Dr. Percival suggests, that this profit, considerable as it is, may admit of increase by future improvements; for in spring and summer feasons, the evaporation might be carried on without the aid of fire, by conveying the dunghill-water from the reservoir through proper flances into shallow troughs or ponds, of such extent as to afford a sufficient surface for the action of the sun and wind. These might be covered in rainy weather with awnings of canvas painted on the outside black, and white on the inside; the former with a view to absorb, the latter to reflect, the rays of light.

From the experiments of Dr. Percival, it appears that this potash is of a greyish-white appearance, deliquesces a little in moist air; but if kept in a dry room, near the fire, acquires a powdery texture. It is hard, and of a fungous texture when broken, with many small crystals in its sub-fibrous. The colour of its internal part is dusky and variegated. To the taste it is acrid, fat, and phosphorous. It emits no smell of volatile alkali, either in a solid form, dissolved, or when added to lime-water; neither does it communicate the faphire colour to a solution of blue vitriol. Silver is quickly tinged black by it, a proof that it contains much phlogilone. Ten grains of this potash required eleven drops of the weak spirit of vitriol to faturate them. The like quantity of salt of tartar required, of the same acid, twenty-four drops; a strong effervescence occurred in both mixtures; from the former a sulphurous vapour was exhaled. A tea-spoonful of the syrup of violets, diluted with an ounce of water, was changed into a bright green colour by five grains of the salt of tartar; but ten grains of this potash were necessary to produce the same hue, in a similar mixture. Half an ounce of the potash dissolved entirely in half a pint of hot water; but when the liquor was cold, a large purple sediment, subsided to the bottom; and it was found that this sediment amounted to about two-thirds of the whole quantity of ashes used.

The fame ingenious writer concludes with observing, that this potash is a true fixed vegetable alkali, produced by putrefaction; that the quantity of alkali contained in it may be estimated at one-third of its weight, whereas the white Mufcovy ashes are said to yield only one-eighth part; that no quick-lime appears to be contained in this potash, for a solution of it poured from its sediment, remained clear, though long exposed to the air; that it would be worth trying, whether the large purple sediment, which subsides when this potash is lixiviated, might not be applied to the manufacture of Prussian blue, or used in the manner recommended by Macquer for dyeing wool and silk; and that this manufacture will furnish the farmer for top-dressing for his garden and land, of great fertilizing powers.

Dr. Watfon (the present bishop of Landaff) suggests, that the investigation of a method of extracting its alkaline part from rock-fall, would be a most serviceable discovery. We have inexhaustible mines of rock-fall in this country, which, (he observes) the proprietors can afford at ten shillings a ton. A ton of rock-fall contains about half a ton of mineral alkali, which is for most purposes far preferable to potash. To those who have leisure to attempt such a discovery, he gives the following hint: whether the alkaline part of rock-fall may not be obtained by calcining it in conjunction with charcoal in open fires? His reason for this conjecture is founded upon the following experiment: upon burning fea-wrack to a black coal, and flopping the processes at that point, he has obtained great plenty of common salt, but no mineral alkali from the black ashes; though we are certain, that when the black ashes are thoroughly calcined, or reduced to white ashes, mineral alkali may be obtained from them. This makes it probable, that the common salt contained in the black ashes of fea-wrack is decomposed, and changed into a mineral alkali, during the burning of the black ashes. There are rea ons to suppose, that the cinder of pit-coal would answer the purpose better than charcoal.

POTASH, in Agriculture, as a manure, is beneficial in four cafes of grass land. It is stated that, in the county of Elene, Mr. Tweed, at Sandon, has a potash fabric on his farm; the value of the ashes 6d. per bushel. He spreads on his grass-lands 160 bushels to the acre, once in five years. It more than doubles the produce. And Mr. Vaisey, of Halthead, in the same county, has manufactured it largely. When he uses the ashes alone, he also spreads 160 bushels, or thereabouts, on the acre; but he prefers mixing them with his yard-dung. Mr. Porter, of Little Leigh, in that district, has likewise remarked that these ashes sink like quicksilver, as readily as clay: shallow tillage is, therefore, good after them.

Other sorts of ashes are also frequently employed in this tract of country. At Chesterford, many coal-ashes are brought from Cambridge, at the distance of eleven miles, for claver, fainfain, and grasf; the price 2s. a bushel, besides carriage. The Rev. Mr. Macklin uses a wagon-load to the acre. And lord Braybrook, at Audley-End, manures largely with these ashes; 38 acres of fainfain in one year, 60 bushel to the acre, coaling, carriage included, nearly 6d. the bushel. His tenant and steward, Mr. Nockold, likewise manures ten acres of famfain with them every year. Another very spirited tenant and improver, Mr. Claydon, also laid down 50 acres to fainfain; and in three months he brought from Cambridge 6300 bushels of these ashes, and in the same year dunged all his meadows besides. Such exertions are truly meritorious. These ashes are constantly attended with the best effects in this application. Corrected Agricultural Report.

In the county of Suffls, too, they have found this sort of ashes a great improvement to grasf. Lord Egremont has doubled the value of his park, by draining and these coal-
coal-ashes, which before was covered with moss, rushes, and rubbish. The difference of the grasses, where the land has been covered with ashes, and where it has not, is most striking. They have created a sweet bite of white clover and trefoil, liked much by sheep. Corrected Agricultural Report. See MANURE and TURF-Asbes.

POTASSÆ impura carbonatas, called also Cineres clavel- lats, and kali impurum, impure potash, carbonate of potash, potash, and pearl-ashes, in the Materia Medica and the Arts, enters under a variety of forms into preparations for medicinal use, and for many mechanical purposes.

As to the origin of that fixed vegetable alkali called potash, it is disputed whether it exists really formed in vegetables previously to their combustion, by which it is obtained, but which only digests substances which envelope and distil it; or whether vegetables contain only the materials proper for its formation, which consequently takes place in the act of burning, and whether it be, properly speaking, produced by fire.

The author of the Chemical Dictionary, art. Alkali, fixed vegetable, says, that the reasons for and against these two opinions are so strong on both sides, that there are grounds to believe both of them to be true; or, that the fixed alkali, obtained after burning a vegetable, did partly exist ready formed in that vegetable before it was burnt, and that the other part was produced by the “very act of combustion.” The alkali prepared by the incineration of vegetable substances, and by lixiviating and evaporating to dryness, is far from poising that degree of purity, which is always requisite in exact chemical experiments. It is almost always altered, 1. By some remaining inflammable principle, from which it may be purified either by calcination or applying to it a body on which it cannot act, and which has a stronger affinity than itself with this inflammable matter: 2. By a portion of super-abundant earth, which may be easily separated from it by drying it once or twice, by solutions and filtrations; 3. By the mixture of different saline matters, which can be separated by no chemical process but crystallization; 4. By mixture with iron, for purifying it from which no practical method is known.

Besides referring to the preceding articles Potash, Carbonate of Potash, and Pearl-ash, we shall select some other specimens of its combination.

It has accordingly been supposed that in living plants, the bafe only of potasfs exists as an element, and is oxidized so as to form the alkali during the combustion. Such is the conjecture of Mr. Murray (Chem. ii. 195.), and this may take place during the spontaneous decomposition of plants, where much water is present, for potash can be obtained, as we have already stated, by the evaporation of dunghill-water.

The pearl-ash of commerce is a very compound mass, containing besides the sub-carbonate of potash, sand, muriate of potash, muriate of iron, and oxides of manganese, to the last of which Scheele attributes its blueish or greenish colour. Different parcels of pearl-ash must undoubtedly contain different quantities of potash; and, therefore, no accurate standard of the proportion of the ingredients can be fixed. M. Vauquelin has examined samples from different countries, and the result is exhibited in the following table.

N.B. The quantity of each was 1152 parts. Annal. de Chimie, xi. 284.

The proportion of real alkali in any quantity of pearl-ash, may be ascertained in the following manner: pulverize 500 grains of the pearl-ash, and digest in successive portions of hot water, as long as any thing is dissolved. Mix the solutions, and drop in some diluted sulphuric acid, (previously prepared by mixing one part of concentrated acid with thrice its bulk of water), from a phial containing a known quantity of it, until litmus paper indicates the lightest possible excess of acid. Then heat this mixture to expel the carbonic acid; and on trying it again with the litmus paper, if it fiew any excess of alkali, add a few drops more of acid. Acertain now, by weighing the phial of acid, how much acid has been expended in saturating the alkali; and for every 100 parts of real acid set down 121.2 of pure potash. The value of the diluted acid must be previously ascertained, (see Aikin’s Dict. i. 263.) by adding to 100 grains of it muriate of barytes as long as any precipitate falls. This forms sulphate of barytes, which, when washed and dried at a low red heat, contains 83.3 per cent. of sulphuric acid; by which the proportion of real acid in the diluted acid may be known. See Pearl-ash.

POTASSÆ Acetas, Acetate of potasfs, is prepared, according to the directions of the London pharmacopoeia, by mixing together in a large glass vessel, 14 lb. of subcarbonate of potash, and a gallon of (diluted) acetic acid; and having evaporated the solution to one-half over the fire, add gradually as much more (diluted) acetic acid as may be required for perfect saturation. Let the solution be again evaporated to one-half, and strained; then let the evaporation be continued in a water-bath, fo that, on being removed from the fire, crystals shall form.

The Acetis potassæ, or acetate of potash, of the Edinburgh pharmacopoeia, is obtained by the following process: take of pure carbonate of potash, 1 lb.; boil it with a very gentle heat, in four or five times its weight of distilled acetic acid; and add more acid at different times, until the watery part

---

**Note:** The table is not fully transcribed due to the complexity of the chemical processes and the need for scientific notation which is beyond the scope of this transcription. The text refers to various chemical processes and properties of potash and its compounds, emphasizing the challenges in accurately determining the purity of potash and its various forms. The text also mentions the use of potash in agriculture and medicine, highlighting its diverse applications. The table provides a comparison of different kinds of potash and their chemical compositions.
part of the former portion, being nearly dissipated by evaporation, the acid newly added occasions no effervescence, which will be the case when about 20 lbs. of acid have been confounded; then evaporated slowly to dryness. Liquefy the remaining impure falt with a gentle heat for a short time; then let it be dissolved in water, and filtered through paper. If the liquefaction has been properly performed, the filtered fluid will be limpid; but otherwise, of a brown colour. Afterwards evaporate this fluid in a shallow glas vessel, with a very gentle heat, occasionally stirring the falt as it concretes, that it may the more quickly be brought to dryness. Finally, the acetate of potash ought to be preserved in closely shut vessels, to prevent its being liquefied by the air. This falt was first clearly described by Raymond Lully, and has at different periods assumed the following different names; "arcanum tartari, secret folidated earth of tartar, effential falt of wine, regenerated tartar, diuretic falt, digestive falt of Sylvius, and acetated kali."

It has a faint peculiar odour, and a warm sharp taste. It is usually in white masses, of a foliated soft texture, and becomes soon moist when exposed to the air; one fluid-ounce of distilled water at 60° defolves 504 grains; or 100 parts of it are soluble in 105 parts of water, and in twice its weight of alcohol. In the watery solution it is spontaneously decomposed; and it is also decomposed by the strong acids, by a decoction of tamarind, the fulphates of foda and of magnesia, the muriate of ammonia, the tartrate of potas and foda; and also by solutions of oxymuriate of mercury, and of the nitrate of filver; and consequently these cannot enter into formule with it. According to the experiments of Dr. Higgins, its constituents are 35.5 of acid, and 61.5 of alkali, in 100 parts. In medical ufe, acetate of potash is mildly cathartic and diuretic; and is found to be occasionally beneficial in febrile affections and jaundice; but it is principally employed in dropfies and other difeafes, in which a copious discharge of urine is required. For producing the latter effect, the dose may be from 3j to 3j, given every three or four hours, in any bland fluid. Doses of 5jj or 5jj open the bowels.

**Potassa Carbonis.** See **Carbonat of Potas.**

**Potassa Lique.** Solution of potas. See **Lixivium.**

See also **Alkali and Caustic.**

The **lixivium causticum,** caustic ley, is delineated in the Edinb. phar. under the denomination of **aque potassas,** and in the Dublin phar. under that of **aqua kali caustica,** water of caustic kali. This solution of potas, prepared according to the formule of the pharmacopoeias, is not fimple, but contains small portions of muriate and sulphate of potas, silica, and generally fome lime; however, these contaminations do not alter its effects as a remedy, nor as a pharmaceutical agent. This solution is diuretic, antacid, and lithotropic. As a folfent of calculi, both in the kidneys and bladder, this alkali has been long celebrated; it has been observed, however, that it acts only on calculi composed of uric acid, or of urate of ammonia; and there is reafon to believe, that its solvent effects on these calculi in the bladder are not equivalent to the irritation it excites both in the fomach and bladder; as a prophylactic its place can be better supplied by magnesia and the alkaline carbonates. Dr. Willan has perceived that the internal ufe of this folution produced the most beneficial effects in lepra. It is also ufed as a local stimulant, much diluted, in the form of lotion, to the joints, in rachitis and gouty swellings; and in its concentrated falt as a caustic, to destroy the poison introduced by the bite of rabid or venemous animals. The dose may be from 2d to 5j, taken in chicken-broth, milk, or almon mixture; or in cafes of acidity of the fomach, in fome bitter infution.

**Potassa Fusa,** or fused potas, of the Lond. phar. is prepared by taking a gallon of folution of potas, and evaporating the water in a clean iron vefsel over the fire, until the ebullition having ceased the potas fballs, and then pouring it out upon a clean iron plate into proper forms. This preparation of potas was formerly called **causticum commune accordinum,** or stronger common caustic; it is in the Edinb. phar. defcribed under the name of pothas, and in the Dublin phar. under that of kali causticum. In order to procure it as free as pooffible from carbonic acid, the evaporation should be performed very quickly, and in a deep vefsel, fo that the watery vapour which rifes may exclude the atmospheric air. It is generally run into moulds, which form it into folid cylinders, which are covered with paper, and kept in well-topped bottles. Berthollet’s method of obtaining it in perfect purity is defcribed under the article **Potas;** but the following procefs of Lozow is faid to be more economical. Evaporate a folution of potas until a pellicle forms on its surface, and then let it cool; and carefully separate the falt deposit. Renew the evaporation, ftripping off the pellicles that form on the surface, and as foon as they ceafe to be formed, and the ebullition is ended, let it be removed from the fire, and conflantly ftrirred till it is cold. The mass is then to be diffolved in twice its weight of diftilled cold water, the folution filtered, and evaporated in a clean iron or silver ftrain (a glas retort would be diftilled by pure potas, when hot) until crystals are depofited. If the heated fluid confiditates into a mass, in any degree, a fmall portion of water must be added, and the mass again heated to fluidity. The fupernatant liquor is left of a brown colour, which, after being kept for fome time at refl in well-topped phials, depofits the colouring matter, and may be again evaporated and cryftallized as before. The crystals obtained in the various evaporations are colourless pure potas. (See Nicholoffs Journ. 4to. vol. i. 164.) This concrete potas is a white brittle fubftance, having the peculiar odour of faking quick-flime, and a degree of cauficity which will not allow its being tafted. It attracts water rapidly from the atmofohe, and is completely foluble in fles than its own weight of that fluid at 60°. When heated to 360° it melts, and at a red heat is volatilized. It unites with fulphur, the acids, many of the metallic oxides, and the fixed oils. Its confituents, according to the analyfis of Sir H. Davy (Elem. of Chem. Phil.), are in 100 parts, 83 of potaffium and 17 of oxygen. See **Potas, fupra,** and **Potassium.**

This folution is ufed only as an efcharotic, for forming fiffes in difeafes of the hip-joint, the fpine, and deep-feated difeafes. It has been lately much recommended for the removal of ftrictures of the urethra.

**Potassa cum Calce.** Potas with lime, is formed, according to the Lond. phar. by taking three pints of folution of potas and a pound of frefh burnt lime. Boil the folution down to a pint, then add the lime previously flaked by the water, and intimately mix them. This was the former **causticum commune mitius,** or milder common caustic; it is the caustic kali with lime of the Dublin college. The addition of the lime in these preparations makes the potas less deliquescent, and consequently more manageable as an efcharotic.

**Potassa Nitritus,** nitrat of potas, nitre, or saltpetre, is a neutral falt, composed of nitric acid and potas in a flate of perfect mutual faturafion. The most ufal form which this falt affumes is that of the common quartz cryftal, or that of a straight fix-fided prism, terminated at each extremity by a fix-fided prism. Its specific gravity, according
POTASSÆ.

to Newton, is 1.9, according to Mufchenbroek 1.901, and according to Haffenfratz, 1.9369, which latter is said to be the least correct. Nitre, when fully crystallized, is very brittle; and if the large prismatic crystals are held in the warm hand, they will crack transversely with a very audible noise. The moisture which it generally attracts on being exposed to the air is probably owing to the caudal mixture of a small portion of deliquecent salt. Some differences of opinion subsist with regard to the solubility of nitre in water of different temperature. According to Bergman, this salt is soluble in seven times its weight of water at the usual temperature, and in about its own weight of boiling water; but from the experiments of Haffenfratz it appears, that a hot saturated solution of nitre, after being cooled down to 61° Fahr., and remaining at this temperature 24 hours, holds nearly a fourth of its weight of salt, and at 54° Fahr. about a sixth of its weight. According to Beaumé, 4 oz. of boiling water will take up 10 oz. of nitre when the solution is made in a matrafs, but if a basin or other open vessel be used, a pellet begins to form at the surface of the liquor, when it contains water and salt in equal proportions. Haffenfratz has constructed the following table of the specific gravity and composition of solutions of nitre in water at 61° Fahrenheit.

</table>

Nitre is easily fusible at a heat almost equal to that of melting zinc, or somewhat below that of ignition, and at this temperature it undergoes no change except a slight loss of weight by parting with its water of crystallization; and a piece of charcoal may be immersed in it without producing any detonation. Poured on any flat surface it presently congeals into a white translucent mass, commonly known by the name of ‘cystal mineral.’ (See Crystal.) But with a heat more than sufficient to maintain its liquidity, a decomposition commences; bubbles of gas are difganged; and if the heat be continued as long as any air escapes, the acid is entirely decomposed, and nothing remains but the alkaline base of the salt: the gas that first comes over during the process is tolerably pure oxygen, but the latter portions are largely mixed with azot. When the fusion is not continued long enough for the total decomposition of the nitre, the residue contains free alkali, and a variable proportion of nitrite of potash.

The decomposition of nitre is more rapid, if some inflammable sub stance be present; in this case a detonation of nitre takes place: the added inflammable matter combines with the greater part of the oxygen of the nitric acid, and is converted into an oxyd or acid; if the latter, it generally unites with the alkaline base of the nitre in proportion as its own acid is decomposed or driven off. Accordingly, if a few grains of sulphur be projected on red-hot nitre, the former immediately takes fire, burns rapidly with a reddish-purple flame, and is converted into sulphuric and sulphuric acid, at the expense of the nitrous acid, which is more or less decomposed: the sulphuric acid mixed with nitrous vapour flies off, while the sulphuric acid remains in combination with the difganged potash of the nitre, forming “fulphat of potash.” When the quantity of sulphur added is not sufficient to effect a total decomposition of the nitre, the result is a mixture of the two neutral salts, and was known among the old chemists by the name of “Glafer’s polychrest salt.”

The detonation of nitre with charcoal is very rapid; whether the charcoal is added to the nitre brought previously to a flat of fusion, or the two ingredients are mixed together by pulverization, and then thrown into a crucible, or any other vessel heated red-hot, an intense blue flame is difganged, accompanied by a great heat and a white vapour, the nitric acid disappars, and the residual salt is “subcarbonate of potash.” In this case, the charcoal combines with the oxygen of the nitric acid, and is converted into carbonic acid, a portion of which unites with the alkaline base of the nitre, whereby the salt is volatilized, together with the azot produced by the decomposition of the nitric acid. Sir H. Davy’s experiments, detailed in his “Researches,” throw farther light on this subject. Having filled a glass tube with a mixture composed of six parts of nitre and one of charcoal, he detonated it, and received the product into a jar inverted over mercury, and containing a little water; which, after the operation, was so much acidulated as to reftore the colour of red cabbage juice that had been rendered green by an alkali, thus indicating the presence of a little nitrous acid; but the same liquor, when superfatured by caustic potash or quick-lime, gave out a very sensible odour of volatile alkali, so that it appears to have contained acidulous nitrate of ammonia. The gas produced by the detonation being mixed with the carbonic acid, separated by uric acid from the alkaline residue, was found to be composed of carbonic acid, nitrous gas, and azot, in the proportion, by bulk, of twenty of the first, three of the second, and seven of the third. The presence of ammonia in this experiment is attributed by Mr. Aikin to the decomposition of the water of crystallization by the charcoal, and the combination of its hydrogenous base with the azot of the nitric acid.

Those compound acids into which carbon enters as an effential constituent, decompose nitre with nearly the same energy as charcoal does: thus, if equal parts of nitre and crude tartar are mixed together and ignited, a detonation takes place; the tartarous and nitric acids mutually decompose each other into carbonic acid, and other gaseous products, and there remains subcarbonate of potash, being the alkaline base of both salts. Among the old chemists this alkali was much esteemed, and by them it was named
POTASSÆ.

"white flux," “extemporaneous alkali,” and “nitre fixed by tartar;” but it is not in any respect different from purified pearl-ash, if the nitre has been all decomposed.

Most of the metals, as Aikin observes, if reduced to filings or powder, and mixed with nitre, will produce a detonation at a red heat; the metal in a state of high oxidation unites with the alkali, and the nitric acid is more or less completely decomposed. The most inflammable metals, such as zinc, antimony, tin, iron, and bismuth, produce the most violent detonation. The effect of pure hydrogen on nitre has not been examined; but those readily-fullicable inflammable bodies, into the composition of which it largely enters, are not capable of detonating with nitre, except in exact proportion to the amount of carbon which they contain beyond what is requisite for the production of carburetted hydrogen; or as Macquer, who made the discovery, states it, no detonation will happen till the inflammable matter be burnt and reduced to a coal; then the detonation commences, and is always proportional to the quantity of coal produced by the inflammable matter.

Nitre is entirely decomposed by distillation at a moderate heat with sulphuric acid, and at a higher temperature with phosphoric, boracic, and arsenic acids. These combine with the alkali of the salt, while its acid passes over in the state of vapour. A similar effect is produced by flex or alumina, or a mixture of both; but the heat requisite in this case being considerably higher than in the former, a proportionately larger quantity of nitric acid is decomposed during the process. Strong muriatic acid will also in part decompose nitre. The only substance capable of decomposing nitre, so as to liberate its alkali, is caustic barytes; a quantity of each in fine powder being mixed together, and then moistened with a little water, re-acts on each other, and produce nitrate of barytes and caustic potash, of which the latter alone (if too much water is not used) remains in solution.

The exact analysis of nitre is difficult, and hence the most able chemists have varied in their statements of its composition. Bergman found that 49 parts of potash, when saturated with nitric acid, afforded 100 of crystallized nitre; and accordingly he gives the proportions of this salt at:

<table>
<thead>
<tr>
<th>Potash</th>
<th>Nitric Acid</th>
<th>Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>49</td>
<td>33</td>
<td>18</td>
</tr>
<tr>
<td>100</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

According to Wenzel, 100 parts of nitre contain:

<table>
<thead>
<tr>
<th>Potash</th>
<th>Acid</th>
<th>Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>48.13</td>
<td>51.87</td>
<td>0.00</td>
</tr>
<tr>
<td>100.00</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

But according to Kirwan, 100 parts of crystallized nitre, dried at 70° Fahr., are composed of:

<table>
<thead>
<tr>
<th>Potash</th>
<th>Acid</th>
<th>Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>51.8</td>
<td>44.0</td>
<td>4.2</td>
</tr>
<tr>
<td>100.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

And as this estimate is incidentally confirmed by other experiments of Berthollet and of Kœr, it is probably, says Mr. Aikin, very near the truth. Macquer’s Chem. Dict. Aikin’s Dict. of Chem. and Min., to which we are chiefly indebted in the compilation of the preceding article.

For the natural history and manufacture of nitre, and its various uses in the arts, we refer to the article Saltpetre.

As to its medical properties and uses, it is considered as refrigerant and diuretic; and externally applied, it is cooling and astringent. When taken in repeated small doses, it abates heat and thirst in cases of increased excitement, diminishes the force and frequency of the arterial action, and increases the secretion of urine, in which the salt may be detected by chemical tests. It is efficaciously given in all inflammatory cases, active hemorrhages, and in herpetic eruptions. Although diuretic, it is of little use in dropsies, and is contraindicated in typhus and hectic fevers; in the latter of which, as Dr. Percival has justly observed, it lowers the pulse at first, but afterwards raises it higher than before. A small portion of it allowed to diffuse slowly in the mouth often removes incipient inflammatory fore throat; and hence its utility in gargarisms for that complaint. It is most advantageously given diffused in mucilaginous fluids, as almond emulsion, in moderate doses not exceeding grs. xv, frequently repeated. In large doses it excites nausea; and 51 given for a dose, which has sometimes occurred for sulphate of soda, occasions vomiting, hypercarcharias, bloody froths, convulsions, and sometimes death. Opium and aromatics are the best antidotes. Thomson’s Lond. Dip.

Potassæ Subcarbonates, subcarbonate of potash, is prepared, according to the directions of the London pharmacopoeia, in the following manner: take of impure potasæ (pearl-ashes) reduced to powder, 3 lb.; and boiling water, 3 1/10 pints. Diffuse the potasæ in the water, and filter; then pour the solution into a clean iron pot, and evaporate the water with a gentle heat until the liquor thickens; then withdraw the fire, and filter afiduously with an iron spatula, until the salt concretes into small grains. A pure sub-carbonate of potash may be prepared in a similar manner from tartar, previously burnt till it is of an ash-colour. (See Carbonat of Potasæ, and Tartar.) Its constituents, according to Berard, are 29.79 alkali, and 70.21 water, in 100 parts. (Annal. de Chim. lxxx. 55.) As an article of the Materia Medica, it is debatable, diuretic, and antacid. In small doses, it is sometimes given in cases of glandular obstructions of the abdominal vifera, particularly hepatic obstructions, with feeing advantage; but it is not certain, that the benefit does not arise from the effects of the remedy in correcting acidity of the prime vitæ. Its effects on the kidneys are considerable, when aided by plentiful dilution. The principal use of this salt in medicine is in the formation of saline draughts, for which purpose it is given in combination with a solution of citric acid, or with recent lemon juice, in the proportion of 39 of the salt to 14 of the lemon juice, or the acid solution, in febile affections: when given as an antacid, its taste and acrimony are most perfectly covered with milk.

Potassæ Sub-carbonas, liquor, a solution of sub-carbonate of potasæ, is prepared by dissolving 1 lb. of sub-carbonate of potasæ in 12 fluid-ounces of distilled water, and filtering the solution through paper: Lond. Pharm. The medical properties and uses of this solution are the same with those of the concrete salt. The dose may be from 1/10 to 1/8, in any convenient vehicle.

Potassæ Sulphas. See Sulphat of Potasæ.
Potassæ Sulphats cum Sulphure. formerly Polychrest salt.
See Sulphat, &c.
Potassæ Sulphites. See Sulphite of Potasæ.
Potassæ Sulphureum. See Sulphurat of Potasæ.

Potassium Tartrate and Tartris. See Tartrate and Tartrites.

Potassium, or basis of potash. The splendid discovery which brought to light this extraordinary sublimation, is so much connected with the history and progress of electro-chemistry, that it is impossible to enter into the former subject without, in some degree, encroaching upon the latter.

Immediately after the discovery of Volta's pile, philosophers began to make some observations respecting its agency in producing chemical effects. Mefris, Carislile and Nicholson, and Mr. Cruickshank, were the first chemists who turned their attention to the subject. On the continent, Mefris, Fourcroy, Vaauquelin, Thenard, Ritter, Berzelius, and Volta himself, followed up the inquiry, and many interesting facts on the chemical effects of electricity were soon established. It was by the British chemists just mentioned, however, that the important fact of the decomposition of water by electricity was first discovered. Mr. Nicholson showed, that by introducing wires connected with the two extremities of the Volta pile, into a tube filled with water, a stream of hydrogen gas arose from the wire connected with the negative pole, and the wire connected with the other pole became oxidated; but when the latter was of a metal not susceptible of oxidation, oxygen issued from it.

It is about this period (1806) one of the most memorable in the annals of natural philosophy, that Sir H. Davy began his researches. He had no sooner turned his fertile genius to this inquiry, than a number of new and interesting facts were added to this department of science. He showed in particular, that whenever a saline sublimation is exposed to the action of the Volta pile, it is invariably decomposed, the alkalies being attracted towards the negative pole, and the acid towards the positive.

Similar experiments were instituted upon a variety of sublimations, and a sufficient number of facts were obtained to enable Sir H. Davy to conclude, in general, that hydrogen, the alkaline sublimations, the metals, and certain metallic oxides, are attracted by negatively electrified metallic surfaces, and repelled by positively electrified metallic surfaces; whilst oxygen and acid bodies are attracted by positively electrified metallic surfaces, and repelled by negatively electrified metallic surfaces; the electrical attractions and repulsions thus affording a new and powerful means of chemical decomposition.

These were the important results which Sir H. Davy laid before the public in 1806. For some time the philosophical world waited in silence; and although Davy had advanced in his first paper the conjecture that many bodies, hitherto considered as simple, might probably be decomposed by electricity, no one ventured to take up the subject; and it was not until a twelvemonth afterwards that Davy himself renewed his researches, and obtained those results which placed him amongst the first discoverers of the age. The fixed alkalies were the bodies to which he first directed his attention; and, after a few days' labour, he was able to demonstrate that the alkalies are compound bodies, and that they consist of a new and highly curious metallic sublimation, combined with oxygen. His first experiments, which were upon potash, are thus related in his own words. Phil. Tr. f. 1807.

A small piece of pure potash, which had been exposed for a few seconds to the moisture of the atmosphere, so as to give conducting power to the surface, was placed upon an insulated disk of platinum, connected with the negative side of the battery in a state of intense activity; and a platinum wire, communicating with the positive side, was brought in contact with the upper surface of the alkali. The whole apparatus was in the open atmosphere.

Under these circumstances, a vivid action was soon observed to take place. The potash began to fuse at both its points of electrization. There was a violent effervescence at the upper surface; at the lower, or negative surface, there was no liberation of elastic fluid; but small globules having a high metallic lustre, and being perfectly similar in external appearance to quicksilver, appeared, some of which burnt with a brilliant flame, and others remained, and were merely tarnished, and finally formed by a white film which formed on their surface.

"These globules," continues Davy, "numerous experiments showed to be the sublimation I was in search of, and a peculiar inflammable principle, the basis of potash."

It is to this metallic sublimation that the illustrious discoverer has given the name of Potassium, and it now remains for us to describe its properties, which we shall do nearly in Sir H. Davy's own words. See Davy's Elements of Chemical Philosophy.

Potassium is lighter than water; its specific gravity is between 8 and 9, water being 10. It is a solid at common temperatures; it is very soft, and easily moulded by the fingers. It fuses at about 150° Fahrenheit, and rises in vapour in a heat a little below that of redness. It is perfectly opaque. Its colour is white, like that of silver when it is newly cut, but it rapidly tarnishes in the air; and to be preferred from change must be kept under naphtha.

It is a conductor of electricity. When thrown upon water it acts with great violence, swins upon the surface, and burns with a beautiful light, which is white, mixed with red and violet; the water in which it burns is found alkaline, and contains a solution of potash. It inflames when gently heated in the air, burns with a red light, and throws off fumes, which are alkaline. It burns spontaneously in chlorine, or oxymuriatic acid gas, with intense brilliancy. It acts with energy upon all fluid bodies containing oxygen or water; and in attracting oxygen from water, it dilates hydrogen.

Potassium combines with oxygen in different proportions; if gently heated in common air, or in oxygen, the result of its combustion is an orang-coloured fulible sublimate, which, as Mefris, Gay Lussac, and Thenard have shown, is an oxide of potassium, containing a larger proportion of oxygen than that which constitutes potash. When thrown into water, this oxide effervesces, and oxygen is diluted. If heated strongly upon platinum, oxygen is expelled from it, and pure potash remains, which dissolves in water without effervescence, but with much heat. This oxide of potash is not to be confounded with pure potash, dried by mere ignition, since, as was observed in the article Potash, the latter never contains less than 17 or 18 per cent. of water.

The inflammation produced when thin pieces of potash are introduced into chlorine, is very vivid. The attraction of chlorine for potassium is much stronger than that of oxygen; so that potash and the orange oxide of potash are immediately decomposed by chlorine, the chlorine combining with the metal, and the oxygen being left free.

The result of the combination of chlorine and potassium is the sublimate called muriate of potash, a nomenclature to which Sir H. Davy strongly objected; since, according to his view of the subject, this compound contains neither muriatic acid nor potash, but potassium and chlorine. As, however, some of the most eminent chemical philosophers
of the age still entertain great doubts respecting the accuracy of Sir H. Davy's views in regard to the nature of oxymuriatic acid, this part of the subject may be considered as still dubious; and until the point is proved or controverted by more decisive arguments, it would be better to postpone the proposed changes of nomenclature.

Potassium and sulphur combine with great energy when they are heated together, producing much heat and light, and forming a subphuret of potassium, which is of a grey colour, and appears to consist of 30 parts of sulphur to 75 of potassium.

A subphuret of potassium may be produced in a similar manner, which burns with great brilliancy when exposed to air, and when thrown into water produces expulsions, with diphosphidation of phosphuric hydrogen.

From the exclusive attraction which potassium has for oxygen, it may be used as a general agent for detecting the presence of that principle in bodies; and a number of substances, undecomposable by other chemical agents, are readily decomposed by this body.

Such are the principal circumstances relating to the history of this extraordinary substance. It will be seen under the article Sodium, how sods, the other fixed alkali, yielded to the fame powers of chemical decomposition; so that this important class of bodies, the nature of which had evaded the researches of all former chemists, and was deemed an almost insoluble problem, suddenly yielded to a bold effort of British genius. Davy feized upon the powerful instrument which others had discovered, but which he knew best how to use and appreciate.

With this wonderful agent he brought to light bodies which the human eye had never beheld, and which, without him, might have remained eternally concealed under their impenetrable disguise.

An important circumstance remains to be mentioned. When the bafes of alkalis were discovered, it was thought that they could be obtained by means of the Voltaic electricity alone, and could be procured that way only in very minute quantities. But Mellers, Gay Lussac and Thénard discovered, in 1808, that potassium might be procured by chemical means, without electricity. If iron turnings be heated to white heat in a curved gun-barrel, (Plate XXIV. Miscellanies, fig. 7.) and if melted potsia be made flow slowly to come in contact with the turnings, air being excluded, potassium will be formed, and may be collected in a cold part of the tube. Potassium may in this way be now prepared in almost any quantities, and it is peculiarly satisfactory to observe, that when Sir H. Davy's experiments could be repeated at pleasure upon a large scale, his conclusions were confirmed in all the important particulars.

POTATO, in Gardening, a well-known, useful, and common root. See SOLANUM.

Potatoes, in Agriculture, the name of a well-known plant of the knobby-rooted kind, much used as human food in most places. It may be noticed, that the discovery of this inoffensive root has been of the greatest consequence to mankind, as it is now almost generally cultivated, though at first its introduction was very much opposed. Mr. Donkin says, that it may with the greatest propriety be denominated the bread-root of Great Britain and Ireland. It was first brought from Virginia by the memorable, but ill-fated, Sir Walter Raleigh; who, on his return home, in the year 1623, planting at Ireland, distributed a number of potatoes in that kingdom. There having been planted, multiplied accordingly; and in a few years, the cultivation of them became general. And they became food of the greatest benefit to the people, in the scarcities of grain that have since occurred in that country, as well as in this, especially in the last severe famine. They were brought from Ireland into Great Britain; and owing to a ship, loaded with potatoes, being wrecked on the coast of Lancashire, the cultivation of that root, in the field, was first generally established there. Further, that within these last fifty years, the culture of potatoes has been introduced and extended in every part of the kingdom; but it is now much more general in Scotland than in England, except in a few counties.

During the great scarcity of grain which happened in the north of Scotland, in consequence of the failure of the crop of 1795, many thousands of the inhabitants must have been reduced to the greatest distress, but for the relief which potatoes afforded them. And although the crop of potatoes failed to a considerable degree in 1795, every one knows how much the miseries, consequent on so great a failure of the crop of grain as then happened, were alleviated, in consequence of this root being so generally cultivated, and in such abundance. The culture of a root so highly valuable as the food of man should, of course, be particularly attended to by the farmers in all places.

It is now well known that there are two general kinds of this plant, which are distinguished into the red-rooted, which has purple flowers, and the white-rooted, which has white flowers; but in raising the root from the seed, or apple, numerous varieties have been introduced, and are daily introducing themselves to the planter.

It is supposed by the writer just noticed, that great improvements may still be made, both in the quality and productivity of this plant, by raising it from seed, as will be fully shown below. It is obvious, therefore, from the mode of raising the plants by seed, that the varieties in cultivation must be extremely numerous, and be liable to continual change. The following sorts have been distinguished by an extensive cultivator in Lancashire, where this kind of culture is in general well managed.

**Early Kinds.**

- Smooth yellows,
- Red champions,
- White ditto,
- Lady queens,
- Drunken landlord,
- Birch's golden yellows,
- Smith's feedings,
- Fox's ditto,
- Boffow's kidneys,
- English champions,
- Britain's dwarfs,
- Bates's ditto,

**Late Kinds.**

- American white range,
- American red ditto,
- Derbyshire reds,
- Late champions,
- Late kidneys,
- Pink eyes,
- Pink-nosed kidneys,

There are also other varieties of the late fort.

- White Scotch,
- Magpie,
- Rough red,
- Purple,
- English white,
- Silver skin,

These
These last fix were formerly much in cultivation in this district; but the pink eyes, champions, and dusns, are now a great deal more in estimation.

But as for use as human food, the old winter red has been found highly useful and keeping well to a late period in the spring, when most other fruits are unripe for the table. As castle potatoes, the ox noble and clutter fruits have been most commonly employed. The first, though formerly very productive, has lately been found to decline in some degree; it is, however, a good fruit. The latter is also a very productive fruit in this view. The royal, or Cumberland early, is likewise an useful fruit, being both large in size, and more productive. A late writer rates, that the pink eyes and copper plates are of a hardy nature, and probably capable of being grown with less perfect culture than most of the other varieties. The white and the apple fruits are only proper to be used in the early part of the season.

Various attempts have been made by different cultivators, to ascertain the difference of productivity in different parts; but the matter has not yet been decided with any degree of accuracy. But in Mr. Young's trials under the drill system, the results were these:

**Kinds** | **Produce**
--- | ---
Clutter | 360 bushels per acre
Red-nosed kidney | 144
Golden tags | 207

And with Mr. Baker in Ireland, the results, as stated in the report on potatoes, published by the Board of Agriculture, were these, on a similar space of ground:

**Kinds.** | **Produce.**
--- | ---
Common wife | 21 lb. 6oz.
Apple | 20 12
Red French | 15 12
Munster white | 16 0
Crones | 15 6
Spanish | 15 10

But on repeating the experiment, they stood thus:

**Kinds.** | **Produce.**
--- | ---
Black | 111 bushels per acre.
Quaker wife | 108
Red French | 88
White ditto | 85
Common wife | 103
Apple | 76
English white | 83
White Munster | 79
Spanish | 70
Crones | 60

In Cheshire, there are different kinds of both the early and the late fruits made use of, in different parts. Among the early varieties, in the Frodsham district, they chiefly employ the Foxe's seedlings, and the perins; but in the tract about Wirral, the early manleys, Foxe's seedlings, and Broughton's dours, none of which ever bloomed; and in the Arlingham range, the principal kinds are the Foxe and the green seedling. Some other early fruits are, however, occasionally had recourse to in these situations, though they are seldom such free bearers.

