vehement pain about the pit of the stomach, affords the most certain diagnostic of this illness. I have seen a man of patience and courage rolling upon the floor and crying out through the violence of this pain, which I was hardly able to pull into a tolerable state with nine grains of opium given within twenty-four hours, to which he had never been accustomed, and yet his pulse was all the time as perfectly quiet and natural, as it could have been in the sweetest sleep of perfect health." (Med. Transact. vol. ii. p. 32.) In such cases, without examining the pulse, a careless practitioner might proceed to a copious blood-letting, which might be injurious to a feeble habit, and would be productive of no relief; whence, on the other hand, if a violent inflammatory pain in the bowels were suppos'd (from not attending to the pulse, which would, in this case, be quickened,) to be merely spasmodic, as in colic, and no bleeding were employed, but a large dose of opium administered and repeated, no relief would be procured, and the inflammatory disease would probably pass on rapidly to a fatal suppuration or gangrene.

When gangrene has commenced, there is commonly a sudden cessation of the pain, and patients themselves and their attendants imagine that the pulse at this time will generally explain the real condition of the patients; for it will be found either quick and extremely feeble in its beats, or tremulous rather than pulsating, or probably altogether imperceptible at the wrist, implying that the powers of life are sinking, and that death, and not recovery, is impending.

With respect to the degree of disease and of danger, indicated by increased celerity in the pulse, we cannot do better than quote some of the observations of the late experienced Dr. Heberden. He says, "if the pulse of either of a child or of an adult be quickened so as to exceed the utmost healthy limit by ten in a minute, it is an indication of some little disorder. But a child is so irritable, that during the first year a very light fever will make the artery beat 140 times, and it will beat even 160 without danger; and as there begins to be some difficulty in counting the pulse when the motion is so rapid, the throst, quickness of breathing, avertiveness from food, and above all the want of sleep, enable us better than the pulse to judge of the degree of fever in infants." Indeed, to shew how little can be determined by the state of the pulse in infants, Dr. Heberden adds, "a child of two years will die of an inflammatory fever, though the artery beats only 144 times in a minute; and I have seen a child of four years recover from a fever, in which it beat 156 times; and one of nine, where it beat 152.

"In adults ill of an inflammatory fever, the danger is generally not very great, where the beats are fewer than 100; 120 shew the beginning of danger, and they seldom exceed this number unattended with delirium. In the patient does not die. There are two exceptions to this observation: the first is, that before some critical swelling or deposit of matter begins to shew itself in fevers, the pulse will be so rapid and indistinct as hardly to admit of being counted.
PULSE.

counted; but I have known it certainly not less than 150, and yet the patient has recovered. Acute rheumatisms afford a second exception, in which the artery will beat above 120 times without any fort of danger; and in both these cases we may remark, that the appetite and fenes and sleep and strength are put lefs out of their natural state, than where the life of the patient is in immediate danger.

"Though it may be difficult to count above 140 strokes in a minute, if they be unequal in time or in strength, yet where they have been very distinct, I have been able to count 180." Some authors have denied that the pulse can be distinctly counted when it exceeds 160; and in common fevers, before it reaches that degree of celerity, it is generally so feeble that its beats are very indistinct; there is one disease, however, in the latter stage of which the pulse retains a sharpness combined with extreme velocity, which renders it perfectly countable, even above the number stated by Dr. Heberden. We have distinctly counted 190 beats in the last stage of hydrocephalus; and Dr. Whytt, who observes that no patient dies of this disease, while his pulse remains under 150, in one case counted it at 210 on the day of death.

On the other hand, disease and danger are likewise indicated by a preternaturally slow rate of the pulse, which is usually connected with some degree of compaction of the brain. Even in children, as Dr. Heberden remarks, "if the pulse be 15 or 20 below the natural standard, and if there be at the same time signs of consideriable illness, it is a certain indication that the brain is affected, and consequently such a quiet pulse, instead of giving us hope, should alarm us with the probability of imminent danger." In adults, whenever the pulse is reduced to 50, or lower, if there be also a lethargic disposition, or flupor, danger of an apoplectic or paralytic attack is to be apprehended. During an attack of apoplexy, the continuance of the slowness of the pulse, together with the infensibility, heavy, flow, and stertorous breathing, and coma, is in the highest degree unfavourable, as indicating the great extent of the compaction of the brain. The pulse, in these cases, is often under 40, and sometimes less than 30 in a minute. The operation of large doses of digitalis, and some other narcotic vegetable substances, also renders the pulse remarkably slow. The sudden change from quick to slow in the pulse, when it occurs in disease, is therefore to be considered as indicative of an unfavourable termination; if the other bad symptoms continue at the same time unalleviated: it is a proof not of the decrease of the disorder, but of the diminished irritability of the patient, the disease being transferred to the brain, and coma, palsy, apoplexy, or death, is to be apprehended.

Of the many fanciful variations of the pulse, which many writers a century or two ago indulged themselves with describing and naming, and with pointing out the indications to be deduced from them, as they are altogether incomprehensible to ordinary observers, we shall say nothing, referring those who have any desire to investigate the subject to the works of Borde, Nehel, Bellini, Mascaria, and if they please to the various treatises of Galen.

We must observe, however, with Dr. Heberden, that though in many cases an useful index of the state of the health, yet the pulse is by no means a certain guide in all, and without a due consideration of concomitant symptoms may greatly mislead; for there are many anomalies observable respecting it. A good pulse, as that author observes, (which is sometimes found in comatose fevers,) with delirium, rapid loss of appetite and strength, sleeplessness, quickness of breathing, and great thirst, would afford very little hope; and a bad one without any of these might be

harmless. "I remember two young women," Dr. Heberden says, "ill together with others in the same house of the same infectious fever; the pulse of one of which was never above 84, and the pulse of the other was always extremely quick, and I once counted it when I thought her dying 180. Both of them recovered, and the latter quite beyond my expectation.

"Some books," Dr. Heberden remarks, "speak of intermittent pulses as dangerous signs, but I think without reason; for such trivial causes will occasion them, that they are not worth regarding in any illness, unless joined with other bad signs of more moment. They are not uncommon in health, and are perceived by a peculiar feel at the heart by the persons themselves every time the pulse intermits." We have generally considered these intermittent pulses as of dyspeptic origin, and have seen them removed, in fevers, by a purge. Where the pulse intermits, and is very unequal in its beats, and there is at the same time palpitation of the heart, oppression of the breathing, lividity of countenance, or other ferious symptoms, then the intermission is probably one among the signs of some affection of the heart; but in ordinary cases, occurring with symptoms of indigestion, or flight feverishness, it is perfectly void of danger. It is curious, indeed, that irregularities of the pulse are sometimes habitual, and disappear only with good health. Dr. Heberden says, "many persons will likewise have unequal pulses without any other sign of ill health. I have met with two who, in their best health, always had pulses very unequal, both in their strength and the spaces between them; and upon their growing ill, their pulses constantly became regular; and it was a never-failing sign of their recovery, when their arteries began again to beat in their usual irregular manner."

Med. Tran.

Pulse is also used for the stroke with which any medium is affected by the motion of light, sound, &c. through it.

Sir Issac Newton demonstrates, lib. ii. prop. 48. Princip. that the velocities of the pulses in an elastic fluid medium (whose elasticity is proportionable to its density) are in a ratio compounded of half the ratio of the elastic force directly, and half the ratio of the density inversely: so that in a medium whose elasticity is equal to its density, all pulses will be equally swift.

Pulse, in Agriculture, a term applied to all leguminous plants, as peas, beans, vetches, lupins, &c. Many of these are highly valuable as food, and for being made into hay.

And all the species and varieties of pulse afford great abundance of excellent manure when turned into the soil, in the state in which nature presents them. The custom of ploughing in green succulent plants of this kind is very ancient. "All the Roman writers commend it highly. Columella, particularly, advises lupins as a manure, which, if cut down and turned in while green, will have as good effect as the best and strongest dunging whatever. They may be sown upon poor land about the middle of September, and be ploughed in before they attain their full growth. In gravelly soils they should be cut down after they have put forth their second flower; and in strong lands, when a little more advanced. In the former of these grounds they are turned in while young and tender, that they may quickly rot; and in the latter, are let stand till they grow stronger, that they may produce a better effect on the stiff clods of earth, and render them more mellow and friable. Peas, beans, lupins, vetches, and other succulent plants, have also been strongly recommended by the older writers on husbandry, as excellent manures, especially for sandy ground. These plants en-
rich the earth greatly if ploughed in either green, or when in bloom. In strong land they are advised not to be turned down till the pods begin to harden.

Pulse Crops, any of those crops which have been just noticed. In improved husbandry they are now seldom cultivated with the view of being turned in as manure, but as a row or green crop, for the purpose of cleaning and improving the land, being mostly interposed between those of the white corn kind, so as to prevent the necessity of having so frequent recurrence to the more uneconomical practice of naked fallowing. In this way they are found highly beneficial. And Lüter has recommended for the improvement of sandy, light ground, or any clay well fended, all plants of the pulse or pea kind, and particularly, upon experience, the wood vetch, which, besides its being perennial, (at least with respect to its roots,) and its thriving even in woods and among bushes in almost every country, has those qualifications, that it shoots out a thousand roots far and wide, and spreads itself under ground, like quick-grass; whilst it is so rampant above ground, that it will climb a fathom and a half upon measure, and preferre itself in spite of weeds or drought. It may be set as well as fown, in furrows. For the former of these purposes the roots may be dug up in September, which is also the time for gathering the ripe seed. The growth of the plants will be greatly advanced by fetting their roots; for the older they are, the stronger, more numerous, and fuller of buds their shoots will be. He fowed in the latter end of March the seed which he had gathered in September, and had that year a very great increase, the bed being thick covered over with grass above two feet high: but it did not flower that year. He reckoned that one pease had put forth above thirty shoots in August of the first year. In the second year it flowered by the middle of June, and bore a wonderful crop, the roots being innumerable. He has observed this pease very common in all the mountains as well as plains of this country where bushes or hedges are. Both the pease and gras are very sweet, and very agreeable to cattle, as he has found on trial. See Vetch.

But buck-wheat and vetches are the two plants most commonly fown in this country for being turned in as manure. The best time for ploughing them in is when they are coming into bloom; being then in their most succulent state. Some farmers turn down their second crop of clover to enrich the land for wheat in the autumn. This should be done early enough to give the plants sufficient time to putrify thoroughly before the grain is fowed; otherwise it might prove prejudicial.

However Mr. Elliot, of America, prefers millet to every other plant for green dressing of land, on account of the cheapness of the feed, and the largeness of the flanks and leaves, which must afford a good coat to turn in when ploughed. An old farmer who had long been in the practice of green dressing, assured him that he had increased the strength of his land to a great degree, in a few years, by the following method: After his oats were harvested, he added a little feed to the scattered grains, and then ploughed them in. Towards the end of September, he ploughed in the green oats, and fowed rye; and the next summer, when the rye was well grown and full of sap, he ploughed that in at the usual sowing season, then fowed wheat, and always had a large crop. See Beans, Buck-wheat, Pease, &c.

Pulse-Glys, a well-known instrument invented by Dr. Franklin, and serving to check the quick evaporation which would take place if we had no atmosphere. This is a small tube with a bulb at each end, exhausted of its air, and containing a small quantity of spirits of wine. If this instrument be held floating, with one end in the palm of the hand, the heat of the hand will quickly cause the spirit to boil, but the vapour rising to the other end becomes condensed as soon as it is in contact with the cold glass. This shews that a very small degree of heat would be sufficient to evaporate most fluids, if we had no atmosphere. It also shews, that evaporation produces cold; for at the instant when the spirit begins to boil, a sensation of sudden cold is felt on that part of the hand where the bulb rests.

PULSIOLOGIUM, a name given by authors to a pulse-watch, or instrument to measure the celerity of the pulse. Sanctorius was the first inventor of this machine; but several have since spoken very largely in favour of it, and sir John Floyer wrote a treatise on this subject.

PULSION, formed from pello, I drive, the act of driving or impelling a thing forwards.

PULSLATER BAY, in Geography, a bay on the S. coast of Wales, and county of Pembroke; two miles N. of St. Gowen's Head.

PULSNITZ, or PULSNIZA, a town of Lusatia, on a river of the same name, with a citadel; 15 miles N. E. of Dresden. N. lat. 51° 10'. E. long. 13° 30'.

PULST, a town of Bavaria, in the bishropic of Bamberg; two miles S.W. of Mark Schorgart.

PULSUS LATUM. See Latus Pulsus.

PULTAVA, in Geography. See PULTAVA.

Gen. Ch. Cal. Perianth inferior, of one leaf, permanent, bell-shaped, two-lobbed; the upper lip in two deeply separated, broadish segments; lower in three narrower ones, about the same length; with a lanceolate appendage at each side, between the two lips, sometimes at the base of the tube. Cor. papilionaceous, of five petals, with claws; standard obovate, emarginate, ascending; wings two, half-ovate, shorter than the standard, with an angle at the upper edge; keel as long as the wings, of two obovate petals, cohering by their lower edge, with an angle, toward the base, above. Stam. Filaments ten, separate, awl-shaped, nearly equal, declining, rather shorter than the keel, as others small, roundish, two-lobed. Pilf. German superior, sessile, ovate, with rudiments of two seeds; style awl-shaped, ascending; stigmas simple, acute. Peric. Legume a little longer than the calyx, ovate, acute, turgid, of one cell and two valves. Seeds two, roundish-kidney-shaped, on short stalks, inflected into the upper edge of each valve, near the base, "with a lobed notched appendage." Brown.

Ell. Ch. Calyx five-leafed, two-lobbed, with an appendage at each side. Corolla papilionaceous; wings shorter than the standard. German sessile. Style awl-shaped. Stigma acute. Legume of one cell, with two seeds; their appendages lobed and notched.

clothed with crowded, rather spreading leaves, an inch long, narrow, deep green, many fringed in an early state, on short flat stalks, with intransalicious, fibrous, deeply cloven, acute, chaffy stipulas. Flowers of a golden yellow, in large, terminal, solitary heads; their standard marked with a purple ring. Calyx reddish; its appendages inferted about the middle of the tube. Legume brown, inviolate below with the withered calyx, and crowned with the recurved style.