Among the later kinds, in the first of these districts, are the ox noble and the Irish apple, the kidney potato now wholly given up here; in the second, the fruits commonly grown for winter ufe are the pink eyes, the ink eyes, the Scotch white, the ox noble, &c.; and in the last situation, the fruits mostly had recourse to are the white and red champions for the more early, and the dark colored potato, called the sweep, for the later winter months.

About Hord, in Essex, the favourite potatoe, for the general crop, was formerly the red-nosed kidney; but this is now much neglected, in consequence of its being almost sure to curl; and the champion very much preferred, as it does not curl.

**Soil and Preparation.**—In regard to soil, the potatoe will grow in almost any, even in that of the most indifferent quality; but that in which it thrives best, and where potatoes of the best quality are produced, is a light loam, neither too dry nor too moist; but if rich, so much the better. They may, however, be grown well on many other sorts of land, especially those of the mossy, moory, and other similar kinds, where they are free from flagrant moistures, and have had their parts well broken down by culture. And the differences in the produce, as depending on soil, are in some manner shown below, in the result of Mr. Townley's trials, detailed in the report of potatoes by the Board of Agriculture; though the very stiff sorts of land do not seem to have been tried. The experiments were made by planting four eyes or buds of the clutter variety on four different descriptions of land.

**Kinds of Soil.**

<table>

<tr>
<td>Sand</td>
<td>15</td>
</tr>
</tbody>
</table>

From this it is evident, that though this sort of crop succeeds in the most perfect manner in the light friable sorts of soil, it does not answer on those of the purely sandy descriptions, as they are apt to become too dry in hot seasons, and to have too little of the earthy material in their composition. The wires of these roots have been found to shoo and extend, and the roots to diftem themselves, and become of the largest sizes, in such soils as abound the most in good rich mellow mould. In cultivating this root in the field, it is of course of much advantage to have the land well broken down and divided by repeated ploughings and harrowings in the autumn and early spring months, being careful never to stir the land when it is wet. It may likewise be of utility in this view, to have recourse to the culture of this root, after such sorts of crops as have a tendency to loosen and render the land mellow and friable.

In Cheshire a considerable depth of dry, light, or loamy soil, is thought the most suitable to the cultivation of the potato, though other sorts of land may answer the purpose very well. But whatever is the nature of the soil, the ground should be well laid up in the autumn, to receive the beneficial action of the frosts, and in the spring be ploughed in a cross direction, torn well to pieces, and completely pulverized by the harrows; after which, about the end of April, or beginning of the following month, it is dunged and ploughed in a deep manner, into the form in which it is to be planted. In the Arlingham district of this county, a dry sandy soil, and tolerably warm situation, is always preferred for the early sorts; but for the later kinds, a cooler bottom, if not clayey, is more generally chosen.

In Essex likewise, the potatoes are put into the ground after they have been prepared by an autumnal breaking up, and spring ploughings and harrowings for the most part two or three times.

However, where the practice of putting this sort of crop in...
in upon sward or lay ground is employed, which by some is supposed advantageous, the best method of preparation is that of padding and burning, or the use of the kilm-coulter plough, the dung and ashes being ploughed together, in the first cut by a light harrow. In the Survey of the North Riding of Yorkshire, the land intended for potatoes, if wheat, bean, or oat rubble, should, it is observed, be ploughed before Christmas, or as soon after as possible, about the middle of April; if the land has got well dried, it should be harrowed well, repeating the operation, and also using the roller till the land is become fine. In a few days afterwards it should be ploughed again, being harrowed and rolled, as in the former case, and where the land is in a bad condition, it may be necessary to give it one or two ploughings more, with suitable harrowings and rollings, working it according to its particular state, letting it remain a few days between the ploughings; then it should be ridged up according to the state of the land in respect to fertility for being planted.

Manuring.—It is probable from the nature of this root, and the circumstance of its produce being formed in the soil, that it can never be cultivated to advantage without the use of manure. In some forts of the more heavy kinds of land, such as is of the long littery kind may be made use of, as keeping such sorts of land more dry and open, but in those of the light, dry, friable kinds, the more reduced fort of manure may be better. Mr. Young considers farm-yard dung the best, and the more the better, unless the soil be very rich, and upon an average of soils, 6s. should not be laid than twenty-five or thirty large loads to the acre, being spread equally that it may plough in well. But Mr. Bingleley, in his Survey of Somersetshire, supposes rotten horse dung as the best manure for this crop, after which he advises hogs' dung, and then all sorts of farm-yard dung; but he observes, that lime, marle, foapers' ashes, and rags, make the potatoes feably. In Lancashire, the good littery stable dung is mostly set apart for this crop. In an excellent report on the culture of the potato, presented to the public by the Board of Agriculture, the comparative advantages of different sorts of manure, have been in some measure shown in different experiments as below.

<table>
<thead>
<tr>
<th>Quantity of Manure per Acre.</th>
<th>Crop: Bushels.</th>

</table>

But in the culture of this kind of root on the heavier kinds of loamy lands, various sorts of littery materials have been made use of on the principle of preferring the soil in a more open and porous condition for the knobby roots to extend themselves. With this view, wheat-straw, flibble, furze, broom, heath, sea-weed, and other similar materials, have been made use of after being reduced by chopping, with good success, being laid in the bottom of the drills to be planted upon. Various kinds of luxuriant green vegetable crops have likewise been turned into the soil, and planted upon as a manure with success in some instances, where that substance could not be procured. And also substances of the petty kind have been found advantageous in the same way, as well as in keeping the drier sorts of land in a better state of moisture, and those of the heavy sort in a more light and open state, and of course more free from that moisture. Good rich mould and decayed leaves may be of use in cases where they can be had in sufficient quantity. All the trials that have been made with lime, seem to shew, that it has a tendency to induce the curv and canker in whatever state it is employed.

A curious practice in manuring for potatoes is had recours to about Welton, in the county of Chester, which is situated close to the junction of the two rivers, the Mersey and the Weaver. Sea-mud is there made use of as manure for crops of this sort; twenty loads being the quantity usually laid upon the acre. The ground thus manured, not only, it is said, gives a large produce of potatoes, but is in a state of excellent preparation for a succeeding crop of either wheat or barley. And the adoption of this practice has increased very greatly the value of the land therabouts.

The quantity of common manure which is used all about Frodsham for this crop, is various, from twenty to thirty tons to the acre. This is there procured at the rate of six or seven shillings the ton, and it is spread upon the land previously to the last ploughing. In all the other parts of this district, they also constantly manure the land for the growth of this root, except in some particularly and naturally rich spots.

Near Ilford, in the county of Essex, as well as in most other parts, they manure their potato land by dunging in the spring, at the rate of about fourteen loads to the acre, which costs five shillings a load; they are spread upon the field just before the second ploughing, on which they plant.

In some parts of Lancashire, rape-dust is found a good manure for potatoes; but night-soil, both there and in Essex, makes them scabby.

But the ashes of burnt land are found highly beneficial in producing good crops of this root, which affords an opportunity of cultivating the coarse and wafte sorts of grass land to much advantage, as by a crop or two of this sort they will mostly be in a condition to afford those of the grain kind.

Whatever sort of material may be made use of as a manure for this kind of crop, a sufficient proportion should always be employed to afford a due supply of nourishment to it while upon the ground. In the drill method of putting in crops of this kind, the manure is usually placed in the bottom of them in an even manner, but in the other methods, it is usually spread out evenly over the surface, and then turned down. It has been supposed by some, that for the early crops of this root, it is better to apply the manure to the crop that precedes them, as by that means the danger of their over-luxuriance may be prevented, and the crops be better in their quality. In general it is, however, the best practice to apply the manure to the crop.

The manner of placing the manure so as to afford the greatest advantage, has been a disputed point by different cultivators. The following experiments, made by a correct farmer, however, shew the propriety of placing it below the fet, and not upon it, as is often done.

R r 2

Experi-
Experiments made by Mr. Baker on Potatoes planted in an under-stratum of poor yellow Earth, April 27th and 29th, 1771, with the Rows 20 Inches aunder, and the Sets 12 Inches apart in the Rows, and 30 Sets in each Row.

*Some error of the men suspected in this sort.

Whoever casts an attentive eye over the preceding table, will see that several circumstances of information are immediately pointed at; there are very many others which are omitted; those before us appear to be satisfactory, in the several variations which arise upon the face of the table, that he shall, at convenient time, pursue all the changes which the subject will admit of. In the mean time he proceeds upon the present information.

The first question is this, whether planting potatoes under or over the dung, is most advantageous to the crop? This question appears to be conclusively answered by every species of potatoe in the first and second set; and the totals of each clearly determine in favour of putting the seed over the dung.

N° 1 to N° 6, over dung, gros produce lb. oz. 105 4
— 7 to — 12, under dung, ditto lb. oz. 84 3

Over dung superior to under, by lb. oz. 21 1

This difference of 2 lb. upon so small a quantity of ground, would be a very great object upon an acre. Happily in this kingdom (Ireland) the potatoes are chiefly laid over the dung. In England they practice the contrary in many places.

The second object in this enquiry was, to determine, by fair experiment, whether the small feed is equally prolific, as thousands assert it to be, with that which is reasonably large. For this purpose, he cut single eyes with his own hands, and was
POTATO.

was careful not to cut them thin, but like pellets. This set was planted under dung; and therefore we must compare it with our second set of experiments.

N° 7 to N° 12, under dung, gross produce 8. 4. 3
— 13 to — 18, under dung, gross produce 6. 4. 12

Reasonably large seed preferable to very small, by 19. 7

This upon an acre would be a prodigious difference; and seems decisive in favour of seed moderately large. Whereas, N° 19 to 24, both inclusive, seem by no means to prove very large seed to be necessary: for if we compare those numbers with N° 7 to 12, both inclusive, we see the greater produce from the larger seed is by no means regular, and therefore that point is not decisive in the present enquiry; and the remark upon N° 22 should not be forgotten.

Our third object in this enquiry is a truly important one to the poor labourer of Ireland, viz. to ascertain, with accuracy, which kind is most prolific upon poor broken ground. As N° 25 and 26 did not come to hand time enough to introduce them in the whole set of experiments, he must throw this part of his enquiry into two divisions, as there is some material a difference between planting over and under dung. To do this in the shortest manner, he shall only throw the several kinds into two little tables, according to their merit in quantity; the quality is a consideration chiefly at the gentleman's table.

Here we always have the order of merit in point of quantity of the merchantable potatoes, from equal culture. The totals vary a little, as in the preceding table. The wife and apple potatoes keep their places in both tables, as to produce; but the red French and Munster white, and crones, contend pretty closely as to produce; and in the second table vary in their places of merit. Hence we may conclude, that some of these kinds agree better by being put under the dung than others; but every examination of the latter point clearly proves, that under dung lefns the crop. The Spanish potatoes, which are certainly the best in the world for eating, uniformly keep their place, of being last in point of produce. There is another very material point, worthy of the cultivator's attention in his choice of his potatoes in these tables. He will observe, doubtless, that he has given the number of the merchantable potatoes of each kind; he will therefore see that there is a prodigious difference in their sizes, a circumstance that comes strongly against the wife potatoes. A table upon that point, framed from the preceding ones, according to the order in point of size, is given below.

</table>

Time Sets and Method of planting. - Mr. Donaldson says it has been proved from long and general experience, that the month of April is the best season for planting the root, so as to produce a farinaceuous or mealy crop. Potatoes are frequently planted in the end of May, and sometimes even in June; but the crops, although often as abundant, are neither so mellow nor so mature, as when the sets are planted in April, or in the first eight or ten days of May. A late
practical writer, however, contends, that this sort of work should constantly be performed as soon as possible after the danger of the frost is over, which, in the more northern districts, is generally from about the middle of March till the latter end of April; and in the northern ones, from about the middle of April till towards the close of May, according to the differences in the state of the climate. The earlier the crop can be got into the ground, the better it becomes. Besides, the potatoes have a better chance of being taken up and removed from the land, while the season is dry; and there is less risk of injury from moisture and frosts, after they are fit for taking up. It may also be added, that the land will derive much advantage from being ploughed up while it is in a dry condition, after the potatoes have been removed, as in this way it is preferred in a less moist state during the winter, and the weeds are more effectually destroyed. But at whatever period the crop may be put into the ground, the business should be performed as much as possible when the weather is dry, and the land not too much soaked with moisture, as under such circumstances the early vegetation of the crop always proceeds in a more regular and expeditious manner, by which the produce is generally rendered better in quality, and more abundant.

In the Present State of Husbandry in Great Britain, it is observed, that there are a number of what are called eyes in every root, each of which produces a separate plant. This points out the propriety of planting the large and middle-sized roots, properly cut, in place of the smalllest, uncut; as when the larger potatoes are properly cut, one, or at most two eyes only, being left in each set, there is no danger of too many plants springing from the same root, which must often happen, when small potatoes, with a great number of eyes, are set whole. It is the common practice, and against which there appears no well-founded objection, to cut potatoes, intended for seed, into small pieces, about half an inch square, in the course of which operation, attention is paid to single out the eyes that appear strongest, and most vigorous.

In this way, one root of ordinary size furnishes three or four sets, or pieces proper for planting. This, for the reason above-mentioned, is a better method than setting either large or small potatoes uncut. There has, however, been much difference of opinion in respect to the best sort of sets for the raising of this crop, whole potatoes and large cuttings having been contended for by some cultivators, while others, on the ground of experience, are equally strenuous in support of small cuttings, sprouts, shoots, or even only the eyes or buds. With all these different sorts of sets, good crops are flated to have been raised; though tolerably fixed cuttings of pretty large potatoes, with two or three good eyes or buds in each, are probably to be preferred. Independent of the increased expense of the feed, it is never a good practice to make use of whole potatoes as sets. The experiments of the Rev. Mr. Campbell, of Argyleshire, as flated in the ninth volume of the Bath Papers, not only show much light on this subject, but also on the most proper distances of planting in regard to the rows.

</table>

The real produce from 50 yards of row, planted with shoots, was only two pecks a yard, but only 63 of 150 came up; if none had failed, the produce would have been more than what is stated in the table. This calculation, then, it is supposed, goes on the supposition that the 150 shoots had borne in the proportion in which the 63 did. And further, that each of the experiment rows in 1790, was 75 yards in length; in 1791 and 1792, 200 yards; in 1794 and 1795, 50 yards. And that the numbers prefixed to the rows in 1794, Table II, and in 1795, point out the order, or juxta-position, in which they were planted.
A specimen of the manner in which the experiment tables were originally constructed is given in this instance.

The potatoes were planted in rows upon dung, except where it is otherwise mentioned, and then covered up with a double earth-board. In 1790, 1791, and 1792, the rows were three feet; and in 1794 and 1795, two feet and a half asunder. This, with the difference of seasons, will account, it is supposed, for the greater produce in the last two years. The distances at which the potatoes were planted in the rows, were measured by a stick with notches, and taken from the centre of the potato-sets. Care was taken to have the rows as equal in quality of soil as possible, and to have equal justice done them in manuring, where manure was applied, and in hoe-hoeing them. The quantity planted and raised was carefully marked in the field by the author of the experiment, and no part of the proceeds of management was intrusted to any other person. It is likewise noted that, in the experiments, the acre is the English statute acre of 4840 square yards; so that when the rows are three feet asunder, 4840 yards of row make an acre. When the rows are two feet and a half asunder, it will take 5808 yards of row to make an acre. The bolls and pecks are the Linlithgow measure, and the Amsterdam pound is used as a measure of compound parts, being the nineteenth of this peck; the value affixed to potatoes is the price they produce, communis annis, at the Edinburgh market.

From the comparatively small produce of potatoes confined to one eye and stem, (see experiments in 1794, Table II. row 2.), it is supposed, that the method recommended by some writers on farming, to pull away the superannuated stems, is evidently improper. The potatoes in row 2., were not only confined to one eye, but to one stem, by pulling up the superannuated ones. This last precaution became more necessary, as stems were found issuing in abundance from potatoes which had been deprived of all the eyes; and even from two out of twelve potatoes, which had been planted after the outer surface was pared off. The result was, that row the 2d, though it had most weight of feed, had the least produce of all the experiment rows; it had more than four times the quantity of feed contained in row 4., the produce of which, however, exceeded it at the Edinburgh prices, by more than 6s. per acre. The productiveness of potatoes, then, it is observed, is probably not occasioned by the weight or quantity of the sets planted, but by their having that number of sound and perfect growths, which the soil they feed in can bring to perfection. The general result of the experiments is favourable to the opinion, that the weight of bulb has any effect in determining the quantity of produce; in most of the five years experiments, the produce from pieces of potatoes was inferior both to large and to small whole potatoes; yet, in general, the pieces exceeded the small potatoes in weight of feed.

Though the large and small potatoes, mentioned in the experiments, were relatively so, compared with one another, yet some of those, called large ones, might perhaps, with more propriety, be denominated middle-sized potatoes. An acre of very large potatoes would require a quantity of feed so great as to deter any person from planting them; nor is it likely, that the productiveness of potatoes will continue to increase with their size. There is certainly, the writer thinks, a maximum and minimum, a ne plus ultra in the quantity of potato feed, as well as in every thing else. The middle-sized of the human species, as well as of the different species of other animals, are the best calculated to undergo fatigue and labour; they are therefore more perfect in their kind, and consequently fitter to answer all the purposes of their creation. May we not argue from analogy, that potatoes of a moderate size are the most perfect in their kind, and consequently the best fitted to send forth those vigorous shoots, which infuse a well-sized and healthy progeny? And that, the greater the number of strong fibres and roots, the more do they search for food, and the more earth do they displace in the course of their growing; which divides the soil more minutely, and gives it the advantage of better pulverization; and the greater abundance there is of leaf, the more nourishment is extracted from the air and dews, which are thus made to co-operate more with the vegetable paniture in the soil, in bringing the plants to perfection; and the thick foliage of the crop, by its amiable appearance, has the same ameliorating qualities with a heavy crop of peas or beans, in destroying weeds, retaining the dews, and preventing the drought from penetrating and exhausting the soil. The writer says, however, it is to be observed, that too many, as well as too few, items are unfavourable to the prevalence of fibres, and to the luxuriance of the leaves. Perhaps pieces about 2 oz. weight are the most proper for being planted, and whole potatoes from that weight to one ounce; these may be called large pieces and small potatoes; and from them, it is probable, there will issue a sufficient number of items to produce so many roots as the immediately surrounding earth can bring to perfection. To produce more would make the roots small; to produce fewer, would give a less quantity of root from the acre. The roots procured from small whole potatoes, and from large pieces, both planted at twelve inches distance in the row, were better fixed than those from large whole potatoes; and the roots from plants at twelve inches were larger than from plants at fix. And large potatoes planted whole at any distance, and whole potatoes or pieces at a nearer distance than twelve inches in the row, send forth so many items, that, like cattle upon overstocked pastures, they starve each other, and the produce is dwarf. And it is supposed that shoots, small pieces, and potatoes confined to one item, or a very few, resemble cattle upon pasture not nearly
frocked; which, therefore, cannot make the proper returns to the owner. Large potatoes are more easily disengaged from the foil than small ones, and are more readily perceived at the time of taking them up; and therefore are in less danger of being left ungathered. They take less time in gathering, which makes the expense of that operation smaller; and they fell better in the market. An objection to them, that they are not so easily boiled, is removed by splitting them, which will likewise make them drier, and better tailed. These advantages attending the produce of small potatoes and large pieces, added to the economy in the article of feed, and the saving of time in planting them, seem to balance any little inferiority, in point of quantity, gained by planting large whole potatoes at twelve inches, or any size of potatoes or pieces at a nearer distance in the row; and roots, fo small as not to be distinguishable from the produce of curled potatoes, ought never to be planted where potatoes are subject to that disease. From eight potatoes, the produce of one curled one, planted in 1795, three came up curled, and that in a farm where it was a matter of difficulty to find a curled plant upon which to make the experiment. This fact deferves the attention of cultivators in general.

A disadvantage attendant upon planting shoots instead of potatoes is, that they do not ripen near fo soon, and are therefore more exposed to injury from the equinoctial gales, and from early frosts; neither do they admit of being planted so early as potatoes, as they are more delicate, and more apt to be hurt by the cold. But the chief disadvantage is, that many of them fall entirely, or become such bad plants as to have very little produce. Other writers seem, however, to have been more successful with shoots.

The following are some observations offered on the experiments alluded to, in Table 1, in 1794.

Observation 1.—It is of great consequence to the farmer to pay attention to the kind of potato used for planting; see the amazing difference between N° 4 and N° 5. Though the most productive kind should not be the belt tafted, it ought, however, to be planted for the use of horsfs, cows, hogs, and poultry. The potato in N° 8 is the best eating potato of those mentioned in the experiments; yet the produce from it, with little dung, exceeded that from N° 6, with much dung.

Observation 2.—From the difference between N° 6 and N° 7, the former of which had three times the quantity of dung that was applied to the latter, the farmer will judge whether it is his interest to dung sparingly or plentifully; always paying a due regard to the condition of his soil, and the expense at which he can provide manure.

Observation 3.—From the produce of N° 3 it appears, that undug potatoes are preferable to a tinner-fallow without dung. And from comparing N° 1 with N° 2, it is clear, that a dugged summer-fallow is not so profitable as a dugged crop of turnips, both followed by a crop of potatoes with dung. An acre of potatoes at 27l. 10r. 2fl. after a dugged fallow, will bear no comparison with an acre of potatoes at 25l. 10r. 8fl. added to a crop of turnips, the produce of the preceding year, of 30 to 32l.

Observation 4.—From a comparison between rows 5 and 6, planting potatoes upon dung in the row seems to be a better method than dibbling them in the top of the row, after the dung is covered up. But where the farmer is situation, as to be under a necessity of planting them in a wet foil, perhaps it may be his interest to place them in the top of the row, as this method will keep them from the cold and moisture at the bottom, which would be apt to destroy them.

It is supposed by different writers, in the second volume of Transactions of the Dublin Society, that in scarce seasons, the shoots and the eyes or buds, scooped out by an implement for the purpose, are capable of being set with equal advantage as the cuttings; but they are obviously liable to many objections, and should never be had recourse to, but from necessity. They prize that proportion of matter about them, which is essential to the health, generation, and establishment of the plants. The following interesting experiment on scooping potatoes, made by the Rev. Mr. Findlater, of Fundale, and inserted in the Farmer's Magazine, is highly deserving the cultivator's attention.

He chose a number of potatoes of the same species, similar in size as might be; he scooped out a parcel of the best looking eyes with cutler Wright's hemispherical scoop; he cut also out a number of equally good looking eyes with a knife, taking as much as possible of the mother potato to the eye; he chose out nine of the bell looking scoops, and an equal number of the bell looking cuttings,—the he planted in alternate drills upon a border, three in each drill. His whole sets sprouted, and no accident occurred; but the scooping came up, and continued perfectly dwarfish in comparison of the cuttings. They were raised in two separate baskets in the beginning of November, and laid by in a closet to be weighed. The weighing was neglected to the middle of December; but the result was what might be expected from inspection at raining; the produce of the cut ones weighed a stone and a half ton; that of the other, three quarters of a ton, without reckoning very inconsiderable fractions. The experiment was merely made to ascertain which throw best. Anxious to do the scooping justice, he prefixed the scoop deep in, with considerable violence; and probably the forcing of the scooped piece into the narrow contraction of the hemisphere, bruised and damaged its substance. Would not an open ring anfarer better? And he adds, that captain Mackay, of Scottston, in this parish, cut one peck with the knife; he scooped also an equal quantity; (the scooped ones were not weighed before and after scooping, which would have ascertained the saving of potatoe substance in the seed). They were set in the same field; no difference was observable in their growth; at raining, the difference of the produce, by measure, was in favour of the cuttings by one peck and a half; the deficiency in produce of the scooping was being probably more than compensated by the saving of substance in the seed. He apprehends, that the writer's error in the mode of scooping had been avoided. It is, however, observed, that the produce of the scooping were the bell fixed potatoes.

But in speaking of the difference of opinion in respect of scooped cuttings, Mr. Young remarks, that from some experiments carefully made, the result of which he is well acquainted with, it appeared, that these contradictory opinions might be equally just, when founded on variations in practice. When the soil is sandy, or in a very light pulverized, or highly manured state, and every other requisite for succés beneficially secured, these scooped cuttings succeeded just as well as larger sets; but when the soil was more llif, unfavourable in water, or not equally manured, or the sets ploughed in, under circumstances not very favourable, then the larger cuttings had a considerable superiority. The property, therefore, on any future occasion, of having recourse to this expedient, will depend on the state of the lands, the soil, the manuring, &c. If an cutting be done by the bushel, two-pence is a fair price, where woman's labour is eight-pence a-day. This sort of work is, however, seldom well performed when left to women. Therefore
POTATOES.

Therefore it may on the whole be concluded, with respect to the proper feed or fets for the raising of potatoe crops, that though the quantity of produce does not, as has been commonly supposed, bear any exact ratio to that of the weight of the fett, yet that it in some measure depends upon that circumstance, and there being a suitable number of eyes as well as of pulpy material about them.

The proportion of ground that can be advantageously cultivated under this root, must depend wholly upon the circumstances of the farmer. Mr. Young strongly advises those farmers who are unacquainted with the culture of it, againf applying too much land to it. If they have a great plenty of dung at command, they may enter largely into the husbandry; but they should determine to plant no more land than can be manured at the rate of twenty-five or thirty large loads per acre; for one acre well cultivated, will pay better than five or even ten indifferently managed. But besides this, there are many other points to be considered before he fully decides, such as the number of acres of carrots he has fown; for if his fett be suitable to that crop, they are greatly to be preferred to this root, being cheaper, not requiring dung, and being applicable to all the uses to which potatoes are applicable. They do not at all impoverish the land, whereas potatoes fcoruce it, if the expreffion be permitted, more than any other crop the farmer puts in. There are very material motives to influence a preference. But if the fett will not suit carrots, then it will be neceffary to plant to much the more potatoes. The fame obfervation may be applied to cabbages, which also, in a great measure, answer the purpofes of potatoes. If he deals largely in that crop, it fleftens the neceffity of having this root; and rutabaga is as useful to hogs as the potatoe itfelf; but being far more uncertain, and the difficulty of securing a crop of it being greater, it cannot be depended on like potatoes. The fly and drought, &c. are too fatal to it, that many farmers in Norfolk have fowed in vain for feveral years togethcr. But whatever the extent of land may be that is appropriated to this fort of crop, fuch of it as is designed to be planted early, fhould in the latter end of April all be hand-hoed over the whole furface, to cut up weeds clean, and loofen the earth. This management is known only in the neighbourhoof of London, but it fhould be extended over the whole kingdom, for the excellence of it is indifpenfable. The expence of hoeing, when there is a clear space to cut, is trifling, and the fucceeding cleaning which the potatoes receive after they are up, is performed at a much lefs expence on account of this operation, and at the fame time in a more effeclual manner. And the cheapest and moft effeclual method of performing this neceffary operation is by a large fhim, which cuts three or four feet of furface. For this purpofe, there fhould be a small broad wheel at each end of the beam, to regulate the depth. The work is confined to the furface, the intention of it being merely to cut up weeds and to loofen the earth, which rain and fucceeding fumifhe may have encrufed. The operation is of great importance, and fleftens the expence of the hoeings that may be afterwards given very greatly.

Where land is scarce, and of course dear, the borders near hedges, and other waste parts, may also be converted to the raising of this crop with advantage in many in- 

flances.

With respect to the planting of this root, there are many different methods in ftre, in different diétricts; but the great object fhould conftantly be, to prefervc the plants, as much as poifible, in a medium rate of drynefs. They are likewife grown after different forts of crops and other forts of land. The author of Modern Husbandry flates, that they are cultivated by farmers in general, after every fort of white-corn crop; but in Lancashire, for the moft part, on lands broken-up from grafs for the purpofe. This practice was no doubt borrowed from Ireland, where it appears to have been generally eftablfished soon after the in- 

duction of potatoes into that country. And that there are different methods of applying the dung, which however ought always to be done with a liberal hand. Sometimes the field is formed into one-furrow ridges at the fcond ploughing. The dung is then laid in the furrows, and the potatoes being planted by hand on the dung at the diftance of eight, ten, or twelve inches afunder in the furrows or drills, they are then covered up with the plough, which is done by splitting the one-furrow ridges. In Lancashire, where this fort of buhnefs is well performed, in planting, the practice is, after the land has been made fine and per- 
fectly level on the furface, to make equidiftant drills the whole length of the field, in doing which, the plough, after making a furrow up the field, is drawn down again on the contrary fide clofe by the fame, throwing the foil equal heights on eacfride. These drills are made as wide and deep as to render them capable of containing the dung, which is laid in the bottom of each. The diftance of the drills is fuch, that when the horfes ftand in one, each wheel of the cart or tumblir may be in the middle of the next drill on each fide. The next operation is to carry in the manure, and as the horfes ftand in one drill, and each wheel of the cart in a familiar situation, the neatnefs and order of the land is little injured. The dung is then thrown out of the cart in small heaps, sufficient to supply the three drills or furrows which the horfes and the wheels of the cart occupy, a moderate scattering of which is put into the bottom of each; the whole being completed in a very short time by perfonfs with forks with two fimes or prongs. The long frawy dung lately thrown out of the ftables or cow-houlfs, or collected from the farm-yard, is always employed where it can be had. When the drills are thus prepared, the fets are put into them upon the dung, about fix or eight inches diftant from each other. After this the plough is run on each fide of eacfr drill, to throw the earth, that was raifesd out of it, upon the potatoes, and cover them, which operation elevates it in the middle, and causes it to lie floping on each fide like the roof of a houfe, when the buhnefs is completed until the ftems of the potatoes begin to make their appearance above the furface.

But according to the author of the Agricultural Report of the West Riding of Yorkshire, where the culture of this root is likewife well performed, after the land has been properly prepared, the belt cultivators begin to ride it up, by ploughing a furrow round it down, and then taking a fuitable diftance according to the nature and qualities of the foils, as from about two feet eight inches to three feet, fuch as are rich and fertile requiring more space of ridge, than fuch as are poor and exhaufted. The manure, where neceffary, is deposited with regularity in rows by means of a labourer with a fork, in the ridges, the potato fets being then placed at proper diftancc upon it and covered with the plough.

And another method of ridging, which has been found beneficial in some of the norther: diétricts, is, as fon as the land has undergone a full preparation, and is made perfectly fine and level, by repeated ploughings and harrowings in different directions, to draw ftraight paralieal furrows by means of a double earth-boarded plough, drawn by a fingle horfe, at the diftance of two feet and a half from each
other. This operation is performed in the most correct manner, by paffing the plough twice in the fame place, which, when the land lies hoppin and uneven, should be down hill the first time. The manure is then brought on in carts from the higher fides of the fields, where they are hilly, the horfes paffing in one furrow, and each of the wheels in others on the different fides; they are then emptied by the drivers, who walk behind them with crooked three-pronged forks, confructed for the purpofe, leaving it in small heaps in the furrows in which the horfes go, in fuficient proportion for the three drills. It is then divided and fpread out in the different rows, in as equal a manner as po fible, by women and children, the fets being put in upon it at the diftances of about eight or twelve inches from each other, the whole being afterwards covered in by the plough, by splitting or di viding the ridges betwixt the rows, and paffing twice in the fame track, as in the work of opening the furrows for the rows of the crop.

There is still another raised mode of planting this ufeful root, which is flated in the original Agricultural Report of the County of Cheshire. It is the custom there to form the land into narrow beds, of about three, four, or five feet in breadt, by the plough; the manure, when neceffary, being previously fpread out evenly upon the ground, and turned down. The fets are then planted by means of a dibbling-flick to the depth of about three inches, in rows ten inches apart, and alternately eight or ten and twelve inches in them, fo as that the root-fhoots of the plants may occupy the ground as completely as po fible, without interfering with, or injuring the other. When the fhoots of the plants firft appear upon the surface, each of the furrows or divifions between the beds is dug out to the depth of about one foot; the loofe earth thus raifed being caff as evenly as po fible over the plants in the beds, by which they, as well as any weeds that may have sprung up, are covered, and the growth of the former greatly promoted, while the latter are in a great meafure deftroyed. And in cafes where the flaple of the land will admit of it, in about a week or ten days afterwards a fecond covering is dug out, and thrown over the crop in the fame manner, by which its growth is fiill farther promoted. In this mode of planting, as much fresh earth is from time to time applicable to the plants, their vigorous vegetation is not only fecured, but the extenfion of the roots rendered more full and complete. As a quantitv of fresh earth is thus annually furnished for the growth and support of the potatoes, it is affifted in the firft volume of the Agricultural Magazine, that repeated crops may be taken from the fame land, even where manure is not made ufe of, without its being exhaufted in any great degree. It is therefore fuppofed, that it may be had recourse to with advantage where manure cannot be easily procured. And from fuch lands as are inclined too much to the retention of moistu re, for the perfect growth of crops of this fort.

But the raifing of the land into high ridges is not adapted to every fort of foil. It is obvious that fuch forts of land as are very dry, and of a fandy nature, fhould have the surface kept as level as po fible, in order that the proper degree of moistu re may be more effectually retained and preferred for the support of the crops.

In moif circumstances, and where the soils are left subjed to be injured by parting with their moistu re, it may, however, be the mostuitable practice to raife them into ridges, as by fuch means the depth of the flaple is augmented, the manure more concentrated for the support of the crop, a better bed provided for the fubtle roots and wires of the plants to eflablish and extend themselves in, the danger of flagrant moistu re guarded againft, and the after-culture of the crops rendered more easy, beneficial and convenient, by which they may be kept more clean and free from weeds, and be earthed up at different times, fo as to infure the moft full and perfect extenfion of the roots in the fine mould that is thus con tinu Plantly laid up to them. And as the whole of the pro cefs is capable of being performed by means of the common plough, with a horfe or two, it is probably the moft advantageous where fuch crops are cultivated on land that has been some time in the ftate of tillage. In cafes where the ridges are only required to be small, the operation is completed in one blow of the plough, or by going up with one furrow, and laying another up to it in returning, fo as to produce a ridge in the middle between them.

And where the method of horfe-hoeing this fort of crop is in ufe, by which great crops are in many cafes obtained, the practice in refpect to diftance is various; but whatever mode is adopted, the land must be ploughed into proper ridges for them accordingly. Mr. Young fays they have been tried in equidiftant fingle rows, at two, three, four, and five feet; in double rows at one foot, on four-feet ridges; thefe, and also three rows on five-feet ridges. But though attended with fuccefs, thefe wide diftances between the fingle rows certainly lose too much ground. When equally diftant rows are employed, he thinks three feet preferable. And double rows on four feet have been fuccesful. Equal diftant rows, at two feet, with a neat horfe-hoe, which turns no furrow, only cutting the surface of the earth, and earthing up afterwards with a double mould-board, have likewife anwered very well.

Also in planting this kind of crop upon the plain surface, there are likewife different modes made ufe of in different districts, and under different circumftances. In dif tricts where the foids are inclined to be dry, it is in some cafes the practice, after the land has been brought into a proper condition by ploughing over twice, or oftener, and well harrowed, to spread the manure regularly over the whole surface, the fets being planted in every third furrow, and the dung with the fine earth turned upon them by the next furrow of the plough. In this way the manure is however placed upon the fets, which has on experiment been fully fewn to be injurious to the produce. Besides, from the whole of the surface of the ground being covered with dung, a coniderably larger proportion muft be requisite, than when deposite only in the drills, and of course the crop be cultivated to disadvantage in that refpeft.

In the above-named district, on shallow foilcd land, pota toes are, however, generally planted and foiled with the plough, a method which is faid to confume lefs manure than others. In this mode of planting, the land being firft prepared as above, a furrow about four inches deep is turned; the manure is fpread lightly in the hollowed space, the potato fets having been previously dropped into it, at the diftance of about eight or ten inches afunder, or, which is as commonly praftifed, put upon the dung after it has been put into the furrow in the fame manner, by which they are fpupofed to vegetate more fpedilily; the fame furrow is then turned back upon the fets: the next row of fets is dropped and covered with the manure, or put upon it, in the hollowed space of a furrow, which is turned towards the firft row, at the diftance of about eighteen inches from the firft line of fets for infance, leaving something more than two furrows width of foil untouched by the plough; the fets and manure are then covered as before, and the fame method purfued till the whole of the ground intended to be planted is finished. The foiling with the plough is performed in this way. As soon as the plants begin to appear, the ground, which had previously been left untouched, is split
or turned to each side upon the young plants with a long wretched plough, so as to effectually cover them. After this has been done, the crop is to be kept clear of weeds by the hand and hoe.

But in other cases, as soon as the land has been properly ploughed and harrowed in a smooth even manner, the manure is spread equally over the whole surface, as above, and then ploughed well in, when the planting is immediately begun, and executed in the following way: a man has a dibble with an iron point, and a place for him to set his foot upon to strike it into the ground, in order to make a hole for the set. He is followed by a woman or boy with the sets, who drops one into each hole; after which the land is harrowed over once or twice, or more, when the work is finished. In this way they are set promiscuously, at from nine inches to a foot apart; and the busines is effected with expedition, and without much expense, from fifteen to twenty bushels of potatoes being sufficient for setting an acre of land.

About Ilford, in Essex, they plant immediately after the plough; a man dabbles across the land, followed by a woman who drops the sets, for both which operations they are paid seven shillings or eight shillings the acre; the rows twelve inches by fourteen or fifteen, and some twelve square. Early in the spring, sixteen or eighteen hundred weight are planted on an acre; they are hand-hoed twice, each time at the expense of four shillings.

In other parts of the same district they are sometimes planted on three-feet ridges, one-bout ridges, and in rows at eighteen and thirty inches.

In planting this sort of root on level land, after it has been prepared by the use of a plough that just pares off the surface, and deposits it in the furrow, it is advised by Mr. Somerville to place the sets upon the inverted sod, and cover them with the loose mould from below, by means of a common plough. Or, the trench plough may be used with perhaps more advantage. But the best method is that of paring and burning, as has been shewn above.

In some cases the practice is, however, to turn down the turf with or without manure, and then to put in the sets by a dibble; though the former is probably the better practice, as the turfy material on which the sets are put soon begins to decay, and the purpose of manure is in some measure answered by it. It is a plan that may be adopted with advantage where manure is scarce, as in bringing walle and other coarse grafs lands into the state of preparation for grain crops.

And Mr. Donaldson states it as the custom in the neighborhood of towns and villages in Scotland, for the farmer to let a field to the inhabitants at a certain rate by the rood or perch. The renters or hirees of the land pay a specified rent, and agree to furnish a sufficient quantity of dung. The farmer is at the expense of carrying the dung, and of ploughing and harrowing the field. The renters attend at the last ploughing, and plant the sets in the bottom of every furrow.

However, though these are the common modes of setting potatoes where that sort of husbandry is carried on upon an extensive scale in the field, there are others with the spade which are probably preferable on soils of proper depth where labour is cheap; the first of which is pretty commonly adopted in Lancashire, and in some districts in the north-east of Scotland; which is, to trench the land. The farmer having carried the dung, and laid it on the field in heaps, at proper distances, the operation is performed by the manufacturers and people who rent the field, and in the following manner: across the end of the ridge a trench is formed, about three feet wide, and from ten to fourteen inches deep, according to the depth and quality of the sub-

foil. That being done, a second trench of the same breadth is made off, and the surface-foil, to the depth of six or eight inches, is thrown into the bottom of the former trench, over which a sufficient quantity of dung being laid, the potatoes are planted at the distance of eight or ten inches from each other, and then as much earth is taken from the bottom of the second trench, as is necessary for covering the potato-sets, and of making up the first trench to its former level. Thus the field being completely trenchcd, well manured, and kept thoroughly clean by repeated hand-hoeings, must not only produce an abundant crop of potatoes, but also be in high condition for receiving whatever kind of feed may be afterwards sown.