3. P. palaacea. Chaffy Pultenaea. Sm. Tr. of Linn. Soc. v. 9. 246. Wild. n. 2. —Leaves linear, pointed, revolute; recurved at the point. Stipulas solitary, two-ribbed, sheathing, membranous, torn. Heads of few flowers. Gathered in New South Wales, by John White, M. D. This shrub is much smaller, and more branched, than P. stipularis; with small, but very numerous, heads of yellow flowers, whose long pointed bracts rise much above them. Leaves silky beneath, with close-prefiled hairs, but not fringed. Stipulas dilated, thin, membranous, white, with two brown ribs; their teeth, I am told, and are very conspicuous, though liable to be injured, and partly obliterated, by time and weather.

4. P. elliptica. Elliptical Pultenaea. Sm. Tr. of Linn. Soc. v. 9. 246. —Leaves elliptical, concave, rather hairy. Stipulas solitary, two-ribbed, villous, imbricated. Flowers axillary. Native of Port Jackson, New South Wales. The leaves differ from all other known Pultenaea, with simple stipulas, in their elliptical form. They are concave above; convex, and rough with prominent points, beneath; their margin now and then furnished with long woolly white hairs. Stipulas intransalicious, simple, closely prefiled to the branches, and so long as to lap over each other; their shape likewise is elliptical, with two ribs and an intermediate furrow, and they are shaggy with white hairs. Flowers deep yellow, axillary, but it crowded about the tops of the branches as often to seem terminal and capitulate, at least till the fruit advances. Appendages attached to the base of the calyx, whose teeth are long, slender, and hairy.

5. P. linophylla. Flax-leaved Pultenaea. Schrad. Hort. Hannov. 28. t. 18. Wildl. n. 3. Sm. Tr. of Linn. Soc. v. 9. 247. Ait. n. 5. —Leaves linear, abrupt with a small point, hairy. Stipulas minute, in pairs. Bracteas ovate, shorter than the calyx. Flowers capitulate. From the same country. It first flowered at Kew, in January 1791, and was given us by Mr. Aiton. Its habit is more upright and wand-like than P. palaacea, n. 3, the leaves somewhat angular and dilated at their apex, as well as slightly pointed. The minute separate stipulas, shorter than the foot-stalks, and the ovate blunt bracts, which, instead of rising above the flowers, are shorter than the calyx, abundantly distinguishes this species from all the foregoing.

6. P. cotyta. Obverse-leaved Pultenaea. Sm. in Ann. of Bot. v. 1. 502. Sm. Tr. of Linn. Soc. v. 9. 247. Ait. n. 4. —Leaves linear, abrupt, pointted, smooth. Stipulas minute, in pairs. Bracteas ovate. Flowers capitulate. —Native of New South Wales. Said to have been introduced at Kew, by Sir J. Banks, in 1789. It flowers in the green-house in April and May. This is very like the last in habit, but the leaves are quite smooth, and moreover not dilated at their apex. We have found the bracteas shorter than the flowers; but Mr. Brown characterizes them as rather longer than the calyx; so that it appears they are variable in this respect.

7. P. seabra. Rough-leaved Pultenaea. Brown in Ait. n. 3. —Leaves wedge-shaped, revolute, abrupt, with a brilly point; rough above; villous beneath. Stipulas in pairs, fuscous, recurved. Flowers capitulate. Found in New South Wales, by Dr. Brown, and sent to Kew, in 1805, by Mr. G. Cailey. It blooms from May to July. There are said to be but few flowers in each head.

8. P. obcordata. Heart-leaved Pultenaea. Andr. Repof. t. 574. Brown in Ait. n. 2. —Leaves invercly heart-shaped, abrupt, smooth, with a spinous point. Stipulas minute, in pairs. Flowers capitulate. Gathered in Van Diemen's island by Mr. Brown. Sent to Mr. Lambert from thence by Mr. Littlejohn, in 1808. It is a garden-plant, flowering in summer, and differs from the following chiefly in the obcordate shape of its leaves, which are nearly half as broad as they are long. The flowers are large and handsome, yellow, variegated with purple. Their appendages stand about the middle of the calyx.

9. P. daphnoides. Daphne-like Pultenaea. Sm. in Ann. of Bot. v. 1. 502. Sm. Tr. of Linn. Soc. v. 9. 247. Andr. Repof. t. 98. Curt. Mag. 1. 1802. Wildl. n. 6. Ait. n. 1. —Leaves obovate, smooth, with a spinous point. Stipulas minute, in pairs. Flowers capitulate. Bracteas ovate, shorter than the calyx. —This was among the first plants received from New South Wales; we had specimens from Dr. White in 1789. It was also raised from seed in the gardens soon afterwards, and has attracted general notice by its fine and beauty, veining in thole particulars with P. stipularis, n. 1. The leaves are about thrice as long as broad, obovate; not obcordate like the last. Stipulas separate, very small. Flowers large, yellow, with a purple keel, and purplish-brown hairy calyx, forming large heads at the tops of the branches.

10. P. flexilis. Shining-leaved Pultenaea. Sm. in Ann. of Bot. v. 1. 502. Sm. Tr. of Linn. Soc. v. 9. 248. Ait. n. 9. —Leaves linear, somewhat obovate, flat, with a small point, quite smooth, as well as the calyx. Stipulas longer than the foot-stalks. Flowers axillary. —Native of New South Wales, where the late Col. Paterfon is said to have first discovered it. Sir Joseph Banks sent seeds to Kew, about the year 1781. It flowers in the green-house in spring, and is an elegant, slender, rather drooping shrub, quite smooth in every part, with shining leaves, of a dark green, and copper-coloured branches. The foliage which usually attains the flowers is sometimes deficient, so that the latter become in appearance raceme, but the stipulas are always present. The perfectly smooth-fided calyx distinguishes this species from all the rest.

11. P. villiofa. Villous Pultenaea. Sm. in Wildl. n. 5. Ann. of Bot. v. 1. 503. Sm. Tr. of Linn. Soc. v. 9. 248. Ait. n. 8. Sims in Curt. Mag. t. 967. —Leaves elliptical, concave, hairy, as well as the stem and calyx. Flowers axillary, —From the same country, sent by Dr. White among his earliest communications. This is a dense bushy shrub, with numerous short leafy branches, and copious axillary villous yellow flowers. The leaves are scarcely half an inch long, oval, concave, pointted, clothed with prominent hairs; and the branches are more densely villous. Stipular longer than the foot-stalks, often connate. No bracteas are observable. The appendages of the calyx originate from near its base, and are longer than its tubular part, having a more leafy appearance than in any other species of Pultenaea. Mr. Andrews has published under the name of P. villiofa, t. 309, a very
a very different shrub from the above, constituting a new and distinct genus, which the writer of the present article has named Aotus villoza, in Ann. of Bot. v. t. 504, and which is figured under that appellation in Curt. Mag. t. 949.

PULTENAY, Richard, in Biography, a distinguished literary botanist and practical conchologist, as well as an able physician, was born at Loughborough, Feb. 17, 1730. He first settled as a surgeon and apothecary at Leicester; but having been educated as a Calvinistic disfitter, the good Chriftians of that town, who chanced to have different prejudices, of course gave him but little support. He struggled against pecuniary difficulties with economy, and shielded his peace of mind against bigotry, in himself or others, by looking "through Nature, up to Nature's God." His remarks and discoveries were communicated first to the Gentleman's Magazine, in 1750, as well as several subsequent years; and he intermixed antiquarian studies with his other pursuits. His botanical papers printed by the Royal Society, on the Sleep of Plants, and the Rare Plants of Leicestershire, procured him the honour of election into that learned body in 1762. In 1764 he obtained a diploma of Doctor of Physic from Edinburgh, even without accomplishing that period of residence, than uflually required, and now indispensaible; and his thesis on the Cineboma officinale simply justified the indulgence of the university.

Soon afterwards, Dr. Pulteney was acknowledged as a relation by the earl of Bath, who had moreover imbued a favourable opinion of his talents; which circumstances induced him to attach himself to that nobleman, as travelling physician. His lordship unfortunately died soon after, on which the subject of our memoir, becoming at a loss for a situation, hesitated whether to settle at London or elsewhere; but he soon decided in favour of Blandford in Dorsetshire, where there happened to be a vacancy. Here he continued in great reputation, and extensive practice, till his death, which happened on the 13th of October 1801, to the deep regret of all who knew him, in the 72d year of his age. His decease was an inflammation in the lungs, of only a week's duration.

Dr. Pulteney married, in 1770, Miss Elizabeth Galton, of Blandford, a lady who bore him no children, but whose society and attentiments contributed very essentially to his happiness, and who has in every respect proved herself worthy of her amiable and distinguished husband. His remains were interred at Langton, near Blandford, a tablet to his memory having been placed, by his widow, in the church of the late-mentioned town. This monument is decorated with a sprig of the Pultenaea sapulonis, fee that article; but in obedience to the strict commands of the deceased, the inscription is of the simplest kind.

As an author, Dr. Pulteney was conspicuously distinguished, by his General View of the Writings of Linnaeus, and his Sketches of the Progress of Botany in England. The former, published in 1782, in one volume 8vo., has contributed more than any work, except perhaps the Travels of Stillingfleet, to diffuse a taste for Linnaean knowledge in this country. It proved a very popular book, and a new edition was soon called for. This however did not appear during the author's life; but has been published by his learned and much-valued friend Dr. Maton, who has prefixed, to this handsome quarto, portraits of Linnaeus and his biographer, with a life of the latter, to which we are principally indebted for the above particulars. A translation of Linnaeus's celebrated manuscript diary of his own life is subjoined. Of this we have spoken in its proper place. See LINNAEUS.

The "Sketches of the Progress of Botany," making two octavo volumes, appeared in 1790, but did not become so popular as the Account of Linnaeus. These volumes, nevertheless, abound with original and valuable information; nor is it any reproach to the memory of their intelligent author, that they do not contain, as he was well aware, all that might have been collected on every subject. Their most learned readers will ever be more sensible of their merits than their defects.

Dr. Pulteney had been associated with the Linnaean Society, soon after its first institution, and he ever retained a great attachment to that body, as well as to its founder. Several of his papers appear in the Transactions of the Society; and he gave a final proof of his regard, in the bequest of his valuable museum of natural history. He stipulated that his collections should always be kept separate from any others which the Society might possess; and he provided that it should be at the option of the members, either to keep this museum entire, or to dispose of it, in order to raise a fund, whose interest should be expended annually in a medal, for the best botanical paper read before the Society in the course of the year. It was without hesitation determined, that these treasures should be preferred entirely, as the best and most useful memorial of a benefactor to science, to whom a large portion of this corporate body were individually and strongly attached. Few men have enjoyed more entirely the respect and affection of his acquaintance than Dr. Pulteney. An air of urbanity and gaiety was diffused over his countenance and manners, which bespoke the simplicity, candour, and liberality of his mind. His ardour for science was unbounded; and as lively at the close of his life, as at the beginning of his literary career. His religion was unaffected, and devoid of bigotry or intolerance; the only feelings which he contemplated without sympathy or indulgence. His conversation, like his morals, was spotless; and his cheerfulness flowed from the never-failing spring of a benevolent and honest heart. Pulteney's Works. Maton's Memoirs of Dr. Pulteney, prefixed to his View of the Writings of Linnaeus.

PULTENAY's Island, in Geography, an island in the Mercurian archipelago, of an oval form, about eight miles in circumference. N. lat. 10° 40' N.

PULTURA, formed from pulvere, to knock, to ask, in our Old Law Books, denotes a previous demand or examination: on account of the monks, who, before they were admitted into the monasteries, pulsilant ad fores, knocked, at the doors for several days. "Et vole, ut fini quieti de omnibus caulis, et querelis, et platicis bullivorum et prepositorum hundredi, et pulsa forestarum, i.e. from the examination of serjeants: "et de rewarde forestarum," i.e. the vitiolation of the forests.

PULTUSK, in Geography, a town of the duchy of Warsaw, late in Masovia, on the Narew; 25 miles N.N.E. of Warsaw. N. lat. 52° 36'. E. long. 21° 10'.

PULVERARIA, in Botany, so named from its powdery habit, a genus of Lichenes in the Methods of professor Acharians, subfusively sunk in his Lepraria. See LICHENES.

PULVERATICUM, in Roman Antiquity, the fee paid to surveyors for their trouble; also a sum exacted from the provincial cities by their garrison.

PULVERIZATION, Pulverizatio, the art of pulverizing, or reducing a dry body into a fine powder. This is performed, in friable bodies, by pounding or beating in a mortar; but to pulverize malleable ones, other methods must be taken. To
To pulverize lead, or tin, the method is this: rub a round wooden box all over the inside with chalk; pour a little of the melted metal nimbly into the box, when, shutting the lid, and shaking the box briskly, the metal will be reduced into powder.

Pulverization, in Agriculture, the separation of the earthy particles of soils, in such a manner, as to render them of a fine mellow mouldy quality, or to partake of the nature of powder. This state of mould is obtained in different ways, as by frequent ploughing and harrowing in the lees still forts of land; and in those of the more heavy and retentive descriptions, by the same means, and the frequent exposure of them to the influence and effects of the atmosphere, with the growth of such forts of crops as produce a clove thick shade upon them. This state of the soil, when produced in lands, has various advantages, the roots of plants penetrate it with more readiness and greater facility. It admits of the particles of moisture more equally, and in a more extensive manner, by which the fibrous roots of the crops are more fully supplied with nourishment. It likewise produces a more equal and regular mixture of the different materials of which the soils are constituted or composed, so as to yield the nutrition of plants in a more extensive and abundant manner. The rains in the vernal months are also, by this means, more abundantly drank up and retained, in consequence of their sinking to a greater depth, as well as more equally diffused through the different parts, from which much advantage is derived in the support of the crops. By this fineness in the particles of the soils, the manures, or other ameliorating substances, are also more extensively and perfectly blended and incorporated with them, and of course a more equal and abundant supply of nutritious materials provided for the growth and increase of the crops, of whatever kind they may be. And the air of the atmosphere is more intimately and abundantly received and blended with them. These are a few of the various advantages that may be derived from the pulverization of land; but there are many others noticed by writers on agriculture and rural economy. See Following.

In consequence of these beneficial effects, it is evidently a state of tillage that ought as much as possible to be aimed at by the intelligent cultivator, by the judicious ploughing, harrowing, and laying up of his lands, at those seasons when they can be the most acted upon and influenced by the extensive operation of atmospheric and other agents. See Ploughing and Tillage.

Pulvillus, in Surgery, a term used to express a little pledget-bolster, or compres.

Pulvinaria, in Roman Antiquity, cushions upon which the statues of the gods were laid in the temples, at the time that thanks were given for some signal victory.

Pulvinated, Pulvinatus, in the Ancient Architecture, a term applied to a frieze, which swells, or bulges out, in manner of a pillow, pulvinus; whence the name.

Pulvis, in Chemistry and Medicine. See Powder.

Pulvis Antisyphus, was originally composed of equal parts of the lichen cinerius terrestris, or ash-coloured ground liverwort, and black pepper; but this quantity of pepper rendering the medicine too hot, only one part of the pepper is now used to two of the lichen. See Antisyphus Folicis, and Lichen.

Pulvis Facundus, in Natural History, a name given by late writers to that fine powder, which is contained in capsules upon the stamens or threads in the flowers of plants, and is called by some English writers the male dust; and in general the farina of flowers. See Farina, and Fecundation of Plants.

Pulvis Fulminans, or the thundering powder. See Fulminants.

Pulvis Patrum, the Jesuit’s powder. See Cortex Peruensis.

Pulvis Puteolanus, in Natural History, the name of a fossil substance, found in form of powder, and famous for its consolidating under water. The accounts of it seem, however, to be a little erroneous. See Pozziolana.

Pumice-Stroke, Lat. Pumex. Fr. Pierre Ponce, in Mineralogy, a light, spongy, vitreous stone, found in the neighbourhood of some volcanoes, and used for polishing metals and marble, and smoothing the surface of wood and pasteboard. It is said to form a good glaze for pottery. The specific gravity of the lighter pumice-stones does not exceed 0.914; they swim on water. The constituent parts of pumice from Lipari, according to Klaproth, are:

<table>

<td>1.75</td>
</tr>
</tbody>
</table>

The characters of the different kinds of pumice, and the situation from which they are chiefly procured, are periphrastically described by Dolomieu, in his "Voyages aux Isles de Lipari.”

The island of Lipari, he says, is an immense magazine of pumice-stones for all Europe; notwithstanding the quantity which has been taken away, they do not appear diminished. Whole mountains are entirely formed of pumice. Quarries of vast extent have been dug in this stone at the feet of the mountains, and in the valleys the whole island appears to have a base of this singular substance. The effential characters of the pumice-stones of Lipari are a white or greyish-white colour, a coarse grain, and a fibrous texture. The pores are long; they have a glassy or silky lustre. Pumice-stones are generally lighter than common solid lavas, and are less hard. They are nearly free from admixture with iron, and to the absence of this metal part of their quality is to be attributed. Pumice-stones may be divided into five species.

The first kind is grey, and have a compact grain, the pores and fibres being fearlessly discernible; they have a considerable degree of weight and solidity; the fracture presents a surface somewhat vitreous. These stones are easily worked, and much used in the island for masonry. The city of Lipari is almost entirely built of this variety of pumice.

The second kind of pumice is equally grey, but much lighter and more porous; the fibrous texture is more strongly marked than in the preceding species, but these stones will not float on water. They are used in the construction of cellars, and are exported in great quantities into the maritime towns of Naples and Sicily. The third kind are light, porous, and fibrous, they have a glassy lustre when broken, they swim on water, and unite a coarse grain with a certain degree of confluence, which fits them for the purpose of polishing marbles and metals. These are the only kind of pumice-stones known in foreign countries. The fourth species is a very white and extremely light stone, of a loose texture, and a light degree of confluence. It appears to have arrived at the extreme degree of rarefaction which a substance can attain, and preserve a union of its parts. It is not used for any purpose. When it falls into the sea, it swims on the surface, and is carried to a great distance, being commonly found on the coasts of Sicily, Calabria, and the kingdom of Naples. A fifth species of pumice might be added, which is formed of the latter species, rared by heat, so as to have the affinity of aggregation of the particles destroyed,
PUMP

destroyed, and is pulverized by a kind of volatilization. Pumice-flakes appear to have flowed in the manner of lavas, and like them to have formed great currents, which are found at different depths over each other round the group of mountains in the centre of Lipari. They are thus piled in great homogeneous masses, in which quarries are opened for building flone. The heavy pumice occupies the lower part of these currents or masses; the light pumice-flakes are above. This arrangement is conformable to that of common currents of lavas, of which the porous lavas always occupy the upper part. This position proves the identity of the nature of the heavy pumice with that which is light and porous, and shews that this great lightness is not an essential character of these flones. The elongated fibre of pumice-flakes is always in the direction of the volcanic currents, and appears to have depended on the semifluid state of the lava, which draws out in threads, like melted glass.

When pieces of pumice-flake have the fibres bent in every direction, we may be assured, says Dolomieu, that they have been ejected in detached masses, and have never been part of the current. The felky threads of pumice are almost a perfect glass. Spallanzani, who visited Lipari after Dolomieu, describes the Campo Bianco, from whence most of the pumice-flakes are procured, as a lofty and extensive mountain, formed wholly of white pumice-flakes. When seen at a distance, it excites the idea that it is composed entirely of pure snow, from the summit to the foot. This prodigious mass of pumice is not one solid whole, but an aggregation of numerous beds of pumice successively placed on each other; which beds are distinguishable by their colour, and in many places project from the mountain. They are almost always disposed horizontally, and their position is not dissimilar to stratification. Each bed of pumice does not form a distinct whole, but it consists of an aggregate of globular masses of pumice united together, but without adhesion. Hence Spallanzani is led to infer that these pumices were thrown out of the volcano in a state of fusion, and took a globose form in the air, which they preferred at the time of their sudden congelation. We have, however, many instances, in the mineral kingdom, of substances assuming a globular form, which we cannot suppose to have been thrown out of volcanoes in detached masses; as in mountains of basalt and granite, and even in some lime-flake. In the process of glass-making, various phenomena are frequently presented, which, if properly attended to, would elucidate the formation of many volcanic products, and particularly of their tendency to assume a globular form. "Glass vessels are well known to be convertible into Reaumur's porcelain, by the internal arrangement of their particles, without losing their external form, and consequently at a temperature much below that requisite for fusion. The change of glass into Reaumur's porcelain does not arise from an evaporation of the alkali, as has been asserted, but from a regular arrangement of the molecules of the glass. It commences by the formation of fibres perpendicularly to the surface of the glass, and penetrating into it. At nearly the same time, smaller radiated globules are formed in the interior of the glass, and the reunion of these with the fibres by their mutual increase, forms the whole into a new substance." See Experiments of G. Watt, Phil. Trans. 1804.

The globes of pumice on the mountains of Lipari were probably formed by a similar arrangement of the particles during the cooling of the lava. A great quantity of these globular pumices, which Spallanzani observed on the sea-moore near Campo Bianco, were probably detached from the mountain by gradual disintegration, for it scarcely seems possible, for balls of a substance so light and fragible to have preferred their form in falling; or if we suppose them to have been in a semifluid state, they must have been flattened by the fall. It is a singular fact, that the islands of Lipari and Vulcano are almost the only volcanoes in Europe that produce pumice-flakes in considerable quantities. Dolomieu suggests that this may be owing to the nature of the mountains in which the volcanoes break out, and to the great degree of heat which has been in action. From the similarity of the constituent parts of felspar and pumice, it may be inferred that felspar, or granitic rocks containing a large portion of felspar, have been the substances from which pumice was formed, but a more than common degree of heat appears to have been requisite. The immense bed of lava which burst from the sides of Etna in 1669, and traversed Catania, has, according to Dolomieu, a base of granite, the constituent parts of which are not changed. When this lava is exposed to a strong heat in a furnace, it vitrifies, and is changed into an opaque porous frit, resembling pumice, a certain proof, adds Dolomieu, that this vast bed, by a more active heat, would have been converted into flones similar to those of Lipari.

By a long continued heat, pumice-flake melts into a vitreous, semi-transparent mass, in which a number of small crystals of white felspar are discernible. By intense heat, common flone is in some instances so rarefied as to resemble pumice. Brongniart describes a red pumice found on Vesuvius, and a greenish pumice from the external volcanoes of Auvergne. Ferrara also mentions a flake ejected from Etna in 1802, of which one half was lava and the other half pumice. Probably this was formed from a rock composed of hornblende and felspar. Some geologists have carried their attachment to theory so far, as to deny the volcanic origin of pumice, because it is sometimes associated with rocks, which they assert were not of igneous formation. To this opinion it will scarcely be thought necessary to reply, further than to observe that pumice is sometimes seen floating on the sea, at a vast distance from land, which appearance can only be accounted for by the action of submarine volcanoes. Mr. Dove, captain of an Indiaman, observed immense quantities of pumice on the Atlantic ocean, in S. lat. 35° 36'; W. long. 9°; the shales of it continued floating over the surface of the sea for several days, and extended 317 miles. Phil. Trans. vol. xxxv. p. 444.

The volcanoes of the Molucca islands are said to eject such prodigious quantities of pumice, that the ocean sometimes appears covered with it for many leagues.

Though Dolomieu describes a white or greyish-white colour of a distincting character of the pumice-flakes of the Lipari islands, it would appear, from the description of Brongniart and Ferrara, above referred to, that pumice may be of various colours, according to the nature of the flake which has been fused; but rocks which melt into a colourless glass, and are composed principally of felspar, seem to be the base from which most pumice-flakes have been formed. See Volcano.

PUMMEL. See POMMEL.

PUMP. ANTIA, in Hydraulica, a machine formed on the model of a syringe, for raising of water.

Vitruvius ascribes the first invention of pumps to Ctesibias the Athenian; whence the Latins call it machina Ctesibiana, or organum Ctesibicum.

Pumps are distinguished into several kinds, with regard to the several modes of their acting. As the Common sucking-pump, which consists of a pipe open at both ends, in which is a moveable piston, bucket, or sucker, as big as the bore of the pipe in that part in which it works, and leathern round so as to fit the bore exactly; and may
be moved up and down, without admitting any air to come between it and the pipe or pump barrel. There are several kinds of buckets: the most simple of all, which is commonly used for ordinary pumps, consists of a cedric piece of wood, whose diameter is somewhat less than the bore of the barrel, that it may move in it freely, having a hole quite through the middle of it. Upon the top of this there is an iron piece fastened to a rod of iron or wood, which goes quite to the top of the pump, and by means of which the motion is given to the bucket. Near the top of the cedric wood, there is a leather ring fastened round it, which goes a little higher than its top: the hole in the wood is flopped by a valve, made of a round piece of leather, fastened in one part of the wood with nails. Upon this there is an iron plate, a little larger than the bore of the hole, and another iron plate under it, a little less than the fame bore; and the plates and leather are fastened together by means of a rivet or srew in the middle of them. When the bucket is put into the barrel, and the leather becomes wet, it will apply itself to the sides of the barrel, and prevent the passage of the air. The use of the two iron plates is to sustain the pressure of the water which would otherwise bend the leathers. For larger pumps, the bucket is made in the following manner: there is a hollow piece of brafs, almost equal at top to the bore of the barrel, but small at the bottom, having at its top a brafs bar, and at the bottom two notches to receive the ends of another brafs bar, of the fame figure as that at the top. Round the brafs piece there goes a leathern ring, fastened to it at its lower part by means of an iron ring, which, being almost at the bottom of the brafs piece, is not so large as its top, and consequently does not touch the sides of the barrel: this leathern ring should go a little higher than the cedric-piece at bottom. The valve consists of a piece of leather almost equal to the top of the brafs piece, covered by two iron plates of the fame size as the leather, and having under it two plates somewhat smaller than the bore of the brafs piece at its top; these iron plates and leathers are fastened together with ferews. This valve must be applied to the top of the brafs piece or box, so that the brafs bar upon it may be between the two iron plates under the leather. The whole is fastened together by means of an iron piece, whose lower part goes through the holes in the middle of the valve, and the two brafs rods, so that its upper part getting between the two upper iron plates of the valve, presses upon the leather, and makes it apply itself close to the upper brafs bar. This iron piece or rod ought to have two holes, one at the bottom, just under the lower brafs rod, to hold it close by means of a pin or key; and another at its top, to fasten it to another iron rod, which is continued quite to the top of the pump, in order to give motion to the bucket. The chief advantages of this kind of buckets are, that they give the freest passage to the water, having the least friction possible, as they touch the barrel only at the upper end of the brafs box; and that the sand or gravel, which is commonly mixed with the water, cannot get between the bucket and the barrel, because the leathern ring is higher than the brafs tube; besides, if by any accident the motion of one side of the valve were hindered, the other would serve till it were mended. See Valve.

The construction of pumps is usually explained by glass models, in which the action both of the pistons and valves may be seen. In order to understand the structure and operation of the common pump, let the model D C B L, (Plate XIV. Hydraulics, fig. 4.) be placed upright in the vessel of water K, the water being deep enough to rise at least as high as from A to L. The valve a on the moveable bucket G, and the valve b on the fixed box H, (which box quite fills the bore of the pipe or barrel at H,) will each lie close, by its own weight, upon the hole in the bucket and box, until the engine begins to work. The valves are made of brafs, and covered underneath with leather for closing the holes the more exactly; and the bucket G is raised and depressed alternately by the handle E and rod D d, the bucket being supped at B before the working begins.

Take hold of the handle E, and thereby draw up the bucket from B to C, which will make room for the air in the pump all the way below the bucket to dilate itself, by which its spring is weakened, and then its force is not equivalent to the weight or pressure of the outward air upon the water in the vesel K: and, therefore, at the first stroke, the outward air will press up the water through the notched foot A, into the lower pipe, about as far as e; this will condense the rarefied air in the pipe between e and C to the same state it was in before; and, then, as its spring within the pipe is equal to the force or pressure of the outward air, the water will rise no higher by the first stroke; and the valve b, which was raised a little by the dilatation of the air in the pipe, will fall, and stop the hole in the box H; and the surface of the water will stand at e. Then depress the piston or bucket from C to B, and as the air in the part B cannot get back again through the valve b, it will (as the bucket defends) raise the valve a, and so make its way through the upper part of the barrel d into the open air. But upon raising the bucket G a second time, the air between it and the water in the lower pipe at e will be again left at liberty to fill a larger space; and fo its spring being again weakened, the pressure of the outward air on the water in the vesel K will force more water up into the lower pipe from e to f; and when the bucket is at its greatest height C, the lower valve b will fall, and stop the hole in the box H, as before. At the next stroke of the bucket or piston, the water will rise through the box H towards B, and then the valve b, which was raised by it, will fall when the bucket G is at its greatest height. Upon depressing the bucket again, the water cannot be pushed back through the valve b, which keeps close upon the hole whilst the piston defends. And upon raising the piston again, the outward pressure of the air will force the water up through H, where it will raise the valve, and follow the bucket to C. Upon the next depression of the bucket G, it will go down into the water in the barrel B; and as the water cannot be driven back through the now, close valve b, it will raise the valve a as the bucket defends, and will be lifted up by the bucket when it is next raised. And now, the whole space below the bucket being full, the water above it cannot sink when it is next depressed; but upon its depression, the valve a will rise to let the bucket go down; and when it is quite down, the valve a will fall by its weight, and stop the hole in the bucket. When the bucket is next raised, all the water above it will be lifted up, and begin to run off by the pipe F. And thus, by raising and depressing the bucket alternately, there is still more water raised by it; which getting above the pipe F, into the wide top I, will supply the pipe, and make it run with a continued stream.