And another mode of setting the root with the spade is that which is termed the lazy-bed method, which was formerly well known in many parts of England, as well as all over Scotland, although now confined to the very remote districts of the latter kingdom. The term applied to this mode of culture, indicates that it was invented to save labour, and must have been adopted for any length of time by those who indulge in ignorance precluded from following other methods. These beds are formed of such a breadth, as that any man used to the spade, can with ease throw earth almost from one side to the other. The manner of forming them is as follows: the size of the bed is first marked off with a line, and from two to four feet left on each side for trenches. The surface of the bed being then dug, or turned over with the spade, the dung is spread, and the sets planted, at about the distances last mentioned, after which earth from the trenches on each side of the bed is thrown over the dung and the plants, so as to cover them to the depth of three or four inches. Mr. Young, however, advises a neater mode of executing this business, in which the land is marked into beds five feet wide, with narrow slips between them two feet wide. These are then dug about fifteen loads per acre; on the dung are laid the potato set, after which the turf is thinly in the two-feet intervals, and laid on the sets, which, with another split, and the loose mould, completes the covering. This mode is not equal to digging all the ground, on account of its being left whole for the succeeding crop, but the crop of potatoes is generally good; for, besides the dung, they have the turf below to spread upon, and are partly covered with that from the trenches, so that they lie hollow, and in a rich bed of mould.

And in planting the shoots as sets for this crop, the best practice may perhaps be that of putting them in flight hollow forts of drills, made by a very small light plough for the purpose, at the distance of eight or ten inches from each other, and seven or eight in the rows, putting the root part downwards, which may be readily executed by women or children. After this has been performed, a small proportion of dung is to be laid thinley over them, and the earth from the sides of the drills lightley drawn over so as to protect them against any frosts that may happen. As soon as they have thrown out the leaves and are about four inches above the surface of the ground, a second covering is to be applied, so as to leave about two inches above the surface; and as they advance in growth, continuing to cover them in the same way, until the earth between the ridges elevates the drill at least twelve or fourteen inches in height. It is observed that the shoots that are made use of in this way should be strong and vigorous, about five or six inches in length, and planted while perfectly fresh and in a state of full growth. In respect to keeping the shoot sets, they may be preferred for planting by taking them off from the potatoes either at once or occasionally as they are wanted,

S l 2
without bruising, and placing them across upon each other, spreading a light covering of earthy materials over them. By this means they may be kept a month, six weeks, or longer, until the land is in a proper state of preparation for their being planted out. Another method has likewise been prepared for raising this sort of root, which is that of transplanting such young plants as have come up by chance on grounds that have had this sort of crop, or been prepared for the purpose, in beds of rich earth, or mould and dung, or by planting seed in dung-hills a few weeks before they are set out. However, as much injury must be done to the shoots of the young plants in the taking them up, and as this sort of root seldom grows well after being transplanted, it is probably a method of planting that can seldom or ever be practised with benefit, unless it be in the filling up the rows, when broken and defective, or in producing more early crops, whether in the field or garden practice of cultivating such sorts of crops. But whatever methods are employed in putting them into the earth, it has been stated that it is necessary that the greater care be taken not to deposit the sets too great a depth in the soil, as the potato root has a tendency to rise to the surface of the ground; three, four, or five inches at most is sufficient in all the light dry sorts of soil, and in those of a moist and heavy nature, the sets may be sufficiently adequate to the purpose. And another circumstance deserving of much attention in the planting of this useful root, is that of all the sorts of sets being set in and covered by such mould as is in a fine state of friability and mellowness, as when the earthy material by which they are covered is of a lumpy and unreduced quality, the crops are never found to be so fine or so productive. Many facts of this nature have been mentioned by writers on husbandry. Some likewise suppose that where this sort of crop is planted in the row method on a fine mouldy preparation of the land, without any manure being applied, or where it has been incorporated with the soil some time before, the drills should be made in a more light and shallow manner than where the common methods are purposed; otherwise mischief may be done by the sets being deposited to such a depth as to cause them to rot and be destroyed.

In the Lancashire original agricultural report, it is stated, in respect to the raising of early potatoes, that upon the same ground from which a crop has already been taken, the early fed potatoes are in some places afterwards planted; which, after being got up about November, are immediately cut up into sets, and preferred in oat shells, or sawdust, where they remain till March, when they are planted, after having had one split taken off, and planted with another, of a length sufficient to appear above ground in the space of a week.

But that the most approved method is, to cut the sets, and put them on a room-floor, where a strong current of air can be introduced at pleasure, the sets laid thinner, as about two or three sets in depth, and covered with the like materials, (shells or sawdust,) about two inches thick; this screens them from the winter frosts, and keeps them moderately warm, causing them to vegetate; but at the same time admits air to strengthen them, and harden their shoots, which the cultivators improve by opening the doors and windows on every opportunity afforded by mild soft weather; they frequently examine them, and when the shoots are sprung an inch and a half, or two inches, they carefully remove one-half of their covering, with a wooden rake, or with the hands, taking care not to disturb or break the shoots. Light is requisite as well as air, to strengthen and establish the shoots; on which account a green-house has the advantage of a room, but a room answers very well with a good window or two in it, and if to the sun full better. In this manner they suffer them to remain till the planting season, giving them all the air possible by the doors and windows, when it can be done with safety from frosts; by this method the shoots at the top become green, leaves are sprung, and are moderately hardy. They then plant them in rows in the usual method, by a setting-tick, by this method they are able to bear a little frost without injury. The earliest potato is the paper-white kidney; from this sort, upon the same ground, have been raised four crops, having sets from the repository ready to put in as soon as the other were taken up; and a fifth crop is sometimes raised from the same land as the same year as transplanted winter lettuce. The first crop had the advantage of covering in frosty nights. It is remarked that this useful information was communicated by I. Blundell, of Ormskirk, and has hitherto been known only amongst a few farmers.

In the neighbouring district to the south, in the mild warm tract about Wirral, there is also an improved practice in raising the early sorts of potatoes, which has some resemblance to the above. In this situation the potatoes which are defegued for the sets are got up in September or the following month, or even before; the sooner after they are mature, the better; and in November are laid in a warm dry room, where they are spread rather thinly, not more than two, or at most three potatoes in thickness, and covered with wheat chaff, or dry sand. They are further protected from frost, whenever it is necessary, by a blanket or rug spread over them. By this mode of management, they are generally well sprit by the month of February or the beginning of the following one; but if this should not be the case, the sprouting is accelerated by sprinkling them from time to time with a little water. A potato is said to be well sprit, when it has a shoot from two to four inches long, as thick as a small quill, and terminated by two little leaves. In this state they are planted whole; all the shoots being cut off, except one, as early in February as the season will allow; they are not more than five or six inches under, the tops just within the ground. As long as there is any danger from an exposure to the frosts, they are carefully protected by a covering of straw or peafe-haum; which is taken off in the day, unless the weather be extremely severe, and put on again at night. By these means it is asserted that potatoes are now as plentiful in the Liverpool market, in the middle of May, or even sooner, as they were, before they were transplanted, in the middle of June. At the same time the culture of this vegetable is productive of very considerable profit to the farmer; a second crop being, in almost every instance, raised from the same land in the same year.

And it is stated by Mr. Marshall in his Rural Economy of Yorkshire, that in raising potatoes from seed there, the following method is purposed.

In autumn, when the apples are beginning to fall spontaneously, they are gathered by hand, and preferred in land until spring, when they are mashed among the sand, or among fresh mould, separating the seeds, and mixing them evenly with the mould. As soon as spring frosts are judged to be over, they are sown in fine garden mould, and as laid as the plants get into rough leaf, and are strong enough to be handled without injury, they are transplanted from the seed-bed into another bed of fresh, rich mould, in rows, which are kept clean during the summer. In autumn bunches of small potatoes are found at the roots of these plants, varying in size the first year, from the hazel-nut to the crab. These being planted next spring produce potatoes of
of the middle size; but they do not arrive at their fullest bulk until the third or the fourth year.

Where the use of the stove or the garden-frame can be had, this process may be shortened. The seeds being sown within either of these, early in spring, the plants will be fit to be planted out as soon as frosts are gone; by which means the size of the roots will be much increased the first year; and will, in the second, rise nearly to perfection. And it is added that potatoes raised from feed are a miscellany of endless varieties. Sometimes these varieties are planted miscellaneous; sometimes particular varieties are selected.

In selecting varieties from seedling potatoes, two things are to be attended to; the intrinsic quality of the potatoe, and its productiveness. If these two desirous properties can be found in one plant, the choice is determined. To this species of attention and industry we are indebted for the many valuable kinds, which have been, and now are, distributed throughout the island.

It is observable, however, that varieties of potatoes, like those of corn, are partial to particular soils and situations. Hence the propriety of husbandmen raising potatoes from feed; as by this means they obtain, he says, with a degree of moral certainty, a sort adapted to their own particular soils and situations.

In Cheshire, it is remarked that the various kinds of potatoe, which were formerly known and cultivated, are now almost totally lost; and that other kinds have been substituted by raising new varieties from feed. And in doing this, some mystery is pretended; but it is clear, that, in truth, there is none. The potatoe apple is gathered when ripe, and is kept dry during the winter; the feeds are sown in the spring, and the plant transplanted, after it has obtained a certain size. The varieties thus produced are infinite; but their real value is not perfectly ascertained during the first or two of their cultivation. This is only known by time and a full trial of them. It has likewise been noticed, that the produce from feed parts frequently of the qualities not only of the mother plant, but of other kinds which may have been propagated in the neighbourhood. And farther, that a singular idea is prevalent here, among many who cultivate this root, that by planting the green tubers, which sometimes proceed from the stem, the root is renewed, if wearing out; but upon enquiry no facts sufficiently substantiated to confirm the opinion have been found. Besides, T. A. Knight, esquire, a gentleman of superior information on this subject, expresses it as his decided opinion, that no benefit can possibly arise from the practice of such a practice.

Alfo, in answer to a query put to the fame gentleman by Mr. Willbraham, whether artificial heat might not be of use in raising potatoes from feed, as this plant was originally a native of a warmer climate than our own; he states it as his practice to raise them in a hot-bed, to harden them by degrees, and plant them out in May; by which means he has had a very considerable produce even the first year. He has likewise discovered a method of making the early kinds of potatoe bloom and bear feed, which they do not in general. This is effected by planting cuttings from the roots at the foot of a strong flame, and wafting away the mould from the base and the limbs, whence the tubers would have sprung.

A conjecture is also offered by the same person, that varieties of the potatoe, still earlier than those now in cultivation, may be obtained; and that it might be expedient to attempt this by the infirment of the farina into a larger, and moderately early variety, with the view of producing an early kind of a larger size. If success attended such an experiment, its utility would be very great; as in the event of a failure in the corn crop, the planting a small additional portion of land with potatoes would afford a very seasonable relief during the summer months, when the grain is usually at its highest price. These opinions may be seen more fully explained in the various papers of the same writer, inserted in the Transactions of the Philosophical Society; those of the Society of Arts; and in the Transactions of the Horticultural Society.

After-culture.—There cannot be any doubt, but that by proper attention to the keeping the crops of this kind in a suitable state of cleanliness and culture, after they have been put into the foil, much advantage must result both in the goodness and abundance of the produce. The manner in which this is effected is different, according to the mode in which the crops have been planted and the nature of the land. It is, however, mostly applied, by hoeing with the common or horse-hoe, and by hand-weeding. The first is the method usually followed where the old modes of planting are practised, the second where the drill system is had recourse to, and the last occasionally in both cafes. The horse-hoeing mode has been applied on the principle of faving a part of the expense of hand-weeding the crops, as well as with a view of promoting in a more efficient manner the growth of the roots. It is admitted by the advocates of this husbandry that there are more plants in the old practice; but they contend, that the tillage by the use of the plough, is so much more complete and effectual than that of the hand method, and the admission of air among the plants for much more free and extensive, that the loss in respect to number is much more than supplied by the augmentation in size.

But whatever may be the advantages of the drill culture in this fort of crop, there cannot be any dispute, but that the finer and more loofe and mellow the mould is kept during the time in which the plants are forming their wires and knobby roots under the ground, by frequent flirrings, the better and more abundant the crops must be, from their growth and diffusion being more perfect and complete.

With the intention of effecting these purposes in the best manner, it is the usual practice in those districts where this root is much cultivated, to have recourse at different times to such means as are capable of cleaning, mellowing, reducing, and bringing up to the roots of the plants the fine mould which has been in this way produced. And the implements commonly made use of in this intenion, are the harrow and the hoes just noticed, by the firlt of which the particles of the foil are broken down and reduced into a fine flate, and by the latter laid up to the roots of the plants.

In the ninth volume of the Bath Papers, it is stated that the potatoe land is harrowed, when the growths from the fets under the surface are about an inch long; this can be known only from inspection. It is impossible to say, in how many days it will happen after their being planted, as it will depend on a variety of circumstances; such as the favor of planting, the quality of the soil, the state of the weather, the kind of potatoes, the nature and quantity of the manure, &c. Harrowing potatoe land defroys the first crop of weeds, and creates a fine pulverized foil for the plants to feed in, when they arrive at the surface. And by delaying this operation till the above time, the vegetation of the weed is more advanced, and consequently more effectually destroyed; but by delaying it much longer there would be a danger of breaking off the potatoe shoots. The harrow used by the writer is a folding-harrow, invented by himself, drawn in the intervals by a single horse; it applies stuff to the opposite sides of two contiguous rows, destroys the weeds, and pulverizes the foil without levelling the row, which would tear up many of
of the potatoes, or break off their shoots, and deprive the land of the advantages it has, by lying dry when the shapes of the rows are preferred. A lighter harrow, on the same plan, is employed in smoothing the rows intended for turnips and other small seeds, immediately before they are sown.

When the potato plants are all early seen, the earth and weeds are removed from them, going as near as possible to them with a shallow furrow, and turned into the middle of the intervals by a horse-hoe; which is the same with the writer's large plough, on a smaller scale, with a very narrow earth-board. If it be done sooner, there will be danger of tearing away the shoots which are not seen, if the hoe be allowed to come near enough to the root. If it be delayed longer, there will not be the same benefit derived from horse-hoeing. Any weeds and grubs which shall have escaped the plough, both now and to the time of taking up the potatoes, are carefully to be pulled up by the hand. And in a few days after the first hoeing, the same instrument is to go deeper in the former track. This flailing will make the earth in the intervals free, that has been trampled down by the weeds, and it will bury the weeds they have pulled up. When the weeds, buried in the intervals, are rotted or converted into vegetable food, the earth is returned to the plants with a double earth-board plough, going twice in the same track with a shallow furrow; the first of these times down hill, if the land be hilly, a boy following the plough to uncover any plants that have been buried in the row; for, if left in that situation, their growth would be entirely stopped, or very much retarded. If, by avoiding to bury the plants, they should be left in some places without the mould touching them, it is drawn towards them in those places with a hand-hoe. And that when the plants are about six inches in length, the earth is raised higher towards them, by the double earth-board going twice in the track of the former earthing, but much deeper than before; which finishes the horse-hoeing of the crop.

Mr. Young advises that, some time in May, the early planted potato crop should have a hand-hoeing, which should be done with good attention, that not a weed may be left, and the surface of the land be left well cut, and in fine order. And that the crops in rows should receive, besides this hand-hoeing, the first horse-hoeing, which should be given with a common swinging plough drawn by two horses, one before the other, and turn a furrow from the rows, throwing up a small ridge in the middle of each interval. These operations should be well and attentively performed; for the weeds grow at a great rate, and, without such an attention, will destroy, or at least greatly damage the crop. And another hand-hoeing should be given in June, and so effectually executed as to render any succeeding ones unnecessary, as the plants may be so grown as to be injured by it. The crops planted for horse-hoeing must also have that operation now again performed with the double mould-board plough, splitting the ridges before thrown up, and applying them to the rows in an equal manner. And in July, in some cases, the crops in rows should have a third horse-hoeing. But that the common mode of ploughing backwards and forwards every time of performing the operation is not well suited to the crop; as cutting the roots when the plants are in full growth hurt the crop, and destroys the runners that would afford potatoes. The third horse-hoeing should therefore be executed with the flail, which loosely cuts the surface of the ground, without turning it over or forming any ridge. Some of these tools work with many little triangular shares, others with fling flat ones, and still others hoe with coulters; however, any that cut up fresh mould at the bottom of the furrows do very well. They should be followed, in about a week, by the double mould-board plough, striking the furrows, and throwing up all the loose mould to the ridges, banking them up. This is useful by affording fresh mould for the roots to shoot into, which is better than the practice of taking it away from them, when they have begun to advance in growth. And in August the rows of this sort of crop should be hand-weeded when necessary, as it is probably too late to horse-hoe them. But when the intervals are very weedy or much bound, or the plants not sufficiently earthed up, he advises the flail to be carefully run through them to destroy the weeds and loosen the earth, so as that they may be flicken clean by the double mould-broad plough, and well earthed up for the wiry roots to extend into and increase the produce.

And this sort of crop is shown to have attained a sufficient degree of ripeness, as well as full size, by the decay of the leaves, and their dropping off the stems. And they should be taken up as soon as possible after the appearance of frosts in the autumn, as in the latter end of September, or beginning of the following month at latest.

Taking them up.—In the taking up of potatoe crops, the modes that are followed are different according to the nature of the culture under which they have been managed; when they have been planted in drills, and horse-hoe'd, the common method is, first, to turn a furrow from each side of the drill, and then to turn over with the plough that part of the drill in which the potatoes are lodged, and which are afterwards gathered by women and children hired for the purpose. Sometimes the middle part of the drill, after the two-side furrows are taken from it, is turned over by men with three-pronged forks. In other places the three-pronged fork entirely supplies the place of the plough, which is never introduced. Where a sufficient number of women and children can be procured for gathering the crop, using the plough is certainly the most expeditious and least expensive mode. In order to avoid the risk of cutting the potatoes with the couler, it is commonly taken out, and the plough with only a harrow, or fork, is used for turning over the middle part of the drill, which, as it performs the operation as effectually, is no doubt an improvement, and may be considered the best implement that can be used in taking up a crop of horse-hoe'd potatoes. When potatoes are planted with the spade or the plough, and with an intention of hand-hoeing the crop only, the common method of taking up the potatoes is with the spade, one gatherer attending every person who is employed in turning over the ground. Care of potatoes thus cultivated, are sometimes, however, taken up with the plough. When that happens, it is found necessary to plough the field two or three times over, otherwhise it is scarcely possible to get the crop properly collected. Mr. Campbell remarks, that in his district the roots are taken up with a fork with three prongs. And that, to make this operation easier where the land is stiff, the outside of the row, in which there are no potatoes, is pared away by going round every other row with the horse-hoe, and when these are dug, returning to the remaining ones; that is, the earth is removed from the 1st, 3d, 5th, 7th, &c. and when the potatoes are taken out of these, it is removed from the 2d, 4th, 6th, 8th, &c. The injury done to the roots by the plough and harrow, and the great number unavoidably left in the soil, is not, he supposes, compensated by the saving of time and labour in taking up with these instruments.

Mr. Young, however, thinks, that there is not the same reason for digging up this crop as for carrots; the plough among the latter is apt to cut, break, and bury them; but not so with potatoes, for it turns them over, damaging scarcely any. In performing this work, first, says he, let a number
a number of women, preceded by a cart, pull up the tops, and throw the potatoes that adhere to them into baskets, and the stalks into the carts, which should convey them to the hog-yards, where they will presently be trampled into dung; then each plough taking us ground, attended by fix or eight women, or more, if the crop is very large, each with a basket, divide the furrow, by setting up white sticks into as many parts as there are women, that each may pick her own share; a range of buffalo fleas being placed at a small distance, for the baskets being emptied into, and three or four carts ready for men who do nothing else, one to eight or ten women, to take the fleas to the carts. The furrow being picked, he used many years ago to work it with men with three-pronged forks, each with a woman, or boy, to pick up the roots; but finding this expensive, he contrived a diagonal harrow in a thin beam, with two or three teeth, drawn by one horse, which tears the furrows in pieces, and lays bare the mafs of the crop: the women then pick again; and another common cradle-harrowing, with a second ploughing and harrowing, all three attended with two women to each plough, will finish the business, and clean the roots all away; so that he has found the pigs, when let in, make but very poor gleanings. The use of the little harrow saved him from 14s. to 20s. per acre in labour, which would otherwise have been necessary. An implement of this fort is shown in the plate on agriculture, under the title of Potatoes Harrow.

Storing.—As soon as potatoes are gathered they should be allowed to remain some days to dry, before they are stored up, as it will give them a much better chance of keeping. There are several ways of storing up potatoes; the best is certainly that by which they can be kept moist, effectually dry, and at the same time free from the influence of frost. Putting them into close houses, and covering them well up with straw, is the most effectual mode, and that which is generally adopted. In Lancashire, and some parts of Scotland, it is a common practice to dig pits in the potato field, when the soil is dry and light, and, putting in potatoes to the depth of three or four feet, to lay a little dry straw over them, and then cover them up with earth, so deep that no roots can affect them. Another method, which is practised in England as well as Scotland, is to put them together in heaps, and cover them up with straw, in the manner of preferring turnips, with this addition, that the heaps are afterwards well covered with earth, and co closely packed together as to exclude frost. The farmers in Lancashire and perhaps separate the potatoes in the course of taking them up, according to their size, and are particularly careful to throw aside all those that are spoiled before raising, or that are cut in the taking up. This is very necessary and proper precaution, (although by no means generally attended to,) as the crop may have a much better chance for keeping, than when diseased or cut potatoes are stored up with it. It is also of great advantage to have the work performed in a dry season, as the potatoes seldom keep well when taken up wet, or when placed in any sort of repository for keeping while in that state. But the best way of storing the roots is, Mr. Young says, in what are called potato-pits. A trench, one foot deep and six feet wide, is dug, and the earth clean shovelled out, and laid on one side; this has a bedding of straw, and the one-horse carts shout down the potatoes into the trench; women pile them up about three feet high, in the shape of a house-roof; straw is then carefully laid on six or eight inches thick, and covered with earth a foot thick, neatly smoothed by flat strokes of the spade. In this method he never lost any by the severest frosts; but in case of its freezing with uncommon severity, another coat of straw over all gives absolute security. But these pies, when opened, should each be quite cleared, or they are liable to depredation. To receive one at a time, besides also being at first filled for immediate use, he has a house that holds about 700 bullocks, formed of polls from sir plantations, with wattled sides, then a layer of straw, and again that earth six feet thick at the bottom, and eighteen inches at top; the roof flat, with a flack of beans upon it. This he has found frost tight. The beans keep out the weather, and yet admit any beam which rises from the roots, which, if it did escape, would rot them.

However, besides these, there are several other modes of preserving potatoes in ufe in different places. In Rutlandshire, Mr. Marshall says, the method of laying up potatoes, is, universally, that of camping them; a method somewhat similar to the above, but which requires to be described. Camps are shallow pits, filled and ridged up as a roof with potatoes; which are covered up with the excavated mould of the pit. This is a happy mean, between burying them in deep pits, and laying them upon the surface. The camps are of various sizes; being frequently, too, made in a long square form like a corn-rick, and of a size proportioned to the quantity to be laid up. It has, however, been found, by experience, that when the quantity is large, they are liable to heat and spoil; much damage having sometimes been sustained by this imprudence. Experienced campers hold, that a camp should not be more than three feet wide, (four feet is, perhaps, as wide as it can be made with propriety,) proportioning the length to the quantity; or, if this be very large, forming a range of short ones, by the side of each other. The usual depth is a foot. The bottom of the trench being bedded with dry straw, the potatoes are deposited; ridging them up as in measuring them with a bullock. On each side the roof, long wheat straw is laid, neatly and evenly, as thatch; and over this the mould, raised out of the trench, is evenly spread; making the surface firm and smooth with the bottom of the spade. A coat of coal ashes is sometimes spread over the mould; as a still better guard against frost. It is needless to observe, that a camp should have a dry situation; and that the roots ought to be deposited in as dry a state as possible. These camps are tapped at the end; some battens, or a quantity of loose straw, being thrust close in the opened end, as a bung or safeguard.

And as it is a matter of the highest importance, to preserve this root without spoiling the whole year, it has been suggested, that the best method yet discovered for keeping potatoes found for the longest period, is to spread them on a dry floor early in the spring, and to rub off the eyes occasionally, as they appear to have a tendency to pull out; by using these precautions, Mr. Donaldson has frequently seen potatoes kept in good condition till the month of June.

The following is an ingenious method of procuring a supply from the new crop, which merits attention. It is to take up carefully with the hand the potatoes that lie nearest the surface; this, in place of injuring the crop, will rather improve it. If this practice were generally adopted by the poor people, who are often obliged, from necessity, to have recourse to the new crop at a very early period, and to dig up a considerable part of it before it comes to maturity, that diminution of the crop would, the above writer says, be in a great measure prevented.

Disage.—Potato crops are exposed to the attacks of dicaele, and that of the curl or blight is the dissembler to which this plant is most liable. It thaws itself very early
in the season, by a curling in the leaves, and sometimes to such a degree, that whole fields are rendered thereby in a great measure unproductive. The cause of this disease is not yet perfectly understood, but the remedies most likely to prevent the evil, are those of frequent changes of feed, using large fets, cultivating and manuring the land in a proper manner, and not repeating this species of crop too often on the same land.

Mr. A. Knight says, that the disease of curled leaves in potato crops, appears to be occasioned by moulding the plant; and that the way to prevent it, is to allow the potatoes to remain in a moderate heat during the winter; some what late in the spring they begin to shoot; let these young shoots be taken off, when two or three inches long, from the tuber, and planted as fets, and the plants thus afforded will be entirely free from the curl.

These sorts of crops have likewise enemies of other kinds, which attack them in their growth; the fly called the thousand legs sometimes eats and makes them scabby, and the large bottle-green grub often eats out the hearts of them. See Curb.

Expenses of Raising and Produce.—The expenses of cultivating, and the produce of this sort of crops, have been differently stated, and they must obviously differ greatly, according to the soil, and the manner in which they are grown, as well as other circumstances that attend them.

In the Report of the West Riding of Yorkshire, Mr. Brown, in 1799, states them in this way.

Expenses upon an Acre of Potatoes.

It is supposed, that the small that dress'd out of what is shipped to London, will deliver them, or rather more. And in the North Riding of the same district, from 200 to 300 bushels per acre are rated to be considered as a good crop of the farts for the table, and that those kinds raised for the purpose of cattle, will generally afford more by 50 or 100 bushels on the same extent of land. And the same is considered as a good produce in the Lancashire mode of cultivating the root.

In the county of Essex, about the town of Ilford, the common calculation of the expense of producing an acre of potatoes is about fifteen pounds, which may be made out somewhat in this way.

This is exclusive of the expense of picking, sorting, packing, and carrying to the market. The prime cost to farmer in his barn 50s. a ton, at ten tons an acre; at seven tons and an half, 40s. a ton, or 11s. 3d. a bushel; six tons at 4s. per cwt., which is 24l. per acre, will leave a good profit; but crops will rise much higher, and the price likewise. It is evidently an exceedingly profitable culture; and when the wheat is considered, will be found to rank amongst the most advantageous classes of British agriculture, according to the opinion of the writer of the Corrected Agricultural Report of the district.

In Young's Survey of Norfolk, it is stated that Mr. Cubitt, at Catfield, had an acre two years ago which produced forty-eight facks, at 6s. a fack.

In Cheshire, the produce of those crops of potatoes, which acquire their full growth, varies from one hundred and fifty to two hundred and fifty bushels, of ninety pounds weight each, on the statute acre. The pink eyes generally give the smallest, the ox noble the largest produce. But there is a great variation in different places, as in the Altrincham district; three hundred bushels the acre is only considered a fair crop.

In Lancashire, the produce of these sorts of crops is from two hundred and fifty to three hundred bushels, and sometimes even so high as three hundred and fifty and four hundred bushels.

In Essex, from two hundred to three hundred bushels, and occasionally more. About Ilford, when the crops stand to full perfection, the produce is from eight to fifteen tons on the acre.

F. Kirchaffer, Esq. of Dublin, in a paper in the fourth volume of Communications to the Board of Agriculture, observes, that of the feed potatoes that were planted in a field, there were just 32 hundred-weight, which he procured from the south of Scotland, at a very considerable expense. These were a clean white and good kind, a little flatted, and had been raised in a moist soil. They were planted in some of the drills. Some were planted with white feed, raised in the bag of Allen; some were also planted with black, and a few with very fine apple potatoes, from the same quarter. The remaining drills were planted with white, black, and apple potatoes, all of which had been raised on land very similar to that in which they were now put; in fact, had grown in the very next field. He found that in their growth the Scotch feed made the earliest, and by much the most luxuriant shoots; the bag's whites and blacks were the next; the home blacks and bag apples were the next; and the home apples were the worst of all. It is added, that as the Scotch whites were the earliest, so they were the first that were dug out; and here the produce was astonishing to the workmen, and to numbers of strangers who came to see the digging. They lay in the drills like hanks of onions, from the bottom, on which the feed had been laid, to the crown. There was very little difference in their sizes, none either remarkably large or small; and they turned out of the ground as clean and beautiful as possible.
possible. A great number of the roots produced from two
to three and four pounds each, and several were more abun-
dant. He had scales brought to the field; and before
respectable witnesses, fix perches of each kind of potatoes
were dug out of the drills, three of which were such as were
supposed to be the best, and the other three the worst; but
in fact they seemed to be pretty equal. The weights of the
produce of the fix perches of each kind were as below:

<table>
<thead>
<tr>
<th>Produce per Perch, of seven Yards.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Bulk apples</td>
</tr>
<tr>
<td>Home whites</td>
</tr>
<tr>
<td>Home blacks</td>
</tr>
<tr>
<td>Home apples</td>
</tr>
</tbody>
</table>

And as all the drills were 38 perches long, and 5 feet
distant from centre to centre; of course they were 18 times
38 perches of drills in an Irish acre, or 664 perches of
7 yards running measure. This number, multiplied by the
average of each sort of feed produced in a perch, gives the
atable produce of every kind in pounds, which, reduced
into barrels of two hundred and a half, is as follows, viz.

The Scotch whites gave 126 of these barrels per acre.

Bot whites                           | 100  |
| Bulk blacks                         | 85   |
| Bulk apples                         | 56   |
| Home whites                         | 78   |
| Home blacks                         | 66   |
| Home apples                         | 44   |

But Mr. Donaldson says, that the multiplicity of weights
and measures, by which potatoes are sold in the various
market-towns in the kingdom, renders it almost impossible
to give an accurate account of the value of the crop by the
acre. It varies, he supposes, in weight from five to eight,
and sometimes ten tons; probably the general average may
be nearly fix tons the English acre. The medium price of
barrels at Dundee has, for some years, about 35l. the ton, equal to 10l. 10s. the acre.

These roots may be readily forted, by having recourse to
a sort of wide riddle made for the purpose.

Application as Food. It has been stated that this sort of
root, joined with hay, straw, chaff, and other similar mat-
ters, has been found useful in many cases, especially in the
later winter months, as a food for horses, cows, and other
sorts of live stock; and with these substances, as well as in
combination with other materials, as bean or barley-meal
and pollard, in the fattening of neat cattle, sheep, and hogs.

But as there is considerable trouble and expense in pre-
paring them, it being found that they are much more safe
and nutritious for such animals when boiled, they do not
appear to have paid greatly, when employed in this way.
The results of numerous trials, detailed by different writers
in the Annals of Agriculture, do not shew them to have been in this mode of application worth more, in general,
than from 4d. to 5d. the bushel. When given to horses, it
may be something more, as there is more difficulty in ascer-
taining the savings in other articles of fodder that are thereby
made, and the advantages that are gained by the animals:
its has been flated to be about 10d. the bushel.

It is flated in the Cheshire Corrected Agricultural Re-
port, that when the crops are favourable, very considerable
quantities of the potatoes raised about Frodsham, and par-
ticularly of the ox-nobles, are given by the farmers in the
neighbourhood to different kinds of stock; feeding cattle,
milch cows, horses, hogs, sheep, &c. The success which
has attended this practice, and the extent to which in many
instances it has been carried, renders it, in the writer’s
opinion, an interesting subject of inquiry. Mr. Antwis in-
foms him, that he frequently applies not less than 2000
buohles of potatoes in a year to this purpose; and flates it
as his opinion, that it is as good, if not a better, food for
cattle of every description than turnips. This, however, is
by no means the general idea on the subject. Some variety
of opinion exists there as to the most eligible manner of
giving this root; whether boiled, which may be done either
in fleam or water, or unboiled. Both of these modes are
practised, and have their respective advocates. Cattle are
more partial to the food in the former state: to horses,
howevers, potatoes are frequently given raw, among other
provisions of the provender kind, and answer extremely well
in this way. An addition of chaff, or rough oats, is com-
monly made to counteract their laxative effect; about two
quarters of this provender being usually mixed with fix
pounds of potatoes, and 40 to 45 per cent. On this subject
Mr. Pittman, an extremely large cultivator of them, finds
nothing better for fattening bullocks, hay being given at
the same time. They are also excellent for cows, and
fatten hogs very well, with a small mixture of barley-
meal.

J. C. Curven, Esq. M.P., in a paper in the fourth
volume of Communications to the Board of Agriculture, ob-
serves, that his former success in feeding horses with fleam-
ced potatoes and cut straw, has encouraged him to attempt
to remove the only inconvenience he found attending it,—
the length of time and labour requisite to fleam any consider-
able quantity. He confounded half year at his works upwards of
60,000 stone. The washing was an operation of great la-
bour, and, if not particularly attended to, was often ill
done. But in a fleaning-house which he has contrived,
there is a washing-machine, which will most completely clean
eleven stone in two minutes, and requires only a trifling ex-
ertion.

He gives this statement of the expense of feeding his
work-horses. The work-horses are employed from eight to ten hours, and, from the nature of their work,
are obliged to travel quickly; these horses stood their work
remarkably well the last year, and continue to do so at pre-
sent. He began to feed with potatoes the 7th of October:

| The average cost of potatoes 3d. per stone, one art. 4| 4d. |
| Oats, at 2s. 4d. per Winchester bushel, weighing from 39 lb. to 40 lb. 8 lb. of ditto | 6 |
| Hay, at 6d. per stone, 7 lb. of ditto | 3 |
| Cut straw, 4 lb. | 1 |
| Steaming the potatoes | 2 |

Per day 1 3

As to the hay and potatoes, it is difficult to say with
precision, without taking every day's accounts, and
Vol. XXVIII.
But horses of great draught, and such as cannot be allowed to rest at noon, will require 12 lb. of oats, which will make the cost of feed per day 1s. 6d. These horses consume rather less hay, but have double the quantity of cut straw with their oats, (which are bruised,) which makes the expense nearly equal. And the steaming 120 fole of potatoes requires two and a quarter Winchelsea buftheels of coals = 137 lb., the weight of the buftiel 61 lbs.

The coals cost

The labour costs

120 fole steaming, at 1/4d.

The difference

This 3½d. per day may be applied towards the first coft, and the neceffary repairs of the machinery, and will in seven months amount to 2l. 16s. 10½d.

It is suppos'd that one acre of potatoes is equal to four of hay, and, under proper management, the ground will be in as good condition for wheat as if it had been under fallow. The potato crop will not in general pay the ex pense, but there will be a considerable saving in putting in the wheat, compared with a fallow, equal to 40s. per acre.

No pains have been spared in having the estimate made as accurate as poftible; he has, therefore, taken the price of hay and potatoes on the average of common years. He has seldom, if ever, cut less than 300 acres of grafs, and has found that quantity inadequate to his annual consumption; and has always been obliged to purchase hay, and has paid from 6d. to 1s. per fole, besides the ex pense of carriage, which would make the average coft 10d. per fole. On the whole, he is fully persuaded that work and farming-horses may be fed with potatoes at a much eafier rate than with hay. The wrete in steaming this root is about one-eighth part. And that lately cut straw has been substituted instead of hay, and the horefs have kept their condition, and done their work equally well.

The baking of potatoes, for the purpoje of feeding leafl, and fattening other forts of flock, has been propagated by Mr. Pierrepont in a letter to the Society for the Encourage ment of Arts, as another and preferable mode of preparing this root, to that of the above. Not altogether satisfied, says he, with the fystem of curing or preparing potatoes by flem from heated water, which he had practifed, and conceiving that fome better method might be found out, he, in 1801, made feveral experiments, and bentowed much attention and trouble upon it, before he brought his plan to bear, which is that of having an oven, and a proper digefer placed in it for containing the roots, which is lehen in the plate, on fleming, roasting, and preparing cattle food. It is observed that potatoes cured in this way are not fo apt to turn four or five fole, the more dry, fo that the animals fed with them drink a deal more, and they become more hard when cold, fo as to be flung to the flock with more convenience than when flemed. In 1802 the writer fattened fifteen brace of bucke chiefly with them. He fays chiefly, as after the potatoes were gone, they had a few beans. They were very fine, and peculiarly fine flavoured. He also fattened the same year with them two oxen, three cows, and two pigs, which were equally well flavoured, particularly the fift. The pigs had, towards the latter end, a few white peac after each meal. The buckes had fix pounds per day, each at an average. The lean deer in the parks do very well, with a little more than a pound per day instead of hay. And this year (1803) he has fatt ened two very large oxen, and twenty Welsh wether. The wethers, with which there were two South Down rams, and one ewe, had eighty pounds of the potatoes per day, with a little cut hay. The ewe was put with them, to teach the other sheep to eat them, she has since had twin lambs, and the bailiff acknowledges that the lambs do better than the other at tumips, though he, with some others, diludied the writer from trying more ewes, under the idea that the potatoes would dry up their milk. Four dairy cows never did fo well with very good hay, as they did last winter, with about four pounds of potatoes, and about five pounds of rough hay and straw cut. One of the oxen weighed, on the 22d of March, 343 foles alive, upon a weighing machine; he had about forty pounds three times a day. It is obferved by the earl of Egremont, that he knows nothing of the ex pense of preparing potatoes in this way; but they appear to him to be more nutritious than in any other mode of drefsing, and much better tasted for the table. He adds that he did not think it poftible to bring such large oxen to such a state of fatinesf upon potatoes. In the feeding of milch cows, they have been found useful in some cafes, even when given without being prepared by being exposed to the heat of boiling, or any other means.

And they are slated by Mr. Young to be sometimes given to horned cattle in the cribs that hay is given in. Giving hay in the morning, about ten o'clock potatoes, at noon hay, about two o'clock potatoes, and at night hay. An ox of one hundred and forty foles (eight pounds to the fole) will eat one buftiel and a half per day; from eighty to one hundred fones, one buftiel, with about ten pounds of hay; they will not eat much hay if they have that quantity of potatoes. They get very fat cattle with hay and potatoes. Mr. Clofe alfo flates, that he has, for feveral years, kept his hogs entirely upon his refuse potatoes, and can always, without difficulty, or the ex pense and trouble of confining them, fell ftole of about seven to eight fome weight, to the butchers, for roasting meat, at 4s. 6d. per fole; pork fed in this method is remarkably fweet, the flesh delicate and moif. This food succeeds admirably, except for bacon, and he finds, from experience, that it is neceffary to keep those intended for that purpofe about a fortnight upon ground peaf mixed with boiled potatoes. If the hogs are awarded with potatoes before they are combined, two buftiels of pea-meal, and four buftiels of boiled potatoes, well incorporated, will fat a hog of twelve foles, fit for hams or bacon; this method greatly reduces the ex pense commonly attending the fattening of fwine. The beft way is, however, to give this fort of food to the fcare hogs.