So, at every time the bucket is raised, the valve b rises, and the valve a falls; and at every time the bucket is depressed, the valve b falls, and a rises. As it is the pressure of the air or atmosphere which causes the water to rise, and follow the piston or bucket G as it is drawn up; and since a column of water 32 feet high is of equal weight with as thick a column of the atmosphere, from
from the earth to the very top of the air; therefore the perpendicular height of the piston or bucket from the surface of the water in the well must always be less than 32 feet; otherwise the water will never get above the bucket. But when the height is less, the pressure of the atmosphere will be greater than the weight of the water in the pump, and will therefore raise it above the bucket: and when the water has once got above the bucket, it may be lifted by it to any height, if the rod D be made long enough, and a sufficient degree of strength be employed, to raise it with the weight of the water above the bucket, without ever lengthening the stroke.

The force required to work a pump, will be as the height to which the water is raised, and as the square of the diameter of the pump-bore, in that part where the piston works. So that, if two pumps be of equal heights, and one of them be twice as wide in the bore as the other, the widest will raise four times as much water as the narrowest; and will therefore require four times as much strength to work it.

The widenenss or narrowness of the pump, in any other part besides that in which the piston works, does not make the pump either more or less difficult to work; except what difference may arise from the friction of the water in the bore, which is always greater in a narrow bore than in a wide one, because of the great velocity of the water.

The pump-rod is never raised directly by such a handle as E at the top, but by means of a lever, whose longer arm (at the end of which the power is applied) generally exceeds the length of the shorter arm five or six times; and, by that means, gives five or six times as much advantage to the power. Upon these principles, it will be easy to find the dimensions of a pump that shall work with a given force, and draw water from any given depth.

The quantity of water raised by each stroke of the pump-handle, is just as much as fills that part of the bore in which the piston works, be the size of the rest of the bore above and below the piston what it will. The pressure of the atmosphere will raise the water 32 feet in a pipe exhausted of air; but it is advisable never to have the piston more than 20 or 24 feet above the level of the surface of the water in which the lower end of the pump is placed; and the power required to work the pump will be the same, whether the piston goes down to be on a level with the surface of the well, or whether it works 30 feet above that surface; because the weight of the column of air that the piston lifts, is equal to the weight or pressure of the column of water raised by the pressure of the air to the piston. And although the pressure of the air on the surface of the well will not raise or force up the water in the pump-bore more than 32 feet, yet when the piston goes down into the column so raised, the water gets above it, and may then be raised to any height whatever, above the piston, according to the quantity of power applied to the handle of the pump for that purpose.

Pumps ought to be made so (says Mr. Fergusfon) as to work with equal ease in raising the water to any given height above the surface of the well. And this may be done by duly proportioning the diameter of the bore (in that part where the piston works) to the height the water is to be raised, as that the column of water may be no heavier in a long pump than a short one; or indeed equally heavy in all pumps from the shortest to the longest, on a supposition that the diameter of the bore is of the same size from top to bottom; and whatever the size of the bore be, above or below that part in which the piston works, the power required to work the pump will be just the same as if the bore was of the same size throughout.

In order that a man of common strength may raise water by pumps with the same ease, to any height not less than 10 feet, or more than 100 feet, above the surface of the well, Mr. Fergusfon has calculated the annexed table, in which the diameter of the bore is duly proportioned to the height; and in these calculations he supposes the pump handle to be a lever increasing the power five times.

</table>

In the first column, look for the number of feet the water is to be raised; then, in the second column you have the diameter of that part of the bore in which the piston or bucket works; and in the third column, the quantity of water which a man of ordinary strength can raise in a minute by the pump to the given height.

The quantity of water contained in a pipe of either of those heights in the table, supposing the diameter of the bore to be the same from top to bottom of the pipe, is 4523.2 cubic inches, or 19.58 gallons in wine measure, as near as the hundredth part of an inch in the diameter of the bore can make it.

Mr. Fergusfon has calculated the following table, by which the quantity and weight of water in a cylindrical bore of any given diameter and perpendicular height may be very readily found.

For tens of feet high, remove the decimal points one place towards the right hand; for hundreds of feet, two places; for thousands, three places; and so on. Then multiply each sum by the square of the diameter of the given bore, and the products will be the answer.

Example.

Qu. What is the quantity and weight of water in an upright pipe 85 feet high, and 10 inches in diameter of bore? The square of 10 is 100.

Multiply by 100 100 100

Anf. 80110.613850 42255.4890000 46360.3081500

Which number (80110.61) of cubic inches being divided by 231, the number of cubic inches in a wine gallon, gives 342.6 for the number of gallons in the pipe; and 42255.489 troy ounces being divided by 12, gives 3521.29 for the weight of the water in troy pounds; and finally, 46360.3 avoirdupois ounces being divided by 16, gives 2897.5 for the weight in avoirdupois pounds.

The power required to work a pump, or any other hydraulic engine, must not only be equal to the weight of the whole column of water in the pump bore, but as much superior to it as will overcome all the friction of the working parts of the engine.

Pump, the forcing, raises water through the box H (fig. 5) not in the same manner as the sucking-pump does, when the plunger or piston g is lifted up by the rod D D. But this plunger or force (see Former) has no hole through it, to let the water in the barrel B C get above it, when it is depressed to B; and the valve b (which robs by the ascent of the water through the box H when the plunger g was drawn up) falls down and fl oats the stop in H, the moment that the plunger is raised to its greatest height. Therefore, as the water between the plunger g and box H can neither get through the plunger upon its descent, nor back again into the lower part of the pump L L, but has a free passage by the cavity around H into the pipe M M, which opens into the air-vessel K K at P; the water is forced through the pipe M M by the descent of the plunger, and driven into the air-vessel; and in running up through the pipe at P, it opens the valve a; which shuts at the moment the plunger begins to be raised, because the action of the water against the under side of the valve then ceases.

The water being thus forced into the air-vessel K K by repeated strokes of the plunger, gets above the lower end of the pipe G H I, and then begins to condense the air in the vessel K K. For as the pipe G H is fixed and tight into the vessel below F, and the air has no way to get out of the vessel but through the mouth of the pipe at I, and cannot get out when the mouth I is covered with water, and is more and more condensed as the water rises upon the pipe, the air then begins to act forcibly by its spring against the surface of the water at H, and this action drives the water up through the pipe I H G F, from whence it spouts in a jet S to a great height; and is supplied by alternately raising and depressing of the plunger g, which conjointly forces the water that it raises through the valve H, along the pipe M M, into the air-vessel K K.

The higher the surface of the water H is raised in the air-vessel, the less space will the air be condensed into, which before filled that vessel; and therefore the force of its spring will be so much the stronger upon the water, and will drive it with the greater force through the pipe at F: and as the spring of the air continues whilst the plunger g is rising, the stream or jet S will be uniform, as long as the action of the plunger continues; and when the valve b opens, to let the water follow the plunger upward, the valve a fl运用s, to hinder the water, which is forced into the air-vessel, from running back by the pipe M M into the barrel of the pump.

If there was no air-vessel to this engine, the pipe G H I would be joined to the pipe M M N at P; and then the jet S would flow every time the plunger is raised, and run only when the plunger is depressed.

Mr. Newsham’s water engine, for extinguishing fire (see Fire-Engine), consists of two forcing-pumps, which alternately drive water into a close vessel of air; and by forcing the water into that vessel, the air in it is thereby condensed, and compresses the water so strongly, that it bursts out with great impetuosity and force through a pipe that comes down into it; and makes a continued uniform stream by the condensation of the air upon its surface in the vessel.

By means of forcing-pumps, water may be raised to any height above the level of a river or spring; and machines may be contrived to work these pumps, either by a running stream, a fall of water, by horses, or by steam. See Water Workings.

The rod of the bucket in a sucking-pump is sometimes made to work through a collar of oiled leathers and brass plates connected with the barrel of the pump by screws, and kept moist by water contained in a vessel at the top; it prevents the water filling from the top of the pump, and therefore, by a pipe, it will rise to any height. This is called in the North, a jack-head. Degasguliers's Exp. Phil. vol. ii. p. 152, &c. Ferguson’s Lectures, p. 73, &c. 410.

Pump, the lifting, differs from the sucking-pump only in the disposition of its valves, and the form of its piston frame. This kind of pump is represented in fig. 6. A B is a barrel fixed in a frame I K L M, which is immovable, with its lower part communicating with the water. G E Q H O is a frame with two strong iron rods, moveable through holes in the upper and lower parts of the pumps I K and L M; in the bottom of this frame O Q H, is fixed an inverted piston B D, with its bucket and valve upon the top at D. Upon the top of the barrel there goes off a part F E, either fixed to the barrel, or moveable by a ball and socket; but in either case water and air-tight. In this part, at C, is fixed a valve opening upwards. It is evident, that when the piston frame is thrust down into the water, the piston D descends, and the water below will rush up through the valve D, and get above the piston; and that, when the frame is lifted up, the piston will force the water through the valve C up into the cistern P, there to run off by the spout. The piston of this pump plays below the surface of the water. Mr. Martin has described a mercurial pump, which works by quicksilver, invented by Mr. Hoffs, and perfected by Degasguliers; and another pump of the lifting fort, invented by Merh. Goffet and De la Denille, and set up in the king of France’s garden at Paris, the piston

Pumps, Strickens's, the first of all the kinds, acts both by suction and pulsion. Its structure and action are as follows:

A brafs cylinder A B C D (fig. 7.), furnished with a valve in L, is placed in the water. In this is fitted the embolus M K, made of green wood, which will not swell in the water, and adjusted to the aperture of the cylinder with a covering of leather, but without any valve. In H is fitted on another tube N H, with a valve that opens upwards in I.

Now, the embolus E K being raised, the water opens the valve in L, and rises into the cavity of the cylinder: and when the same embolus is again depressed, the valve I is opened, and the water driven up through the tube H N.

This is the pump used among the ancients, and that from which both the others are deduced. Sir S. Morland has endeavoured to increase its force by lengthening the friction; which he has done to good effect, insomuch as to make it work without almost any friction at all.

Pumps for draining Mines are worked by horses, or water, but more than either by the steam-engine, which, had it produced no other advantage than the facilities it offers in mining, would have been of more real value than any philosophical discovery ever made. The pumps for this purpose are generally sucking-pumps of the common construction, made of cast-iron, except that they have an opening at the lower part of the barrel, to give access to the valve or bucket when they require repair or renewal of the leathers, and this is closed by a door or lid, fastened on with ferrets. The pump rod is suspended by chains from the arched end of a lever situated over the pit, and put in motion by the piston of the steam-engine acting at the opposite end, or by a crank turned from a horse-wheel or water-wheel. When the depth is considerable, the pit is divided into two or three lifts, and as many different pumps used; the lowest to raise the water from the bottom of the mine into a cistern at the first lift, in which the second pump lands, and raises the water to a second cistern, from which the third or upper pump raises it to the surface, or to the level or subterranean passageway, at which it can run off to some lower land than that on which the engine is erected. The rods of the three pumps are brought into one by bolting them together at the top, and are suspended from the beam or lever, as before-mentioned. They are made of wood, the lengths being united together by iron joints; but even these in deep mines are of such great weight as to require a second beam or lever, placed on the opposite side of the pit to the engine, and having a balance weight at the outer end; because it would be too great a weight for any beam to bear, if a sufficient balance were put upon the opposite end of the same working beam that bears the strain of working the pumps; if they are of light wood, a considerable portion of their weight is taken off, by their being immersed in the water which the pumps contain.

A plan which is common in the mines of Cornwall, obviates the necessity of thus balancing the pump rods; it is by employing forcing-pumps instead of lift or suction-pumps. In these the engine is employed to lift the weight of the rods, and their descent is the power that raises the water in the pump, by pressing down the piston or forcer, and expelling the water from the barrel at the bottom through a valve into a pipe, which ascends the pit. The construction of the pump is varied from that in common use, though its principle is the same. Instead of the barrel being bored correctly within, and fitted with the leathered forcer, the forcer is made rather longer than the stroke of the pump, and being made true and smooth on the outside, it is fitted in a collar of leather at the top of the barrel of the pump. By this means, when the piston is raised up and down, it increases and diminishes the capacity of the barrel, which being provided with valves at the bottom and at the foot of the pipe, it will raise or force up the water, in the same manner as the force-pump before described.

The suction-pumps before mentioned, used in mining, are always made of cast-iron, in lengths of six or eight feet, ferreled together at the flanches, forming a long tube, which is called the pile or pillar of pumps.

The working barrel of each lift of pumps, or that length of pipe in which the bucket moves, is usually fourteen to twenty feet above the bottom, and has at its upper end a wider part, and a cover, which, like that above-mentioned, takes off by screws to new leather, or to repair the bucket. The bottom length of mine-pumps is called the wind-bore, usually enlarged at two or three feet from the bottom, and diminishing thence to a point like that of an egg, which part is full of rows of holes three quarters or an inch in diameter. The upper row of these holes is plugged up with deal plugs, which the miners can open or stop as the water increases, or otherwise, and according to the going of the engine. When a pit or mine is first sinking, it becomes necessary to contrive the means of drawing the water completely from the bottom, that they may not have to stand in the water to work, which, besides its inconvenience, prevents them using gunpowder if the bottom is rocky. Sometimes, instead of the plugs of wood, the holes of the wind-bore are surrounded by a circular apron of strong leather, made fast and tight above the pipe; which apron the miners can from time to time turn up or down like the cuff of a coat, so as to regulate the access of water, and prevent, as much as possible, the drawing of air by the pumps, as this deranges the motion of the engine. In sinking pits, the lower lift of pumps should stand in the deepest hole which has been made in the bottom of the pit, and for this purpose, when a new hole has been made, either by picking, or blasting, near to the pumps, they are leveled towards, and let to sink into such new hole. In long lifts and heavy pumps, this lowest and moveable length of the pump is wholly or in part suspended by strong ropes attached to the great windlasses, which is, in all such cafes, provided near the shaft for drawing the pump rods, or the pumps themselves, in cafes of need. As the shaft is deepened, new lengths of pump barrels are added at the top of the lower lift, generally about a yard at a time, and the pump rods are lengthened as the pump requires. This, which is the common mode of working in sinking pits, has many inconveniences: 1. As it is necessary for the pumps, whilst sinking, to keep the water very low in the pit, the engine frequently goes too fast, in consequence of the pump drawing up air, and carries up by the violence of the current small pieces of stone, coal, or other substances, and lodges them above the bucket upon the valves, which must considerably retard the working of the pump, and wear the leather. 2. When the engine is set to work, (after having been stopped whilst working upon air, and consequently a quantity of air remaining in the pump-barrel, with the small ropes, &c. depofited on the valves of the bucket,) it often happens that the comprefure of the air by the descent of the bucket, is not sufficient to overcome the weight of the bucket valves so loaded with rubbishes, and the column of water in the stand-pipes: the pump is hereby prevented from catching
catching its water. The usual remedy for this is to draw the bucket out of the working barrel, until a quantity of water has escaped by its sides to displace the air: this evil often arises from the unnecessary magnitude of the space between the bucket and clack. 3. The pumps being suspended in the pit by capstan ropes for the purpose of being readily lowered as the pit is funk, the stretching of the ropes, (especially when sinking in soft strata,) occasions much trouble, by suffering the pumps to rest on the bottom and choke; but the most serious evil is, that the miners, in shifting the pump from one place to another, that they may dig in all parts of the pit, throw them very far out of the perpendicular, thereby causing immense friction and wearing in all parts, besides endangering the whole apparatus, by breaking the bolts and slays, and training the joints of the pipes.

Mr. William Brunton, of Buttery iron-works in Derbyshire, has presented to the Society of Arts an improved pump for mining, which obviates all the above difficulties. To avoid the pump drawing air, he has introduced a side pipe, connecting the parts of the working barrel which are above and below the bucket, which pipe has a stop-valve, that the miner can regulate with the greatest ease, so as to keep the engine to its full stroke, without drawing air, by letting down the water from the upper part of the barrel into the lower, so that it is working again in its own water. Instead of having the whole weight of the lower lift of pumps standing on the bottom, it is fixed in the pit by beams, and the miner has only to lift and move an additional pipe or wind-bore, which slides upon the lower length of the pump like a telescope, to lengthen down, and this additional wind-bore is besides crooked, and turned aside like a short crank, which, by the facility with which it turns round in the leathered collar above the nose of it, can easily be removed into every fresh hole which is made in the bottom by the miners. The pumps are supported in the pit by beams placed across at proper distances, so as to suit the lengths of the pipes, or lengths of the pump, which are nine feet. Short pieces are laid across these, with half circular holes in them, which being put round the pump, just beneath the flanges, firmly fullain its weight, but may quickly be removed when it is required to lower the pumps in the pit; and as they are not fastened by any bolt, they do not prevent the pumps being drawn upwards, if it becomes necessary to take out the pumps when the pit is full of water. The pumps by these means remain stationary and the suction-pipe lengthens as the pit is funk, until it is drawn out to its full extent; the whole column is then lowered to the next flanges, and another pipe is added to the top. The pumps being thus kept stationary till nine feet are sunk, the pipe at the top will of course deliver the water at the same level at all times, and instead of being obliged to lengthen the column every yard sunk, it will only be necessary every nine feet.

Fig. 4, of Plate XV. Hydraulics, explains the construction of Mr. Brunton's pump, being a clack through the centre of the working barrel and suction piece. A is the door which uncerfs to get at the clack of the pump; B is the working barrel, with the bucket D working in it; E is the clack, also shewn enlarged in figs. 5 and 6; F is the suction-pipe, and G G a moveable lengthening piece; this slides over, and includes the other when the pump is first fixed; but as the pit is funk, it slides down over the pipe F, to reach the bottom. The outside of the inner pipe, F, is turned truly cylindrical and smooth, and the inside of the outer pipe G, at the upper end, for about six inches down, is made to fit it. The junction is made perfect, by leather being placed in the bottom of the cup a a, which holds water and wet clay over them, to keep them wet and pliable, and consequently air-tight. The lower extremity of the suction-pipe G terminates in a nose R, pierced with a number of small holes, that it may not take up dirt. This nose is not placed in a line with the pipe, but curved to one side of it, like a crank, so as to describe a circle when turned round. By this means the miners, by turning it round upon the pipe F, can always place the nose R in the deepest part of the pit; and when they dig or blast a deeper part, they turn the nose about into it, the sliding tube lengthening down to reach the bottom of the hole, as shewn in the figure. By this means there is never a necessity to let a shot for blasting, so near the pump-foot as to put it in any danger of being injured by the explosion, as is the case in the common pump, in which this danger can only be avoided by moving the pump-foot to one side of the pit, which necessarily throws the whole column of pumps out of the perpendicular.

The construction of the clack is explained by figs. 5 and 6, the former being a section, and the latter a plan. L L is a cast-iron ring, fitting into a conical seat in the bottom of the chamber of the pump, as shewn in fig. 4; it has two flaps, l l, rising from it, to support a second iron ring M M; just beneath this, a bar, m, extends across from one flap to another, and has two screws tapped through it; thesepref, down a second cross-barm n, which holds the leaf of the valves down upon the cross-bar of the ring L L, and this makes it fall, forming the hinge on which the double valves open, without the necessity of making any holes through the leaf, as is common; but the chief advantage is, that by this means the clack can be repaired, and a new leather put in, with far less loss of time than at present, an object of the greatest importance; for in many situations, the water gathers so faint in the pit, that if the clack fails, and cannot be quickly repaired, the water rises above the clack door, so as to prevent any access to it, and there is no remedy in the common pump but drawing up the whole pile of pumps, which is a most tedious and expensive operation. In Mr. Brunton's pump, the clack can at any time be drawn out of it, by first drawing out the bucket, and letting down an iron prong Z Z, which has hooks on the outside of its two points; this, when dropped down, will fall into the ring M M, and its prongs springing out will catch the under flap, and hold it fast enough to draw it up. Another part of Mr. Brunton's improvement consists in the addition of a pipe H, (fig. 4,) which is cast at the same time with the barrel, and communicates with it at the top and bottom, just above the clack; at the upper end the pipe is covered by a flat sliding plate, which can be moved by a small rod b, passing through a collar of leather; the rod has a communication by a lever, so that the valve can be opened or shut by the men in the bottom of the pit. The object of this side pipe is to let down such a proportion of the water which the pump draws, as will prevent it drawing air, though, of course, the motion of the engine will be so adapted as not to require a great proportion of the water to be thus returned through the side pipe, yet it will not be possible to work the engine to corrects as not to draw some without this contrivance, and if it does, it draws up much dirt and pieces of stone into the pump, besides causing the engine to work very irregular, in consequence of partially losing its load every time the air enters the pump. Another use of the side pipe is to let down water into the chamber of the clack to fill it, when the engine is first set to work, after the pumps have been standing still, and the lower part of the barrel and chamber empty.

Fig. 7 and 8, of Plate XV. are a section and elevation of a three-barrelled force-pump, of a very good construction,
construction, which was used by Mr. Smeaton in the numerous water-engines which he erected at London bridge, Stratford, and other places for the supply of towns with water. It has the advantage of the valves being very accessible, and the water-way may be kept to the full size of the barrel without contractions, which, as they occasion great resistance to the motion of the water, are a waste of power. It acts on the same principle as the ordinary forcing-pump, only that three barrels are connected together, for the advantage of raising a constant stream of water. A, B, C, are the barrels, which are bored out truly cylindrical. If the pump is small, the barrels are usuall used of brass, but for larger work cast iron is used. From one side, near the bottom of each, proceeds a curved pipe B, turning up, and ending with a flap, to screw to the under side of the forcing chamber L. There is also, near the bottom, at the opposite side of the barrel, a projectin gneck or short pipe, D, covered at the end by a door screwed on, that it may be removed to give access to the valve, m, in the bottom of the barrel. The barrels have projecting rings or flanges, by which they are screwed down upon the forcing chamber H, which is common to all three barrels; it has a pipe from each of its ends terminating in a flap b, to screw on the pipes which bring water to the pump. The upper flap, or top of the forcing chamber H, has three holes in it, one under each barrel, and each is covered by a valve shutting downwards, as is shown in the section, fig. 7. These valves are made of iron, to shut down upon hinges like a door, and are covered with leather at the lower side. Mr. Smeaton made his valves with the centre pin of the hinge removed backwards from the hole which the valve covers, and it is also raised above the surface of the under side of the valve, by which means the valve opens in some degree on that side where the hinge is, as well as on the other, and any obstruction getting into the valve, will be left liable to be detained, and will not have such a great leverage to break the hinge of the valve when the force of the water shuts it down, as it would if the hinge was on a level, and close to the edge of the hole, because the obstacle will not be so near the centre. The hinge is fallowed to the pump by a screw, &c, passing through the metal, and screwing into the hinge; this being withdrawn, and the door, D, opened, the valve is quite loose, and may be taken out to renew the leather. To give facility to this, the doors, D, are made oval, as shown in fig. 8. Another similar valve, n, is fitted at the top of each of the pipes, B, to cover their apertures; they are all covered by a common forcing chamber, L, which is exactly similar to the forcing chamber, except that it has nozzles, R, in the top over each valve, and covered with doors to give access to them. The conducting pipes are carried away from either end of the forcing chamber, flanged being provided to unite them. Each barrel is fitted with a piston or force M, which consists of three metallic plates, secured to the rod: the middle plate is turned true, and fitted as accurately as possible to the barrel; the upper and lower plates are somewhat smaller. Two round pieces of leather, larger than the barrel, are placed above and below the middle plate, being held fast between it and the upper and lower plates. When forced into the barrels, these leathers turn up and down round the upper and lower plates, forming two cups of leather, which accurately fit the barrel, and will not permit any fluid to pass by them. The parts of the pump are fastened together by screws and nuts, as will be understood by inspection of the figures. The whole pump is supported on two ground-cills, and by means of two iron flanges of the forcing chamber, H, the whole pump is bolted down upon the ground-cills. The action of this pump is simply this; when the piston or force of one barrel is raised, it causes a vacuum in it, and the pressure of the atmosphere forces the water up the suction pipe H, (if not more than 30 or 33 feet,) opens the valve, m, in the bottom of the barrel, and fills it with water; on the descent of the force the lower valve shuts, and the forcing valve, n, opens by the water the barrel contained being driven through it into the forcing chamber, L, and thence to any place whither the forcing-pipe is carried. On the re-ascen of the force, the lower valve, m, opens, and the shutting of the forcing valve, n, prevents the water returning into the barrel. The three forces work up and down alternately, so that while one barrel is filling water up the force pipe, the others are lifting it up the suction pipe, and the third continues the action in the interval, when the change of motion takes place between the two. In this manner, the pump will raise a very constant stream of water, if the forces are worked in a proper manner, which is best done by means of cranks, placed at such an angle to each other, upon the same axis, that they will act in due succession.

**Pumps for Ships.**—Among the perils of a seafaring life, a leaking ship may be reckoned the most dreadful and fatal of all: here not only one man, or a few men, perishes, but every living creature on board. When a ship strikes against a rock, and is wrecked, some lives may be saved by floating planks and rigging; if the magazine takes fire, death comes instantaneously, and kills, perhaps, in the most gentle manner; but in the desperate case of a leak, how slowly does the awful monarch advance, attended by all the terrors of anxious suspense.

In such a melancholy situation, all their hopes and expectations for help and safety must be placed in the pumps, and this consideration renders those machines of vital estimation and consequence; it highly imports every commander of a ship (to whom the lives of his men are committed) to take the utmost care that his ship be supplied with such pumps as will be able to perform against, and ward off, these impending dangers. By any negligence in this respect, he may become guilty of destroying his own life, the lives of his men, and of the ruin and misery of many families; it therefore becomes his duty to be furnished with the best pump that can be procured for evacuating the hold from the water that may, at any time, get in, with the least force, and in the shortest time.

At different times, almost every description of pump has been employed in ship service; but custom has at length decided in favour of the chain-pump, although, from the friction naturally attending its construction, it takes somewhat more power to raise a certain quantity of water than some other kind of pump when well made. Yet on the whole, from being so little liable to choke up or be deranged by violent use, it has gained the preference of the seamen. Consequent attempts have been made to produce a pump that would raise a greater quantity of water than the chain-pump with the same power, and still to preserve the other advantages of that machine.

These inventions have been offered to the public one after another, with pompous recommendations by their respective projectors, who have never failed to report their effects as considerably superior to that of other pumps with which they have been tried. It is, however, much to be regretted, that in these sorts of trials there is not always a scrupulous attention to what may be called mechanical justice. The artil who wishes to introduce a new piece of mechanism, has generally sufficient address to compare its effects with one of the former machines which is crazy, or out of repair: a report of this kind, indeed, favours strongly
of the evidence of a false witness; but this fiction is not always discovered. The persons appointed to superintend the comparative effect of the different pumps, have not always a competent knowledge of hydraulics to detect these artifices, or to remark, with precision, the defects and advantages of those machines, as opposed to each other. Thus, the several inventions proposed to supplant the chain-pumps which are now generally used in the British navy, have hitherto proved ineffectual, and are no longer remembered.

In many instances, for want of a proper knowledge of mechanics and hydraulics, these inventions have proceeded upon a mistaken principle, supposing it possible to make some contrivance or other, by which a pump should raise more water with a certain power than has ever been done before. This is a mistaken idea, for pumps, in point of the quantity of water they will raise, have long ago been brought to as great a degree of perfection as it is perhaps possible; and to raise a greater weight of water than the power applied is equal to, is an impossibility, as no power or effort can really be increased by any kind of machinery, it can only be modified; and what is gained in the magnitude of the effect the machine produces, is lost in the time expended to accomplish it: in truth, rather more is lost, because of the friction of the machine, and the power expended in working its parts; we should, therefore, ascertain the quantity of water that can be raised in a given time by the force of one or more men, without deductions for friction; and when a ship's, or other pump is to be considered, if its produce comes near to this standard, we should be satisfied as to its performance, and look for improvements in the conveniences of its construction.

Defaguliers, in the second volume of his Experimental Philosophy, has taken much pains to find out an average of the quantity of water which can be raised in a given time by any number of men; and this will serve to guide us in these pursuits, and to enable us to value the pretensions of projectors in the art of raising water. He found, that the mean strength of a man, when applied to the bell kind of pump that had been in his time in use, amounts to no more than the raising of one hoghead of water in a minute, to the height of ten feet. Mr. Symes, says, he made a variety of machines, and many observations of this kind, but never found the value of men's strength at a medium quite equal to what is set down by Defaguliers, unless they are suppos'd to work in haste or difficulties for a few minutes.