In the survey of Norfolk it is obferved that Mr. Repton has raised potatoes for the consumption of his farm; but not when he has any prospect of buying them, which he has done at 1s. 6d. to 2s. 6d. a fack. He flates them for young cattle, &c. having a very complete apparatus for the purpofe; boils five cutters, which flem 50 or 60 buftiels a day, and answers well; also tumips, and pours their liquor out to cut claff, giving the whole mixed together; it answers extremely well; the cattle licking it up with very great avidity, and doing perfectly well on this food.

And Mr. Newman of Bayford, Hertfordshire, has fed cattle on potatoes, but as they were too watery, they would not anfwer; he therefore left off the practice. But Mr. Rooper, of Berkhamfide, who has ufually had four or five acres for fifteen years palt, thinks very differently from Mr. Newman, and uces them raw for fattening beef, as he affures Mr. Young, with much fuccefs; for hogs also they anfwer very well. He plants them after oats in every

third
third furrow; and ridges up the stubble soon after harreft; he harrows it down in the spring, and spreads eight loads of long fresh dung per acre; then plants near 20 bushels per acre; he hore-fhoes and ploughs up the crop, which produces from 150 to 200 bushels per acre, on a flinty loam, on a chalk bottom. Wheat will not do after them; but the barley is good. They are, he is clear, a very exhausting crop.

And Mr. Hill has a field of uniformly light land, on the ridge or higher land in the parifh of Kempton, containing about two acres and three quarters; this field was cropped with potatoes in 1794, when he saw it, and the year before produced about 400 bushels per acre, worth on the average 15s. 9d. per bushel, 35l. per acre; every attendant expense about 5l. 30l. clear. He fed his milch cows and flore pigs with the potatoes in winter; the cows gave abundance of milk, but not cream in proportion.

According to the fift of the above writers, by much the moft general as well as the moft useful application of this fort of crop is in that of human food, for which purpose the roots are rendered meal, nutritious, and fit for undergoing the different proceses of digestion, by means of heat, either dry, or in water, or flteam. Their acid juices being in this way converted into mucilage, and probably some portion of that into a fine farinaceous or floury fluftance. Experience fems to prove, that where the heat is properly applied through the medium of steam, the potatoes become more meal and nourifhing than where water is made ufe of for the fame purpofe. But the differences in the mealiness produced by the boiling of this root is fuppofed by fome to depend more upon the nature of the soil on which it is grown than on any other circumstance. And it has been fuppofed by Dr. Darwin, that the mealiness of fome potatoes that have undergone the operation of boiling, may be fometimes affected by the acidity of the water in which they have been boiled; but it is believed to depend more generally upon the mucilage in fome of them being more coagulable than in others, a circumstance the caufe of which has not yet been fully investigated.

Washing.—The cleaning of this root, where it is made ufe of upon an extenfive faile, is frequently confidered as a troublesome operation; it may, however, be performed with great cafe and convenience, by having a vessel conftucted in the form of a barrel, with fmall ftrong narrow laths on the fides nailed to the fold boards, forming the ends at fuch distances as may be fufficient for preventing the potatoes or other roots from falling through, and at the fame time for admitting the water to pass freely. The potatoes are to be introduced and evaftuated by means of a door fixed in one of the fides. The vessel being thus prepared it is to be hung upon a frame of wood over a large square tub containing water, in fuch a manner as that about one-half of it may be immerfed; a crooked handle projecting at one of the ends, by quickly turning which, when the potatoes are put in, a large quantity may be expeditiously washed. There should likewise be a contrivance in the frame higher up and nearer the fide of the ciftern for lifting the barrel from the place in which it turns into, in order that, by opening the door and turning it round, the washed roots may be easily delivered into a barrow or other vessel placed below, fo as that it may receive them. A more expeditious mode of doing this may be feen under the head fleming and washing apparatus.

Effects on Land.—In regard to the effects which are produced on the foil by this fort of crop, it feems probable, the author of Practive Agriculture fays, that both from the nature of the root and the large portion of manure that is necessary to ensure a great crop, except under particular circumftances of the land, that the potatoe is a fort of plant that has a tendency to draw a large quantity of nourifhment from the foil on which it is grown, confequently to exhaust and impoverifh it in a confiderable degree, though these injurious effects are in fome measure counterfby the great abundance of the green and the clofeness of the foliage, producing a flagnated state of the air, and a confiderable deposition of vegetable and other matter on the surface, as well as by the pulverization and aeration that is afforded in the culture and removal of the crop from the ground. It is perhaps in this way only that the contradictory accounts of the effets of this fort of crop on the foil, and the occafional fuccfesfve production of full crops on the fame land, can be well reconciled. The experience of potatoe cultivators in general appears to support the conclusion; as upon more ftong and heavy forts of foil, where benefit can be produced in the above manner, full crops may often be taken in fuccfion without much injury being felt; while on the lighter kinds, where much less advantage is derived in this way, they become too open and exhausted for the fuccfesfve repetition of this fort of crop, and even for the growth of wheat. And that in Mr. Young's trials with the potatoe, introduced in a great many courfes of crops, it was found that the rate of deterioration of the foil was in proportion to the frequency of the occurrence of fuch crops in the rotafions. In the experience of the writer of the report of the North Riding of Yorkshire, this kind of crop does not impair the fertility of the foil on which it is produced; as he has always found that the crop of corn succeeding the potatoe, and the seeds after the corn have been equal to those succeeding a crop of turnips. And it is well known and generally allowed, that a well-managed crop of potatoes, leaves the foil in a mellower and more fertile ftate than any summer fallow, or any prefent mode of cultivation of any other crop. This arises from the frequent affirnings in the fore part of summer with the plough and hoes for the deftrufion of weeds; the thick flade of the plants which keeps a perpetual moifure in the foil, and the decay of fo large a quantity of leaves and ftalks, before and after the crop is taken up, all tend to enrich the foil. A quefion also affires on the food and fupport of this plant; do not all fucculent plants derive a greater proportion of their nourifhment from the atmosphere by their tops, than those of a drier texture? This, though not capable of proof, is probably the fæt; and it is confirmed by the circumstance of all meliorating crops being of a more fucculent nature, as beans, peas, vetches, turnips, and clover, than wheat, oats, or barley, which are exhausting crops.

The facts fiated on this fubjef in the Hertfordshire re¬port are thefe; Mr. Penrose, of Hatfield, has often fows wheat after potatoes, but very rarely gets a good crop; finding this culture, as the reporter was informed, a bad prepa¬ration for that grain.

Mr. Caffmajor, at North Mims, has cultivated this root, and has had confiderable crofs, but he uniformly found it so exhausting, that he could never get fuch crops of corn after them as satisfied him; he therefore gave up the culture. And Mr. Marsh, near Hatfield, a very improving farmer, has cultivated this root for some years; he manures with hore-dung; plants chiefly the champion fort, and gets 600 or 700 bushels per acre. He has had good wheat after thefe, but little crops of barley.

Mr. Hill, of Whittle, has generally four acres: he has had 1100 bushels on two acres and a half. He finds that giving them to foare hogs is the moft profitable application. His men dig up the crop with four-pronged forks, at 1d. per

Turnips and cabbages, if they out-weather the severities of winter, occupy the soil in the spring when it is wanted to be prepared for the succeeding crop; while potatoes, if properly laid up, are a food which may be continued without inconvenience until the crop be finished, or the graft has acquired the requisite bite for finishing them in the field.
On the other hand, potatoes are a disagreeable crop to cultivate: the planting is a tedious dirty businefs; and taking them up, may be called the filthief work of husbandry, especially in a wet autumn.

Potatoe, Canada. See Helianthus Tuberosus.

Potatoe, Spanish, a name given to several species of the convolulus, or bindweed.

Potatoe Harrow, in Agriculture, an implement of the drag kind, made ufe of for harrowing out the potatoes after the plough. Mr. Young, as has been seen, ufed formerly to work the furrows after the plough by men with three-pronged forks, but that finding the method expensive, he contrived a diagonal harrow in a flim beam, with two as three teeth, to be drawn by one horse, managed by a man or boy, which tears the furrow to pieces, and lays the potatoes bare, and by repeating the operation clears the ground of the crop. It saved him from fourteen to twenty shillings per acre in labour. It is seen in the plates on agriculture, under the head Potatoe Harrow, at figs. 2 and 3; in which the following are the dimensions in the firft figure.

From 12 to 13 straight line across.

At fig. 3. is a side view of the harrow-part of the implement.

In working with this tool, the curved iron slides against the unploughed land, at the bottom of the open furrow, and thereby keeps the teeth diagonally placed, to avoid driving the earth in heaps in their work. In loose friable soils three teeth may be employed, but in stiffer ones only two. The tool performs its work well.

Potatoe Scoop, a fort of scoop made ufe of for taking out the eyes or buds of the potatoe for the purpose of fets; they are made of different fizes, according to the intention of the cultivator. Scoops of this fort are reprezentd in the plate on agriculture, under the head Potatoe Harrow, at figs. 4 and 5. They are chiefly employed when potatoes are fcarce.

Potatoe Bay, in Geography, a bay on the S. coaft of the ifland of St. Christoper's.

POTCHENSKOJ, a town of Ruflia, in the government of Archangel; 42 miles N.N.W. of Kola.
POTCHINKI, a town of Ruflia, in the government of Nizniei Novgorod; 112 miles S. of Nizniei Novgorod. N. lat. 54° 24'. E. long. 44° 14'.
POTEE, a town of Candahar; 25 miles E.N.E. of Candahar.

POTEMKIN, Gregory Alexandrovitch, in Biography, a favourite of Catharine II., who governed Ruflia with no lefs detropic authority than other miniflers of that barbarous country, was defcended from an ancient and noble family, eftablifhed in the province of Smolenfko. At an early age he entered the army, and soon became diftinguifhed as an adherent to the emprefs. He served with applaufc under marfhal Romanzoff, in the campaign againft the Turks, and was deputed to deliver the keys of Bender to the emprefs, when it capitulated to the Ruffians in the year 1770. Before this period Potemkin affected a violent attachment to the emprefs; but Catharine paid little attention to mere marks of passion, and after having occupied a poft at court about fifteen months, he received the ufnal order to abfcind himfelf; but he foon contrived to regain his political influence, though compell'd to yield to a new favourite. From this period he maintained an ascendency over the counfels of the emprefs, and introduced and dihmfed fucceffive favourites, according to his own caprice. He was perfeclly well acquainted with the temper and disposition

per buhel; which crop is easily meafured by a fifteen-buhel cart. Mr. Roper finds them a very exhaufting crop.

Mr. King, of Barkway, has had wheat after potatoes, but not good crops: this year he will take barley, which he is well convinced is the moft profitable management.

In Norfolk, Mr. Everit has found that they exhauft the foil more than any thing.

But the dispute respecting their effects on the foil may, Mr. Marshall fuppoles, perhaps, be settled fatisfactorily in this manner. The potatoe contains, indifputably, a great quantity of nourifhment; and is therefore, perhaps, as indifputably a great exhaufter of the foil. But the quantity of vegetable nourifhment carried off in the potatoe crop is not the only caufe of exhaustion: it is notorious to common obervation, that this crop leaves the foil in a fingularly friable fertile flate, caufing an abundant produce of the crop which fucceeds it. If taking the advantage of this prodigality of the foil, the husbandman keeps cropping it year after year with corn; and, when it will no longer anfwer his unreasonable expectations, lays it down to grafs; it is no wonder that it fhould be unproductive: for, having lavifhed all its riches on an ungrateful occupier, it is, of course, reduced to extreme poverty.

On the contrary, if, after a crop of potatoes, well dunged for, only one or two crops of corn be taken, and the land be laid down to grafs, while yet in a flate of fertility, the potatoe crop is, to vulgar appearance at leaft, friendly to the crop which fucceeds it.

Hence it follows, that land which has been cropped with potatoes fhould prefently afterwards be laid down to grafs, or fhould be timely replenified with a quantity of manure proportioned to the degree of exhauftion it has undergoen.

The value of potatoes as a fallow crop, and as an article of food for cattle, compared with turnips and cabbages for the fame purpofes, may be confidered thus: potatoes are more nutritious; and, in the opinion of thofe who have ufed them, fat cattle much quicker than either turnips or cabbages. Potatoes, too, being secured from the severities of winter, are a more certain article of fatting than turnips or cabbages; both of which are liable to perish under an alternacy of frost and thaw; and the turnip, more particularly, is locked up, or rendered more difficult to come at, during a continuance of snow or frost. Turnips and cabbages, if they out-weather the severities of winter, occupy the foil in the spring when it is wanted to be prepared for the succeeding crop; while potatoes, if properly laid up, are a food which may be continued without inconveniently until the crop be finished, or the grafs has acquired the requisite bite for finishing them in the field.

On the other hand, potatoes are a disagreeable crop to cultivate: the planting is a tedious dirty businefs; and taking them up, may be called the filthieft work of husbandry, especially in a wet autumn.

It saved him from fourteen to twenty shillings per acre in labour. It is seen in the
POT

disposition of the empress. In his correspondence with her he affected a great spirit of independence; returned the most laconic answers to letters written by her own hand; and governed her, it is said, no less by remonstrating against her weaknesses, than by inducing her passions. His honours, titles, and employments, now exceeded in number and distinction, those ever before possessed by any Russian subject. He was dignified by all the Russian orders of knighthood, and the principal orders of Prussia, Poland, and Sweden: he was field-marshal, and commander-in-chief of the Russian army; grand admiral of the Euxine and Caspian seas, and created a prince of the German empire. His revenues corresponded to his dignities: besides large estates, he received nine millions of rubles in money; he was lord over 40,000 peasants in Polich Ruffia, and 5000 in Ruffia: he had also a pension of seventy-five thousand rubles, and thirty thousand for his table. This income, extraordinary as it may appear, was found to be inadequate to his expenses. During his campaigns, his march was constantly preceded by an English gardener, and several hundred labourers, who formed a garden on the spot where the tent of the prince was pitched, if he continued ever so short a space of time. He purchased enormous quantities of diamonds, with which he ornamented his dreds; he lavished vast sums on his numerous mistresses; and expended still more on buildings, which he either never inhabited, or never used, but for the purpose of giving a magnificent entertainment or fête. To supply these expenses, and gratify his passion for accumulating riches, he drew on the treasury for sums to an unlimited amount, and none of his drafts were ever rejected. He died at the close of the successful campaign against the Turks. He had been attacked at Yaffy by an epidemic distemper, which he increased by every species of intemperance; and on his journey from Yaffy to Nicolaief, he was feized with a violent fit of the colic, that carried him off. When the empress heard of his death, she was at first much affected with the news, but recovering from her first grief, she seemed pleased with her emancipation from his influence. Potemkin was clumsy in his person, but of herculean size and strength. In mixed companies he was silent and revered; but among those with whom he was intimate, he was affable, cheerful, and indulged in mimicry and farcical raillery, in which he was thought to excel. He was attached to religious ceremonies, particularly to the pomp of the Greek church, and was well versed in ecclesiastical matters. In domestic life he was kind and liberal. He was voracious as well as capricious in his appetite. By nature and habit he was extremely indolent, and frequently neglected important concerns; but when roused to exertion his activity was as remarkable as his supineness. With all his faults and vices, he encouraged commerce and manufactures, was a great patron of learning, and promoted, as far as he was able, the study of Greek literature. He possessed a quick comprehension and a surprising memory; yet his knowledge of books was superficial. His reading was confined chiefly to the French, the belles lettres, and translations of the classics, and to Russian authors who had written on religious ceremonies; but the information which he drew from persons of eminence in every profession was prodigious. See Tooke's Translation of Callers's Vie de Catharine II.

POTENDORF, in Geography, a town of Austria; 4 miles N.E. of Steyregg.

POTEMBER, in Geography, an English writer, was born at Winchester in 1647. He was educated at Corpus Christi college, Oxford, after which he entered himself of the Temple, and was called to the bar. He died at Dorchester in 1733. He was author of a poem on Death, and translated the life of Agricola from Tacitus.

POTENT, or Potence, in Heraldry, a term for a kind of a cross, whose ends all terminate like the head of a crutch.

This is otherwise called the Jerusalem cross.

He beareth fable, a cross potent, or, by the name of Aegypt.

POTENT, Counter-potent. See Counter-potent.

POTENTIA, in Ancient Geography, a town of Italy, in Picenum, towards the S.E., at the mouth of a river of the same name, which became a Roman colony in the year 568.—Alfo, a town of Italy, in Lucania, S.W. of Opimum.

POTENTIA, Power, that whereby a thing is capable either of acting or being acted upon. See Power.

POTENTIA, To exist in, is used among school-writers to denote that existence which a thing has in a certain capable of producing it, but which has not as yet actually produced it. In which it stands opposed to existence in actu.

POTENTIAL, Potentialis, in the Schools, is used to denote and distinguish a kind of qualities, which are supposed to exist in the body in potentia only; by which they are capable, in some manner, of effecting and impelling us the ideas of such qualities, though not actually inherent in themselves.

In this sense we say, potential heat, potential cold, &c.

Brandy and pepper, though cold to the touch, are, as they say, potentially hot.

POTENTIAL Cold is a relative term, by which we mean, that such a thing is not actually cold to the touch, but in its effects and operations, if taken inwardly.

This quality is suppos'd, by those who have adopted the terms, to arise from the fize, shape, &c. of the component particles of a body, which give fome check or retardation to the blood's motion, whereby it is feds agitated, and upon which the fensible parts of the body are not fo briskly thruck by it; the perception of which diminution or change of motion in the organs of feeling, is called cold.

Hence every thing that lessens the blood's motion, with relation to the sensation before made, is cold; and every thing which increases it, may be called potentially hot.

POTENTIAL, in Medicine, &c. Cauteries are either actual, viz. a button of red-hot iron; or potential, as lime, and other caufic drugs.

POTENTIAL is also used by Schoolmen, for something that has the quality of a genus.

A potential whole is that which has its parts under it, as a genus has its species; to distinguish it from an actual whole, which has its parts in itself; as a body composed of matter and form.

Grotius, with a view to this distinction, uses the phrase, potential parts of a flute, in opposition to the subjective parts.

By potential, he means those parts possessed of the sovereign power; by subjective, those subject to it; which are such with regard to the sovereign power, that several species are with regard to the genus of which they are the subjective parts.

Grotius maintains, that though the sovereign power be one and indivisible, yet it may have several potential parts: for as in the Roman empire there have been two potential heads, the one ruling in the East, the other in the West; yet the imperial authority, all the while, single and indivisible; so is it possible, the subjective parts combining to give away their sovereignty, may not give it entirely, but reserve a part of it for certain emergencies. In which case the subjective part
part becomes potential; and thus there are two potential parts, and yet the sovereignty single.

Potential, in Grammar, gives the denomination to one of the moods of verbs.

The potential mood is the same, in form, with the subjunctive; but differs from it in this, that it hath always implied in it, either _poffium, volo, or doce_; as _roget_, that is, _rogere potest_, the man may ask.

It is sometimes called the permissive mood, because it often implies a permission or concession to do a thing; as _habeat, volat, vivat, cum illa_ Terent.

Gen. Ch. Cal. Perianth inferior, of one leaf, nearly flat, divided half way down into ten segments; the alternate ones smaller and reflexed. Cor. Petals five, roundish, or in-feriously heart-shaped, spreading, attached by their claws to the calyx. Stam. Filaments twenty, awl-shaped, shorter than the corolla, inserted into the calyx; anthers elongated into the form of a crefcent. Pfl. Germinns numerous, minute, collected into a head; fylces thread-shaped, the length of the flaments, inserted laterally into the germens; flfgmas obfute. Peric. none. Common receptacle of the seeds roundish, dry, minute, permanent, covered with the seeds, and enclosed in the calyx. Seeds numerous, ovate, rather comprifed, pointed, generally tranfverfely corrugated.

Eff. Ch. Calyx in ten segments, inferior. Petals five. Seeds roundish, naked, tranfverfely corrugated, affixed to a small dry receptacle.

The fpecies of this pretty genus are all, except the fril, herbaceous, and for the most part perennial. Their flowers are generally yellow, sometimes white, very rarely with a tinge of pink. The leaves are compound, and mostly cut or fer- rated; more or less sparingly hairy, or fily. Inferted axillary or terminal, fimple or forked. Linnernus describes twenty-feven fpecies in his Sp. Pl. Wildenow has forty-one. They are natives of cold or temperate climates, and rather mountainous situations. The genus is divided into three fections.

Section 1. Leaves pinnate. Thirteen fpecies, three of them British.

P. fruticofa. Shrubby Cinquefoil. Linn. Sp. Pl. 709. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 88. Leaves pinnate. Stem shrubby.—Native of mountainous fuffy places in the north of Europe, but rarely. It has been found in Siberia, the fouth part of the Swedish ifle of Oeland, and about the river Tees, in Yorkshire. In our gardens and shrubberies it is frequent, forming a fuffy _fbrub_, three or four feet high, covered throughout the winter with folidary terminal flowers of a golden yellow, the calyx of which has five of its segments remarkably large and leafy. The leaves of the plant are alternate, fładked, com- posed of five, rarely seven, oblong, entire leaves. _Stipulis_ folidary, oblong, membranous, placed within each ffootleaf, and united to its bafe.

P. anumefina. Silver-weed, or Wild Tanfey. Linn. Sp. Pl. 710. Willd. n. 2. Ait. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 861. Curt. Lond. fac. 3. t. 31. Fl. Dan. t. 544. (Argentina; Ger. Em. 993.)—Leaves interruptedly pinnate, ferrated, fily beneath. Stem creeping. Stalks axillary, angle-flowered.—Native of pastures, offer-holts, and low commons, in England, and other parts of Europe, flowering through the fummer. It prefers a clay foil, though it often grows in peat earth. Linnernus fays this fpecies always indicates the prefence of clay under the surface. His translators have by mistake referred this remark to _P. argentea_ hereafter defcribed, fee Roof's Botany. 382; and indeed Linnernus himself is partly reponsible for this error, which has crept into Engl. Bot. at p. 89. _P. anumefina_ is a very handfome plant, confpicuous for its ample filvery foliage, and large golden flowers.

—Found in shady alpine fspots, in Sweden, Siberia, Germany, Switzerland, and, according to Ray, on the fides of Craig Weiridin, Montgomeryshire; but we have never seen a wild British fpecimen. In gardens it is a hardy perennial, of easy culture, flowering copiously in the early part of fummer. The flems are about a foot high, brachmed. Leaflets obtufe, hairy, not hoary. Flowers remarkably like the haufois strawberry, copious, somewhat panicled. The feds too are smooth, as in _Fragaria_, not rugged.

P. penflyfanica. Pennflyvanian Cinquefoil. Linn. Mant. 76. Willd. n. 12. Ait. n. 9. Jacq. Hort. Vind. v. 2. 89. t. 189. Figured also in GMNL. Sib. v. 3. t. 34. f. 1. Leaves pinnate, with deeply toothed decurrent leaflets; the uppermost only ternate. Stem erect, downy.—Native of North America, as well as of Siberia. Miller cultivated it at Chelfea, and Jacquin at Vienna; but this is one of those ordinary looking plants, which, unless they can take care of themselves, seldom remain long in any garden. The stem is a foot or two high. Leafes deeply cut, of a hoary green. Flowers small, yellow, not ornamented, difposed in a kind of downy panicle.

P. fipina. Trailing Cinquefoil. Linn. Sp. Pl. 771. Willd. n. 13. Ait. n. 10. Jacq. Aufftr. t. 426. (Penta- phyllum furpimum, potntifilae facie; Ger. Em. 988.)—Leaves pinnate, deeply toothed. Stem prostrate. Flowers axillary, solitary.—Native of Siberia and Germany; cultivated in England before 1696, but it has as few attractions as the last, from which it differs in having a prostrate stem and defiered flowers. The root is tapering, fingular in this fection for being annual.

Section 2. Leaves digitate. Twenty-one fpecies, five British.

P. reca. Upright Cinquefoil. Linn. Sp. Pl. 711. Willd. n. 14. Ait. n. 11. Jacq. Aufftr. t. 383. (Quinquefolium majus recaum; Ger. Em. 587.)—Leafes five to seven, obovato-lanceolate, coarfly toothed. Petals inverfely heart-shaped, larger than the calyx. Stem erect, corymb- bole, forked, many-flowered.—Native of Italy, France, Switzerland, and Germany, in flowry dry places, flowering copiously in fummer. It has long been cultivated in botanic gardens, and sometimes finds a place in flower borders, being recommended by its copious yellow blofoms, which often allume a pale sulphur-like hue. The plant is a hardy perennial, very hairy, and grows in a corymb fhape manner, to the height of two feet.

POTENTILLA.

latt-mentioned, distinguished by the snow-white cottony hoariness of the flacks and backs of the leaves, to which the name argentata does not well apply. Indeed we are persuaded that Linnaeus, in his recollection at Hall, confounded this with the anserina, a species very widely different in all but whiteness; and that is cottony in the present, silvery in the anserina. The flowers of the argentata, though small, are conspicuous for their golden colour.

P. opaca. Saw-leaved Hairy Cinquefoil. Linn. Sp. Pl. 713. Wildl. n. 23. Ait. n. 16. Engl. Bot. t. 2449. Jacq. Linn. Ber. t. 91. (Pentaphyllum incanum, minus, sens; Gen. Em. 989.)—Radical leaves of seven hairy, linear-wedge-shaped, deeply serrated leaflets; stem-leaves mostly opposite, of three stems, slender, decumbent.—Native of Germany and Switzerland; found, since the publication of Fl. Brit., on the mountains of Scotland, flowering in June. The opaca of Hudson was only verna. The plant bears many spreading, partly decumbent, stems from the crown of the perennial root, which compose a lax tuft, a foot wide, or more, green and hairy. The radical leaves grow on long flacks; the rest are nearly sessile, and mostly opposite; leaflets so deeply serrated as to be almost pinnatifid. Flowers handsome, of an orange yellow, on long, hairy, lateral flacks.

P. verna. Spring Cinquefoil. Linn. Sp. Pl. 712. Wildl. n. 24. Ait. n. 17. Fl. Brit. n. 6. Engl. Bot. t. 37. (Fragaria verna; Crantz Aultr. fave. 2. 12. t. 1. f. 1.)—Radical leaves of five wedge-shaped, serrated, furrowed, fringed, rather coriaceous leaflets; stem-leaves of three. Stem reclining.—Found in dry pastures of the north of Europe, where the ground is barren, and chalky or gravelly; flowering with us in April or May. Its growth is humble, and texture more coriaceous than the last. The leaflets are nearly obovate. Flowers about the ends of the stems, on longish flacks; their petals yellow, scarcely so long as the calyx.

P. aurea. Golden Cinquefoil. Linn. Sp. Pl. 712. Wildl. n. 25. Ait. n. 18. Fl. Brit. n. 5. Engl. Bot. t. 561. Fl. Dan. t. 114. (Quinquefolium minus, flore aureo; Gen. Em. 990.)—Radical leaves of five obovate, deeply serrated, hairy, somewhat membranous leaflets; stem-leaves of three. Stem nearly erect.—Native of the mountains of Norway, Germany, Switzerland, Italy, &c. as well as of the Scottish Alps, flowering in July. This is larger, more erect, and far more handclorose than the last, with more conspicuous golden flowers, and less coriaceous leaves. The segments of the calyx are all nearly equal in length, though not in breadth.

P. alba. White Cinquefoil. Linn. Sp. Pl. 713. Wildl. n. 28. Ait. n. 20. Fl. Brit. n. 7. Engl. Bot. t. 1384. Jacq. Aultr. t. 115. (Quinquefolium sylvaticum majus flore albo; Gen. Em. 989.)—Leaflets five; silky beneath; with converging serratures at the summit. Stems thread-shaped, procarbent. Receptacles very hairy.—Native of the Alps of Germany and Hungary, in shady-places. Hudson records it as a Welsh plant, on the authority of a Mr. Haveland; but his assertion has never been confirmed. This Potentilla is a favourite decoration for rock-work in most gardens, flowering from May to August. The glaucous silvery leaves, and abundant snowly blossoms, each on long slender flacks, are elegant and uncommon. The receptacle is remarkable for long densa hairs. Seeds slightly corrugated.

P. nitida. Peach-blossom Cinquefoil. Linn. Sp. Pl. 714. Wildl. n. 32. Ait. n. 23. Jacq. Aultr. append. t. 25.—Leaflets five or three, downy, with three converging teeth. Stems single-flowered. Receptacles woolly.—Native of Austria, as well as of Mount Baldus, and of the Tyrol. Sir Joseph Banks procured it for Kew garden in 1798, and it flowers there in the middle of summer. Nothing can be more elegant than the silvery leaves and pink flowers; which last are well compared by Poni, Bauhin, and Ray to the blossoms of a peach. This humble plant forms dense tufts, from one to two inches only in height, though the flowers are nearly an inch wide.

Section 3. Leaves ternate. Seven species, one of them Britich.

P. nivosa. White-leaved Cinquefoil. Linn. Sp. Pl. 715. Wildl. n. 37. Fl. Dan. t. 1035.—Leaflets three, cut, downy beneath. Stem ascending.—Native of the Alps of Norway, Lapland, and Siberia; a stranger to our gardens. The structure of the herbage, as Linnaeus observes, resembles P. verna, but the leaflets are only three, broader and much more hairy than in that species, very downy and white beneath. Petals yellow.

P. speciosa. Silvery Cretan Cinquefoil. Wildl. n. 38. Sm. Prod. Fl. Græc. Sibth. v. 352. Fl. Græc. t. 484. (Fragaria speciosa; new. unpublifhed.)—(Fragaria cretica saxatilis fruticofa, folio pubitis argenteo; Tourn. Cor. 21.)—Leaflets three, elliptic, obtuse, toothed, downy beneath. Stem shrubby.—Native of the hills of Crete, as well as of Mount Parnassus. Sibth. The stems are a fain high, rigid, and rather woody, with a deciduous bark. Leaves resembling the wild strawberries, but snow-white at the back. Flowers on very downy corymbose terminal flacks, accompanied by one or two hinnen leaves. Calyx woolly. Petals white.

P. tridentata. Trifid-leaved Cinquefoil. Soland. in Ait. Hort. Kew. ed. 1. v. 2. 216. t. 9. ed. 2. v. 3. 279. Wildl. n. 39. Sm. Tr. of Linn. Soc. v. 10. 343. Engl. Bot. t. 2386.—Leaflets three, wedge-shaped; smooth above; hairy beneath; three-toothed at the summit.—Native of Newfoundland; and discovered by the late Mr. Geo. Don, on a mountain called Werron, in Angushire. It has, for nearly 30 years, been cultivated in our more curious gardens, and flowers early in summer. The stems are erect, three to four inches high, herbaceous, though the root is woody. Leaves several, stalked, dark green and smooth above; pale and rather hairy beneath. Flowers few, terminal, pure white with purple anthers.

P. grandiflora. Great-flowered Cinquefoil. Linn. Sp. Pl. 715. Wildl. n. 40. Ait. n. 28. Curt. Mag. t. 75. (Fragaria; Hall. Hill. n. 1114. t. 21.)—Leaflets three, toothed, somewhat hairy on both sides. Stem reclining, longer than the leaves.—Native of Siberia, Switzerland, Italy, and the Pyrenean mountains, long cultivated in the gardens of Britain, where it decorates rock-work, flowering in June and July. The aspect of the flowers and herbage is not very unlike our common P. reptans, but the stems do not creep, and the leaflets are only three. In a wild state, the plant has a more elegant appearance and brighter colours.

Potentilla, in Gardening, contains plants of the herbaceous and shrubby kinds, of which the species cultivated are, the shrubby cinquefoil (P. fruticosa); the straw-
berry cinquefoil (P. fragarioides); the upright cinquefoil (P. recta); the Montpellier cinquefoil (P. montpeliensis); and the great-flowered cinquefoil (P. grandiflora).

Besides these, other species may be cultivated for variety.

Method of Culture.—The first sort may be readily increased by suckers, layers, and cuttings, which may be laid down or planted out in the autumn or spring, and be removed into the nursery in the spring following; and after having two or three years' growth in that situation, they will be fit for planting out in the clumps or shrubby borders.

When removed from their natural situations into these places, the bell saffron is in the autumn, before the frosts begin, that they may get well rooted. They should be watered occasionally in dry weather.

They succeed bell in a cool moist soil and shady situation.

All the other kinds may be increased by parting the roots, and planting them out in the autumn, or by sowing the seeds either in the autumn or spring saffrons.

They all afford ornament and variety in the different parts of pleasure-grounds.

POTENZA, PASQUALE, in Biography, an opera singer, with a feeble and uncertain soprano voice, and an affected actor, not without vocal taste, suppled the place of Riccarielli as first man in our operas, when the Mattei was first woman, from 1757 to 1759.

POTENZA, in Geography, a town of Naples, in Bafilicata, the fee of a bishop, suffragan of Matera; built on the ruins of an ancient town, which was destroyed in the year 1250; 54 miles S.E. of Benevento. Lat. 40° 40'. E. long. 14° 4'.—Alfo, a river which rifes in the marquisate of Ancora, and runs into the Adriatic, Lat. 43° 22'. E. long. 13° 45'.

POTERII ANTHETICUM. See Antheticum.

POTERIUM, in Botany, an ancient name, adopted by the Latins from the Greeks, whose ποτέριον, at leat that of Dioceorides, evidently appears to have been a species of Astragalus, confounded by Linnaeus with A. Tregecantha, but distinguished by Lamarck under the denomination of creticus; see Sm. Prodr. Fl. Græc. Sibth. v. 2. 91. Perhaps Linnaeus, in the choice of the name in question for the genus of which we are about to treat, had in view ποτέρια, a cup; the herb being, in some countries, infixed, along with borage, in cooling potations.—Linn. Gen. 495. Schreb. 645. Willd. Sp. Pl. v. 4. 421. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1024. Ait. Hort. Kew. v. 5. 286. Jull. 336. Lamarck Illust. t. 777. (Pimpinella; Tourn. t. 68. Gartn. t. 32.)—Clas and order, Monoccia Polyandria. Nat. Ord. Miscellanea, Linn. Roffacce, Jull. Gen. Ch. Male, Cal. Perianth of three or four oval, coloured, deciduous leaves. Cor. of one petal; tube cylindrical, about the length of the calyx; limb in four deep, ovate, concave, spreading, permanent segments. Stam. Filaments numerous, from thirty to fifty, capillary, very long, filiform; anthers roundish, of two lobes.

Female, in the upper part of the fame spike. Cal. Perianth inferior, refembling the male. Cor. of one petal, wheel-shaped; tube fliform, roundish, contracted at the mouth; limb in four deep, ovate, flat, reflexed, permanent segments. Pfl. Germenis one or two, ovate-oblong, within the tube of the corolla; styles one or two, capillary, coloured, filiform, the length of the corolla; vessels tufted, coloured. Peric. Drupa formed of the thickened, hardened, closed tube of the corolla. Seed. Nut of two cells.

Eff. Ch. Male, Calyx of three or four leaves. Corolla deeply four-cleft. Stamens: thirty to fifty.

Female, Calyx of three or four leaves. Corolla deeply four-cleft. Pflilis one or two. Nut of two cells, invested with the hardened tube of the corolla.

Linnaeus describes three species of Poterium, to which Willdennow adds three more. The most remarkable are P. Sanguiforba. Common Burnet. Linn. Sp. Pl. 1414. Willd. n. 1. Ait. n. 1. Engl. Bot. t. 860. Curt. Lond. t. 2. 164. Mart. Fl. t. 69. (Pimpinella hortensis; Ger. Emm. 1045.)—Spines none. Stem herbaceous, somewhat angular. Native of exposed limestone or chalky situations, in the more temperate parts of Europe; plentiful on the chalk hills of England, flowering in July. The root is woody and perennial. Stems branched, leafy, more or less angular, many-flowered, smooth, often reddish. Leaves pinnate; of several pairs of roundish or elliptical, serrated, smooth, rather glaucous leaves, with a terminal one about the same size. Heads of flowers flaked, terminal, solitary. Calyx and corolla greenish. Stems like a tassel of purple silk. Fruit rugose. Some of the male flowers have occasionally an abortive pistil. The leaves possess a flavour like cucumber, which they communicate to any liquor in which they are infused. They are also ingredient in fallalads.

Willdenow's P. polygamum, adopted from Waldstein and Kitaibel's Plants Hungarica, v. 2. 217. t. 198, feems a very trifling variety, some of the intermediate flowers of whole spikes, or heads, have both flammis and pflilis.

Poterium, in Gardening, contains plants of the herbaceous and shubbby perennial kinds, of which the species cultivated are, the leller upland, or common garden burnet (P. fanguiforba); the sweet burnet (P. hybridum); and the prickly burnet burnet (P. spinosum).

Method of Culture. The first sort may be readily increased by seeds and parting the roots.

The seeds should be sown in the autumn, on a bed or border of light mould, when they are perfectly ripened. When the plants have attained two or three inches in height, they should be planted out on a bed, at the distance of a foot, when for beds, or in the borders where they are to remain.

The roots may likewise be parted in autumn, and planted where they are to remain, in the same manner as above.

The second sort may be increased in the same way. And the last sort may be raised from slips or cuttings, which should be planted in a bed of light earth during the summer seazon, and covered with glafies or in pots, and placed under a frame and glafies, giving shade and water occasionally.

They may also be had more forward by plunging the pots in a moderate hot-bed under glafies. They should be removed into separate pots when they have stricken good root, and are well eftablished. They should afterwards be protected from frosts in the winter, by being placed in a mild hot-bed, and have but little water in the winter season.

The first sorts are ornamental in the borders, clumps, and other parts; and the latter, among other potted green-houfe plants.

Poterium is also used by many for the prickly pomponell. See Burnet, Samphrage.

Potes, in Geography, a town of Spain, in Asturias; 25 miles S.W. of Santillana.

Pot-herbs, in Gardening, such as are used for different culinary purpofes, confiding of different sorts of the small...
small aromatic kind, and some others. But in a more general
signification, they comprehend many of the other kitchen gar-
den vegetables, but are principally understood to be such as
are in request to improve soups, broths, and some other similar
culinary preparations, in which, sometimes, several different
kinds of small herbs are used in different proportion, both
in composition and effect.

They are chiefly the following sorts: thyme, marjoram,
 savory, fage, parsley, mint, penny-royal, forrel, chervil, ba-
sil, coriander, dill, fennel, marigold, horage, burnet, tay-
sey, tarragon, chives, leeks, onions, green beet, white beet,
spinach, celery, endive, lettuce, love-apple, capucine, and
purflane.

Those made use of separately, as fallad-herbs, are green
and white beet, to boi as separate dishes; celery, endive,
and lettuce, as choice fallad-herbs, and sometimes to stew.
But of the above, the thyme, marjoram, savory, parsley,
fage, mint, marigold, penny-royal, leeks, celery, and
onions, are in the greatest request.

Proper supplies of the different sorts may be raised in the
manner directed under their particular heads. See ARO-
MATIC and Kitchen Garden Plants.