The improvements which are desirable in pumps for a ship's use are, 1st, that as little power as possible should be lost in friction and resistance of the water passing through the valves and pipes; 2dly, that no water be lost by leakage, and that the pump be not liable to be choked up by chips or other extraneous matters getting into the pump: 3dly, it should not be obliged to raise its water to a greater height than is necessary for it to run off, namely, to the load-water line of a ship; 4thly, that it should be so adapted, that the united efforts of a great number of men can be applied, without any of them working to a disadvantage.

The pumps which are at present in use in the navy are of two kinds, the chain-pump, and the hand-pump; the chief dependence of pumping the ship, in emergency, being placed upon the former, the latter being used in ordinary occasions, to clear the hold from that trifling leakage which would injure the cargo, though it puts the ship in no danger.

English ships of war carry four chain-pumps and three hand-pumps, all being fixed in the same well, which also includes the main-mall. (See Plates IV. and VI. of Naval Architecture.) One of the hand-pumps is called the wash-deck pump, being used to raise water from a cistern in the hold to the upper deck, for washing the ship; but in emergency, it affords to pump the ship. The chain-pump (Plate XIV. fig. 8.) is no other than a long chain, A, with a sufficient number of pillars, a, called buckets or saucers, fixed upon it at proper distances: it passes downwards through a wooden tube, B, and returns upwards, in the same manner, on the other side, D; the ends being united together. The chain is extended over two wheels, E and F, called sprocket wheels: one is placed over the tubes, B and D, of the pump, and the other at the bottom, in the space between the two tubes through which the chain ascends and descends. By turning the upper wheel, E, the chain of buckets is put in motion; and the lower part of the wooden tube, in which the chain ascends, is lined with a brass barrel, in which the saucers are fitted. As they are continually ascending in this tube, they raise a constant stream of water, which runs off from the top of the ascending trunk, and is carried by a trunk through the ship's side into the sea. The pump is worked by a crank, or winch, G, fixed on the axis of the upper wheel, whereon several men may be employed at once; and thus it discharges, in a limited time, a much greater quantity of water than the common pump, and that with less inconvenience to the labourers.

The chain-pump now in use in the navy is of a very improved construction, compared with original chain-pumps. It was introduced by Mr. Cole, under the direction of Captain Bentinck. The chain of this machine is simple, and not much exposed to damage. It is exactly similar to that of the fire-engine, and appears to have been first applied to the pump by Mr. Mylne, to exhaust the water from the caissons at Blackfriars bridge. It has thence been transferred to the marine by Captain Bentinck, after having received some material additions to answer that service. The links of the chain (fig. 9.) are each formed of two long plates of iron, e, e, with a hole at each end, and fixed together by two bolts, serving as pins for the joints. The buckets or saucers fixed upon it are two circular plates of brass, g, with a piece of leather between them. The sprocket wheels for the chain are formed in the same manner as the trunnels used in mills, by two iron wheels fixed at eight inches distance upon the axle, and united by several round iron bolts, forming a reef for the chain; and its links have hooks, b, which are taken by these bolts; and thus the chain is secured upon the wheel, to prevent it from jerking back, when charged with a column of water.

This pump was a great improvement upon the old chain-pumps used in ships before, in which the chain was of too complicated a fabric, and the sprocket wheels used to work it were deficient, in wanting some contrivance to prevent the chain from sliding or jerking back upon the surface of the wheel, which frequently happened when the buckets were charged with a considerable weight of water, or when the pumps were violently worked. The links were too short, and the awkward manner in which they were connected exposed them to a great friction in passing round the wheels: hence they were sometimes apt to break, or burst, and in very dangerous situations, when it was extremely difficult or impracticable to repair the chain. Mr Cole's pump is so contrived, that the chain may be easily taken up and repaired, when broken, or echeved with balls; and it discharges a much greater quantity of water with an inferior number of men, as appears from a trial of this machine with the old chain-pump aboard the Seahorse frigate; where it was found that its effects, when compared with the latter, were as follows: the new pump with four men
PUMP.

men raised one ton of water in 43½ seconds, while the old pump required seven men to raise the same quantity of water in 76 seconds. In this experiment, the chain of the new pump was purposely broken, and dropped into the well, and afterwards taken up and repaired, and set to work again in two minutes and a half; then the lower wheel of the pump was taken up, to shew how readily it might be cleared and refitted for action, after being choked with sand or gravel, which could be performed in four or five minutes. These are advantages which, with a seamman, have a superior consideration to that of increasing the quantity of water which the machine will raise, unless it was in a considerable degree; and indeed the very best pumps will not raise a much greater proportion with the same power. The only alteration which has been made on Mr. Cole's pump, since its first introduction near 30 years ago, is that they now omit the lower sprocket wheel altogether, the ascending and descending pipes being fast united by a curved metal tube, that the chain passes better than if a wheel was used. The cranks are made to take off, and apply when wanted, that they may not be in the way: they are long enough for 30 men to work at once. Of late it has been proposed to add fly-wheels to them: this would be attended with but slight advantage, and several inconveniences, from occupying that room where the men should stand to work. It being an object to employ as many as possible; but if they are crowded, they only inconvenience each other, instead of afflicting.

Hand-pumps for ships, are those which act with a barrel and bucket, worked by a lever or brake. Those in common use are fucking-pumps, made in the rudest manner, with a wooden bucket and valves; but several improved constructions have been proposed, and are now adopted in the navy. Mr. Cole made great numbers of hand-pumps, which had bails, chambers, or barrels, fitted into the wood where the bucket worked. The valves were made of bails, and fitted into a conical feet, and a door was provided in the lower part of the pump, to give access to the lower valve when requisite; it was closed by a loop surrounding the pump, and wedged tight. The brake, or lever of the pump, had a crofs handle at the end, of sufficient length to allow several men to work together, and on occasion other men could apply their strength, by standing on the deck below, and having a rope descending through the upper deck from the end of the brake.

Mr. Smeaton, in 1765, invented a hand-pump for the sea service, in which, besides the advantage that he expected to obtain from better mechanism and proportion of the parts, he had the following objects in view. The common ship's pump, in general, delivers its water upon the main deck, which, according to the size and construction of the ship, is four, five, or six feet above the surface of the sea, or load-water line, at the same time that this line is not above from 14 to 18 feet above the ship's bottom; it therefore appears that the ordinary pumps lift the water from 3d to 4d higher than the level at which the water might be delivered, and thereby require 4d or 4th more power to do the same work, or with the same power they do less work than they might do by 3d or 4th, in place the water was delivered at or just above the water line. For this purpose he used wooden trunks or pipes, proceeding horizontally from the upright trunk of the pump, to carry off the water through the ship's side, being fitted at the other ends into boxes, or short wooden tubes, let in through the ship's side, and caulked just above the load-water line. These side pipes were closely jointed with the boxes in the ship's side at one end, and at the other end into strong planks, which were bolted against the sides of the pump, in order that the side pipes might be got out and in without disturbing the pump, which was a fucking-pump, with its bucket worked by a lever or brake, upon the deck over the pump. From the top of the pump a fland pipe was carried up to the main deck, or as high as was thought necessary, to prevent the water reverting and running back into the ship over the top of the pump, when the sea rose above the orifices of the side pipe, or when, from the ship being in differe, they were under her load-water line. By this, even when both boxes and pipes were wholly under water, it would no ways interrupt the action of the pump, for whenever the water in the fland pipe rose above the level of the water without, the preflure of the column in the fland pipe would cause it to make its way through the side pipes, so that in this case no level was lost, and though the pump was at rest no water could revert down the pump, because there were the valves of both bucket and fixed box or clack which prevented it. The working barrel was of brafs, and very truly bored, the bucket and fixed box being of the same construction as those used in the steam-engines, and the pump rod was made of greater bulk than was necessary, merely for strength, but by way of weight, that when the brake was lifted up, the pump rod should readily descend by its own weight. The brake of the pump had a branch fixed on, rather obliquely at each side, so as to form three handles, for five men to work at once; they stood one on each side the middle of the brake, and one on the outside of each of the branches, and every quarter of an hour they could relieve themselves by changing hands, which was done by changing places. They were intended to make no more than 25 strokes per minute, moving the pump rod 174 inches, up and down, at each stroke, the barrel being a nine-inch bore; this was much better than making shorter strokes and quicker, as they usually do. Their hands moved up and down about four feet five inches, and by working with this stroke at a moderate rate, so as to hold it an hour, five men would in that time deliver 20 tons at a height of 22 feet. This was upon a supposition of raising the water to the usual height, but when by the application of the maxim before described, this perpendicular was shortened to 16 or 17 feet, then nearly the same delivery could be made by three men, or proportionally more by four men, that is, as 17:22:20:26 tons at 17 feet. The foot of the pump was let through the ship's inner planking or ceiling, between two of the floor timbers, and did not touch the bottom or outside planking, within 2¾ inches, the lower end being rounded within like a trumpet mouth, it being a bad plan to have the pump lying upon its lower extremity, with holes bored to let in the water, as it is thus very liable to be choked by dirt. A plank of the ceiling was made to lift up near the pump's foot, that a man could occasionally get in his arm, to clear away any chips, sand, dirt, or other matter, that should happen to be drawn thither.

Mr. Noble has furnished a great number of hand-pumps for the navy, which have two buckets, working one below the other in the same barrel; they rise and fall alternately, so as to produce a confluent stream, like the chain-pump. This is effected by causing the rod for the lower of the two buckets to pass down through the upper bucket in a collar of leathers; the rods of the two buckets are united to the brake or lever, upon opposite sides of its centre or fulcrum, so that the descent of one produces the elevation of the other; thus one is always raining a stream of water, whilst the other is defending for a freth supply. Such a pump requires no lower valve, aulefs by way of precaution, in case either bucket should fail, in which case it would become a single pump. The idea is ingenious; but the com-
PUMP.

The ingenious Benjamin Martin invented a ship's pump with two barrels drawing from one suction-pump, so as to raise a constant stream. This has so much merit, that we have given a section of it in Plate XV. fig. 9. Here A is the suction pipe, conducting the water from the ship's hold up to the pump, where it is enlarged, to communicate with both barrels D, D, through the valves C, C, in the bottom; E, E, are the pistons of the barrels, with double valves in them; they are not, like other pistons, fitted to slide in the barrels, but are simply braoz rings, in which the valves are fitted, and being smaller than the barrels, have large circular pieces of leather fixed on them, the outside edges of which are attached to the inside of the pump barrels; hence when the pistons are moved up and down, the leather folds sufficiently to admit the motion, as is shown in the figure; but being close all round, the pistons can have no leakage or friction, and only a small resistance from the stiffness of the leather. To fallen the edges of the leather piston to the barrels, they are made in two lengths, an upper and a lower, and the leather is introduced in the joint between them, being held fast, and the pump kept together by bars, I, I, fixed over the barrels, and bolts to press the upper length of the barrels down upon the lower. Both the barrels are included within a box or cistern, B, B, fixed upon the ship's deck, with trunks L, L, which carry off the water as it runs over the tops of the barrels into the cistern. The pump is worked by the piston-rods, H, H, being united by chains to a wheel K, the axle of which is supported by stanchions from the sides of the cistern B, B, and is put in motion by the double lever M, at the ends of which crooks handles are fixed for several men to work at once. Mr. Martin's pump acts extremely well; the constant stream raised by the alternate action of the two barrels upon one pipe produces an advantage that was shewn by experiment, for the water not only rises while the piston rises, but continues to do so even after the piston begins to descend; and therefore the pump was found to deliver more water than was expected from calculation of the contents of the barrel, and the number of strokes made.

To account for this, it must be considered that as this pump has both its large pistons working (alternately ascending and descending), at the same time there must be produced a constant rising column of water in the pipe, whose velocity through a bore of five inches, to supply the barrels of twelve inches diameter each, must be so great, that it cannot be checked or stopped at once, or upon the first descent of the piston; and therefore a surplus of water is produced. Notwithstanding these advantages of Mr. Martin's pump, it has objections which are serious obstacles to its use on board ships, though in other situations it is a good machine: these are the shortness of its stroke, which renders it very fatiguing for men to work for a long time; but another more serious objection is, that the leathers would, in general, remain dry, and thus become liable to harden and grow stiff, so as to break into holes when used at first, before they become soaked, and to fill the cistern first with water would be very troublesome.

Mr. Robert Clarke, of Sunderland, has proposed an improvement in the mode of applying men's force to pumping, which is worthy the consideration of seamen. It is to change the posture of standing to sitting, and making the action the same as that of rowing, which, besides that it is by philosophers considered as the most efficacious application of a man's force, is to feamen most particularly so from their habitual practice of it. He objects to the ordinary action of pumping with a brake, as the posture is weak, and requires much force to preserve it. It oppresses the man by overstretching his loins on one side, and incommodes respiration, by the flexure of the body on the other side. Too much motion of the shoulder-joint is required, as the muscles which act on the arm-bone at this joint are disproportionate to the effort they must make, when the arm vibrates on the shoulder-joint as a centre, for the force to be communicated by the hand. Besides this, the arms themselves are at one instant enfeebled, by being thrown above the head, and requiring a pull, and the next instant require a pushing effort, which changes of direction in the exertion and sustaining force, are too continual and rapid for long continuance; in standing, the body is a continued dead weight upon the legs.

The action of rowing is powerful to a surprising degree, and so well adapted to a man's ease, that he can continue it a greater length of time without fatigue, than any other mode of exertion; for though the motion is large, it is made up of easy motions in several joints; the velocity and resistance of which suits the muscles employed. Very little sustaining force is required, for the body is supported, and returns unloaded to its charge; the breathing is free. The manner of carrying this effect is very simple, the lever or brake being bent at right angles at a centre pin, so that it hangs straight down when it is at rest, instead of being horizontal; then to the lower extremity a rod is joined, which is carried rather in an inclined direction upwards to the seamen, who is seated before the pump with a rest for his feet. The rod has a crook handle, to hold by both hands, and in some cases it may be made long enough for two men to sit side by side upon the same seat; and by drawing and pushing it, in the same manner as rowing, the perpendicular lever is caused to vibrate, and the horizontal arm, or bended part, which suspends the pump spear, partakes of the motion sufficiently for pumping.

The latest improvements in hand-pumps, are by Capt. Jekyl, R.N. This gentleman has invented an addition to the pump of an air-velve, and flushing-box for the rod to pass through, by which it will raise the water to a greater height than the head of the pump, and a hoist being attached to the pump spout, by very simple means, the water is conveyed to any desired part of the ship, and thrown in a jet through a nozzle pipe with great force, to extinguish fire, if such a calamity should befal a ship, and thus the pump is rendered of twofold service. The idea of converting the pump to a fire-engine is not new, having been attempted in many different ways by forcing-pumps, but these having pipes proceeding from the lower part of the barrels and valves, which are not very accessible, are always liable to choke up by obstructions, and have not succeeded in general use. The air-velve has always been in the way, if made of a sufficient size, to answer the purpose of equalizing the stream. Capt. Jekyl has obviated these objections, and, without altering the material parts of the hand-pump, has rendered it as complete a fire-engine as can be wished. This is explained by fig. 1. Plate XV, which is a section of the pump through its whole length. A B C is the iron brake or lever to work it; it is branched at the extreme end, and has a wooden pole, C, fixed in it, for several men to hold at once; D is the iron flancon or fulcrum of the brake; it is fixed to the pump head by means of strong iron hoops at E E and F F, which at the same time strengthen the work of the pump. The centre pin is to be at a height of two feet.
feet six inches above the ship's deck. H are the flings of the pump, united by a forecastle or pin to the end of the brake, and suspending the pump spear I, by means of the joint-piece g. I K is the pump spear, made of copper in the upper part, I, and the lower length, K, of iron; the latter has the bucket, M, attached to it. The valve of the bucket is made in a very simple and effective manner, the valve being merely a round plate of brafs, with a hole through the centre, to receive the rod, upon which it rises and falls, and covers the aperture in the bucket. The bucket is a ring of brafs, with a crofs-bar to fix the rod in it; it is made in two thickneles, one above the other, and a cup of leather is held in between them, projecting all round the upper part of the bucket, and turning up, to make a tight fitting in the barrel. The two rings of the bucket are held together by the pifton-rod passing through both, and a crofs-wedge beneath. L is the brafs chamber in which the bucket works; it is well fitted into the wood of the pump-tree, so that the water cannot leak by it, and is bored smooth withinide. N is the lower box, fitted into the lower part of the pump-tree, beneath the chamber; it has a groove round it, into which oakum is placed, and when it is put down, makes a tight joint: its valve is of the same construction as that of the bucket, with the addition of a ring or eye on the top of the pin, on which the valve rises and falls. By this eye the box can be drawn up when it needs repair, by firft drawing up the bucket of the pump, and putting an iron hook down into this eye. O O P is the air-veffel; this is a cylinder of sheet copper, folded over a cover of brafs; within the centre of it is a tube, likewise folded over the cover, through which the copper pump spear paffes, and it is frounded round at top with a collar of leather and fluggling. To prevent the escape of the water, it is packed with hemp, and two rings of leather. R fhes the place of two iron bars, fitted through the head of the pump, and confining the cover, O O, of the air-veffel; they are falled by the wedges d; it is by thefe only that the air-veffel is held down: a circle of leather is firft put round the air-veffel, juft beneath its lid, and this being prefled upon the recefs in the wood, makes the joint tight. T is the pump nozzle, which delivers the water. When it is used as a fire-engine, a hofe is fixed on by its link-joints, and keys or wedges: the nozzle is fixed to the pump by four fcrew-bolts going through the thickneles of the pump, and it is fixed in such a direction as will most conveniently lead to a receiver, fig. 2, which unites the hoes from all three of the ship's pumps.

Fig. 3. is the link-joint of the hohe, T representing the pump-jout made of cial iron, and fcrewed to the pump-tree; e e is the collar or focket, made of brafs, with the hohe X bound upon it: this has two trunions, on which a link, f e, is fitted, one on each fide; these links pafs through grooves, in the cial-iron piece T, and a key g, put down through the link behind it, draws the joint tight, without any fcrewing or fpecial trouble. The focket, e e, is fitted into the nozzle, and has a leather ring to make it tight. The outide of the pump is to be hooped at every three feet, to prevent it from burfling by the preflure of the water. The disposition of the three hand-pumps in a ship's well, renders their connection with a common receiver very convenient to bring all the water into one stream, which will then be very powerful, and more capable of extinguifhing a fire than any moveable engine. Two hand-pumps are always placed on the larboard fide of the main-mast, in the well, and one of them being the cial pump used for wafling decks, its foot stands in a small ciallern fixed upon the top of the main-mast, and suppofed with water by a pipe through the ship's fide, with a cock to admit it at pleafure; there is one pump on the larboard fide of the main, three feparate hoes being united with each of the pumps by a link-joint, like fig. 3, at one end, and with three necks, k, k, k, of a receiver, fig. 2, by fimilar joints at the other, brings all the water into one, and a hohe being joined by a link-joint, l, to the oppofite end of the receiver, conveys the whole water to any part of the fhip. The receiver has the three nozzles, k, k, k, at one end made in a diverfent direction, agreeable to the direc-ions in which the hoes came from the three different pumps, and a valve is placed withinide, before each nohe, to open inwards, in order that the receiver may be used for one or two pumps, while the others are repairing, or getting ready, or that if any of the hoes burst, the water may not escape from the receiver at that hohe. There are two handles fixed to the receiver, to lift and carry it, as it is to be moveable, and when in ufe, is propofed to be laid on the grating of the main hatchway, as the moft central fution, from which the hohe may be carried in any direction. Z is a branch pipe, or jet, fcrewed at the end of the great hohe, X; and it also unfcrews at the extreme end, to fit on jets of different hoes, in the fame manner as all other fire-engines.

In some experiments which we have witneffed upon this pump, it performed as well as could be defired, a single pump forming a very effective engine; but when the three were combined, it was superior in force to any we have ever seen, and would throw a stream, of an inch in diameter, over the main-top-maft head of a 74-gun fhip. Besides, the length of the handle, C, admitting seven men to work at once, an effeafion of force is gained by a rope, m, made fast to the brake A B, and conducted through a single block, hooked to the deck at v, and thence along the fhip's deck. At this any number of men may be applied very advantageously, to produce the ftrke, leaving those at the handle only to return it by lifting the handle. If the fhip proves leaky, and the ftrke is thought to be an ob-plant to the working of the pump, the air-veffel may be taken out, by drawing the wedges d, and taking out the bars R, which confine it; then after taking out the key which connects the joint-piece, g, with the copper rod, also removing the brake, lift out the air-veffel by the two fcrews of the ftrking-box, and fix on the joint piece again, but fix the guide-eye, H, in the loweft pair of holes, so that it will receive the top of the copper rod, and prevent the pump fpear having any play in the flings. In this flate it acts as a common hand-pump, but the air-veffel can be refixed to its place, and be ready for work in two minutes. To prevent any of the work being neglected from carelessness, the in-ventor propofes that one of the pumps shall be always used to wafl the fhip by the hohe and jet in the morning, which it would do much more effeafively than by the prefent mode of razing the water into buckets; and the force with which the jet of water is thrown would very completely wafl into every reef of the gun carriages, and other places, where a bruffh cannot reach; while, by this conffant exercife the pumps would always be ready at a moment's notice on an alarm of fire.

**Pump** in *Pneumatics*, is a machine, by means of which the air is emptied out of veffels, and a fort of vacuum produced in them. For the invention, truiture, and ufe of this pump, fee *Air-pump*; and for Smeaton's improved gage, fee *Gage*.

**Pumps** are small ones made of cane, or a piece of wood bored through, ufed in lieu of cocks, &c, to pump beer or water out of the cafls.
Pumps, Bur, called also bilge-pumps, are chiefly used by the Dutch, who have them by their ship's sides. In these is a long fluff, with a bur at the end like a gunner's spognge, to pump up the bilge-water.

Pump-Cilfera, cisterns of wood fixed over the heads of chain-pumps, to receive the water until it is conveyed through the sides of the ship by the pump-dales.

Pump-Dales, a large tube or pipe, generally made of fir, fitted to the cisterns, with a large scupper hole through the side, through which the water is conveyed from the pumps overboard.

Pump, Fetching the. See Fetching.

Pump, Rotary. See Rotatory Pump.

Pump, Spiral. See Archimedean Screw, and Spiral.

Pumpelemoes, a name used by some for a species of orange.

Pumping at Sea, is usually done by spouts, that is, by releasing the men with fresh ones, and counting how many strokes they pump each watch. By this means they know if the ship be flancing, or how her leaks increase.

When all the water is drawn up, and there comes up nothing but wind and froth, they say the pump facks.

Pumpkin, Cucurbita, in Botany. See Cucurbita. The pumpkin is frequently cultivated by the country people in England, who plant them upon their dunghills, where the plants run over them, and spread to a great distance; and when the feaou is favourable, they will produce plenty of large fruit; these they usually allow to grow to maturity, then they cut open a hole on one side, and take the seeds out of the pulp as clean as possible, after which they fill the shells with apples sliced, which they mix with the pulp of the fruit, and sone add a little sugar and spice to it; then bake it in an oven, and eat it in the same manner as baked apples; but this is a strong food, and only fit for those who labour hard, and can easily digest it.

For the Method of propagating them, see Cucurbita.

Pumpltiz, in Geography, a town of Switzerland, in the canton of Berne; four miles S. of Berne.

Pun, or Punn, a lufus verborum, the wit of which depends on a resemblance between the sounds and syllables of two words, which have different, and, perhaps, contrary significations. See Paronomasia.

Such are,—Can, de cane, cane. — Far mole mole mole. — Lux Dei, lux dies. — All houfes are turned to ale-houses. — Matrimony is become matter of money. — Some men's paradise is a pair of dice. — Was it fo in the time of Noah? — Ah no. — L'ordre tiré du désordre, ou désordre ordonné, is the title of a French book.

Puns, when they come easily, and are very ingenious, poignant, and apposite, are allowed of in conversation, letters, epigrams, madrigals, and the like compositions; but they are absolutely banished out of the grave, serious, and sublime, because they weaken its force, and diminish its beauty, which consists in something great and elevated. The Greeks and Romans, it is true, sometimes indulged themselves in the practice, and used puns as ornaments in the most serious discourses; but the most severe and philosophical genius of our age, is by no means satisfied with such an outside of wit. Devices, symbols, rebus, mottoes, &c. are their proper sphere, where they shine to most advantage.

Puna, in Geography, an island in the Pacific ocean, near the W. coast of America, in the bay of Guayaquil, about 50 miles in circuit. The land is flat and low, and on account of its numerous rivers and strong divergent tides, it is encompassed by many dangerous sand-banks. Its capital is Puna, which is situated at the head of the harbor, in the N.E. part of the island: it consists of about 50 small houses and a church; the houses are erected upon pilots ten or twelve feet high, and ascended by ladders on the side, on account of the inundation to which the river Guayaquil is subject; they are thatched with palmetto leaves, and their chambers are well boarded. Tradition reports, that the inhabitants formerly amounted to between 12 and 14,000; but at present they do not exceed 500, consisting of Cafts and Spaniards, the Indians being very few. The large ships, which cannot lie at Guayaquil, on account of the sand-banks, load and unload here; the anchorage against the middle of the town being very good, with five fathoms of water within a cable's length of the shore. S. lat. 45°. W. long. 75° 46'.

Punagri, in Hindus Romanes, is the name of a mythological animal composed of man and bird, on which their god Vishnu is conveyed. Another of its names is Superna; which see.

Punanaru, in Ichthyology, the name of a small fish of the alauda kind. It has an oblong body, and a thick head, obtuse at the finot. The mouth is small, and in the lower jaw there are only two oblong teeth, which are sharp and pointed like needles. The eyes stand high in the head, the pupil is black, and the iris yellow; and over these there are two short red filaments. The gills are large, and have two oblong fins placed behind them. The back-fin reaches from the head to the tail, and is prickly at the edge. The belly-fin reaches from the anus to the tail. The skin and fins are all brown.

Besides this, there is another species, variegated on its sides with lines of a dull purple; its jaws bent with very small teeth, and its fins not prickly. Both kinds are found among the rocks about Brazil, and sometimes get into the shells of the larger shell-fish. Margrave Hill of Brazil.

Punay, in Ornithology, a name given by the people of the Philippine islands to a very beautiful species of turtle, common in their woods.

It is of the size of a small parrot, and is of a fine green colour, but the extreme feathers of its wings are tipped with white, and the lower part of its belly is of a fawn colour. Its back is yellow.

Puncateah, in Geography, a river of Bengal, which runs into the Hooringottah. N. lat. 22° 4'. E. long. 90°.

Punch, an instrument of iron or steel, used in several arts, for piercing and flaming of holes in plates of metal, &c. being fo contrivd, as not only to perforate but to cut out and take away the piece; whence the French call it, porte-piece, q. d. take-off piece. The punch is a principal instrument of the metal-button-makers, wafer-makers, patch-makers, shoe-makers, &c. The punch of the makers of plate-buttons serves to cut and parcel out the plates of gold and silver with which they cover their moulds. It is large, round, four or five inches high, the bottom hollow for about half an inch, well faced, and the edge very tharp.

To use it, they extend the plate of metal on a leaden table or block, and with a pretty heavy hammer strike the head of the punch, &c. See Button-making.

Punch Horsp, in the Manage, is a well-figd, well-knit horse, short-backed and thick-shoudered, with a broad neck, and well lined with flech. Thus, we have the Suffolk punch horse, &c.

Punch is also a name of a sort of compound drink, frequent in England, and particularly about the maritime parts of the country.

Vol. XXVIII.
its bafia is spring water, which being rendered cooler, 

brillier, and more acid, with lemon-juice, and sweetened
again to the palate with fine sugar, makes what they call

sifberet; to which a proper quantity of a spirituous liquor,
as brandy, rum, or arrack, being superadded, the liquor
becomes punch.

Several authors condemn the use of punch, as prejudicial
to the brain, and nervous system. Dr. Cheyne infils, that
there is but one wholesome ingredient in it; viz. the mere
water.

The proportions of the ingredients are various. Some,
instead of lemon-juice, use lime-juice, which makes what
they call punch-royal; this is found less liable to affect
the head, as well as more grateful to the stomach.

Some also make milk-punch, by adding nearly as much
milk to the sifberet as there is water, which tempers the
acrimony of the lemon. Others prefer tea-punch, made of
green tea instead of water, and drunk hot.

Lastly, What they call punch for chamber-maids, is made
without any water, of lime-juice, sharpened with a little
orange and lemon-juice; twice as much white wine as lime-
juice, and four times as much brandy, with sugar.

PUNCHENEE, in Geography, a town of Moring; 75
miles E. of Ameerpour.

PUNCHEON. See PUNCHION.