POTHERIE, LA, in Geography. See CHALAIN.
POTHERY, in Rural Economy, a provincial word signi-
ifying clove, muggy, or fultry, in speaking of the weather.
POTHIER, ROBERT-JOSEPH, in Biography, a confi-
derable French writer on legal subjects, was born at Or-
leans in the year 1699; of the university of which city he be-
came professor of the law. He, at first, directed his studies
to Roman jurisprudence, and for the elucidation of which
he held weekly meetings of the learned on the subject at his
own house. He next applied himself to the French law,
and was, without any solicitation on his part, appointed professor
by the chancellor d'Agueneau; and in order to excite the emula-
tions of students, he established prizes for proofs of great proficien-
cy. He died in 1772, with a charac-
ter not less respectable for morals than for learning and
industry. His works on French and Roman law were nu-
merous. Among the principal are "Pandecta Jullinian," 3
vols. folio, 1748; "Traite des Fief," 2 vols. 1776; Po-
thumous Works, in 3 vols. 4to.

POTHOLT, JACOB, organist and carillonneur in 1772,
in the old kirk at Amsterdam. He was blind, having been
deprieved of his sight at seven years old by the small-pox;
and this misfortune suggested to his friends the idea of making
music, which had hitherto given him pleasure, his profes-
sion; but it afterwards became his darling amusement.

The organ at the old kirk is that organ builders call a
16 feet instrument, from the length of the lowest pipe in the
open diapason, or Bordouin flops. This instrument is very
full of work, and has 64 flops, three sets of keys, both in
the manuals and pedals, with nine pair of bellows.

Potholt was organist of the Wetter Kirk 22 years be-
fore he obtained this place; his hand, taste, and abilities in
every particular, were truly astonishing; the touch of this
instrument was the heaviest that we ever felt; each key re-
quiring almost a two-pound weight to put it down; and to
play it, there was a firing of communication, by which
the keys of the great and choir organ were moved at the
same time, which likewise added very much to the stiffness
of the touch; however, such was the force of M. Potholt's
hand, that he played this organ with as much lightness and
rapidity, as if it were a common harpsichord.

This admirable organist was never out of Amsterdam, ex-
cept for a few days at the Hague, many years ago; and yet
his taste was of the best modern kind; his appoggiaturas
were well taken, and admirably expressed; his fancy was extremely
lively; and though he played very full, seldom in less than five
parts, with the manuals and pedals together, yet it was nei-
ther in the dry nor crude way, which we had so frequently
heard in Germany. He discovered, though not injudiciously,
by many of his passages, that he was a harpsichord player;
but so well was he acquainted with the different genius of the
organ, that his most rapid flights, of which he had many,
occaisioned none of those unpleasing vacuities of sound,
which so commonly happened, when this instrument was
shocked by mere harpsichord players.

M. Potholt played two fugues in a very matterly man-
ner, the subjects of which he revered, and turned to a
thousand ingenious purposes.

He published, in 1777, a work for young organists, with
the following Dutch title: "Mufyk (de) van de CL Fia-
men met Interluden in Ballen door." Jacob Potholt, Amster-
dam, 4to.; the CL palms harmonized, with interludes.

POTHOS, in Botany, a genus of plants unknown to us, and
which signifies desire or love. Some have applied it to the Cumboline, Aquilegia.

Perhaps Linnaeus adopted it in the bad sense of certain ancient writers, as
meaning nosius, or offenent, because of the intolerable
factor of some species, and the acrimony of others.—Linn.
Lamarck Illifir. t. 732. —Clas and order, Tetrandra Mo-

Gen. Ch. Cal. Sheath globose, of one leaf, burbling at
one side, enclosing a simple, oblong, thick receptacle,
entirely covered with feffile flowers. Perianth none, un-
less the corolla be taken for such. Cor. Petals four, wedge-
shaped, oblong, erect. Stam. Filaments four, flatfif, erect,
narrower than the petals, but of the same length; anthers
minute, in pairs. Pf. Germen superior, oblong, angular,
abrupt; styled none; stigma simple. Per. Berry roundish,
of two cells. Seeds roundish, solitary in each cell.

Ell. Ch. Sheath of one leaf. Receptacle oblong, covered
with flowers. Perianth none. Petals four. Berry with
two seeds.

The plants of this genus are mostly of tropical origin,
with the habit of Arrum, perennial, smooth, often coriaceous
in texture. Linnaeus enumerates but six of them in his Sp.
Pl. but Willdenow has twelve. The Hortus Kewenfis con-
tains ten. The following will serve as examples.

Mag. t. 603. Ait. n. 4.—Leaves elliptical, with simple
parallel veins.—Native of the West Indies; sent to Kew in
1789, by Mr. Alex. Anderfon, under the name of P. od-
rata, alluding to the sweet scent of its flowers, unusual in
this tribe. It blooms in the flore in April and May. The
leaves are radical, pointed, much resembling thofe of Cana
indica. Flowers whitefit, as well as the inner surface of
their sheath. The latter, like the receptacle, is three or four inches
long.

P. macrophylla. Large-leaved Pothis. Swartz Ind.
Occ. 269. Willd. n. 8. Ait. n. 7. (P. grandifolia; Jacq.
Ic. Rar. t. 610.)—Leaves heart-shaped, with disctivated
lobes. Receptacle much longer than the sheath.—Native
of the Wett Indies. Flowering in our flores in June. This,
like the foregoing, is diftinct of a stem. The leaves are
about two feet long, ribbed and veiny. Receptacle above a
foot long, covered with brown flowers, and subtended by a
green recurved sheath.

Ic. Rar. t. 611. Willd. n. 11.—Leaves digite; of about
nine oblong, sharpish leaflets.—Native of the warmest parts
of South America. This has a thick climbing stem, throw-

Vol. XXVIII.
POTIERS, in Geography. See PUTI.

POTICARA, in Ancient Geography, a town of Asia, in the interior of the Periplus, between Cotamaba and Ardea, according to Ptolemy.

POTIDEEA, a town of Macedonia, and one of the five places which Scylax, in his Periplus, has assigned to the peninsula of Pallene. According to Thucydides, it was situated on the isthmus which joined the peninsula to Macedonia. Livy says that this town had been built, or as he should have said, repaired, by king Caffander, from which circumstance it took the name of Caffandria.

POTERS, in Geography, a town of France, in the department of the Coté d’Or; three miles from Molemesmes.

POTIGNY, a town of France, in the department of the Calvados; 5 miles N. of Falaize.

POTUJ, a river of Brazil, which runs into the sea, S. lat. 5° 43’. 

POTINCBA, in Botany, a name by which some authors call water-pepper, or the sharp armift.

POTION, Potio, a liquid medicine, in the quantity of a draught, or so much as is to be taken at one time.

A potion only differs from a julep, or a mixture, in the quantity, as being confined to one dose.

There are purging potions, emetic potions, diaphoretic, peptoral, cephalic, cardiac, stomacic, hysteria, vulnerary, carminative, &c. potions.

POTIRENE, in Botany, a name given by the people of Burgundy to a linking kind of fungus, found about the roots of trees. They have also extended the name much farther, and use it for a fort of touchwood, or rotten wood of the oak, and other trees common in the forests of those countries, which fumes in the night, and has the fame flemel with that fungus.

POTITII, in Antiquity. See PINARII.

POT-METAL is formed of lead mixed with copper, in the proportion of one part of lead to four of copper. This metal is harder than copper, or even brass.

POTNIAE, in Ancient Geography, a town of Bocotia, N.E. of Platea, and S.W. of Thes. It was ruined in the time of Paufanias. Here still remains a grove, consecrated to Ceres and Proserpine; and in this grove are some statues denominated “Potianiades.” Although the town is destroyed, the scite of it is still held in veneration, and at a certain time of the year, sacrifices are offered to Ceres and Proserpine. Near this sacred grove is a temple of Bacchus, furnamed “Egobula.”

POTOKA, in Geography, a river of America, which runs into the Wabash, N. lat. 38° 18’. W. long. 88° 28’.

POTOSI, a celebrated city of the viceroyalty of La Plata, or Buenos Ayres, and next in importance, if not superior, to Buenos Ayres, the capital. It is situated in a district, inclosed by the province of Porco, which is mountainous and cold, and confluently very barren; the valleys are entirely deftitute of wood, and nothing grows on the slopes and declivities of the mountains but mosses. The summits of the mountains are covered with perpetual snow, notwithstanding it affords a scanty supply of sheep, and some vicuna; and in this desolate country nature has placed some of the richest mines of silver in the world. The district of Potosi is battered by the river Pilcomayo, which joins the Parana not far above Corrientes, so that there is a natural connection between this province and Buenos Ayres. The mines of Potosi were discovered in 1545, and the city, which stands on the S. side of a mountain of the same name, in a glen formed by a rivulet, was founded in the year 1547. The mint was established in 1562, and has continued richly to supply all Europe with silver. By a census of its inhabitants, made in 1611, its population is said to have amounted at that time to 160,000 souls. If this account, extracted from the “Mercurio Peruiano,” be correct, Potosi must have greatly declined from its ancient state, though Helms, a late writer, ascribes to it a population of 100,000. Dr. Robertson, from the best Spanish authorities, affixed to it 25,000, and the same number is given by Aledo. According to the report of the “Mercurio Peruano,” its whole population in 1792 consisted of only 18,181 souls; of whom 256 were ecclesiastics and persons under vows; 3482 Spaniards; 4872 Mestizos; 8575 Indians; 1012 Negroes and Mulattoes. The wealth of Potosi produced the establishment of numerous convents, a vow of poverty not at all interfering with great riches. Within the city and district there were 14 curates; but in the year 1759, seven curacies were abolished. In the neighbourhood of the city are warm medicinal baths, called those of Don Diego, and highly esteemed. As soon as the mines of Potosi were discovered, and the town was established, it became a place of great reforest; and in process of time it reckoned among its inhabitants many noble families, particularly those concerned in the mines; and it is estimated to be about two leagues in circumference. By the Spanish writers it is styled an imperial city; it is the residence of a corregidor, and of a tribunal of finance, composed of a comptroller and treasurer. Its commerce was formerly compared with that of Lima, and in time became superior to it, confiding in the exchange of ingots of silver for the articles imported; but it is now said to be upon the decline. A cold and violent wind, called “tomahwi,” prevails during the months of May, June, July and August. Although the air of the mountain, on the declivity of which it is situated, being cold and dry, renders the adjacent country remarkably barren, so that it produces neither grain, fruits, herbs, nor other cereals, the town is so plentifully provided, as to enjoy abundance of every kind; and the trade for provisions is greater here than in any other place, Lima alone excepted. This may be naturally ascribed to the attraction of a mountain of silver, and to the number of people employed in the mines. Some provinces send the best of their grain and fruits; others their cattle; others their manufactures; and those who trade in European goods resort to Potosi, as to a market where is a great demand, and no want of silver to give in exchange.

The celebrated mines of Potosi were discovered, as we have said, in 1545, by an accident seemingly fortuitous. An Indian, called by some Guala, and by others Huipalpa, pursuing some wild goats to the mountain of Potosi, and arriving at a very steep part, laid hold of a small shrub in order to ascend with the greater security and speed, but the shrub, unable to support his weight, was torn up by the roots, and discovered a mass of fine silver; and at the same time he found...
found some lumps of the same metal among the clods which adhered to the roots. This Indian, who lived at Porco, not far distant, had been home with the fruits of his discovery, washed the silver and sold it, repairing, when his stock was nearly exhausted, to his perpetual fund. At length an intimate friend, named Guanica, observing the happy change that had taken place in his circumstances, became solicitous to investigate the cause, which Guanica disclosed to his friend. For some time they retired in concert to the mountain for fresh supplies of silver, till Guanica refusing to discover his method of purifying the metal, Guanica revealed the whole secret to his master, Villaroc, a Spaniard who resided at Porco. Immediately on this information he went, on the 21st of April 1545, to view this fortunate breach in the mountain, and the mine was worked without delay and with immense advantage. This mountain, which had been affidiously worked from its first discovery, and which is said to produce weekly about 5000 marks of silver, that is from 30 to 4000,000 dollars, is of a conic form, about 20 British miles in circumference, and perforated by more than 500 rude shafts, through a fine yellow argillaceous schistus. Here are veins of ferruginous quartz, interlaced with what are called the horn and vitreous ores, of a peculiar dark-red, reddish colour. This mountain rifies void of all vegetation, blasted by the numerous furnaces, which in the night form a grand spectacle. These mines are distant 1873 English miles from Buenos Ayres; and the greatest part of the journey to them lies through a barren uncultivated country, and the last 400 miles of it are across mountains very difficult to pass, the bed of a torrent being in many places the only road. To an enemy, therefore, it must be a very hazardous enterprise to penetrate from Buenos Ayres to Potosi, and quite impossible, if any resistance be opposed to it. The true road to Potosi is not through Buenos Ayres, but by Peru; not through the country to which it has been artificially annexed, but through that on which it depends for its subsistence. The benefit of the mines is open to all who chuse to avail themselves of it; but labourers are not easily procured. On account of the small population, scarcely one quarter can be found of the necessary number, Indians being always employed; and in this view no mine is so useful as that of Potosi; for every 18 months there are sent from the provinces of the viceroyalty 6000 Indians, enrolled and divided into parties, in order to work in the mines. This expedition of Indians is called "Mita;" and they are distributed by the governor of Potosi according to the funds of the several mines, each being paid four reals a day, and treated according to the ordinance, till they complete their periods of labour. Without this measure the benefits of the mine would cease, as no labourers could be found; the great, and sometimes unfeigned expenses incurred, and the loss which the royal treasury would sustain, if these mines were abandoned, having rendered the "mita" indispenisible, and it is said to be conducted with all possible humanity. See Peru and La Plata.

The annual produce of these mines, at present, does not equal 550,000 or 600,000 marks of silver; but Mr. Helms is of opinion, that if they were wrought with barely moderate skill and diligence, they would yield, every year, 20, and even 30, millions of dollars. The ignorance of the Spaniards at Potosi, in the art of mining, he describes as ex- ceptive; and he represents their mode of conducting the operations of smelting, fusing, washing, quickening, and roasting the ore, as the most slovenly, wanteful, and unscientific. Their process of amalgamation is so defective, that they are scarcely able to extract two-thirds of the silver contained in the ore; and for every mark of pure silver which they obtain, they lose one, and frequently two marks of quicksilver. According to Helms there were coined, from January 1, to December 31, 1790, in the royal mint at Potosi, 299,845 dollars in gold, and 3,983,176 dollars in silver. We shall here subjoin a more minute statement of the produce of these mines.

But, as great part of the silver of Potosi is known not to have paid the duties, but to have been smuggled out of the kingdom, the real produce of its mines must have been greater than what appears by the preceding estimate. It is sup- posed, that for more than half of the eighteenth century, the contraband trade of Potosi with the Brazils was such, that only a third of the silver from its mines paid the royal duties.

It may not be unacceptable to introduce in this place, for the information of our readers, some account of the three descriptions of persons, who find employment in the business of mining, in South America, with which we are furnished by the "Mercurio Peruviano." The first person is the speculator in the mines, who is often a practical miner; this person in Mexico is usually a man of considerable property, who can afford to make large advances from his own funds for carrying on his works, and to whom the whole profit of his speculation, when it succeeds, reverts. But, in Peru, he is in general a person in insidious circumstances, who begins by borrowing money at an exorbitant interest, and ends by selling the produce of his mines at a disadvantageous rate, in order to procure the means of carrying them on. The second person is the "habilitador," who is a merchant and money-lender; he supplies the miner with the capital necessary for commencing and carrying on his speculations; and this he advances on the hardest and most oppressive terms. He obliges the miner to take one-half of the advance in money and the other half in goods, which he may not want, and which are always overcharged. He binds him to pay the advance in "pina" or "pigna," at the end of a short period, generally of four months. "Pina" is silver bullion, freed from the quicksilver with which it has been amalgamated, but not melted. In this transaction he receives a dollar for the loan of five dollars and a half for
four months, and he has other means of exacting, which
he uses without much consideration. By this complicated
system of fury and oppression, a miner, who has bor-
rowed 325 dollars from an "habilitador," one half in
money, and the other half in goods charged above their
value, may find himself compelled, at the end of six months,
to pay fifty-seven and a half marks of pina, worth 411 dollars,
in order to obtain an acquittance of his debt. The " reca-
tador," or " recautario," is a third person, who buys
"pina" from the miner, and gives him money in exchange
for it. A stronger proof cannot be given of the want of
spirit and activity in Peru, than that evils affecting so mate-
rially the vital interests and prosperity of the kingdom,
should have been suffered to continue for so many ages
without any effort to remove them. It is only since the elab-
oration of the Royal Tribunal of Mines in 1786, that banks
"de recate," or redemption, as they are called, have been erected for that purpose in the principal mines.
These banks purchase " pina" from the miners on account
of the Royal Tribunal of Mines; and as they give always a
fair price for it, they keep down the profits of the " reca-
tadores," and secure the miners from their extortions. The
banks "de recate" are also of essential service to the miners,
by supplying them with quicksilver in small quantities as
they have occasion for it. In the metallurgy quicksilver is
indispensable, an article and a little salt being used for every
fifty quintals of the mineral. The houses where the rock
or ilme is powdered are called "ingenios," a name also
given by the Spaniards to sugar-mills. Tho's of Potosi
are magnificent and extensive, and are moved by water,
though it be scarce, and occasion many disputes.

To estimate the riches of the mine or pit, if a certain
proportion of the mineral yield ten marks, it is esteemed
rich; if eight or six, middling; if or less, poor; but at Poto-
si even two marks are advantageous to the adventurer.
As quicksilver is absolutely necessary to the miner, he had
formerly no other resource, when it was wanted, but to
apply for it to the "caxas reales," which are at a great dis-
tance from many of the mines; or to purchase it from the
" recautadores," who charged most exorbitantly for it.
The profits of the " recautadores" have been so much re-
duced by the operation of the banks " de recate," that a
great part of the capital employed in that trade has been
withdrawn from it, and laid out in advances to the miners.
This increafe of capital, on the part of the miners, has
diminished the profits of the "habilitadores," and relieved
them from the oppressions of these avaricious money-lenders.
Hence the operations of mining are prosecuted with greater
activity and success, and the number of bankruptcies among
the miners is diminishing; so that in the end the merchants
themselves will be gainers. Instead of exorbitant profits and
great risks, they will have moderate gains without danger.

The banks "de recate" in the provinces, borrow what
money they have occasion for from the collectors of the taxes,
and the Royal Tribunal of Mines repays these loans to the
treasury at Lima. This arrangement saves the trouble and
expenfe of remitting the produce of the taxes in money from
the provinces to the capital, which, for want of bills of ex-
change, was the former practice; and it prevents the provinces
from being annually drained of their circulating specie by
such remittances; an inconvenience to which they appear to
have been subjected till the erection of the banks. Such a
clumsy and artificial system in the operations of the trea-
ury, is a striking illustration of the little progress which
commerce has made in Peru.

The banks "de recate" in Peru, are private establish-
ments, without any monopoly or exclusive privilege; so that
the private "recautador" is still at liberty to follow his oc-
cupation. But the great bank "de recate" at Potosi, called
the bank of San Carlos de Potosi, belongs to the crown, and
enjoys exclusive privileges of purchasing "pina" from the
adventurers in that celebrated mine. The bank of San
Carlos was founded in 1747, by a voluntary association of
the miners of Potosi, in order to liberate themselves from the
intolerable oppreafion of the " recautadores." In 1779,
they were prevailed upon by D. Jorge Escovedo, governor
of Potosi, to transfer their shares and property in the
bank to the crown; notwithstanding which, the bank, in 1793,
was still in a prosperous state. Besides purchasing "pina,
the bank of San Carlos makes advances of money and other
articles to the miners, and thus exercises at once the trades
of "habilitador" and of " recautador." These two professions are
also not unfrequently conjoined by private adventurers in Peru.

We subjoin a list of the mines of Peru wrought in 1791,
with an account of the quantity of gold and silver obtained
from them since 1780.

The
The "moneda macuquina" is a provincial money which the government was at that time calling in. The surplus of silver, not carried to the mint, was probably used in plate; and the excess of the coinage of gold above the produce of the mines, was probably occasioned by the introduction of gold in bars from Potoi.

Potosi Nuevo, a town of Peru, in the diocese of Lima; four miles N.E. of Lima.

Potoskui, a town of Russia, in the government of Tobolok; 160 miles E. of Emfekil. N. lat. 58° 10'. E. long. 95° 14'.

Pottowmac. See Patowmack.

POTRIMPOS, the name of an ancient Prussian idol, worshipped under oaks, and to which human sacrifices of enemies were offered. Mem. de l'Acad. de Berlin, tom. ii. p. 358.

Perecusos and Picolos were idols of the same kind.

Potschakian, or Potschake, in Geography, a town of Bohemia, in the circle of Bechin; 56 miles S.S.E. of Prague. N. lat. 49° 18'. E. long. 15° 8'.

Potschernitz, a town of Bohemia, in the circle of Kauzin; 8 miles E. of Prague.

Potsiatam Bay, a bay on the S. coast of the island of Java. S. lat. 8° 10'. E. long. 111° 21'.

POTSTONE, Lapis Ollaris, Topfstein of Werner, in Mineralogy, a species of stone of the metamorphic genus in the arrangement of Kirwan; the colour is greenish-grey or greenish and reddish-grey, or yellowish-grey, or sprinkled with red, or leek-green. It occurs in mafs; its internal lustre is glittering and pearly; its fracture undulating foliated, or the folia thin, and discovering rugosities; often also flaty; fragments, long splintered, or plated; often transluent on the edges; soft and greasy to the touch; fragile with difficulty; it is found in beds with perpentine at Como in the country of the Grifons, and in Saxony. The specific gravity of that of Como, which is the most famous of this species, is 2.8729, and by the analysis of Weigleb, this contains about 0.38 of silex, 0.38 of magnesia, 0.07 of argill, 0.5 of iron, 0.01 of aerated calcium, and still less of the ferric acid; but this analysis, as the quantity of air and water is not given, cannot be depended on. The fluid acid and calcium are in too small proportion to affect the effence of the stones. This is often confounded with indurated fleas, but differs from it principally in this, that the magnesia and silex are in a larger proportion to each other, and the iron to both. It is distinguished from shilfsoke tale with greater difficulty than from fleas, whose characters are very different, especially when the potstone is flaty; nevertheless their lustre, specific gravity, and feel are different. The flaty abounds in common tale. According to Sauvage, the specific gravity of that of Switzerland is 3.023. Some of these minerals absorb water; the specific gravity of the potstone of Dauphiné, which is of flaty structure before the admission of water, is 2.7687, after water has been admitted, 2.8214; that of the Swedish, before the admittance of water, 2.3531, after admittance, 2.8629. This substance may be turned in a lathe, and made into a variety of vessels. It is also used as a lining for furnaces, being remarkably refractory.

POTT, PERCIVAL, in Biography, an eminent surgeon, was born in Threadneedle-street, London, in December, 1713. His father dying in his infancy, and his mother being left in indifferent circumstances, he was indebted to the patronage of Dr. Wilcox, bishop of Rocheller, a diletant relation, for the means of a good literary education, which he obtained at a private school at Darne, in Kent. Although this patronage induced his friends to recommend the church as his profession, yet he was strongly predisposed to that of surgery, that no advice or persuasion could alter his determination. He was accordingly, in 1729, bound an apprentice to Mr. Nourfe, one of the surgeons of St. Bartholomew's hospital. In this situation, he had peculiar opportunities of improvement, especially in regard to anatomy, which was at that time little cultivated in London; for Mr. Nourfe was one of the few who then gave lectures upon that subject, and Mr. Pott was employed in preparing the subjects for demonstration, which laid the foundation of his accurate acquaintance with that art, which is the basis of chirurgical knowledge. While he was availing himself of the unlimited opportunities of studying the nature and progress of diseases in the hospital, and attending to practical operations, he was at the same time perusing the early writers on the art of surgery with great diligence and discrimination; often remarking that, though no great instruction was to be derived from them in respect to the practical part, yet the labour of perusal was amply repaid by the accurate description of diseases, which they drew from nature.

In 1726, at the termination of his apprenticeship, he settled in Fenchurch-street, with his mother, and rapidly multiplied his connections and friends; in 1744 he was elected affluent surgeon, and in 1749 one of the principal surgeons of St. Bartholomew's hospital. He had now before him sufficient scope for the exercise of those abilities, by which mankind have been since so much benefited. The state of surgery was then very imperfect: the severe treatment of the old school, in the operative part and local applications, continued in force; the first principles of the art, founded on the natural procees and powers of healing, were not understood, and altogether overlooked; painful and ecchymotic dressings were continually employed; and the actual cautery was in such frequent use, that at the times when the surgeons visited the hospital, it was regularly heated and prepared as a part of the necessary apparatus. Mr. Pott's tuition rigidly adhered to the established practice, and treated with supercilious contempt the endeavours of his pupil to recommend a milder and more natural system. But the dictates of truth soon found a welcome reception with the profession, and with the world in general; and Mr. Pott lived to see these remains of barbarism exploded, and a more humane and rational plan, of which he was the chief author, universally adopted.

After the death of his mother, in 1746, he married, and removed to Bow-lane, where he carried on his professional career with increasing success. His time, indeed, was almost exclusively occupied in his professional duties, until a severe accident, occasioned by a fall from his horse, in 1756, interrupted his practical labours, and occasioned a long confinement. This was a compound fracture of the leg, which was expected to require amputation; but on the suggestion of Mr. Nourfe, a successful attempt to save the limb was made. The appearance of Mr. Pott as an author was the immediate consequence of this confinement; for during this period he conceived, and partly executed his "Treatise on Ruptures," which was completed by the latter end of the year. In the following year, he published an account of the hernia congenita, a complaint not then well understood, which brought forth a paper in the Medical Commentaries from Dr. William Hunter, who claimed the priority of discovery. Mr. Pott
inferted a reply, written with elegance and urbanity, in the second edition of his Treatise on Ruptures. In 1758 he produced a feuible and well-written essay, "on Pituita Lachrymalis," which was the principal cause of the discontinuance of the operation by the actual cautery, recommended by Cheifelden. In 1760, his elaborate disfertation on Injuries in the Head appeared, in which, with a peculiarity till then unknown, he arranged the symptoms of each particular species of injury, and pointed out the appropriate means of relief. In 1762 he published "Practical Remarks on the Hydrocele," and on some other diseases of the testis, as a supplement to his general Treatise on Ruptures.

In 1764 Mr. Pott was elected a fellow of the Royal Society, and at the same time he presented it with a singular cafe of herinia of the urinary bladder, which included a stone. (See Philof. Trans. vol. iv.) His zeal and activity for the advancement of his profession increased, rather than abated, with his increasing avocations; and, with the view of directing students to the proper objects of their inquiry, he instituted about this time a course of lectures on surgery, in which he took great pains to impress upon the minds of his pupils, that the prevention of the necessity of operations should be the first consideration of the surgeon. He was still also actively engaged with his pen, and in 1765 he publifhed his tractate "on Pituita in Aoio," a disease which had been much misunderstood, and the operations for which had been horribly severe, and destructive of the parts they were intended to relieve. The simplicity of the operation which he recommended, can only be valued by those who are acquainted with the severities till then practiced in this country, and even now continued in some others. In a new edition of his book, "on Injuries to which the Head is liable from external violence," printed in 1768, he first published what he modestly called "a few general Remarks," but which is in reality a complete system, "on Fractures and Diflocations." His doctrine at first met with some opposition, but is now become almost the universal practice.

In 1769, finding a more central situation necessary, from the increasing extent of the town to the west, he purchased a house in Lincoln's-in-Fields, in which he resided seven years. He still employed his leisure in committing to paper his observations and reflections, and in 1775 published "Chirurgical Observations relative to the Cataract, the Pulpous of the Nofe, the Cancer of the Scrotum, the different kinds of Ruptures, and the Mortification of the Toes and Feet," which were valuable additions to his former publications, and were marked with that spirit of observation, perspicuity of reasoning, and candour in discussing controverted points, which distinguished his other productions. In 1777 he removed to Hanover-square, and now, in consequence of the retirement of Sir Cazaf Hawkins, he was led into more active professional occupations than ever. But, though he was engaged also in a extensive correspondence with different parts of the world, he still found time to add to his former publications, a "Treatise on the Necessity of Amputation in certain Cases," which he seemed to have been induced to write in answer to a work of M. Bilguer, surgeon to the Prussian army, who had denied the necessity of amputating in almost any case, and to another by Tiffot, "sur l'utilité de l'amputation de Membres." In 1779, Mr. Pott published his "Remarks on the Palsy of the Lower Limbs," which is connected with a particular curvature of the spine; a subject which he treated with more confidence, in a subsequent publication in 1783, after a more ample experience. This was the last of his literary productions; though some other topsies had occupied his attention, which, had his life been prolonged, he would probably have committed to the press.

But, while he was in the possession of the highest professional reputation, sought after and employed by persons in the first degree of rank and power, and universally consulted by his brethren in cases of uncommon difficulty and danger, he fell a sacrifice to his own active disposition, and to a neglect of the first attack of disease. In December, 1788, he was seized with a fever, after exposure to severe cold during a visit to a patient in the country, which in a few days terminated his life, at the age of seventy-five. He was buried near his mother, in Aldemary church, Bow-lane, where a tablet was affixed, inscribed by his son, the Rev. J. H. Pott, archdeacon of St. Alban's. See Earle's edition of Pott's Works, 1792; and Hutchinson's Biog. Medica.

POTTAGENI, in Geography, a town of Samogita; 15 miles S.S.W. of Miednik.

POTTENDORF, a town of Austria; two miles E. of Ebenfur.

POTTENHEIM, a town of Austria; three miles S.W. of Baden.

POTTER, Christopher, in Biography, a learned divine, was born in Wiltshire, in 1591. He studied at Queen's college, Oxford, of which he was afterwards a fellow. In 1635 he obtained the deanship of Worcester, and in 1646 the king nominated him to the deanery of Durham. He died the same year. He published a sermon preached at the consecration of his uncle Dr. Barnaby Potter, bishop of Carlifte. He also published some pieces on predistination, against the Calvinists.

POTTER, Francis, an ingenious divine, a native of Wiltshire, was educated at Oxford; after which he took orders, and in 1637 he succeeded his father in the living of Kilmington. He had an excellent taste for painting and mechanics, and having presented an hydraulic machine to the Royal Society, he was chosen a member of that learned body. He was author of a curious book on the mystic number 666, in the Revelations, and died in 1678.

POTTER, John, archbishop of Canterbury, was born about the year 1674, at Wakefield, in which town his father kept a linen draper's shop. He received the elements of learning at his native place, and at the age of fourteen was entered of University college, Oxford. So early as 1693 he appeared as an author, and displayed the great progresse which he had made in Greek literature, by a publication for the use of students, consisting of notes and various readings to Plutarch's treatise, "De Audientis Poetis," and Bailey's "Oration on the most advantageous mode of studying Greek authors." He was soon after chosen fellow of Lincoln college, and taking the master's degree, he went into orders. In 1697 he published an elaborate edition of Lycophron, which he followed by his "Archaeologia Graeca," which has ever since been regarded as a standard work upon Greek antiquities, and of which there has lately been published a new edition. By these valuable writings he established his reputation at home and abroad, as a man of classical erudition, and paved the way for advancement in his own profession. In 1704 he was appointed chaplain to archbishop Tenison, with whom he resided at Lambeth, and in 1706 he proceeded to the degree of D.D., and was made chaplain in ordinary to queen Anne. He now turned his attention to topics immediately connected with his situation, and in 1707 published "A Discourse on Church Government," the object of which was to support ecclesiastical authority as distinct from that of the state, and to prove the divine institution of episcopacy. Notwithstanding this afleveration of high-church principles, Dr. Potter was still regarded
Pottery, the art of making earthen pots and vessels; or the manufacture of earthen-ware.

Vessels capable of holding liquid food, and drink for the use of man, would be so essential to his immediate necessities, that their fabrication would doubtless be prior to the invention of the humblest cottage. Vessels formed by excavating pieces of wood and leather, were in all probability prior to those of earthen-ware. This manufacture, however, is so ancient, that we have no traces to the period of its invention.

From the great perfection in which we find the porcelain of China, as far back as history will inform us, there is great reason to believe, that many centuries must have elapsed in bringing it to that state, could we even ascertain when it arrived at its climax. It is remarkable, that the oldest specimen of Chinese porcelain does not differ in its essential qualities from the most recently manufactured.

There is strong ground to suppose, that the art of pottery had been long brought to great perfection in the East, before it was known in Africa and Europe. It was afterwards cultivated by the Egyptians, from whom it descended to the Greeks and Romans.

A species of earthen-ware was manufactured in Persia, which was considered a great curiosity, on account of its metallic lustre. Something similar has lately been manufactured in this country, to which the metallic lustre is given by gold; and another with platina, having the colour of that metal.

The Romans appear to have cultivated this art to a considerable extent. The taffle and elegance displayed in their form and ornamental decoration, were doubtless borrowed from what the Greeks had long before practised; the country most celebrated for this art was the ancient Etruria. It was the ambition of that enlightened manufacturer, the late Mr. Wedgwood, to equal the manufacture of Etruria, after which he named the village that has grown out of his genius and industry; let it, however, be said to the praise of this great man, that in his attempt to equal the ancients, he has far excelled any thing of the kind yet produced, in the firmness and compactness of body, in colour, and in elegance of form. It may be truly said of Mr. Wedgwood, that he has increased the value of the raw material in a greater degree than any other manufacturer. The potteries of this country, prior to his exertions and example, produced nothing but of a flimsy fabric, delusive of taffle, and scarcely fit for domestic use. Their first production was the common white ware, richly daubed with blue, to imitate the unmeaning facies painted on the Chinese porcelain; since his time the manufactories of Staffordshire have become celebrated at home and abroad. Among these, however, the modern Etruria, occupied at present by the sons of Mr. Wedgwood, still bears a distinguished sway, and must continue to be conspicuous, so long as they possess the fame spirit of improvement, to which their present establishment owes its existence.

Although very different combinations of the earth, and sometimes metallic oxides are employed in the manufacture of earthen-ware, the ductility of these compounds, or that which admits of their being moulded into different forms, is peculiar to alumine or argillaceous earth. The natural compounds, commonly called clays, consist of pure clay or alumina, combined with silica, lime, and sometimes magnesia, and frequently also with oxide of iron. In this latter case the pottery burns to different shades of red, proportionate to the quantity of iron. When magnesia is combined, it gives to it a foapy feel, from which it has obtained the name of soap-rock. A marked variety of this is called felsite.

The clay from which the Staffordshire ware is manufactured comes from Dorsetshire, and another variety of inferior quality from Devonshire. These are both of excellent quality for working, and polishes great whitenees when burnt. These clays are valued particularly for the latter property, which arises from their being free from iron, which would give them a yellow or reddish colour.
POTTERY.

The clay undergoes such preparation at the place where it is procured, as to free it from stones and many other impurities. In the manufactary of Mr. Wedgewood, the most complete in the kingdom, the clay is thrown into a cylinder of cast metal, four feet high and twenty inches in diameter. In the middle of this cylinder runs a perpendicular shaft, with knives as radii at right angles to the shaft. These knives are so arranged upon the shaft, that their flat sides are in the plane of a spiral thread, so that by the revolution of the shaft the knives do not only cut anything in their way, but constantly force downwards what may be in the cylinder, agreeably to the nature of the screw. Another set of knives is inserted in the interior surface of the cylinder, and extend to the shaft in the centre: these correspond with, and are parallel to, the moveable knives. The two sets, the one active, the other passive, have the effect of sheers in cutting the clay into small pieces, while the spiral form of the active knives forces the clay in its reduced state out at an aperture at the bottom of the cylinder, from whence it is transferred to a vat, for the purpose of mixing the clay with water. This vat is of a cylindrical form, the diameter being about four times the height. In the centre of this vat turns a perpendicular shaft, having crofs arms or radii one below the other. These are connected by perpendicular flaves, giving the moveable part the appearance of two opposite gates, upon the central shaft. These gates revolve in the cylinder just immersed in the pulp, the constant agitation mixing all the fine particles completely with the water, while the flothy particles of greater magnitude remain at the bottom. The pulp is now passed off from this vat through a series of sheets of different degrees of fineness, which work backward and forward by machinery; this separates the coarse parts from that which is fitted to enter into the composition of the ware. We will here leave this refined pulp, to go to the preparation of the flint, a certain portion of which is necessary to be united with the clay pulp, in order to constitute the potter's mafs.

The flint in its crude state is the common flint used for striking fire, which principally consists of pure flaxes. It is first placed in a kiln and heated to a red heat; and while red-hot thrown into cold water. This process is to leffen its aggregation, and make it easier to reduce to powder. Mr. Wedgewood reduces the flints into small pieces by means of hammers, which are worked by machinery. The pieces are laid upon a strong grating, so that as they become of a certain size, they are driven through the divisions of the grate. After this process they are taken to a mill, where the conffs of a cylindrical pan, similar to that used for mixing the clay with water, but the arms of the upright shaft are made to carry large flones of great hardness; the flone is known by the name of claret. These flones are fastened to the arms of the upright shaft, so that the under side, which is perfectly flat, may move over similar passive flones. This cylindrical pan contains a certain quantity of water when the small mafs of flint are introduced. The flint stone gets between the chert surfaces, which from their great hardness reduce the flint to a pulpy consistence. The finer particles become suspended in the fluid, and are run off from time to time near the top of the pan. This pulp is then passed through lawn or silk flives in a manner similar to the clay, the part which remains in the sieve being returned to the mill to be ground over again. The pulp is always made to a certain consistence, with a view to know what quantity of flint is contained in a given measure, and the same with regard to the clay in the same flate. The two pulps are now mixed together in such proportion by measure, that the flint bears a proportion to the clay of about one to five, and sometimes one to six. They are now intimately mixed together, by an apparatus similar to that employed for mixing the clay with the water in the first instance.

It is a well-known fact that clay, when exposed to the fire, continues to shrink to the greatest heat of the bell furnaces. This contraction doubtless goes on till the whole of the water is dissipated, and the clay undergoes fusion. This phenomenon is more conspicuous when the clay is pure alum. Hence we should expect, if the clay were pure, that the fame degree of heat in such clay ought to produce the same decreas of volume. The application of this principle to measure high temperatures, did not escape the sagacity of the late Mr. Wedgewood. He constructed a thermometer which measured the degree of heat in which bits of pure clay had been exposed, by their flrinkage. Flaws! however, as this idea may appear, it became almost impracticable, from the circumstance of the flrinkage of different bits, made from the same mafs of clay, not being uniform.

It is found, that in proportion as pure clay is combined with the other earths, it undergoes less flrinkage; and since the great flrinkage in the manufactary of earthen-ware is attended with other inconveniences, the flint is added for the purpose of preventing the flrinkage to a certain extent. It will appear that when the flrinkage is the greatest, the ware will be the most dene, and will afford a clofer ffracture. Under these properties the articles are less fitted to withstand sudden changes of temperature. The flrinkage may also be diminished by pounding pieces of well-burnt clay, and mixing them with the clay that would be liable to flrink. This expedient is often resorted to in making crucibles, which require to be made of the purest clay, on account of their essential property of infufibility.

When the flint and clay, in their pulpy flate, have been intimately mixed, the next process is to separate the excess of water, which is effected by evaporation. The vessel in which the pulp is placed for evaporation should expose a great surface, its breadth being about five or six feet, its length 20 to 30, and very shallow. The bottom is made of firebricks, and the flame of the fire, which is at one end of the brick-work, passes along a flue under the bottom. The evaporation is slow, on account of the bricks being bad conducters of heat. This inconvenience, however, is compensated by the uniform consistence which the evaporating mafs acquires. When the evaporation has been continued till the mafs is sufficiently fluid, it is cut out in cubical mafs, and is next subjected to a proccefs by which the mafs is rendered of uniform fliftness throughout, and fit for working. This change is brought about in the most complete manner, by allowing it to remain in a heap for a considerable time. The water in the clay may be considered as a chemical compound. Hence we may conceive that the water, by time alone, will constantly be tending to uniformity throughout the whole mafs.

The operations by which this effect is facilitated, are, first by hand, and secondly, by a machine for the purpose. The first is called wedging or evading, and consists in taking a mafs of clay in both hands, and with a twill of both at the same time, the piece is separated into two pieces. They are now brought together with greater violence, but in different parts to those just separated. The piece is now separated at right angles, and two new surfaces brought in contact. This change of surface every time, sometimes 20 or 30 times, effects the uniform mixture of the different parts to completeness; that is, at the commencement of the operation, the mafs consisted of two distinct pieces, one black and the other
other white, at the end of the operation the mafs would become of an uniform grey colour.

This latter process is usually practised immediately before the clay is made in mafs of proper size for working into different articles.

This change is also effected with more dispatch by a machine, very similar to that first used for cutting the crude clay into pieces.

An upright shaft works in a cylinder of cast iron; from this the radiant knives work in the plane of a spiral thread, extending to the circumference of the cylinder. The pieces of clay are thrown into the cylinder in the flate they are cut out of the evaporating vessel. The knives first act by cutting them in pieces, and force them down the cylinder like a serew. From the bottom of the cylinder extends an horizontal opening in the form of a parallelepipedon, the section being about six inches square. The clay is forced through this opening, and cut off in lengths of about one foot each. These mafs are again thrown into the cylinder, and passed through in the same way several times, till they are deemed in a proper flate. The mafs are now, when time will admit, laid together for some time, as the workmen find that they work much better for lying longer. This we have accounted for from the equal force of affinity, which tends to establish an equilibrium of the attractive force of the clay for water in every part of the mafs.

Having prepared the material, we will now proceed to describe the methods of forming it into articles of various forms. This is so very similar to the methods used in the manufacture of porcelain, which we have already described, that we shall merely state some improvements in the machinery introduced by Mr. Wedgewood. The potter's lathe, which is used for throwing the different articles of a circular form, consists of a perpendicular shaft about three feet high, having a circular piece of wood at the top, the face of which, by the shaft, turns parallel to the horizon. The lower end of the shaft runs in a flab; the upper part has a neck a little below the circular piece of wood, which works in a flocket. Formerly this perpendicular shaft was put in motion by a wheel, with spokes fastened upon it, which the workman moved with his foot. In others the shaft has a crank in the middle, with a long rod working upon it. This being pulled backward and forward by a second person, gave motion to the lathe. In the porcelain works of this country, as has been described under that article, the lathe is generally turned by a rope pulling from a pulley upon the perpendicular shaft to a large wheel at a distance, which is turned by a boy. The first of these methods is convenient, as the workman can best suit the velocity to the flate of the work, which varies very considerably in throwing the smallest articles. The labour, however, is so great, that in throwing large articles there would be great time lost. The two other methods, although they afford much ease to the workman, are very inconvenient, as the thrower has constantly to be speaking to the turner, in order to get the proper increase of speed. Mr. Wedgewood has the whole of his lathes, both for throwing and turning, turned by the steam-engine. The perpendicular shaft of the lathe is moved by an horizontal one, which is connected by two bevel wheels. The horizontal shaft is provided with a long drum, from which a strap ascends to two conical drums reversed, and working together; this allows the strap to keep at the same degree of tightness, whilst it traverses from one end of the drum to the other. From these drums, which are moved by the principal one, motion is given to the lathe. During the throwing of any article, a separate piece of machinery is turned by a boy, which causes the strap to move, parallel to itself, along the drum of the horizontal shaft, and at the same time along the conical drum. This changes the velocity very gradually to its maximum, and returns to its slowest motion, when the workman is finishing the article thrown; the strap is then thrown on to a loofe pulley, which stops the lathe. The clay is first portioned into pieces sufficient for the article intended. At the same instant that the thrower places the pieces of clay on the face of the circular board, the strap is transferred from the loofe pulley, and the motion commences. The boy, by turning a winch, begins to move the strap from the small end of the conical drum to the large end, when the velocity is at its maximum, and when the thrower, by means of his wet hands and a thin piece of wood, is giving the proper shape to the clay. At this point he begins to finish the article, and the strap is caused to move back from the large to the small end of the drum, when the work is finished, the machine is stopped, and the thrown article cut off at the bafe with a piece of small wire. It is now carried to a proper place to be dried. When it has been dried to a certain extent, which the workmen call the green flate, it is then taken to the turning lathe, which is similar to the common lathe used for turning wood. These lathes, in Mr. Wedgewood's works, are turned by the steam-engine, and as, during the turning of each vessel, the velocity requires to be varied, the motion is communicated from two conical drums, similar to the throwing lathe, and the strap is made to traverse the drums by a motion given by the foot of the turner. There is also a contrivance for reversing the motion, by which the turned surface is polished.

The same degree of dryness which admits of the clay being turned in the lathe, to give it its proper finish and smoothness, is also the proper flate for fixing on the handles or other appendages, which cannot be effected in the lathe. The parts to be added are previously made, and at a proper degree of dryness are attached to the round work by means of a pulpy mafs, formed by clay mixed with water, which the workmen call dip. The joined parts are then smoothed off with a wet sponge. In this flate they are taken to a stove, which is nothing more than a room provided with shelves, raised from 80 to 90 degrees of temperature. When they are fully dried, if the articles be of superior quality, they are rubbed over with a small bundle of hemp, in order to take off any small bits left after the turning and handling, and to smooth those parts which cannot be turned. The ware is now ready for the kiln, which is to convert it from a soft and tender flate to a hard substance, called biscuit.

A great variety of pottery cannot be made on the lathe, its not being of a circular form. This is made by two different methods, the one called press-work and the other calting. The press-work is formed in moulds made of plaster, one half of the figure being on one side of the mould, and the other half on the other side; these fit accurately together. The clay is first made into two flat pieces, of the thinnest of the articles; one of these is pressed into one side of the mould, and the other into the other side, the superfluous clay being cut away, leaving it a little flush above the mould. The two sides of the mould are now brought together to unite the two halves of the article. The mould is now to be separated from the clay, and the article is finished as to form. It is now dried to the green flate, when it is completed with any other parts to be added. All vessels of an oval form, or such as have flat sides, are made in this way. The spouts of teapot, and all similar articles, are made in two halves in a similar way, and are attached to the vessels in the green flate, when the handles are also put on. The handles, which are sometimes of an oval shape in their section, others fluted...
and otherwise ornamented, are formed by a machine which
confists of an iron cylinder, about 10 or 12 inches high
and six inches in diameter. A piston is made to fit the cylin-
der, and works up and down by means of a screw, similar to
a screw-prefs. In the bottom of the cylinder is a hole, filled
up by a piece of metal, with an opening through it, having
the figure of the handle, or other thing to be formed, in
section. The cylinder is first filled with clay, and the piston
introduced upon it; the latter, being forced down by the
screw, forces the clay through the hole at the bottom.
This is cut into proper lengths as it comes through.
In this way tubes may be formed, by placing a pin in the cen-
tre of the hole at the bottom of the cylinder, equal to the
interior diameter of the tube. The handles are cut from the
above pieces, bent into their proper shape, and at a proper
degree of dryness are attached to the vessels. The different
articles formed by moulds called prefs-work, are finished
before bisecting, similar to those made on the lathe.

The third method of forming earthen-ware is that of
casting, and is perhaps the most elegant of the three for
forming articles of irregular shape. This process, in com-
mon pottery, is so similar to that employed in the porce-
lain manufacture, which has been described under that ar-
ticle, that we think it unnecessary to enter minutely into it
here. The clay is used in its pulpy state, called slip. The
moulds are made of plaster, and lit to close when put to-
gether in parts, as to hold the pulpy liquid. The plaster im-
mediately begins to absorb the moisture contiguous to it,
making a stiff mass capable of supporting itself. The liquid
part is now poured out: that which remains continues to
get stiffer, by more of its water being transferred to the
plaster, so that in a few minutes the articles, completely
formed, may be removed from the moulds. They are now
dried to the green state, and finished for the biscuit kiln,
in the same manner with those made by the two former
methods.

When the ware is thoroughly dry, and a sufficient quan-
tity is accumulated to fill the kiln, the next process is plac-
ing the articles in cylindrical and sometimes oval-shaped
vessels, called faggars. These vessels are about six inches
deep, and of different diameters, from twelve to eighteen
inches. These vessels, containing the ware, are piled up in
the kiln, the bottom of the superior fagar serving as a lid for
the inferior one. The use of these vessels is, first, to keep
fire from immediately acting upon the ware, but principally
to prevent the smoke injuring its colour, previously to
laying one fagar upon another. A ring of soft clay is
placed round the lower one, on which is fixed the bottom of
each superior fagar. This is more completely to secure the
goods from the foot and the intense fire.

The kiln for porcelain is so exactly similar to that used
for the species of earthen-ware of which we are treating,
that we have omitted to describe the kiln under PORCELAIN,
and have referred the reader to this article, to which is an-
nexed a plan and section of the elevation, see Plate Pottery.
The potter's kiln is generally a cylindrical cavity, covered
by a flatthi dome. This was formerly surrounded by a
conical building, reaching something higher than the build-
ings adjacent. The great space between the cylindrical part,
which is the proper kiln, and the surrounding circular wall,
used to be considerably greater than at present, and even
now is much too great. For this reason we have ventured to
contract it, especially in the upper part. On this ac-
count the form in our drawing differs much from the cone,
as may be seen in the elevation. This tends to obviate an
evil, which is equally conspicuous in glafs-houses and in pot-
ters' kilns. The great quantity of cold air which is con-
stantly ascending the cone, tends much to check the draught,
and by that means renders the fuel less efficacious and eco-
nomical. The cylindrical portion, $L$, should so nearly touch
the surrounding wall at $t$, as only just to carry off the
waste smoke. $W W$ is a cylindrical wall, forming the space
$K$, which is the cavity in which the faggars are piled, marked
with the same letters in the plan. $D$ is a door-way, through
which the faggars are conveyed, the space being built up
with bricks when the kiln is filled. The plan is a section
taken at the height $V V$. The elevation is a section at
$X X$, dividing the area into two equal portions. The part
from $A$, down to the opening $e$, is not comprised in the
section, and is shaded lighter, to show that it is a portion of
the front. It is given to represent the front view of the
openings where the fire is introduced. The fire is seen in the
plan at $a$, and in the side view at $a$, on each side of the
elevation. $P$, in the elevation, is the space occupied by
the fire, which is introduced at the opening $a$, which opens
into the arched recess $A$, formed in the surrounding wall.
The hole, $a$, is surrounded by a frame, made of earthen-ware
or call metal, in the shape of an horse-shoe. The flame of
the fire enters the horizontal fume $f$, from whence it is free
also to ascend through the chimney $b$, or branch into the
vertical fume $g$, by which it has access, by the intermediate
fumes $f$, to the central opening $h$, from whence it rises pe-
dendicularly to the top of the kiln, where it escapes into
the chimney $c$, through the openings $o$. The fire in these
furnaces does not rest upon a grate, but lies upon the
ground. The opening at $c$, during the firing, is built up
with bricks, leaving a number of openings for the air to
pass through the fire, which is piled up as high as $a$ in the
elevation, and sometimes a little higher: $e, f, g, h$, are large
fire-bricks, forming a sort of bridge or arch over the opening
$a$, and coming close up to the wall $W$. At this place a
groove made in the bridge forms a perpendicular opening,
which is closed by the flat brick $b$, when this opening is
closed. The current of flame is more considerable through
the upper chimneys $b, b$, and leaves through the horizontal
fumes $f$ and $g$. The former of these currents, however, is
diminished, and the latter increased, by removing the brick
$b$, by which a current of cold air defends through the opening
below. By means of this brick the heat is increased at top
or bottom of the kiln at pleasure, the uniformity of which
is of great consequence. In the plan, the upper floor of
the kiln is removed, to shew the direction of the flames,
the fourth quarter being covered with bricks, as when the
faggars are piled upon the floor. In the direction of each of
the flames every other brick is left out, as may be seen by the
dark shades. This gives the upper floor the appearance of
being full of holes, through which the flame riles among
the piles of faggars. The faggars, being of a circular or
elliptical form, can be piled close together, leaving sufficient
interstices for the flame to pass through. The piling is
commenced at the opposite side of the kiln to the door-way $D$,
and continued till the last pile is raised close to the entrance,
which is then closed up with bricks, till the firing is com-
pleted. This is continued from twenty to thirty and some-
times to forty-eight hours. The whole is allowed to cool
before the faggars are removed. This kiln, which has un-
gone trialling improvement, has many defects, as stated
under the article PORCELAIN. The principal of these defects
are, the fire being allowed to escape at the top of the kiln
instead of the bottom, and the want of a proper supply of
common air to burn the smoke.

The flate in which the ware is drawn from the kiln is
called biscuit: it is yet unfit for vessels, being so permeable
to moisture as to allow water and other liquids to run
through
through it. This valuable property of biscuit earthen-ware has lately been applied to the coction of vessels for cooling wine and other liquids. The water passes from the inner to the outer surface, and constantly presents a humid surface to the atmosphere, which by evaporation carries off much more heat than would be carried off from dry surfaces. Mr. Ledlie has lately made an useful instrument, by taking advantage of this property of the biscuit for flewering the evaporating power of the air.

The next process is to render the biscuit fit to hold liquids, by filling up the pores, and coating the surface with a vitreous sub stance. This process is called glazing. A great variety of substances may be used for this purpose. Powered glafs would constitute a glazing for earthen-ware, where the colour of the body is wished to be seen through the glazing. The composition for earthen-ware, which we have given in this account, is capable of forming two varieties merely from the nature of the glazing. When the glazing is transparent and colourless, the colour of the body is seen, which having a yellowish tint from the presence of a small quantity of oxdy of iron, it is called cream-coloured ware. When the glazing is rendered a little opaque and of a blueish tint, by the presence of tin or arsenic, and a small portion of oxdy of cobalt, it acquires a milky or opal appearance of a blueish-white colour. The glazing formed with pounded glafs, may be considered as a compound of flint and potash, or soda; hence it can be made of different degrees of fulility by the addition of flint or alkali. These glazes are found to have some inconveniences, the principal of which is their not expanding and contracting equably with the body. The glaze is liable to crack and sometimes peel off. Earthen ware glazed with this sub stance may be frequently observed to abound with innumerable cracks on the surface, which are permeable to grease or any other fluid. Such vessels soon become very disagreeable, especially when heat is applied to them, capable of burning the sub stances by which they have been penetrated.

No glazing has yet been discovered for common earthen ware which is free from the above objection, without the use of lead, which, on account of the poisonous quality of that metal, should, if possible, be avoided. The oxdy of lead, even in its vitreous state, and combined with flint or clay, is so completely soluble in acids, that bad consequences have arisen by eating pickles from jars glazed with lead.

The transparent glaze used for the cream-coloured ware, is generally composed of oxdy of lead and ground flint, in equal weights. White lead is preferred, but it is not so economical as light grey or minium. In the commonest earthen-ware, galena (sulphuret of lead) is made use of. The oxdy of lead and the flint are first ground to an extremely fine powder, and then mixed with water, to give the whole the consistency of cream. The biscuit, being then made clean, is dipped into the pulp, and drained out; it is then turned about rapidly into various positions, to prevent the glaze from lying thicker in one place than another. During this change of position the water of the glaze is absorbed by the biscuit, leaving the solid matter of uniform thickness upon the surface. This part of the process is called dip ping. The ware is now placed in the fagars and put in the kiln, exactly the same as in the biscuiting process. The fire is not raised to high, nor so long continued, being only sufficient to bring the glaze into perfect fusion. Dishes and plates, when placed in the fagars for glazing, may be put one upon another, by placing small flints of earthen ware between them, presenting three small points only to each of the surfaces. When this ware is brought from the kiln, it is considered finished.

The ware called white ware is made of the same material, and manufactured precisely in the same way, as far as the biscuiting. Formerly it used to be painted after glazing, and had a second firing, similar to porcelain. It is now painted with copper-plate prints almost always with oxdy of cobalt, which makes the figures of a blue colour. It is in this state called blue and white ware, and constitutes an important branch of the Staffordshire pottery. The subjects of the prints are generally vile imitations of the paintings on the Chinese porcelain, which are of themselves shocking.

The printing is performed while the ware is in the state of biscuit, and the glazing laid over the colouring matter. The design for the ware are engraved upon copper-plates, and prints taken from thee, as in common copper-plate printing. The surface of the paper to receive the impression is first smeared over with soft soap. The plate and the rolling-pens are constantly kept warm. The colouring, which for the blue and white ware is oxdy of cobalt, is greatly diluted with some colourless earthy matter; it is ground up with boiled linseed oil, such as is used for printing ink; its consistence, when laid on the plate, being that of soft paste. The paper, prepared as above mentioned, is now laid upon the plate, and passed through the rolling-pens. The printed part is now cut out of the paper, and being moistened is laid upon the biscuit. The colouring matter is now instantly absorbed by the biscuit. This being done, the paper is washed from the biscuit in a tub of clean water. The colouring matter will now be seen very plain on the surface of the pottery.

The ware, having received the colouring matter, is now set to dry up the water, and is then dipped in the glazing pulp precisely in the same way as the cream-coloured ware. The glazing material, it will be remembered, differs a little from the latter, in containing a little oxdy of cobalt, which gives it a blueish tint, and gives the idea of greater whiteness. The goods are fired in fagars, as has been already described. The oxdy of cobalt now becomes of a beautiful blue, under the glaze. If, instead of the cobalt, a mixture of the oxyds of iron and manganese be employed, the figures will appear of a black colour, which gives the effect of an engraving, and is much more beautiful and consistent than the cobalt. In some potteries pencilling is practised to great extent. This consists in laying on the colours with enamel, after the glazing. This work is very expensive, and is not so general as formerly. This process is so similar to that used in painting porcelain, that we shall refer the reader to that article.

Lately, another variety of ware has been introduced, which is by the potters called lulese: it consists in fixing gold or platina upon the surface of the glazing. The substance from which the platina lulese is procured, is obtained by dissolving platina in equal parts of the nitric and muriatic acids with heat. When the whole is dissolved, add to the solution a solution of muriat of ammonia, but yellow precipitate will fall to the bottom: continue to add the latter till no more is precipitated; decant off the clear liquor, and add fresh portions of hot water, till it becomes tafeful: drive off the first portion of water by heat, and preserve the dry powder for use: let this powder be ground, with a small portion of enamel, in oil of turpentine; spread this thinly over the glazed surface of the plain earthen-ware above described. The ware is now to be exposed to the heat of an enamelled kiln, which is a red heat. The platina attains its metallic form, which acquires greater brilliancy by the presence of the glaze.

The precipitates from gold may be laid on in the same way. The glazed ground, however, on which the gold is laid,
laid, is of a brown colour by adding the oxyds of iron and copper to the glazing matter. By this means the yellow colour of the gold with the brown glaze, gives the lustre the colour more of copper than of gold. It is probable that the lustre is, or may be produced by smearing the glazed surface with the liquid solution of the metal, in a very dilute state. The liquid may contain a little gum, and a little enamel mixed with it, when spread upon the articles to be luted.

A very coarse earthen-ware made in Peria, which we have alluded to in a former part of this article, possesseth metallic lustre, which is doubtless given by gold in the way just described.

The most perfect pottery, particularly so far as regards excellence of workmanship, has been manufactured by the late Mr. Wedgewood, and since by his sons. Among the most superb of their productions are their imitations of Jasper, manufactured into vases, medallions, and other ornamental forms. The substance of which they form their mortars, and a variety of chemical utensils, is extremely hard, and is not acted upon by acids.

The black and the yellow ware made by Meffrs. Wedgewoods, of which the late Mr. Wedgewood was the inventor, possesseth great elegance, and a very compact body. The black ware owes its colour to the presence of oxyd of iron, and a small portion of oxyd of manganese. The yellow ware, which is similar in texture, owes its colour to the presence of a little iron alone. A great number of places furnish natural products capable of affording this yellow tint. The compactness of the body is effected by using a flint in the composition, and giving it more heat in the burning. This biscuit is so compact that it does not require to be glazed, and this is what constitutes its great excellence. Its beauty is much greater in being definite of the glaze or vitreous coating, which, when it is managed in the best way possible, is but a miserable imitation of a polished surface. That species of ware which, from its great hardness, has been called flone-ware, is not encouraged so much as it deserves. It is employed for the most common, and the cheapest articles, when it ought to be used for all domestic pottery. Every other kind, excepting the true porcelain, is objectionable on account of its porous texture, and the lead contained in their glaze. Every species of clay capable of bearing a great heat, may be employed in the manufacture of flone-ware. Those which contain much oxyd of iron cannot be employed, as they would be liable to soften, and even to melt in the heat required for glazing.

This manufacture is at present almost entirely confined to bottles, particularly those used for soda water and artificial mineral waters, their texture being sufficiently close to hold gas supplied to several atmospheres.

The clay is prepared in the same way with that used in making the pottery already described. Indeed, there would be no difference in preparing the vessels for the kiln, whether formed by throwing, moulding, or casting. It is simply in the burning and glazing that the difference consists. In making the common articles, the vessels are piled up in the kiln, and exposed to the naked fire, without being defended by fagars. It is on this account that they receive a much greater heat than the common earthen-ware. When the heat has arrived at its maximum, a quantity of common falt (nitrature of soda) is thrown into the body of the kiln. The falt rives in vapour, which greedily envelopes the hot ware, and glazes it as completely as in any other way, if the heat be sufficient. It is likely that the falt is decomposed, the acid flying off, while the soda combines with the earths of the pottery, forming a vitreous coating. The smoke being in contact with the ware, gives it a brownish colour. The fracture is close and compact, and its strength much greater than the common white ware. This pottery might be extended to a variety of other articles for culinary purposes, and with proper contrivance in the construction of the kiln, articles might be made with as much taste and elegance as any other.

When the Dorsetshire clay is employed, and the ware defended from the smoke while burning, and at the time the falt is thrown in, the colour of the ware would be white, and the glaze transparent. When the clay is not sufficiently white, it may be rendered so superciliously by dipping the dry ware, before it goes into the kiln, into a mixture of Cornwall clay and water in the state of a thinmush pulp. It is taken out, and turned about, as in glaze dipping, in order to spread the coating uniformly. The water is absorbed by the dry ware leaving a coating of the white Cornwall clay upon the surface. A dip made with water and a fine powder of the Cornwall stone, would answer better than the latter, as it would more easily fuse with the fusible falt. The whiteness of the Dutch tiles is produced in this way, as the body will be found of a dirty grey colour.

The most common and worst kind of earthen-ware made in this country is formed of common clay used for bricks. The ware, after being rudely formed, is very lightly burnt, and afterwards glazed with a composition of galena (fulphuret of lead), oxyd of manganese, and the clay of the ware. The glaze is of a dark colour, approaching to black. The lead in this ware is easily attacked by acids, and should not be used where they are liable to be present. The same earthen-ware, unglazed, is used for garden pots, tiles, and tubes for draining land.

We shall conclude this article with some account of the methods of forming crucibles, retorts, and tubes of earthen-ware.

These vessels are required to possess two very essential qualities; first, they should bear the naked fire without cracking; and, secondly, they should bear the heat of the hottest furnaces without fating. The retorts and the tubes should at least possess the first property, and require a greater closeness of body more than that required for crucibles.

The crucibles called Hessian crucibles have held a high character, both on the continent and in this country, but they are not useful for all purposes. The Dutch crucibles, which contain plumbago, are well calculated to bear sudden changes of temperature, but become very tender, and fume at a high temperature.

A similar manufacture is carried on at Chelsea; the crucibles are quite as good as the Dutch ones, and of a much better form.

Very excellent crucibles are made of the Stourbridge clay, particularly for melting cast-iron and steel. This clay is worked up with the powder of the broken pots, which has the effect of making the pots stand sudden changes of temperature. It has been lately found, in the cast-steel works at Sheffield, that the bent crucibles for their purpose are formed of the Stourbridge clay, worked up with powdered coal of pitch. This enables the crucibles to bear sudden changes of temperature, and at the same time to bear the greatest heat of our bent-air furnaces. The Cornish clay might be used with pounded coal with similar success, and might perhaps be superior to the Stourbridge clay for earthen retorts and tubes. None of these articles should be very hard burnt, as they will, in consequence, be more liable to crack with sudden heat, and even in the regular way of bringing them up with the fire.
POTTERY.

Pottery, The, or The Potteries, in Geography, an extensive tract of country in the hundred of North Pyrehill, in the county of Stafford, England, comprehends an area of about eight miles long and six broad, and is perhaps the most populous and busy of any district of similar extent in Great Britain. It derived its name from being almost exclusively appropriated to extensive manufactories of earthenware, for which its situation and peculiar characteristics are excellently adapted. The soil presents, in almost every part, a great variety of clays; covering rich and productive stratata of coal, which lying in general near the surface, are brought to a comparatively small expense. These stratata are usually divided by veins of clays, most of which form excellent fire-bricks for constructing potter's kilns and fagars, to burn the ware in. Finer clays also are plentiful in many places; of which in former times the bodies of the wares themselves were wholly manufactured. To these advantages, joined to the inaptitude of the soil for husbandry purposes, this district is doubtless indebted for its selection as the seat of its present staple manufactories. When this originally occurred is utterly unknown, but the existence of some kind of earthenware manufacture can be traced at least two centuries back. Its principal seat at that period was the town of Burlem, which was called a butter pottery; that is, a manufactory of pots for the preservation of butter; and under that name it is marked in several old maps; but this establishment seems to have been, even so late as the year 1666, very inconsiderable, as Dr. Plot, in his "Natural History" of the county, says, that the sale of its products was chiefly "to the poor cranes, who carried them at their backs over all the country." All the ware was then of coarse yellow, red, black, and mottled kind. The common glaze was produced by lead ore finely powdered, and sprinkled upon the pieces of ware before firing; sometimes with the addition of manganese. Occasionally, when the potter wished "to show the utmost of his skill," he employed, instead of lead ore, calcined lead itself, but still sprinkled it on, in the same rude manner.

The era of improvement commenced about the year 1690, when two ingenious Dutchmen, of the name of Elers, settled here, and introduced the practice of adding common salt to the clay when at its highest heat, in order to give it a superficial vitrification. The same individuals also introduced the manufacture of a new species of ware, in imitation of the unglazed red china of the East; and the clays here being suitable for the purpose, they succeeded wonderfully for a first attempt, so that many of their tea-pots are said to have sold as high as a guinea each. The next improvement was made in the substance of the ware itself by a Mr. Astbury, as tradition affirms, through this incident. Being on his way to London, he happened to have powdered flint recommended to him to cure some disorder in his horse's eyes, and accordingly a little flint was thrown into the fire, to render it more easily pulverizable, which changing to a pure white by the influence of the heat, the potter was struck with the idea, that his ware might be improved by an addition of the same material to the whitest clays. He tried the experiment with tobacco-pipe clay, and the event proved fully answerable to his expectation. Thus originated the white flint wares, which soon supplanted the coloured ones, and continued for many years the staple branch of pottery in this country.

It was, however, about the year 1760, that the most important improvements began to be made in the Staffordshire potteries, by the late Josiah Wedgwood, esq. This gentleman not only improved the composition, forms, and colours of the old wares; but likewise invented, in 1765, a new species of ware, for which he obtained a patent, and which being honoured by her majesty's approbation and patronage, received the name of Queen's ware. Continuing his experimental researches, Mr. Wedgwood afterwards invented several other species of earthen-ware and porcelain, of which the principal are: 1. **A terra cotta;** resembling porphyry, granite, Egyptian pebbles, and other beautiful flones of the fucilane or crystalline order. 2. **Bafaltes, or black ware;** a black porcelain biscuit of nearly the same properties with the natural flone, receiving a high polish, refilling all the acids, and bearing without injury a very strong fire. 3. **White porcelain biscuit;** of a smooth wax-like appearance, of similar properties with the preceding. 4. **Jasper;** a white porcelain of exquisite beauty, polishing the general properties of bafaltes; together with the singular one of receiving through its whole substance, from the admixture of metallic cakes, the same colours which those cakes give to glasses or enamels in fusion; a property possessed by no porcelain of ancient or modern composition. 5. **Bamboo, or cane-coloured biscuit porcelain, of the same nature as the white porcelain biscuit.** And 6. A **porcelain biscuit remarkable for great hardines, little inferior to that of agate;** a property which, together with its resistance to the strongest acids, and its impenetrability to every known liquid, renders it well adapted for the formation of mortars, and many different kinds of chemical vessels. For some further account of this gentleman's discoveries; see Wedgewood, Josias.

The above six distinct species of ware, together with the queen's ware first noticed, have insooned, by the industry and ingenuity of different manufacturers, and particularly by Mr. Wedgwood and his son, into an almost endless variety of forms for ornament and use. These, variously painted and embossed, constitute nearly the whole of the present fine earthen-wares and porcelains of English manufacture.

The number of persons who derive their support from the manufacturing part of the pottery business alone, including the wives and children of those employed in it, is computed to exceed 25,000 persons; and probably three times that number depend for bread on the labour it creates, particularly in the collieries, in procuring the raw material from several distant parts of the kingdom, and in the inland navigation connected with the same, and of the manufactured product. The pottery district lies chiefly in the parishes of Burlem and Stoke; and, as happens in most manufacturing districts, it is remarkable for the great diversity of opinion which prevails among its inhabitants on the subject of religion. Of the various sects, however, the Methodists claim a decided superiority, in point of number, over all the others. The principal towns and hamlets comprised within the limits of The Pottery, are Stoke, Hanley, Shelton, Golden-Hill, New-Field, Smith-Field, Tunstall, Long-Port, Burslem, Cobridge, Etruria, Lane-End, Lower-Lane, and Lane-Delft.

Stoke, or, as it is commonly called, Stoke-upon-Trent, has recently been constituted a market-town; and has a manufactye house furnished with all the accommodations requisite for its object. The church is an ancient and spacious edifice, in the later Norman style of architecture. Like most other parts of The Pottery, this town has increased in size and importance since the Staffordshire canal was cut. It contains many handsome buildings; and from its proximity to a wharf upon the canal, is most conveniently situated for trade. At this place the first steam-engine for grinding burnt flints, erected in this country, was established about twenty years ago by a gentleman named Spode. The earthen-ware manufactories here are numerous; and many of them are upon an
an extensive scale. Close to the town the canal is carried over the river Trent, by means of an aqueduct constructed entirely of brick.

Hatfield is situated about two miles northward from Newcastle-upon-Tyne. This town also has a weekly market on Monday; and is distinguished for the neatness and regularity of its streets, and the elegance of many of the houses which compose them. Here is a church, which was founded in 1788; also several chapels and meeting-houses appropriated to the worship of dissenters.

Shelton is a very extensive place, but has not hitherto been constituted a market-town. It is particularly deserving of notice on account of its china manufacture, which rivals the famed porcellain of the East. The ingenious Mr. Champion of Driffield, who discovered the art of making this species of ware, expended an ample fortune in various trials, but having succeeded ultimately in bringing it to perfection, he obtained a patent for it, which he sold to the firm of Hollins, Warburton, and Co. As the canal passes Shelton, there are a public wharf and store-houses upon it, for the landing and safety of goods.

Green-Lane, from its name, one would suppose to be a considerable and even splendid place; but on comparison it is found to be the least so of any in The Pottery. Its valuable mines of coal, however, make ample amends for its other deficiencies, and from the richness of those mines it derived its name. At the upper end of this village is Green-Lane, which commands a most unbounded and beautiful prospect, on the one side over the greater part of Cheshire, and on the other over the whole extent of The Potteries, and a large portion of the country adjoining.

New-Field is well situated for manufacturing purposes, from the great plenty of coal in its immediate vicinity, but as it lies wholly to one person, who has a handsome seat close to the village, there are fewer pottery establishments here than would otherwise have been the case.

Smith-Fields, like New-Field, is well situated for carrying on pottery manufactories, having several factories of coal and clay close adjoining; but similar reasons prevent their being increased and extended in the same proportion as some of the other villages in the district.

Tunstall, including its environs, is the pleasauntest village in The Potteries. It stands upon high ground, at the distance of four miles northward from Newcastle, and appears to have been formerly the site of a religious institution, of which some remains were visible about the middle of the last century. Thence, however, are now completely gone; and a neat chapel has been erected on or near the spot which it occupied. The principal works here are for bricks and tiles; the clay being of a very superior kind for the manufacture of such articles. The tiles made from it, indeed, by good management take a blue colour, which renders them almost as fit for roofing as flates.

Long-Port is situated in a valley between Newcastle and Burlem. It has many good buildings in it, and several large and extensive manufactories; but owing to its low position, it is at times disagreeable from the smoke hanging upon it longer than it commonly does upon higher ground. The Staffordshire canal passes this village, and has a public wharf upon it.

Burlem, as already stated, is the most ancient town in the whole Potteries, and was undoubtedly the first seat of the earthenware manufacturer in Staffordshire, and perhaps in Great Britain. Plot, in his "Natural History" of the county, makes particular mention of the potteries at this place, and points them out as the greatest of the kind then known. This author likewise gives an ample detail of the process of making the ware in his days. Burlem has two markets weekly on Monday and Saturday, but that on Monday is by far the most considerable. Here are also regular annual fairs, established about twenty years ago, for the sale of cattle. The church, which is parochial, is an ancient structure, but has been much altered, enlarged, and modernized within the last twenty years. The Methodists have two chapels in Burlem, and are very numerous. In this town is a great variety of other sectarians.

Cobridge, which is situated partly in the parish of Burlem, and partly in that of Stoke, is a very large and populous village, and possesess spacious manufactories of the staple articles of the country earthen-ware in it.

Etruria is a large village, in which is a seat belonging to Josias Wedgewood, etc., who has the most extensive manufactory here of any in The Potteries. The name Etruria was bestowed upon it by the father of the present proprietor, whose inventions and discoveries have not only, as before mentioned, advanced his own particular art, but have contributed in a high degree to the enlargement of natural knowledge in general.

Lane-End, Lower-Lane, and Lane-Delf adjourn, and conclude The Potteries on its eastern boundary. The first mentioned of these townships is by far the most considerable of the three, containing, according to the returns for 1811, 1597 houses, and 4930 inhabitants. Here are a chapel of ease to Stoke, a Methodist chapel, and several meeting-houses for dissenters. Among the less important places in this district, where manufactories of earthen-ware are established, are New-Chapel, Wolstanton, Redditch, and Norton, which are the most considerable. A Description of the Country from thirty to forty miles round Manchester, by J. Aitkin, M.D., 4to. Shaw's History, &c. of Staffordshire, vol. 1.

POTTING OF PLANTS, in Gardening, the operation of placing or planting different sorts of plants, roots, slips, and cuttings, &c. in pots. In this business, more care and attention are necessary than is generally bestowed; as unless the work be neatly performed, it seldom succeeds well. The means of performing this sort of work, is fully explained in speaking of planting in pots in the article on planting. See PLANTING.

POTTLE, an English measure for corn and other dry commoditites, containing two quarts: 16 pottles being = 32 quarts = 8 gallons = 4 pecks = a Winchester bushel.

POTTON, or POTTEN, in Geography, a market-town and parish in the hundred of Biggletwade, and deanery of Shefford, is situated on the border of the county adjoining Cambridgeshire, at the distance of forty-eight miles from London. The market, though not so great as formerly, is still supplied with all sorts of grain, particularly with wheat and barley, and is held on Saturday. The date of the charter has not been found on record. A fair on the festival of St. James was granted, in 1227, to Henry de Braybrooke, one of the justices of the king's bench, who is supposed to have been then lord of the manor. There are now four fairs. A great fire happened at Potton in the year 1783, when more than fifty dwelling-houses were destroyed, besides out-houses, &c. The damage was computed at upwards of 25,000l. Above 6000l. were collected for the poor of the sufferers. Since this accident the market is said to have declined. The number of houses, according to the returns made to parliament in 1801, pursuant to the population act, was 239, that of inhabitants 1103.

The manor of Potton belonged to the family of the Nevills from:
from the reign of Edward II. to the year 1431, and was afterwards, for many generations, in that of the Burgoyne of Sutton. It has since been in the Torrington family, and is now the property of Samuel Whitbread, esq. M. P. whose father purchased it in 1795. The De la Poles had a manor in Potten in the fourteenth century, which in the reign of Henry VIII. was in the family of Tanfield, being then called the manor of Potten-Mychnaunred. It has long been united to the other manor.

The great ythes of Potton were appropriated to the priory of the Minories in London, in the year 1394. They now belong to the parish of Thackfield in Elles, having been purched, under a decree in chancery, with a sum of money bequeathed to that parish by William lord Maynard, in 1698, for charitable uses. The vicarage of Potten is in the gift of the crown. When the parish was inclosed, under an act of parliament, which passed in 1774, an allotment of land was assigned in lieu of the vicarial tythes. Lysons's Magna Britannia, vol. i.

POTTSGROVE, a town of America, in the county of Montgomery, and slate of Pennsylvania, containing 1771 inhabitants; 27 miles N.W. of Philadelphia.

POTZDAM, a city of Brandenburg, in the Middle Mark, situated on an island, 16 miles in circumference, formed by the Havel and some neighbouring lakes. It was ceded by the family of Roehan, to whom it belonged, in the year 1416, to the electoral house; and it was made a seat of pleasure by Frederick William, who, in 1662, built a castle, afterwards enlarged by king Frederick I., and ornamented with a fine portal. King Frederick William began to make some costly additions to the town; and he caused several mansions to be filled and built upon, and a canal 50 paces wide, and 2000 in length, to be carried on out of the Havel, through the centre of the town, to a branch of the same river. This canal has plantations of trees on both sides, and it is environed with well-built houses. The town is divided into Old and New, and the Fredericshald, to which also belongs the Bodengraft. Frederick II. raised the castle one story, annexed to it two wings, and adorned it with magnificent apartments. The old houses near the castle have been taken down, and grand buildings erected in their room, at the king's expense. A pyramidal obelisk of four sides, compos'd of variegated Sileian marble, 75 feet high, is erected in the market place, having on one side a marble bust of the king; the pediment being white Italian marble, and at each corner is a small statue of the same. The town-church, situated not far from the castle, is a fine structure; the garrison church is large, and under the pulpit, which is constructed of marble, lies the monument of king Frederick William. The orphan-houses were founded in 1724, and afford maintenance and education to above 2000 soldiers' children, of both sexes; and to this belong one Lutheran and one Calvinist preacher. To this foundation is annexed the neighbouring village of Bornhaft, together with the gold and silver manufacture, and the magazine at Berlin. In this town there are a velvet and silk manufacture, and manufactures of fabrics of other kinds. The king's guards, both horse and foot, with other battalions, have usually garrisoned this town; 15 miles S.W. of Berlin. N. lat. 52° 25'. E. long. 13°.

POTZEL. See Posseck.

POTZLOW, a town of the Ucker Mark of Brandenburg; six miles S. of Prenzlau. N. lat. 53° 11'. E. long. 13° 54'.

POUANCE, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Segré; 11 miles N.W. of Segré. The place contains 1306, and the canton 7382 inhabitants, on a territory of 2623/4 kilometres, in 15 communes.

POUCa, a lake of Little Bucharia. N. lat. 32° 42'. E. long. 80° 14'.

POUCa Hotten, a town of Little Bucharia; 10 miles W. of Tourfan.

POUCH, in the Military Art, is a square case or bag of leather, with a flap over it, hanging to a buffalo shoulder-belt of about three inches broad over the left shoulder of the infantry, used for holding cartridges. The cartridge-boxes within the pouches should be made as light as possible, with thirty-fix holes in each, in order to prevent the addition of boxes to buckle round the waist, which, by blowing up, have occasioned mischief and confusion.

POUCH, in Botany. See Silicula, and Tetradynamia. Pouch, Shepherd's. See Alyssum.