PUNCHIN, or PUNCHION, in Building. See PUNCHION.
PUNCHION, or PUNCHION, a little block or piece of
feel, on one end of which is some figure, letter, or mark,
engraved either in creux, or in relievo; impressions of which
are taken in metal, or some other matter, by striking it
with a hammer.

There are various kinds of these punchions used in the
mechanical arts. Such, for instance, are those of the gold-
smiths, cutters, pewturers, &c.

PUNCHION, in Coining, is a piece of iron filed, on which
the engraver has cut a figure, in relievo, the several figures, arms,
effigy, inscription, &c. that are to be in the matrices with
which the species are to be marked.

Minters distinguish three kinds of punchions, according
to the three kinds of matrices to be made; that of the
effigy, that of the crews or arms, and that of the legend or
inscription.

The first includes the whole portrait in relievo. The
second are small, each only containing a piece of the crews
or arms, &. gr. a heur-de-lys, a harp, a cornet, &c. by the
afflammage of all which the entire matrix is formed. The
punchions of the legend only contain each one letter, and
serve equally for the legend on the effigy-side, and the crews-
side. See COINING.

For the manner of engraving, tempering, and flamping,
these punchions, to form the matrices, see ENGRAVING ON
file, Matrice, &c.

PUNCHIONS, in Printing, are those used in flamping the
matrices, in which the types of printing characters are cast.
See LETTER FOUNDRY.

PUNCHION is also used for several iron tools of various sizes
and figures, used by the engravers in creux on metals. Scal-
gravers particularly use a great number, for the several
pieces of arms, &c. to be engraved; and many flamp the
whole file from a single punchion.

PUNCHION is also a common name for all the iron in-
struments used by the stone cutters, sculptors, locksmiths,
&c. for the cutting, incising, or piercing their several
matters.

Those of sculptors and flintaries serve for the repairing
flatures, when they are taken out of the moulds.

The locksmiths use the greatest variety of punchions;

some for piercing hot, others for piercing cold; some flat,
some square, some round, others oval; each to pierce holes
of its respective figure in several parts of locks.

PUNCHION, or PUNCHION, in Carpentry, is a piece of
timber placed upright between two posts, whose bearing is
too great, serving together with them to sustain some large
weight.

The punchion is usually lower and slighter than either
prick-polls or principal polls, and is joined by a brace, or the
like, of iron. See POST. Those on each side of a door,
are called door punchions.

PUNCHION is also a piece of timber raised upright under
the ridge of a building, in which the little forces, &c. are
joined. Vitruvius calls the punchion column.

PUNCHION is also used for the armor or principal part of a
machine, on which it turns vertically; as that of a crane,
&c.

PUNCHION is also a measure for liquids, containing a
loghead and a third, or 84 gallons, or one-third of a tun.

The Paris punchion is the same with their demiqueue; at
Rouen it is three buthles, &c. See MEASURE.

PUNCHACK, in Geography, a town of Hindostan, in
Bahir; 22 miles N.E. of Bahar.

PUNCTA LACRIMALIA, in Anatomy, the two small
round openings at the inner ends of the eye-lids, by which
the lacrimal canals, conveying the tears to the lacrimal bag
from the surface of the eye, begin. They are distin- guished
by the epithets fuperius and inferius. See EYE.

PUNCTATED HYPERBOLA, in the Higher Geometry,
a hyperbola whole oval conjugate is infinitely small, i. e. a
point.

PUNCTICALIS FERRIS, in Medicine, a name
given by some authors to fever, when accompanied with an
eruption of purple spots, or petechia; these spots being
sometimes called punctularia. See PETECHIE.

PUNCTION, or PUNCTURE, in Surgery, an aperture
made in the lower belly, in dribatical perfons, to discharge
the water, called also paracentesis.

PUNCTUATION, in Grammar, the art of pointing;
or dividing a discourse into periods, and members of periods,
by points expressing the pause to be made in the reading of
it; and necessary both for understanding and pronouncing it.

The points that are us'd are four; viz. the period, colon,
semicolon, and comma. See the particular use of each under
its proper article.

Punctuation is a modern art; the ancients were entirely
unacquainted with the use of our commas, colons, &c. and
wrote not only without any distinction of members and
periods, but also without distinction of words; which
culmin, Lipius observes, continued till the 104th Olympi-
adi; during which time the fenfe alone divided the dis-
course.

The antiquity of pointing, however, has had its advo-
cates; some have ascribed the invention of it to Thrasy-
machus, who was contemporary with Plato; others to Ilo-
ocrates, who flourished about the same time; and others to
Nicanor, in the time of Adrian. A late writer observes,
that pointing was not unknown in the time of Alexander the
1747.

Ciceron's expressions, verborum et sententiarum interpunctae
clausulae in orationibus, lib. iii. de Orat. and clausulae atque
interpuncta verborum, &c. in his Orat. pro Munere, have
been alleged by some as evidences of the antiquity of this
practice; but others have referred the former words to
speaking, and not to writing; the latter, to those points
which were formerly placed after each word, in order to dif-
tinguish
tinguôi word from word, when the whole was written in large capitals, at equal distances from one another; which is a very different thing from that fort of punctuation which divides the sense from subject matter into members and sentences, and parts of sentences, in such proportions as either the sense or the construction may require. The words of Seneca in his 40th Ep. Not stium cum sibi numus interpen- gure folems, are more applicable to this latter fort of pointing than those of Cicero; and yet these have been under- flod to refer to the distinctions of words. See an Eff on the Use of Pointing, by Sir James Burrow, F.R.S. and F.A.S. 4to. p. 6.

There is much more difficulty in pointing than people are generally aware of. In effect, there is scarcely any thing in the province of the grammarian so little fixed and aper- tained as this. The rules usually laid down are im- tertiary, dark, and deficient; and the practice, at present, is perfectly capricious, authors varying not only from one another, but from themselves too.

Dr. Lowth observes, that few precise rules can be given which will hold without exception, in all cases; they must be laid down with as much exactness as the nature of the subject will admit; and they may serve for a general direction, to be accommodated to different occasions, and to be supplied, when deficient, by the taste and judgment of the writer. Intro. to Eng. Gram. Ed. 1772, p. 194.

Indeed, F. Buffier, and since him Dr. Ward, and bishop Lowth, have done something towards a fixed and precise system of pointing, from the reason and analogy of things. Their doctrine the reader will find under the articles Comma, Colon, Sentence, &c.

In the general, we shall only here observe, that the comma is to distinguish nouns from nouns, verbs from verbs, and such other parts of a period as are not necessarily joined together. The semicolon serves to suspend and fullain the period when too long; the colon, to add some new, super- numery reason, or consequence, to what is already said; and the period, to close the sense and construction, and to release the voice. For the proportional quantity, or time of the points, with respect to one another, see Comma.

PUNCTUM, in Geometry, &c. See POINT. In the schools they have their

PUNCTUM Terminans, which is the indivisible extreme of a line, beyond which no part of the line extends.

PUNCTUM Continuans, an indivisible magnitude between contiguous points of a line, by which they are connected, and from whence arises a continuity.

PUNCTUM Initians, an indivisible point, from which the line begins.

PUNCTUM Formanum, or Generantium, in Conics, is a point determined by the interfection of a right line drawn through the vertex of a cone to a point in the plane of the base that constitutes the conic section.

PUNCTUM EX COMPARATIONE denotes either of the foci of an ellipsis and hyperbola; thus called by Apollonius, because the rectangles under the segment of the transverse diameter in the ellipsis, and under that and the distance between the vertex and the focus in the hyperbola, are equal to one fourth part of what he calls the figure of it.

PUNCTUM Lineans, in Geometry, is a term used by some authors for that point of the generating circle of a cycloid, or epicycloid, which in the genefis produces any part of the cycloidal line.

PUNCTUM Spatium, in Anatomy, the heart of the incubated chicken, at the time when it first displays motion. See INCUBATION.

PUNCTUM Aureum, an old mode of operating with a view of accomplishing the radical cure of hernia, or ruptures. An incision was made down to the neck of the hernial sac, under which a golden wire was drawn and tightened, after the bowels had been reduced. The dangerous concomitances which have occasionally followed this method, and particularly its insufficiency to protect the patient from a future defect of the bowels, are the reasons which have led the generality of modern practitioners to abandon the practice altogether.

PUNCTURE, Punctura, in Surgery, &c. See POINT. Any wound made by a pointed instrument.

PUNCTURED WOUNDS. See WOUNDS.

PUND-BRECH, or Pound-Breach, compounded of the Saxon, pound, and brech, fracture, breaching, denotes the illegal breaking of cattle out of the pound; either by breaking the pound, picking the lock, or otherwise.

PUNDFULDA, a pound for cattle, or pinfold. "Pla- cata inter abbat." Glasfon. et Hen. de Hamel, anno 1236.

PUNDIPOUR, in Geography, a town of Hindooftan, in Oude; 20 miles S.S.W. of Fyzabad.

PUNDIT, in the History of Eastern Literature, the name given to the interpreter of the Hindu law.

PUNDNA, in Geography, a town of Aflam; 20 miles W. of Gentiah.

PUNGANORE, a town of Hindooftan, in Myfore; 60 miles W.N.W. of Arcot. N. lat. 13° 12'. E. long. 78° 32'.

PUNGITIUS, in Ichthyology, the ten-spined thistleback of the British Zoology, a species of Gasteroglossus; which see.

PUNGNAN, in Geography, a town of Meckley; 58 miles W. of Munnpour.

PUNGO ISLANDS, a cluster of small islands, at the mouth of the river Gabon, near the coast of Benin; the principal island being about five miles in circumference and governed by a king.

PUNHETE, a town of Portugal, in Estramadura, at the conflux of the Znezere with the Tagus; 8 miles W.N.W. of Abrantes.

Gen. Ch. Cal. Perianth superior, of one leaf, bell- shaped, coloured, permanent, in five acute segments. Cor- Petals five, roundish, rather spreading, inserted into the calyx. Stam. Filaments numerous, capillary, inserted into the tube of the calyx, without any order, and shorter than its segments; anthers oblong. Pif. German inferior, roundish; style simple, the length of the stamens; stigma capitate. Peric. Apple nearly globose, large, crowned with the calyx, separated into two internal divisions by a transverse partition, the uppermost of them subdivided into about nine cells, the lowermost into about three, with memb- ranous partitions. Seeds very numerous, angular, each with a pulpy coat. Receptacle fleshy, pitted, dividing each cell into two parts.

Dwarf Pomegranate. This tree, and as disease spongy 5
our spongy. Punjgoor pots and it green-houfe. one

and aftringent
Flowers felfile.

Calyx: thick and coriaceous. Petals membranous and wavy. Fruit as big as an orange, of a tawny brown, with a thick altrigent coat, containing abundance of seeds, each enu-
loped in a distinct, very juicy, crimson coat, whose flavour, in a wild flate, is a pure very strong acid, but in the culti-
ved plant sweet and highly grateful.

—Native of the Weft Indies. Said to have been cultivated in Sherard’s garden at Eltham in 1723. At prefent it is a rare green-houfe shrub, of humble fize, flowering in fummer, and having all the appearance of a dwarf variety of the foregoing.

Punica, in Gardening, contains plants of the tree and shrub kinds, of which the fpecies cultivated are, the com-
mon pomegranate (P. granatum); and the dwarf pome-
granate (P. nana).

Of the firft there are feveral varieties; as the large double-
flowered, and the striped-flowered.

Method of Culture.—The firft fort and varieties are readily increafed by layers, which fhoild be laid in autumn, chuf-
ing the young branches for the purpofe, giving a little fit underneat at a bud, and laying them in the ufual way, giving occasional waterings in fummer; and by the following autumn they will be well rooted, and fit to be planted in nurfery-rows for two or three years, to get strength, and then planted where they are to remain.

Thefe of the common fort and varieties may be trained as half or full liffandars, or as dwarfs; but thofe designed
for walls fhoild be managed as directed for peasches, &c. This fort may be planted against warm walls, and be pruned
and trained as other fruit-trees.

Of this fort, the double-flowering kind is much more afteemed than the other in this country, for the fake of its large, fine, double fowers, which are of a most beautiful scarlet colour; and, if the trees are fupplies with due nour-
riement, continue to produce fowers for two months suc-
cellively; which renders it one of the moft valuable flower-
ing trees. This fort may be rendered more productive of
flowers by grafting it upon focks of the fingle kind, which
check the luxuriancy of the trees, and caufe them to pro-
duce flowers upon almoft every fhoot.

The fcond fort may be raised also by layers, as the
former, but must be planted in pots filled with rich earth,
and preferved in a green-houfe. In the fummer, when the
flowers begin to appear, if the plants are expofed to the open air, the buds will fall off without opening; they
fhoild therefore be placed in an airy glass cafe, and a large
share of air fhould be given them every day in warm weather.
By this treatment the plants may be continued in flower up-
wards of three months, and make a fine appearance.

These are very ornamental trees for shrubberies and other
places.

Punicus Lapis, in Natural History, a name given by
the writers of the middle ages to a ftone of a fpongy
texture, the powder of which was good in dfifeafes of the
eyes.

This fongs to have been no other than the pumice, the
writers of these times having been strangely incorreft in
their orthography; and all the virtues ascribed to this ftone, as also the places where it was found, which are the Eolian iflands, &c. femeing to have been copied from Pliny’s ac-
count of the pumice.

Puniej, in Geography, a town of Lithuania, in the pa-
linate of Troki; 5 miles N. of Olita.
Punjee, a town of Hindooftan, in the circle of Ellich-
pour; 5 miles E. of Akoat.
Punjere, a town of Hindooftan, in Bahar; 20 miles N.W. of Palarow.
Punjgoor, or Punjger, the name of a small but
fertile district of Perfa, lying about ten days’ journey
N.N.E. from Kej, the capital or chief town of all Mekran.
It is celebrated for the quality and quantity of the dates it
produces, and contains 15 well-peopleled villages, all of which are abundantly fupplied with water from the bed of the river
Burdoo, a few miles N. of them. These villages, two of
which are larger and more respectable than the others, are
governed by an independent chief. Punjgoor is 15 days’
journey from Kelat, by the route of Khozelar, and at the
fame distance from Noofhely by that of Kharan. It is
fpeock of as a very mountainous tract, producing in fome
of its villages grain, sufficient for the consumption of the
few wandering shepherds who inhabit them. The people
are rather a small delicate race; their arms are a match-lock,
fword and shield, and each village has its own chief, who
fettles the disputes which occur among the inhabitants.
This district has plenty of water, except in the months of
April, May, and June, when it becomes scarce; it pro-
duces dates, and furnishes camels, sheep, and goats, but
not in great numbers.