POUNDER, Pie, Court. See Pie Powder Court.

POUDIME, in Geography, a town of Turkish Armenia; 30 miles E.S.E. of Trebifond.

POUDINGORY, a town of Hindooistan, in the country of the Nayrs; four miles N. of Calicut.

POUDRE des Chartreux. See Kermees Mineral.

POVEGIA, in Geography, a small island in the Adriatic, near the coast of the Dogado of Venice, in the inedilata of Malanocco. Damaged vessels put in here to repair.

POVENETZ, a town of Ruffia, in the government of Olonetz, on the N. coast of lake Onezkoe; 120 miles N.N.E. of Olonetz. N. lat. 64° 2'. E. long. 29° 44'.

POVERTY, Penia, in Mythology, was deified among the ancients; accordingly Arrian informs us, that the Gadarians adored Poverty together with "Arts," which they joined in the same worship, because Poverty is the mother of invention. Plautus, in the prologue to one of his comedies (In Trim.) makes this goddess one of the persons in the play, and says, that she was the daughter of Debanckery. Plato makes Love to be her son.

POVERTY Bay, in Geography, a bay on the E. coast of New Zealand, in the South Pacific ocean, called by the natives "Taumee," or Long Sand, discovered by Capt. Cook in the year 1769. The bay is shaped like a horse-shoe, and is known by an island lying close under the N.E. point; the two points that form the entrance are elevated with steep white cliffs, and lie from another about 1/2 or 2 leagues; the water in the bay is from 12 to 6 fathoms, and it has a sandy bottom, with good anchorage; but it is exposed to the wind between the S. and E. In fine weather boats may go in or out at any time of the tide; but the bar at the entrance prevents their going out, when the sea runs high. The shore of the bay, within its entrance, is a low flat land; behind which, at a small distance, the country exhibits a diversified scene of hills and vallies, clothed with wood and covered with verdure. The country appears to be well inhabited, particularly in the vallies that lead up from the bay, where Capt. Cook daily saw smoke rising in clouds, one behind another to a great distance, till the view terminated in mountains of stupendous height. It owed its name to the inhospitable characters of the natives, who afforded to the Endeavour only the little wood, and no other necessary. S. lat. 38° 42'. W. long. 181° 36'.

POUGET, FRANCOIS AIME, in Biography, priest of the oratory, and doctor of the Sorbonne, was born at Montpeller in 1666. He became the father of St. Roch at Paris, and in that office he is said to have converted La Fontaine, on which subject he wrote a curious letter, published by Defo:let in his "Memoirs of Literature and of History." Among the works of which he was the author, or editor, that in the highest estimation is entitled "Instructions in the Form
Form of a Catechism, drawn up by the order of M. Joachim Colbert, bishop of Montpelier." He also wrote "Christian Instructions on the Duties of the Knights of Malta?" and "A Letter to M. Cardinal de Noailles, Archbishop of Paris, on the Subject of the Bull Unigenitus."

POUGET, in Geography, a town of France, in the department of the Herault; 18 miles N.E. of Beziers.

POUGHKEEPSIC, a town of America, in the state of New York, pleasantly situated on the E. bank of the Hudson river, half way between New York and Albany. It has five churches, and a very flourishing academy. The population in 1810 was 4670. N. lat. 41° 41'. W. long. 73° 58'.

POUGOMO, a river of Africa, which runs into the Atlantic, N. lat. 9°.

POUGUES, a town of France, in the department of the Nièvre, and chief place of a canton, in the district of Nevers, situated at the foot of a mountain, whence issues a medicinal spring; six miles N. of Nevers. The place contains 975, and the canton 9768 inhabitants, on a territory of 2725½ kilometres, in 12 communes.

POUGY, a town of France, in the department of the Aube; 13 miles N.E. of Troyes.

POVIGELIO, a town of Italy, in the department of the Parano; 10 miles N.N.W. of Reggio.

POUILLON, a town of France, in the department of the Landes, and chief place of a canton, in the district of Dax; six miles N. of Dax. The place contains 2718, and the canton 12,830 inhabitants, on a territory of 202½ kilometres, in 11 communes.

POUILLY, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Beaune; 19 miles W.S.W. of Dijon. The place contains 661, and the canton 12,561 inhabitants, on a territory of 332½ kilometres, in 28 communes.—Alfo, a town of France, in the department of the Nièvre, and chief place of a canton, in the district of Cosne; 7 miles N. of La Charité. The place contains 2648, and the canton 9212 inhabitants, on a territory of 232½ kilometres, in 11 communes.

POULO POINT, a cape on the west coast of Sumatra. S. lat. 4° 4'. E. long. 102° 5'.

POULONG-TCHEN-TANG, a mountain of Tibet. N. lat. 31° 36'. E. long. 104° 36'.

POULOU-TOU, a town of Chinese Tartary, in the country of the Monguls. N. lat. 45° 33'. E. long. 112° 43'.

POULTICE, or POULTIS, a form of medicine, called also cataplasm.

POULTING LUG, in Rural Economy, a provincial term applied to a long slender rod used in beating fruit off the trees.

POULTNEY, in Geography, a confiderable and flourishing town of America, in the state of Vermont, and county of Rutland, near Skenehorough; containing 1904 inhabitants.—Alfo, a river of Vermont, which falls into Lake bay.

POULTON, or POULTON in the FYELDE, a market-town and parish in the hundred of Amounderness, and county palatine of Lancaster, England. The parish comprizes the townships of Carleton, Hardhorn-with-Newton, Martin, Poulton, and Thornton; and contained, in the year 1811, 646 houses, and 3390 inhabitants. The town is situated near the mouth of the river Wyre, at the distance of 21 miles S.W. by W. from Lancaster, and 233½ miles N.W. by N. from London. Some time aft the conquest, it conftituted the lordship of Roger de Poitiers; and was given by him to the abbey of Shrewsbury, together with the manor of Bificopeham. The vicarage, however, being referved in this grant, was fubfequently improperated to the nunnery of Sion in Middlesex, but of late years has become private property. Poulton market-day is Monday weekly; and the fairs are on the 13th February, 3d May, and 25th July. Here are three free schools.

Five miles west from Poulton is the village of Blackpool, which has attained, within the last 40 years, considerable distinction as a watering or bathing-place, for which its situation and other characteristics are admirably adapted. At the southern end of this village stands a building designated Vauxhall, which was long a retreat for Popish recusants. It 1715 it was fitted up to receive the Pretender in a flat of concealment, till the people should be ready for a general insurrection. Being surrounded by a lofty wall, defended by a pool and a swamp on the south and east sides, and by the sea on the west side, it could only be approached from the north; and having many secret receplies and hiding-places, it was well fitted for guarding against surprife. This building is now levelled with the ground. On the sea-beach here is a fine artificial parade; and in the village a news room and coffee-room have been established for the convenience of visitors, who frequently amount to 500 in one season. For many local particulars relating to this place, see A Description of Blackpool, by W. Hutton, F.S.A., 1824; also Beauties of England, vol. ix. by John Britton, F.S.A.

POULTRY, in Rural Economy, a term applied to all kinds of domestic fowls brought up in the farm-yard, as cocks and hens, ducks, geese, turkeys, &c. The farm-yard cannot be faid to be complete, till well stocked with these forts of birds. The advantage of this fort of flock is, however, probably doubtful, except in particular situations, and where there is much grain cultivated. The poor villager may, however, reap in some cafes benefit from producfts of this fort, as they are able to shift for themselves in some measure the greateft part of the year, by their feeding on insects, corn, or any thing of that nature that they can find.

It is well known that there are many different breeds of these forts of live flock, but tho' best known of the fowl kind are the game breed, the white or Engliſh breed, the black or Poland breed, the Darking breed, the large or smoke-bog breed, and the Malay breed.

The two firft are much smaller breeds than the others. This fort of flock affords profit in the eggs, as well as the chickens; therefore, fuch as are the best layers and fitters fould be chosen, which are in general the game and Poland breeds; but the other breeds have probably the advantage in refpect to the fize of the eggs. As food, the game and white breeds are faid to be the moll delicate. Some advise the choosing thofe that are the best breeders and best layers; the oldest being always reckoned the best fitters, and the youngeft the best layers; but no fort is good for either purpofe, if they are kept too fat. The beft age to fet a hen for chickens is from two years old to five, and the beft month to fet them in is February; though any month between that and October is good. A hen fits twenty-one days, whereas geese, ducks, and turkeys, fit thirty. While fitting, they should have conftantly meat and drink near them, that they may not bite their eggs, and chill them. When fowls are fed with buck-wheat, or with hemp feed, it is faid they will lay more eggs than ordinary; and buck-wheat, either whole or ground, made into paffie, which is the beft way, is a grain that will fatten fowls very speedily; but the common food ufed is barley-meal, with milk or water; but wheat-flour moistened is: some thin
POULTRY.

thought the belt. The hen should not differ from the nature of the cock, but both be working, vigilant, and laborious, for their chickens. It is better for the hen to have no hinder claws, because they often break the eggs. Crowing hens are seldom either good layers or good breeders. To have large eggs, and in plenty, some advise giving the hens plenty of food, and sometimes oats and animal food, with fenugreek to heat them. And to prevent hens eating their nest eggs, plaster or chalk ones may be employed.

Hens may be kept in the proportion of eight or ten to a cock.

Mr. Young notices, that when in the common way the farmer keeps but a few of each, that take their chance at the barn-door, for the convenience of eggs, and not to go to market when a fowl is wanted, no particular attention is requisite; but as, in some situations, they may pay well for more food and closer attention, other circumstances may be remarked. The poultry-house should contain an apartment for the general flock to rest in, another for resting, a third for fattening, and a fourth for food. If the scale is large, there should be a fifth, for plucking and keeping feathers. If a woman is kept purposely to attend them, she should have her cottage contiguous, that the smoke of her chimney may play into the roofling and fitting rooms; poultry never thriving so well as in warmth and smoke; an observation as old as Columella, and strongly confirmed by the quantity bred in the smoky cabins of Scotland and Ireland. For fitting both turkeys and hens, shells should be made in lockers, that have lids with hinges, to confine them, if necessary; or two or three will, in fitting, crowd into the same nest. All must have access to a gravelled yard, and to grafs for range; and the building should be near the farm-yard, and have clear water near. Great attention should be paid to cleanliness and white-washing, not for appearance, but to destroy vermin. See Poultry-House.

In respect to feeding them, boiled potatoes are the cheapest food; and of corn, buck-wheat. Turkeys, while young, demand incessant attention, and must be fed with alum curd and leeks, or onions; for which purpose, flore of those roots should be kept where they will shoot out, and produce much food. If there be not much succes in broods, and a certain high price, they will not answer; for the expenses are heavy in the management of this sort of poultry flock.

In respect to fitting hens, the eggs should constantly be such as are new-laid, and in a perfectly fresh state. The number may be ten or a dozen; but it is best not to have too many, as they can only cover a certain number.

And the broods of chickens should be so managed, as to have them coming in as the seafon begins to get warm in the spring; but by proper attention, they may be had at almost any time of the year. When they are first brought out, they should be attended to with care, where any are weak; and some advise their being removed into warmth, but it is probably best to let them remain with the hen, but they are two days old, rice, split grits, or very small oatmeal, may be given them, some dry, and some steeped in milk, or else crumbs of fine wheate bread; and when they have gained strength, curds, cheese-parings, white bread, crusts soaked in milk, barley-meal, or wheaten bread scalded, or boiled or roasted potatoes, or any such like soft meat that is small, and will be easily digested. And it is necessary to keep them in the house for some time, especially in bad weather, and not to suffer them to go abroad with the hen. Green chives chopped among their meat is very good, and will preserve them from diseases in the head; and they should never want clear water, as puddle water is said to be apt to give them the pip.

Where the chickens are confined under coops, they should not be placed too near each other, as the hens are apt to destroy each other's chickens.

The quantity of food which young chickens mostly consume is about one or two ounces in the day, while in their early growth, as from one to two pounds in weight. They should be prevented from picking up flugs, slugs, &c. from the earth as much as possible.

In the view of fattening chickens, or other poultry, various modes are used: but the best practice is probably that of confining them for a few days in dry well-ventilated places, covered so as to prevent the entrance of too much light, the fowls being taken in, in good condition, from the poultry-yards. In these situations they should be regularly fed three or four times in the course of a day with well roasted or flamed potatoes, which are probably the cheapest food of food; as near Liverpool, in Mr. Wakefield's practice, which was upon an extensive scale, it was attended with the most complete success, the poultry thriving perfectly well. Buck-wheat is likewise an useful and cheap food for this purpose, either given whole or ground into flour; barley-meal, ground malt, and also coarse wheat-flour, when mixed up with milk, or, what is better, water, as milk runs quickly into a state of acidity, have been much recommended in this intention. From some experiments, it has been stated that pea-meal, employed in the same way, possesses a still more fattening property, and is at the same time more economical, as going much further. A confinement of eight or ten days in this way will, in general, be sufficient for effecting the business of fattening. When kept up long, fowls are extremely apt to be affected with disease. Whatever sort of food is made use of, full air and a perfect state of cleanliness are essential in all the utensils employed for the purpose, in order to prevent the food becoming sour, and the fowls affected with diseases of the kinds mentioned below.

It is stated in the Suffolk Corrected Agricultural Report, that North Chappel, Lindford, and other places thence, are famous for their fowls. They are fattened there to a fine and perfection unknown elsewhere. The food given them is ground oats made into gruel, mixed with hog's greas, fugar, pot-liquor, and milk; or ground oats, treacle, and fuet; also sheep's phleg, &c.; and they are kept very warm. They are always crammed in the morning and at night. They mix the pot-liquor with a few handfuls of oatmeal; boil it; it is then taken off the fire, and the meal is wetted, so as to be made to roll into pieces of a sufficient size for cramping. The fowls are put into the coops two or three days before they begin to cram them, which is done for a fortnight, and then they are sold to the higlers. They will weigh, when full grown, seven pounds each, and they are sold at from 4/ 6d. to 5/- a piece; the average weight being five pounds; but there are instances of these fowls weighing double this weight. Mr. Turner, of the birth of the above-named places, a tenant of lord Egremont's, crams two hundred a year. And many fat capons are fed in this manner; good ones always look pale, and wake away; great art and attention are requisite to cut them, and numbers are destroyed in the operation. The Suffolk breed are too long in their body, to cut them with much success, which is done at three-quarters old.

The Darkling fowls, as they are called, are all raised in the weald of Suffolk; but the finest market for them is Norwich. The five-clawed breed have been considered as the best for this; however, this is a great mistake, and it took its
POULTRY.

origin in some fowls with this peculiarity, that happened to be very large and fine, which laid the foundation of what have been since called the Darkling or five-clawed fowls, and considered in other parts of England as the prime flock; but such a thing is hardly known in Suffolk: it is a ballast breed. The fowls of the Suffolk breed, which are used at the table of lord Egremont, have very frequently, it is said, astonished the company by their size.

All about the neighbourhood of Oakingham in Berkshire, also, the practice of cramming fowls is a lucrative branch of business. They are there put up in a dark place, and crammed with a paiste made of barley-meal, mutton-fuet, and some treacle, or coarse sugar, mixed with milk, and are found to be completely ripe in a fortnight. If they are kept longer, the fever, which is induced by this continued state of repose, renders them red in their flesh, and un-saleable, and frequently kills them.

Whether the practice of cramming in these farts of birds, as well as some other kinds, has any very beneficial effect in promoting the fattening process, is a point in their management which has not yet been, by any means, fully ascertained; but it is a method which, as being attended with considerable trouble, would hardly be had recourse to, in so many places, unless some fort of advantage was derived from it. The fattening would, however, in these cafes, seem to depend upon the quantity of nutritious matter which is converted, and taken into the fylkem, as prepared by the procfs of digestion, and not upon the quantity of food forced into the stomack. See TURKEY.

It is stated by a writer in the sixth volume of the Agricultural Magazine, that he has ascertained that three pounds of meal-flour, or grain of such a sort as does not cost more than a penny a pound, or to the farmer and cottager not even so much with water, and what other fare the little creature can find for itself, will feed and fatten a chicken sufficiently from the time of its burfting the shell, till that of its being a growth, and in a condition suitable for its being carried to market. And that the allowance of another penny is sufficient for the attention and labour which its rearing requires. The prime cost of the egg may be a halfpenny. Thus it is supposethat even in the neighbourhood of any great town a chicken that shall bring nine-pence, or rather one shilling in the market, and is, in comparison with other things, worth as much for the use of your own table, whether you be a rich or poor man, may be produced and reared at the expense of four-pence halfpenny. And further, that in proportion as fowls are kept for the consumption of the portion of farinaceous food that is daily in waste about farm-houses, the expence cannot be more than one penny; consequently, by attention to this economical mode, abundance of poultry may be had at a reasonable rate. And that old fowls, even though fed with food, for which money proportionate to the just market value must be paid, will, by their eggs, pay annually at least three times the cost of their subsistence, independently of the advantage of the manure which is afforded.

A system of farm-management in this respect is stated by Mr. Young, as practised by Mr. Boys of Kent, which appears to be extremely simple and beneficial. The labourers' wives and families who live on Mr. Boys' farm do the whole; he supplies them with what offal corn is necessary, and they return Mrs. Boys the grown fowls ready for market at three-pence each; six-pence for turkeys and geese; and three-pence for ducks; and the account, well kept, slates a profit of twenty pounds a-year, after all the expenses are paid, and the family well supplied. And the is likewise all the eggs without any payment. This is a system equally beneficial to the people who undertake it, and to the farmer.

And a gentleman in that part of Berkshire which is called the "Vale of White Horse," to whom comprehensive mind nothing is too great, and to whom no object connected with the farm appears too little, favoured the writer of the Agricultural Report of that district with an inspection of his bailiff's book, from which he made the following extracts on the produce of the poultry-yard. It was the account for one year:

It is suggested, that the estimated price here is much lower than the average of markets in general; but it will furnish some criterion of the comparative value of domestic poultry in a farming point of view.

It is conceived, that the con solidation of farms, among other ill consequences, has diminished the quantity of poultry, and consequently enhanced the price. And that though the gentleman, the yeoman, and the capital rack-renter, may sometimes rear enough for the supply of their own tables; yet it is an object beneath their notice to produce a supply for the public. Therefore the bnefins of breeding poultry for the market is either left to the cottager, whose means and opportunities are limited, or to the little tradesman or farmer.

Eggs, too, from the same cause, are much dearer than formerly; and yet, when we consider the amazing demand and consumption, it is only wonderful they should be procured on any terms. In every part of this county, however, the supplies are pretty abundant, though rather high, of both poultry and eggs; and as fowls are the least expensive of all kinds of live-flock to a poor man, it is suggested, that he should be encouraged to profit himself and the public, by keeping as many of them as his situation will permit.

The market of Oakingham is particularly famous for fatted fowls, by which many persons in the town and neighbourhood gain a living. They are sold to the London dealers; and the sum of 150l. has been returned in one market-day by this traffic. Twenty dozen of these fowls were purchased for one gala at Windsor, at the rate of half a guinea a couple. At some feasons of the year, 15s. are paid for a couple. They constitute the principal commerce of the place.

In the county of Chester, the generality of the farmers seem to be of opinion, that it is more profitable to keep fowls for their eggs, than to breed them for the table; a considerable number, however, are brought into the different markets in the county for sale, and a still larger portion is purchased by the higglers, and carried to other markets in the large towns in the neighbouring districts. In most counties where grain is much cultivated, or where other sorts of proper food are in plenty, poultry of the foul kinds may be advantageously reared, both for the sake of the eggs and the birds.

Birds of the poultry kind are subject to different diseases, as the pip, the roup, the flux, the flupage, and kindred. The first is said to be occasioned by eating foul meat, and drinking dirty water, or the want of water. It is known by...
by a thin white scale on the tip of the tongue, which prevents the fowl from eating; and it is cured by taking off the scale with your nail, and rubbing salt upon the tongue.

The second is supposed to be a sort of swelling on the nape, which disorders the fowl prodigiously; and is observable by the feathers on the affected part standing out of their natural position, the quills being full of blood. Pulling out the feathers, opening the fore, fore-stomach, and washing the part with brine or with salt and water, will effect the cure, it is said, in most cases of this nature.

The flux is supposed to depend on eating too great a quantity of malt fermenting food, and which is cured by giving peas-meal and scalded rice with a little wax. The flappage in fowls is a sort of coffiniveness, which affects them to such a degree, that they are unable to walk, and is shown by their not eating as usual. Its cure is effected by anointing the vents, and then feeding them with corn, or small bits of bread soaked in urine; the obstructing surfaces may also be taken out of the crops. The blindness of fowls is best remedied by a change of food, and letting them have a free air.

It is observed, to distinguish whether poultry is good or not, the following circumstances should be noticed: after a chicken is killed, it will be stiff, white, and firm in the vent, if new killed; but tender and green in the vent, if stale; and if you rub your finger on the breast of a chicken, if it be new killed it will feel rough; but if stale, slippery and slimy.

Guinea fowls are a sort of bird of the fowl kind, which lay very abundantly, but which, from their retaining much of their wild nature, are apt to wander much from home, and of course cannot be kept so conveniently as the more domestic fowl of fowls. They are likewise remarkably shy, and on that account liable to forfeit their nests upon the least disturbance being given them. They are probably better for the table than the common fowl, as being larger, and having more of what is termed the game flavour; they have likewise the property of breeding abundantly when properly managed.

Turkeys are a sort of farm-flock that can only be kept with advantage in districts where grain is the predominant article of cultivation. There are two varieties of these birds in this country, the black and the speckled forts, the former of which is, in general, the larger and more hardy. It is found that they are birds that prosper very well in open countries, where there is not much shelter to harbour vermin to defrey them: for they are naturally inclined to rambles. The hens, likewise, are too negligent of their young, that while they have one to follow them, they never take any care of the rest; and therefore there must be a great deal of care taken of them whilst they are young, to watch them, and to keep them warm, as being birds that cannot bear the cold. But some, where they have the convenience of a small cover near the house, let them take their liberty, and seek their own nests; but it is only in particular places that they do well with such management. It is observed, that a gentleman had a hen-turkey of the wild kind from Virginia, from which, and an English cock, he raised a very fine breed, and much larger than the common, and reared their young ones without any care or trouble, breeding much better than the English forts.

Where they are kept with corn, they are very great feeders, and devour a great deal; but if left to their liberty when grown up, they nearly get their own living, by feeding on herbs, weeds, &c.

This is a sort of bird which breeds without the male birds being kept constantly with the females during the laying season, as is the case with most other sorts of birds. Turkeys are very apt to straggle, often laying their eggs in secret places; and therefore must be watched, and made to lay at home. They begin to lay in March, and will fit in April. Eleven or thirteen eggs are the most they fit on. They hatch in between twenty-five and thirty days; and when they have hatched their brood they must be carefully kept warm, for the least cold kills them. They may be fed either with curds, or fresh cheese chopped in small pieces with onions or leeks, and their drink may be new milk, or milk and water. Some give them oatmeal and milk boiled thick together, into which they put onions or leeks chopped small, and sometimes eggs boiled hard, and cut in little pieces. They must be fed often, as the hen will not take much care of them, and when they have got some strength, be fed abroad in a close walled place, where they cannot fly away; not letting them out till the dew is off the grass, and taking care to have them in again before the night, because the dew is very prejudicial to them.

It is noticed that these birds, when young, may be fattened with great expedition by means of boiled potatoes and good barley meal, mixed well together with chopped onions or leeks, if they are kept fed in a regular manner. The writer of Practical Agriculture says, that the practice of cramping them is a piece of stupid and unnecessary cruelty, as it is evident they can only fatten in proportion to the quantity of food which is digested; whatever quantity may be forced upon them; besides, they will consume it far enough if regularly fed, which is probably the fact, however custom may have sanctioned such a method of fattening them. The author of the original Report of Norfolk thinks, that the fineness of the flavour in the Norfolk turkeys depends on the dryness of the soil in that district, and the extensiveness of the range which they are suffered to poffefs while in their young growth. The difference between the living and dead weight of a turkey, is thus stated by Mr. Young; live weight 21 lb., dead weight 14 lb.

The farmers in many districts of the country are prevented from the raising and keeping birds of this kind, on account of the great mischief which they do to the different sorts of field crops. They are, however, fine farm-yard birds, wherever they can be kept with propriety.

Ducks are a sort of water-fowl that may be raised with benefit in particular situations, where there is plenty of water for them to swim upon in the vicinity of the farm-lead, as they require little trouble or attention. There are different breeds, but the English or white, and the brown or speckled wild breeds, are probably to be preferred. The latter are, however, apt to wander. But it is only in such situations as above, that this sort of flock can be kept with benefit, except it be a few jilt for the purpose of the table. Ducks mostly begin to lay early in the year, as the latter end of January, or beginning of the following month, especially when well fed, and they require great attention at this period, as they lay a great number of eggs, and are very apt to drop them in the water, or at random in other places. One drake is sufficient for four or five ducks. When fed, from ten to a dozen or thirteen eggs are a sufficient number. They sit about thirty days; and, during the time, should be fed, and have water near their nests, to prevent the eggs being injured by their leaving them too long. When hatched, the ducklings should remain with the duck in some inclosed, safe, warm, sunny place, and be well fed with crumbs of bread, grits, or barley-meal, with well roasted or boiled potatoes, well mixed, and fed
in a fresh state, food and clean water being constantly kept before them in shallow pans. It is observed that the duck-breeder has in general a provision of worms, snails, and other similar animals, in readiness for them when a little more advanced in their growth, as well as corn either in its ground or natural state, and that it is likely a point of great importance to keep them perfectly clean, and to let them have plenty of dry clean straw as litter. They should never be left at full liberty till they are become quite strong, as a month or six weeks old, being constantly kept as distinct as possible from the other fowls of poultry.

In the fattening of these birds, which are greedy, but not mice feeders, grain, either in its whole, or reduced mixed state, is probably the best form of food. The use of boiled potatoes well mixed with oatmeal, is found to be an economical and expeditious method. Much, however, depends on their being fed in an exact and regular manner, and on a proper supply of water and land being constantly given; while at the same time they are kept in a perfectly quiet detached situation, not too much exposed to the action of light, but well aired. When fattened on animal substances, which are very expeditious in accomplishing the purpose, they are said to have more resemblance both in the colour and flavour of their flesh to the wild duck, than in the common method. In the acorn feaon they are also capable of being readily fattened on that sort of food, and are allowed to be well flavoured in their flesh from the use of it. And Mr. Wellton has advised the use of malt for this purpose, which, he says, answers in the proportion of something less than a gallon per duck. It has an amazing quality in fattening them when young, and causes the flesh to be very delicate; when old, they readily fatten with almost any food; but for the flavour it gives the flesh, he would always prefer malt before any thing else: before they have been put up to fatten, he has likewise given them plenty of lettuces, which they are exceedingly fond of; they are, he thinks, a very cheap food for them, as they need then have but little corn in completing them.

It has been long ago observed that these birds are useful in destroying flies, caterpillars, &c.; and the author of the Report of Middlesex thinks it is clearly ascertained, that ducks might be kept in such numbers on corn farms, as to prevent any sensible loss or destruction in their crops by worms, flies, or caterpillars; and yet we are always hearing of great losses occasioned by these vermin. The support of a hundred or two of ducks on a farm is a trifling expense, and might be considered in the light of ensuring the young crops against being cut off. It is thought that many farmers receive more damage to a crop in one season, than would support a sufficient number of ducks to give security for twenty years.

And the establishing of decoys for the taking of wild ducks, is a point that deserves the farmer’s notice in particular situations, as where there is a great extent of water in a retired situation, at a short distance from the sea. It is often done in the wilds of Lincolnshire, and in Norfolk, as well as some other districts. Mr. Marshall remarks, that the lakes and large pools, which abound in the southern hundreds of East Norfolk, are the nurseries of innumerable flocks of wild fowl, of various species, but principally ducks; which are taken in great numbers in decoys, formed on the margins of these waters; and which, in eligible situations, may well be considered as objects of rural economy. But that judgment is requisite in forming and managing a decoy. A gentleman in this neighbourhood had, says he, a person out of Lincolnshire to make one for him. But after a great expense of cutting pipes, fixing kreens, nets, &c. it proved unsuccessful. The pipes were too straight, too close and confined, and too narrow at the mouth; without any banks for the wild fowl to候选 upon. Upon the whole it was too much like a trap to be taken in.

He notices, that the leading principles of a decoy are thefe; as the wild duck is a very shy bird, and delights in retirement, the first step, therefore, is to endeavour to make the given water a peaceful asylum, by baffling the ducks to rest on it undisturbed. The fame love of concealment leads them to be partial to waters whose margins abound with underwood and aquatic plants; hence, if the given water is not already furnished with these appendages, they must be provided; for it is not retirement alone which leads them into these recesses, but a search after food also. And further, that at certain times of the day, when wild fowl are off their feed, they are equally delighted with a smooth, gravelly margin, to adjust and oil their plumage upon. On the close-patured margins of large waters frequented by wild fowl, hundreds may be seen amusing themselves in this way; and, perhaps, nothing draws them sooner to a water than a convenience of this kind; hence it becomes essential necessity to succeed, to provide a gravelly, shelving, smooth-shaven bank at the mouth of the pipe, or canal, leading from the water to a tunnel net, fixed at the head of it; but hid from the flight among trees and aquatic plants; the difficulties that remain are those of getting them off the bank into the water, without taking wing; and of leading them up the pipe to the shore which is set for them, in the most easy manner.

With a view to get them off the bank into the water, a dog is necessary, (the more like a fox the better,) which should steal from behind a kreem of reeds, which is placed by the side of the pipe to hide the decoyman, as well as his dog. On seeing the dog, the ducks rush into the water, where the wild fowl consider themselves as safe from the enemy which haddailed them, and of course do not take wing.

Among the wild-fowl, a parcel (perhaps eight or ten) of decoy-ducks should be mixed, which will probably be instrumental in bringing them, with greater confidence, to the bank. As soon as these are in the water, they make for the pipe, at the head of which they have been constantly fed; and in which they have always found an asylum from the dog. The wild ducks follow, while the dog keeps driving behind; and, by that means, takes off their attention from the trap they are entering. When, as soon as the decoyman, who is all the while observing the operation through peep-holes in the reed-kreem, sees the entire flock under a canopy net which covers and encloses the upper part of the pipe, he shews himself; when the wild fowl instantly take wing; but their wings meeting with an impetuous net, instead of a natural canopy formed of reeds and bull-rushes, they fall again into the water, and, being afraid to recede, the man being close behind them, push forward into the tail of the tunnel net which terminates the pipe. He has been told by the proprietor of a decoy, who is himself fond of the diversions, and whole veracity he has no reason to doubt, that he has, in this way, caught ‘nine dozen’ at a pull.

And from this use of the pipe, its form becomes obvious. It ought to resemble the outlet of a natural brook, or a natural inlet or creek of the principal water. The mouth ought to be spacious, and free from confinement, that the wild fowl, on their first rushing into the water, and while they have yet the power of recollection, may be induced to begin to follow the tame ducks; and for the same purpose it ought to be crooked, that its inward narrowness, and nets, may not, in the first instance, be perceived. The lower part
Poultry.

part of a French horn is considered as the best form of the pipe of a decoy that can be had.

But a material circumstance remains yet to be explained. It is the invariable nature of wild fowl to take wing with their heads towards the wind; and it is always imprudent to attempt to take them in a decoy, unless the wind blows down the pipe; for, while their enemy is to leeward of them, they have lefs inclination to go up the pipe, making sure of an escape by their wings. What is of full more consequence, if the wind set up the pipe, when they take wing under the canopy net, some of them would probably escape (a circumstance always to be dreaded), and those which fell again into the water, would fall, of course, with their heads towards the wind, and would with great difficulty be driven into the tunnel. It is also further stated, that this point is so well known by decoymen in general, that every decoy is, when circumstances will admit of it, furnished with three or four different pipes, pointing to different quarters of the horizon, that no opportunity may be lost on account of the wind being in any particular point.

Contrivances of this sort for catching ducks and other kinds of birds, are very frequently met with in England, and it is noticed in the corrected Report on Agriculture for that district, that one of the best, if not the most considerable, decoys in that county, is in the island of Mersea, and rented with a small farm of about sixty acres, by Mr. Buxton, of Layer de la Haye. He was so obliging as to accompany the writer from thence into Mersea, and to shew him his decoy. Not having before viewed a decoy in the taking season, he had not remarked the precaution of each perch taking a piece of lighted turf stuck on a table fork in his hand to approach the decoy; as the wild ducks, it is said, would smell the perch without this caution, and immediately quit the pond. He found the expenses of this decoy considerable; two men attend it, who are paid above 100l. a year; repairs, nets, rent, &c. amount in all to about 300l. a year. Ducks are sometimes fow low as 14s. a dozen.

Dun birds are also frequently secured by means somewhat of this kind, in this district. The contrivances for taking these birds here were new to him. At the decoy for them near Ipswich, there is a series of very high poles set up, to which the nets are attached, for taking them in their flight; and these poles are permanent. But at this Mersea decoy, to which this bird reforts in large quantities, as well as ducks, the net poles are suspended when not at work. Mr. Lee has a decoy at Goldhanger, in the same county, in which he took, at one haul, one waggon-load and two cart-loads of dun birds; but the disturbance made, frightened such as escaped so much, that he took no more that season.

Though the expense, in some cases, as has been seen, is very considerable, yet there is often no small profit attached to these kinds of decoys.

It may be noticed, that the fattening of ducks at any age is easy, and whether it be the duckling, or the grown duck, the method to be used is exactly the same. See Duck.

Geese are a sort of bird that will live upon commons, or any sort of pastures, and need little care or attendance; only they should have plenty of water. The largest English geese are reckoned the best, but there is a sort of Spanish geese that are much better layers and breeders. In providing geese for keeping, the author of Practical Agriculture says, great care should always be taken to procure them as large in fize as possible, and from places where they have been well kept. Geese, like most other birds, begin to lay in the spring months; and the earlier this happens the better, as the price of early green geese is generally high, and in some cases it may be possible to have a second brood. Both these purposes may be promoted by letting them be well fed with oats, grains, or some such kinds of food at the period. The geese generally lays from eight to twelve eggs. It may be known when geese are about to lay, from straw being frequently picked up and carried about by them. The length of time of sitting is about thirty days. When geese are inclined to sit, they generally shew it by remaining on their nests after laying a considerable time. In this case a proper quantity of eggs, as from ten to twelve, should be placed in the nests, and something put before them, so as to prevent the geese from being much fevered. They should also have plenty of food, and, water, near them, in order that they may not remain long off the nests, and in that way let the eggs be too much cooled. The ganders should be left with them as guards. When the weather is warm, they generally hatch sooner than when it is cold. After the gollings are hatched, the best method is to let them remain with the goos, especially where they are strong, in some warm funny place, that is well secured against the entrance of rats, and other forts of vermin, and which is properly supplied with water; being well fed with the crumbs of bread, grits, wheat, and some chopped ciders. They should remain in this confinement until they are grown strong, and capable of following the goos with ease; they may then be put into a small field or paddock, where the grass is short, till they are fufficient to be turned out with the goos. When they are weakly, it is customary to feed them in the house with bread soaked in milk, or a little barley-meal, and where this is done, they should, however, always be put under the goos again immediately after such feeding, and handled as little as possible; warmth in this stage being the most essential article in rearing them. They should never be suffered while very young to go in the wet, dew, or water, as the cold soon destroys them, by giving them the cramp or other diseases.

In the Lincolnshire Report it is stated to be the practice of that district, where sometimes numbers of these birds are annually produced, for their nests to be made of straw, and confined, so as that the eggs cannot roll out when the geese turn them, which they do every day. When near hatching, the shell is broken a little against the beak or nib of the golling, to give air, or to enable it to receive strength to throw off the shell at a proper time: this is, however, seldom necessary. It is added, that the time of plucking them is about the beginning of April, when the fine feathers of their breasts and backs should be gently and carefully plucked: care must be taken not to pull or interrupt their down or pen feathers, and the quills should be pulled five or six of each wing. And it is observed that they will bear pulling in thirteen or fourteen weeks again, or twice in a year: the feathers three times a year of the old geese and ganders, seven weeks from each pulling. The young geese may be pulled once at thirteen or fourteen weeks old, but not quilled, being hatched in March. But when late in hatching, the brood geese should not be plucked so soon as April, but the month after. When well fed with barley and oats, they thrive and do better, and their feathers grow fatter, and are better in quality than where it is omitted. They must confantly have plenty of grass and water; it is further stated, that in many parts of the fenny district, great advantage is made by the frequent pluckings of the goose. At Pinchbeck, it is the practice to pluck them five times in the year, as at Lady-day, Midsummer, Lammas, Michaelmas, and Martinmas. The feathers of a dead goose are worth sixpence, those giving a pound, but plucking alive does not yield more than three-pence a head per annum. Some wing them only every quarter, taking ten feathers from
from each goose, which sells at five shillings a thousand. Plucked geese formerly paid in feathers one shilling a head in Wildmoor fen, but at present it is much more.

In Lancashire no fort of management is pursued with these birds, but those of taking care of their eggs while they lay, and guarding the young gollings from accidents for a week or two, while they get sufficiently strong to take care of themselves. The geese are usually plucked twice in the year, as about Midsummer and at harvest, in each of which pluckings they afford fully one shilling each, producing, on the whole, a profit of about four shillings and sixpence a piece to their owners. When they are killed, each goose yields about half a pound of feathers, independent of the former pluckings.

They are here most commonly fattened with oatmeal and potatoes, in a boiled or flaked state, the two Substances being well mixed together immediately before being used. Each goose requires about two pounds and a half of meal, besides the potatoes, to render it quite fat. A good goose, when completely fattened, will weigh about nine pounds.

Vast numbers of geese are reared and kept upon the common, in this as well as other counties. In fattening green geese, they may be shut up when they are about two months old, and they will be fat in about a month more. They should have a little grass with their dry food, which may be any fort of grain, malt or carrots.

But in the fattening of older geese, it is commonly done when they are about six months old, in or after harvest, when they have been in the stubble field, from which food home kill them, which is a good way; but those who have a mind to have them very fat, shut them up for a fortnight or three weeks; and feed them with oats, split beans, barley-meal, or ground malt mixed with milk, the better to fatten them with being malt, according to Mr. Welton. Green geese will likewise feed on and fatten well with carrots, cut small, and given them. If you give flore-geese rye before or about Midsummer, it will strengthen them and keep them in health, that being commonly the time when they become fickle. See CAPON, CHICKEN, COCK, EGGS, HEN, and PHASIANUS GALLUS.

Poultry House, in Rural Economy, that fort of building which is contrived for the purpose of containing poultry, for laying, hatching, fattening, &c. It is observed, in a paper in the first volume of Communications to the Board of Agriculture, that this fort of Rock, when rightly managed, might be a source of great profit to the farmer; but where many are kept they ought not to be allowed to go at large, in which case little profit can be expected, for not only many of their eggs will be lost, and many of themselves perhaps destroyed by vermin, but at certain seasons they do a great deal of mischief, both in the barn-yard and in the fields. No doubt they pick up some grain at the barn-doors that might otherwise be lost; but if the straw is properly thrashed and flaked, there would be very little of this. In the common caretful way of thrashing, a great deal of corn is undoubtedly thrown out among the straw; but when we consider the dung of the fowls, and their feathers that get among it, and the injury these may do to the cattle, this is no object. It is much better, the writer thinks, to allow the poultry a certain quantity of corn and other food, and to let the cattle have the benefit of what corn may be among the straw. He therefore concludes that poultry ought always to be confined, but not in a clof, dark, diminutive hovel, as is often the case; they should have a spacious airy place, properly contructed for them. Some people are of opinion, that each fort of poultry should be kept by itself. This, however, is not absolutely necessary, for all forts may be kept promiscuously together, provided they have a place sufficiently large to accommodate them conveniently, and proper divisions and nets for each kind to retire to separately, which they will naturally do of themselves. And, he adds, that this mode was practiced with great success at Mr. Wakefield's, near Liverpool, who kept a large flock of turkeys, geese, hens, and ducks, all in the same place; and although young turkeys are in general considered so difficult to bring up, he reared great numbers of them, the writer observes, in this manner every year, with little or no trouble whatever. For which purpose he had about three quarters, or near a whole acre, enclosed with a fence only five or even feet high, formed of flax set on end, or any thinnings of fir or other trees split and put close together. They are fattened by a rail near the top, and another near the bottom, and are pointed sharp, which he supposes prevents the poultry flying over, for they never attempt it, although so low. Within this fence are places done up slightly, but well secured from wet, for each fort of poultry; also a pond or stream of water running through it. These poultry are fed almost entirely with potatoes boiled in straw, and thrive wonderfully well. The quantity of dung that is made in this poultry place, is also an object worth attention; and when it is cleaned out, a thin pearing of the surface is at the same time taken off, which makes a valuable compost, for the purpose of manure. But for keeping poultry upon a small scale, it is only necessary to have a small shed or flight building, formed in some warm sheltered sunny situation, if near the kitchen or other place where a constant fire is kept so much the better, with proper divisions, boxes, lockers, or other contrivances for the different sorts of birds, and for their laying in, fitted up in it.

It is, however, stated in the paper before noticed, that the most magnificent poultry place perhaps that ever has been built, is at lord Penrhyn's, at Winnington, in Cheshire: it consists of a handsome regular front, extending about 140 feet; at each extremity is a neat pavilion, with a large arched window. These pavilions are united to the centre of the design, by a colonnade of small cast-iron pillars, painted white, which supports a cornice, and a slate roof, covering a paved walk, and a variety of different conveniences for the poultry, for keeping eggs, corn, &c. The doors into these are all of lattice work, also painted white, and the framing green. In the middle of the front are four handsome stone columns, and four pilasters, supporting likewise a cornice and a slate roof, under which, and between the columns is a beautiful mosaic iron gate; one side of this gate is an elegant little parlour, beautifully papered and furnished; and at the other end of the colonnade a very neat kitchen, so exceedingly clean, and in such high order, that it is delightful to view it. This front is the diameter or chord of a large semicircular court behind, round which there is also a colonnade, and a great variety of conveniences for the poultry: this court is neatly paved, and a circular pond and pump in the middle of it. The whole fronts towards a rich little field or paddock, called the poultry paddock, in which the poultry have liberty to walk about between walks. It happened while the writer was there to be their dinner time at one o'clock. At this hour a bell rings, and the beautiful scene in the centre is opened. The poultry being then mostly walking in the paddock, and knowing by the sound of the bell that their repast is ready for them, fly and run from all corners, and rush into the gate, every one thriving who can get the small share in the fare in the fare. At that time there were about 600 poultry of different kinds in the place, and although so large a num-
ber, the semicircular court is kept so very neat and clean, that not a speck of dung is to be seen. This poultry place is built of brick, excepting the pillars and cornices, and, he believes, lintels and jambs of the doors and windows, but the bricks are not seen, being all covered with a remarkably fine kind of slate from his lordship's estate in Wales. These slates are closely jointed and fastened with Screw nails, on small spars fixed to the brick; they are afterwards painted, and fine white sand thrown on while the paint is wet, which gives the whole an appearance of the most beautiful freestone. This fort of cleanselines, with as free a circulation of air as possible, and a proper space for the poultry to run in, is essential to the rearing of this fort of flocks with the greatest advantage and success, as in narrow confined situations they are never found to answer in so perfect a manner.

POUNCE, among Artificers, a little heap of charol dust, inclosed in some open stuff, to be passed over holes pricked in a work, in order to mark the lines or designs thereof on a paper placed underneath; which are to be afterwards finished with a pencil, a needle, or the like.

The word is formed from the French ponce, pumice-stone; because they anciently used pumice-stone powdered for this purpose.

POUNCE is much used by embroiderers, to transfer their patterns upon their stuffs; by lace-makers, and sometimes also by engravers; and a kind made of gum sandarach, by writing-masters, which being rubbed on the paper, makes itлся apt to imbibe the ink; it is, therefore, used in this manner by those who are curious in the art of the pen, by which means the writing appears more precise, sharp, and determinate.

The varnish-makers also used to diffuse it in oil of turpentine, or in linseed oil, or in spirit of wine; from which mixture is produced a kind of liquid varnish.

POUNCEs, in Falconry, the talons or claws of a bird of prey.

POUND, LIRRA, a weight of a certain proportion, much used as a standard for determining the gravities and quantities of bodies.

The word is derived from the Saxen pund, or pond, pondus, weight.

We have two different pounds in England; the pound troy, and the pound avoirdupois. The pound troy consisted originally of 7867 grains, but was afterwards reduced to 7760, making 24 grains the pennyweight, instead of 32; these were grains of wheat taken from the middle of the ear. The pound troy is = 7023 French grains = 8766 Dutch ales = 6348 Hamburg or Cologne eichen = 7475 Spanish or Catalan grains. The Tower or Moneys' pound, with which gold and silver were weighed in England before the reign of Henry VIII., and which is still occasionally referred to in the subject of coins, was lighter than the pound troy by 15 pennyweights troy.

One pound avoirdupois is = 7000 grains, troy weight; and, therefore, 14 lb. avoirdupois = 175 lb. troy, or 192 oz. avoirdupois = 175 oz. troy. The pound avoirdupois is = 8357 French grains = 9439 Dutch ales.

The old commercial weight of England, which is still retained in Scotland, and which is said to have been formerly used at Amsterdam, Hamburg, and Paris, is about 1/10th heavier than avoirdupois weight, the pound being 7600 grains troy; and, therefore, 35 lb. old weight = 36 lb. avoirdupois. This is still the weight in England by which the alise of bread is fixed by the magistrate; the peck loaf, newly baked, being 16 lb. old weight, which answers to 17 lb. 6 oz. avoirdupois. See Weight.
In the United States, accounts were formerly kept in pounds, shillings, and pence currency; and this practice is still retained on some occasions; but the value of the currency is not the same in the different states. In Pennsylvania, New Jersey, Delaware, and Maryland, the ratio of currency to fering is as 3 to 4; and therefore 1l. fering = 1l. 134. 4d. currency; or 1l. currency = 115. 15s. 1d. fering. In New Hampshire, Massachusetts, Connecticut, Rhode Island, and Virginia, the ratio is as 3 to 4; and therefore 1l. fering = 1l. 6s. 8d. currency; or 1l. currency = 115. 15s. 1d. fering. In New York and North Carolina, the ratio is as 9 to 16; and therefore 1l. fering = 1l. 15s. 6d. currency; or 1l. currency = 115. 15s. 1d. fering. In South Carolina and Georgia, the ratio is as 27 to 28; and therefore 1l. fering = 1l. 12s. 8d. currency; or 1l. currency = 192. 53d. fering. Hence the exchange between England and the United States is at par, when, for every 100l. fering, Pennsylvania, Maryland, &c. give 166l. 13s. 4d. currency; New England and Virginia, 133l. 6s. 8d. currency; New York and North Carolina, 177l. 15s. 6d. currency; Georgia and South Carolina, 103l. 14s. 0d. currency. A pound fering, in the United States, is valued at four Spanish dollars and 44 cents or 100th parts of a dollar; and no foreign coins, except the Spanish dollar, are deemed a legal tender. But the dollar is valued in the different states according to the currency of each place. Thus, in Pennsylvania, Maryland, Delaware, and Jersey, it passes for 7s. 6d.; in New England and Virginia, for 6s.; in New York and North Carolina, for 8s.; in South Carolina and Georgia, for 4s. 8d. See Exchange.

Pound Flemish, a money of account in Flanders, and a money of exchange at Amsterdam and Hamburg. The pound Flemish is equal to 6 guilders, and is divided into 20 shillings, 120 florins, and 240 pence Flemish, also called groats. (See Rixdollar.) The pound Flemish, or pound Vlams, is reckoned, at Antwerp, at 2½ rixdollars, 6 florins, 20 shillings, 120 florins, 240 groats, or 1920 Drabant pennings. At Hamburg, accounts are sometimes kept in pounds, shillings, and pence Flemish; the pound consisting of 20 shillings, and the shilling of 12 pence or groats; but Flemish money is seldom used here, except in exchanges. The pound Flemish is 2½ rixdollars, 7½ marks, 20 shillings Flemish, 120 florins Lubs, 240 grotes Flemish, 720 dreycings, or 1440 pfennings. The monies of exchange at Amsterdam are florins, florins, and pennings, or pounds, shillings, and pence Flemish. Accordingly 10 pennings = 1 florin; 20 florins = 1 florin or guilder; also 12 grotes or pence Flemish, or 6 florins = 1 shilling Flemish; 20 shillings Flemish, or 6 florins, = 1 pound Flemish; 2½ florins, or 50 florins, = 1 rixdollar.

Pound Nails. See Nails.

Pound, Parcus, is also an inclosure, or strong place, where cattle drained, or caught in any trespas, are put, till they are releved, or redeemed. The pound is either overt, that is, open overhead; or covert, that is, clofe.

Pound Overt is an open pound, built upon the lord's walk; and thence also called the lord's pound, because he provides it for the use of himself, and his tenants. Pound overt also includes back-fides, court-yards, pasture-grounds, or any place whatever, to which the owner of beasts impounded may come to give them meat and drink, without offence or trespas.

By flat, 1 & 2 P. & M. c. 12, no dillrefs of cattle can be driven out of the hundred where it is taken, unlefs to a pound overt within the fame flire, and within three miles of the place where it was taken. This is for the benefit of the tenants, that they may know where to find and repley the dillrefs. And by flat, 11 Geo. II. c. 19, which was made for the benefit of landlords, any perfon draining for rent may turn any part of the premises, upon which a dillref is taken, into a pound pro bice vice, for securing of such dilrefs. If a live dillrefs of animals be impounded in a common pound overt, the owner must take notice of it at his peril; but if in any special pound overt, so constituted for this particular purpofe, the dillriff must give notice to the owner; and in both these cafes, the owner, and not the dillriff, is bound to provide the beasts with food and neceffaries.

Pound Covert, or Clofe, on the contrary, is such a one as the owner cannot come to, for the said purpofe, without trespas or offence; as fome clofe houfe, cattle, fortrefs, &c.

If a dillrefs of animals be impounded in a pound covert, as in a flable, or the like, the landlord or dillriff must feed and fustain them. (Co. Litt. 47.) A dillref of houfhold goods, or other dead chattels, which are liable to be follen or damaged by weather, ought to be impounded in a pound covert, elfe the dillriff muft anfwer for the confquences. See Distrefs.

Pound Breach, in Law. If a dillrefs be taken and impounded, though without just caufe, the owner cannot break the pound, and take away the dillrefs; if he doth, the party draining may have his action, and retake the dillrefs wherever he finds it; and for pound breaches, &c. a writ de parco fialto may be obtained, or an action on the cafe lies, whereon treble damages may be recovered, if the dillref was taken for rent. 1 Inst. 161. 2 W. & M. cap. 5.

Also it is faid, that all pound breaches may be inquired of in the sheriff's tour, as they are common grievances, in contempt of the authority of the law. 2 Hawk. P. C. 67.

Pound Land; of old extent. See Libraria Terra.

POUNDAGE, a fubfidy formerly granted to the king ad valorem, at the rate of 12d. in the pound, upon all manner of merchandise imported or exported, by all merchants, natives, denizens, and aliens. See Custom.

It is called poundage, becaufe fixed at the rate of fo much per pound; viz. one shilling in every pound, or twenty shillings; and for English commodities exported by aliens, one shilling more.

POUNDER, in Artillery, is used to specify a certain calibsr: thus, a twenty-four-pounder, a twelve, or a fix-pounder, are those pieces whose balls weigh twenty-four, twelve, or fix pounds. See Guns and Cannon.

POVOA, in Geography, a town of Portugal, in Estremadura, near the Tagus; two miles N. of Lisbon.

POVOA do AON, a town on the S.W. coast of the island of Zanzibar. S. lat. 6° 20'.

POVOCAO DE NORTE, a town of Brail, in the government of St. Paul, on the N. side of the mouth of the Igua, or Porto de St. Pedro, and 10 miles N. of it.

POUP. See Poop.

POUPART, Francis, in Biography, a celebrated anatomist and physician, was born at Mans, where he received the rudiments of his education under the fathers of oratory. He afterwards went to Paris, where he applied himself, with great avidity, to natural history and philosophy; and, notwithstanding his narrow income, and the little prospects which these studies offered for its improvement, he persevered with ardour in the pursuit. In his researches in natural history, he had been led to the examination and dissection of infects, which turned his mind to the study of anatomy and surgery, as the means of support; for which purpose he presented
POURBUS, Francis, called the younger, who was born in 1570, and who practiced his art with deserved renown and success. He sometimes painted history, but in a formal and dry manner, united with a pleasing kind of colouring.

His own portrait, painted by himself, is honored with a place in the Florentine gallery; and in the French collection are still preferred his portraits of Henry IV. and Catherine de Medicis. In the church of the abbey of St. Martin at Tournay was placed a picture of the Crucifixion, painted by Pourbus, which was very highly commended; but what is now become of it is not known. Pourbus the elder died in 1580, his son in 1622, at the age of 52.

POURCHOT, EDMOND, an eminent French professor of philosophy, was born at Poilly, a village in the diocese of Sens, in the year 1651. At an early age he discovered a great thirst for knowledge, and was sent to pursue his studies at the university of Paris. Here he distinguished himself by his talents and great diligence, and in 1673 he was admitted to the degree of M. A.

In the year 1677 he was appointed professor of philosophy in his own college, whether his reputation soon attracted a multitude of students, and at the opening of the "College des Quatre Nations," he was appointed to fill the philosophical chair in that seminar. M. Pouchot soon became diffamified with the Arifitotelian philosophy, embraced the principles of Des Cartes, applying mathematical principles and reasonings to the discovery of physical and moral truths. He now drew up a system of philosophy, in which his object was to substitute good sense and right reason in the stead of the subtleties which he had been accustomed to teach. The philosophy of our author excited a violent opposition among the professors of the university, who employed themselves in founding the alarm of its dangerous and pernicious tendency. Its admirers, however, both within and without the university, rapidly increased in number. The professor now published his system under the title of "Institutiones Philosophiae," which was very generally applauded, and met with an astonishing sale. His reputation as a philosopher, at this time, stood so high, that his lectures were always attended by a numerous concourse of students. His acquaintance was eagerly courted by the most celebrated literary characters of his time; Racine, Defmaures, Mabilon, Dupin, Baillet, Montfaucon, and Sainte, were his intimate associates. He was honored with the eulog of M. Boffuet and M. de Fencelon. The latter would have procured for him the appointment of tutor to the younger branches of the royal family, but he preferred to employ his talents in the service of the university; and was seven times chosen to fill the post of rector of that body, and was Syndic for the long space of forty years. At a very advanced age he began to apply himself to the study of the Hebrew language, with a degree of ardour which soon enabled him to deliver a course of lectures upon it at the college of St. Barbe. In the midst of his numerous engagements, he found leisure to improve his "Philosophical Institutiones," of which he was preparing the fourth edition for the press, when his eye-light entirely failed him. This melancholy privation he survived between two and three years, and died at Paris in 1734, in the 83rd year of his age. Besides his "Institutiones," he was author of numerous "Difcouriges," which were given to the public in the "Acts of the University," and various "Memoirs." He affiditied the learned Maffon in greatly improving the second edition of his "Grammar of Hebrew," and he aided him in drawing up the Chaldee, Syriac, and Samaritan grammars, which are combined in that edition. Moreli.

Zz

POUR.
POURCOLLY, in Geography, a town of Bengal; 38 miles N.N.E. of Purum.

POURHATO, a town of Chinefe Tartary, in the country of Hami; 23 miles S.W. of Tchontori.

POURINSONG, a mountain of Thibet; 15 miles S. of Skirim.

POURN-TOU-HOTUN, a town of Chinefe Tartary; 18 miles W.N.W. of Nimgouta.

POUROL, a town of Thibet; 35 miles E.N.E. of Tchontori.

POURO-TCHON-TCHI, a town of Thibet; 40 miles S.W. of Tchontori.

POUROUMA, in Botany, Aubl. Guian. t. 341. Juff. 466, a tree of Guiana, with the habit of a Cecropia or Ficus, alternate palmate leaves, and numerous axillary corymbose flowers, whose structure is not sufficiently explained by the above authors.

POUR-PARTIE, or Pour-party, in Law, a term used in opposition to pro indeviso; denoting the share or part of an estate held in common by parceners; which is by partition allotted to any of them.

To make pour-party, is to divide and sever the lands that fall to parceners; which, before partition, they held jointly, and pro indeviso.

POURPRE. See POURPRE.

POURPRESTURE, or PURPRESTURE, Pourprestress, from the Fr. pourpre, an inclosure, in Law, is defined by Glanville to be, when any thing is unjustly occupied, that properly belonged to the king; as is the cafe in the encroaching on his grounds, obstructing the highways, diverting public rivers from their proper course, or building any thing over the high streets of a city; and, in the general, where any thing is done to the prejudice of the king's tenements, highways, or cities.

Crompton, in his Jurisdict, says, pourprestress is properly when a man takes to himself, or encroaches any thing which he ought not; whether it be in jurisdiction, in land, or in franchise; and generally, where any thing is done to the nuisance of the king's tenants.

Some authors divide pourprestress into three kinds: the first against the king, the second against the lord, the third against a neighbour.

Pourprestress against the king, Lib. Nig. in Scacc. fol. 38. is that happening through the negligence of the sheriff, or the long continuance of wars, &c. when those that have lands near the crown-lands, inclose part of them, or lay them to their own. Pourprestress against the lord, is when the tenant neglects to perform what he is bound to do for the chief lord, or deprives him of his right. Pourprestress against a neighbour, is a nuisance against a neighbour, &c. mentioned in the Monast. tom. i.

Gen. Ch. Cal. Perianth inferior, simple, of one leaf, in five deep, ovate, permanent segments. Cor. Petals five, lanceolate, acute, attached to the tube of the filament. Stam. Filaments numerous, united below into a cylindrical tube; anthers ovate, erect. Pyt. German superior, small, ovate, pentagonal; style cylindrical, longer than the stamens; stigma capitane. Peric. Capsule of one cell, not burbling, with five large, rounded, membranous, vein, longitudinal wings. Seed solitary, oblong, striate, with plaited rugous cotyledons.

1. P. arborea.—Native of Peru.—The wings of the fruit are each four inches long and two wide; the seed measures about an inch. We have no account nor figure of the foliage. The flowers are about an inch long.

POURSUIVANT, or Pursuivant, from the French poursuivre, to pursue, a meffenger, anciently attending the king in his wars, or at council table, or in the exchequer, to be dispatched upon any occasion, or meffage; as, for the apprehension of a person suspected, or accused, &c.

Many of the nobility, too, had their poursuivants; a knight banneret was allowed a poursuivant, with the confection of a herald.

Upton, De Re Militari, calls the poursuivants, milites linguae; because, says he, their chief honour was in eystodia lingue. He divides them into foot and horse poursuivants, curfures equitantes et prefectores.

There were also poursuivants particularly employed in martial causes, called

Poursuivants at Arms, a term anciently applied to gentlemen who attended the heralds, and aspired to their office; to which they could not rise, till after seven years apprenticeship paffed in this quality. See Herald.

They were entirely dependent on the heralds, and aspired at their chapter; officiating for them in preparing and assigning tournaments, and all other parts of their ministr.

They were baptized, at solemn feasts, with some gallant name; as Jolicceur, Verluisant, Sanmentin, &c.

Their coats of arms were different from those of the heralds, and they bore plain faves, without ornament.

The term poursuivant, or pursuivant, is probably of French extraction, and is derived from pour, for, and suivre, to follow after; and it is applied to the officers now mentioned, as fome fay, because they attended in the retinue of princes and followed them into the country, to obferve and record the memorable actions that occurred in jufts and other august solemnities; or, as others conceive, because they followed the heralds, to whom they were fersies, actuated, or amanuens, a fort of clerks, apprentices, and novications, candidates and probationers for the office of herald upon a vacancy. Accordingly they have been denominated les aides des herants, from their waiting upon them, and herals are under an obligation of performing their functions either personally, or by their poursuivants, there being formerly one under each herald. Although the original of these officers has not been precifely ascertained, it is reafonable to believe that they are coeval with the heralds, on account of their dependence upon them, and of the ancient institution by which one was made the neceffary step to the other. This office hath, for some centuries, been esteemed the loweft degree of the officers of arms, or the next degree under an officer of arms, and the first step of probation for promotion. Their qualifications, as candidates for future promotion, with regard to parentage and birth, morality, capacity, and competency of age, have been formally and amply flated by ancient authors. Thefe qualifications were formerly fo much the objects of attention, that it was neceffary for each candidate to produce a certificate attesting them. Anciently the term of noviciate was, as we have already faid, seven years; after the expiration of which, and not sooner, the poursuivant was eligible to the office of herald; but in later times, and especially in this kingdom, it has been determined by a judgment in Wett-
minster Hall, that a person may lawfully be made directly, "per saltum," an herald, without being ever a pourfuviant.

Of the great number of pourfuvants annually fubfiding, there are now only four remaining; blue-mantle, rouge-croix, rouge-dragon, and port-cullis; who are the lowest order of officers belonging to the college of arms. Their duties is, to attend with the heralds in marshalling and ordering public solemnities, funerals, interviews, cavalcades, &c.

The four officers, under these denominations, have had a succession, with little interruption, and have been allowed salaries from the crown for some ages; and their titles are taken from the badges of the sovereign, or of the kingdom, or the mantle, supporter, or device of the king. For the title and office of Blue-mantle, see that article.

"Rouge croix," or "Red crofs," is, according to Sir Henry Spelman, the most ancient title of a pourfuvant, and was taken, without doubt, from the arms ascribed to St. George, the tutelar saint of this kingdom, being argent, a crofs gules. This officer was instituted by Henry V.; and from that time the succession was regularly continued until the month of April 1644, from which year this place lay vacant until the restoration, when it was revived.

"Rouge dragon," or "Red dragon," was instituted by Henry VII. on the day preceding his coronation, and denominated from the ensign of Cadwallader, from whom that king sprung in a male line. Some indeed, as Sir H. Spelman, trace its origin to the right supporter of Cadwallader's shield, which supporter was itself ascribed from his ensign; and others, to the banner ascribed to St. George. From the first year of Henry VIII., the names of the several officers are regularly mentioned, and it does not appear, that the office itself hath been in abeyance at any time since its establishment.

"Port-cullis" pourfuvant was likewise erected by Henry VII., and so denominated from that timber instrument or machine, plated over with iron, made in the form of a harrow, hung up with pulleys in the entrances of cattles, to be let down on any occasion (see Portcullis); and which instrument was one of the badges of that king, the same defending to him from the Beauforts by his mother. The succession in this office has never been interrupted since the institution.

Besides the pourfuvants already mentioned, several others occur in our records, under titles, the significations of which are as difficult to be explained as it is to ascertain whether the persons so distinguished were English or foreign officers, or belonged to sovereigns or subjefts. There have been also pourfuvants, as well as heralds, belonging to the prince of Wales, and to the nobility.

Stow, speaking of Richard the Third's end, has these words: "His body was naked to the skin; not so much as one clot about him; and was trussed behind a pourfuvant at arms, like a hog, or a calf."

POURTRAIT, or PORTRAITURE. See Portrait and Portraiture.

POURVEYANCE, or PURVEYANCE, the providing of corn, victuals, fuel, and other necessaries, for the king's houfe. See Revenue.

By a fl. 12 Car. II. cap. 24. no perfon, under colour of pourveynce, shall take any timber, cattle, corn, or other matter, from any subject, without his free consent.

POURVEYOR, or PURVEYOR, an officer of the houfehold, who provides and buys in corn, and other victuals, &c. for the king's houfe; mentioned in Magna Charta, and several statutes.

Pourveyor became a term fo odious in times past, that by flat. 35 Ed. III. the heinous name pourveyor was changed into that of accessor, or buyer. The office itself was much restrained, and even abolished, by the flat. 12 Car. II. c. 24. See PREMUNIRE.

POUSSE, Piet, in Natural History, the French name for a genus of shell-fish, called by writers of other nations the ophiceps.

POUSSEIN, Nicholas, in Biography. This eminent painter was born at Andille, in Normandy, in 1594. Felibien says that he was descended from a noble family, which was reduced in property during the civil wars of the period preceding. He was first instructed in the art (for which he exhibited an inclination at a very early period) by Ferdinand Elle, a Flemih portrait painter, but his ideas of painting soon outran his master's powers, and having acquired friends who lent him prints from Raphael and Julio Romano, he eagerly studied to acquaint himself with their principles of composition, and soon imbibed sufficient to express his thoughts with ability.

He had, at the age of 18, left his father's house privity; not having the sanction of his parents in the pursuit of his favourite design. He first went to Paris, and afterwards accompanied a young seigneur into Poitou; but a fit of ill-necessies obliged him to return home. On his recovery he again reached Paris; and Felibien states, that he then went towards Rome, but was, by some accident, prevented going farther than Florence. He then remained in France till 1624, and in that year attained the summit of his wishes, by arriving in the grand emporium of the arts, the city of Rome.

During his latter residence at Paris, he had acquired the friendship of Marino the poet, and had resided for some time in his house. He would also have accompanied him on his return to Italy, but was prevented by his engagements. When he arrived at Rome, his friend was unhappily in a severe state of illness, which terminated in death; but before that occurred he placed his favourite artift under the protection of cardinal Barberini, nephew of pope Urban VIII. Of the benefits which Poussin might reasonably have hoped to derive from this advantageous connection he was deprived, by his patron being dismissed on a legation from the pope; and our painter was thus left without friends in Rome. The confolution was extreme distress, and the obligation to difpofe of his paintings at very low prices. Felibien says that he sold the two battle pieces which were in possession of the duke de Noailles, at the trilling sum of seven crowns each; and a picture of a prophet for eight livres. Content, however, with the means of satisfying the claims of nature, he eagerly devoted himself to study; copied several of the renowned pictures of his predecessors, those particularly by Titian, Domenichino, and Raphael, and drew fiores of materials for his future labours, by giving clifte attention to ancient sculpture; living a life of privacy and retirement. He lodged with J. Flamingo, the sculptor, and they together sometimes engaged themselves in measuring antique statues; but most chiefly his studies were solitary; applied to nature or to art, as they preferred themselves. By accumulation of means, thus judiciously fought, and afterwards ingeniously applied, Pouslin became the admired and original artift we now know him to be; the head of a class distinct from all others, and which has been rarely entered by subsequent professors. His love of simplicity and of nature led him to disregard the falle glane of the artifts who then held the foremost ranks in reputation; and in whose hands the art had dwindled to a fyllematic exhibition of the power of the pencil; rather than of sentiment or passion. His meed of praise...
praise is therefore the greater, since he made a certain sacrifice of present profit, in the hope of restoring the art he professed, to a just elevation in the scale of utility.

The learned profession of painting in the Royal Academy has, in his last edition of Pilkington's dictionary, summed up the character of Poulin with his accustomed acumen. "He was," says he, "on his arrival at Rome, an artist already formed, but soon found that he had more to unlearn than to follow of his former principles; he renounced the national character," (he might have added those of the existing schools of Italy,) and not only with the utmost ardour adopted, but suffered himself to be absorbed by the antique.

Such was his attachment to the ancients, that he may be said to have often left imitated their spirit, than copied their relics, and painted sculpture. Their costume, their mythology, their rites, were his elements. His backgrounds are pure classical ground. He has left specimens which prove that he was sometimes sublime in his conceptions, and often in the highest degree pathetic; but history, in its strictest sense, was his department, and in that he ought to be followed. In the dramatic representation of Raphael, the action is introduced merely to throw the actors; the agents of Poulin only appear to tell the fact; they are subordinate, they are instruments of the story; generally clear, connected, judicial; he has however sometimes attempted to tell a tale that cannot be told; sometimes obscured one that was clear in itself, by an ostentatious display of erudition; and not seldom, sacrificed the principal figures, to collateral and inferior beauties. If the celebrated series of sacraments are models of historic perfidity; if the Ahafuerus, the deluge, the vision of Coriolanus, the infant Pyrrhus, are full of sublime and pathetic features, the vain attempt to tell by figures, what words only can tell, is proved in the treatment of Eudrunias; and in the story of the adulterous woman, Christ is debased to the character and the gesticulations of an Italian juggler.

"Though Poulin abstracted the theory of his proportions from the antique, he is seldom uniform and pure in his style of design; ideal only in parts, and often so in female than in male characters; he supplies, like Pietro Testa, antique heads and torsoes, with limbs and extremities transcribed from the model. As a colourist he was extremely unequal. Into the deluge, and the plague of the Philistines, he transmuted the very hues of the elements whose ravages he represented, whilst numbers of his other pictures are deformed by crudity and patches.

"The excellence of Poulin in landscape is universally allowed, and when it is the chief object of his picture, precludes all censure; but considered as the scene or background of an historical subject, the eave with which he executed it, the predilection which he had for it, often made him give it an importance which it ought not to have; it divides our attention, and from an accidency, becomes a principal part."

On the return of the cardinal Barberini to Rome, the merit of Poulin was rescued from the oblivion in which it had been sunk. He was liberally employed by his elevation; induced freely to exhibit those treasures which his unceasing studies had accumulated; and from this time enjoyed the full reward of his industry and ingenuity, by a continued series of honours and emolument.

His fame, and many of his Italian pictures, reached his native country, and the king desiring to have his aid in cultivating the arts in France, wrote him a letter defining his return, with which, after much hesitation, Poulin complied, and arrived in France in 1640. He was immediately employed by the court, and experienced the usual accomplishment of court favour, envy, which caused him enemies. Vouet among the painters, and Mercier among the architects, criticized his works with ill-natured severity, because his taste was too pure for their understandings, and by their interest caused him so much disquietude, that he requested, and obtained, permission to return to Rome, which he did in November 1642, and never more revisited his native country; but lived till he attained his 72d year in his beloved Rome, exercising his art with esteem and respect, till within a few months of his decease.

POUST, an Indian name for a very poor and coarse kind of opium made by boiling the flanks and leaves of the opium poppy in water, and then evaporating the clear liquor to the constancy of a solid extract.

POUSTANG, in Geography, a mountain of Thibet. N. lat. 31° 46'. E. long. 97° 39'.

POUTA, a town of Prussian Pomerelia; 20 miles S.S.W. of Dantiziek.

POUT-TEOU. See Poo-Too.

POUTERIA, in Botany, Aubl. Guian. t. 33. Juff. 156, is CHATROCARPUS of Schreber.

POUTING, or Whiting Pou, in Ichthyology, a name given to a species of gadus, which seldom exceeds a foot in length. See GADUS Barbatus.

POUTON, LA, in Geography, a town of France, in the department of Finifterre, and chief place of a canton, in the district of Morlaix. The place contains 212, and the canton 10,361 inhabitants, on a territory of 125 kilomètres, in seven communes.

POUTROY, LA, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Colmar. The place contains 2064, and the canton 10,623 inhabitants, on a territory of 160 kilomètres, in five communes.

POUZAUGES-LA-VILLE, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Fontenay-la-Comte; nine miles N.W. of La Châtaignarye. The place contains 220, and the canton 15,538 inhabitants, on a territory of 380 kilomètres, in 18 communes.

POUZILHAC, a town of France, in the department of the Gard; 8 miles E.N.E. of Uzés.

POUZIN, LA, a town of France, in the department of the Ardèche; six miles N.E. of Privas.

PowaNGUR, a town of Hindooftan, in Guzerat; 60 miles S.E. of Amadabad. N. lat. 22° 26'. E. long. 73° 32'.

POWAY, a town of Hindooftan, in the círcar of Gurah; 32 miles W. of Mahur.—Allo, a town of Hindooftan, in Allahabad; 24 miles N. of Jooapoor.

POWCHES, in a Ship. The feamen call by this name the small bulk-heads made in the hold, to flow corn, goods, or the like, that it may not shoot from one side to the other.

POWDER, or Pouder, in Pharmacy, a dry medicine pulverized, or prepared by being broken and reduced into almost imperceptible atoms, either in a mortar or by chemical operations, &c.

This form of preparing is, upon the whole, the most simple, and in various respects the least objectionable; but many substances cannot be either conveniently or beneficially employed in this manner. Those that are bitter, acid, and fætid, and of course unpleasant to the taste; those that rapidly deliquate when exposed to the air, or are very volatile; and those which require to be given in large doses,
or which do not readily dissolve in water, belong to this class. Others cannot be reduced to powder without being much dried, and heat alters their properties; others again, particularly some resinous substances, are injured by the impalpable form of powders; and many are deteriorated by exposing their surfaces, in the operation of pulverizing them, to the action of atmospheric air, such are cinchona, rhubarb, ipecacuanha, and guaiacum. To prevent the injurious effect of air and light, powders should be generally kept in opaque or green-glass bottles: and in forming compound powders, the admixture should be rendered as complete as possible, and the mixed powder, after trituration, should be passed through a sieve. The Dublin college lays down the following general rule for the formation of powders: *Let the substances to be powdered be first dried, and then beaten in an iron mortar; then separate the finer powder by shaking it through a hair-sieve, and preserve it in close vessels.*

The lighter powders may be mixed in any agreeable liquor, as tea, or water-gruel. The more ponderous will require more confident vehicle, as syrup, jelly, or honey. There are powders of various sorts, the principal of which are mentioned in the following articles and references.

**Powder of Algaroth.** See Algaroth.

**Powder of Aloes, Compound.** is prepared, according to the directions of the Lond. pharmacoepia, by powdering an ounce and a half of the extract of spikenard aloes and an ounce of guaiacum gum-resin separately, and then mixing them with half an ounce of the compound powder of cinnamon. This is the pulvis aloes cum guaiaco of P. L. 1787; pilulae aromaticae of P. L. 1745; and pilulae de diambræ of P. L. 1720.

The Dublin college directs this powder, denominated powder of aloes with guaiacum, to be prepared by rubbing an ounce and a half of hepatic aloes, and an ounce of guaiacum gum-resin separately to powder, and then mixing them with half an ounce of aromatic powder. These powders are warm sordoric cathartics, and may be given in doses from grs. x to 9j; but are not much in use. See Aloes.

**Powder of Aloes with Canella.** is prepared, according to the Dublin Ph., by rubbing one pound of hepatic aloes and three ounces of white canella separately to powder, and then mixing them. This is omitted in the last Lond. pharmacoepia. In the shops it has been long known under the name of *Hiera picnicum,* and is used as a domestic remedy, infused in wine or spirits. The dose may be from grs. x to 9j.

**Powder, Amber, or Pulvis e succino.** is a form of medicine preferred in the late London pharmacoepia, in the room of the troches of amber, or trochisci de carabe of former dispensatories. The composition of the powder is this: take prepared amber and gum arabic, of each ten drachms; juice of hypococitus, balatafines, and Japan earth, of each five drachms; olbanum, half an ounce; strained opium, a drachm; mix these together into a fine powder. Pemberton's *Load.* Diph. Amber, though formerly much esteemed as a medicine, is now only used in pharmacy, for obtaining the oil and acid which it yields by distillation.

**Powder, Antimonial.** See Antimony and James's Powder.

**Powder, Aromatic, of the Edinb. Ph.,** is prepared by rubbing equal parts of cinnamon bark, cardamom seeds, and ginger-root to a very fine powder, which is preferred in a well-stopped phial. That of the Dub. Ph. by rubbing together an ounce of cinnamon bark, and lefier car-
danm seeds freed from the hulls, ginger and long pepper, of each an ounce, to a powder. These combinations of aromatics are stimulant and carminative, and may be used to promote digestion and expel flatus in cold phlegmatic liabits; but they are more generally employed to give warmth to other compositions. The dose is from grs. viij to 9j, given in the form of bolus, or diffiluted in water.

**Powder, Aromatic Purging, is formed by pounding and well mixing the bell Turkey rhubarb, cinnamon, and fine fugar, of each two drachms.** Where flatulence is accompanied with colic, a tea-spoonful of this powder may be taken once or twice a-day, according to circumstances. Buchanan.

**Powder, Afrarabaccæ, Compound,** is prepared, according to the Edinb. Ph., by rubbing three parts of the leaves of afrarabaceæ and one part of the leaves of marjoram, and the fame of thole of lavender, together to a powder. The Dublin college directs one ounce of dried leaves of afrarabaceæ and two drachms of lavender flowers dried together to a powder. A few grains of this powder snuffed up the nostrils for several successive evenings at bed-time, excite feezing and a copious discharge of mucus, which continues to flow on the succeeding days. It has been particularly used in tooth-ache and chronic ophthalmia. See *Asarum.*

**Powder, Astringent, is formed by pounding together alum and Japan earth, of each two drachms.** If the whole be divided into ten or twelve doies, one of them may be taken every hour in an immoderate flow of the menes, and other hemorrhages, or every half hour, if the hemorrhage be violent.

**Powder of Balsam is formed by pulverizing the following ingredients, viz., bole armenic, or French bole, two ounces; cinnamon, one ounce; tormentil root, and gum arabic, of each six drachms; and long pepper, one drachm.** This warm, glutinous, astringent powder, is given in fluxes, and other disorders, where medicines of that class are necessary, in the dose of a scruple, or half a drachm. A powder of this kind is preferred in the late London pharmacoepia, instead of the confecit Frascaflorii, or diaecordium. If a drachm of opium be added, it will make the powder of bole with opium, which may be taken in the fame quantity as the former, but not above twice or thrice a-day. Buchanan. See Compound Powder of Chalk, infra.

**Powder, Bezœaridis, the name given in the late London Dispensatory to the powder, commonly called Gafcoign's powder.** This is now ordered to be made only of crab's claws, one pound; prepared pearls and red coral, of each three ounces; and oriental bezoar, an ounce. The amber and hartshorn are left out of the composition, as improper inefficacious ingredients; and the whole ordered to be kept also without the bezoar, and called by the name of *pulvis e chelis carboniæ compositus,* the name by which Gafcoign's powder used to be known.

**Powder of Carbonate of Lime, Compound, formerly Cretaceous powder, is prepared by the directions of the Edinb. Ph. by rubbing together four ounces of prepared carbonate of lime, one drachm and a half of cinnamon bark, and half a drachm of nutmegs to a powder.** See Compound Powder of Chalk, infra.

**Powder, Carminative, is made by reducing half an ounce of coriander seed, one drachm of ginger, half a drachm of nutmegs, and a drachm and a half of fine fugar into a powder; which quantity will be sufficient for twelve doies. It is employed for expelling flatulencies arising from indigestion, particularly those to which hysteric and hypochondriac permons are fo liable. It may be likewise given in small quantities.
quantities to children in their food, when troubled with
gripes.

Powder, Carthubian. See Antimony, and Kermes
Mineral.

Powder of Caffia. See Cassia's Purple Powder, and
Gold.

Powder, Cerussa, Pulvis e cerussa, a medicine prescribed
in the late London pharmacopeia, in the place of the
white troches of Rhazes or Razi. The late compositions
of that medicine had been much more complex than the
original receipt of that author, and the college have there-
fore retrenched the number of ingredients in them; and as
the medicine is always to be powdered for use, it is now
ordered to be kept in the form of powder. It is thus
ordered to be made: take cerussa, five ounces; farocolla,
an ounce; gum tragacanth, half an ounce; and make the
whole into a fine powder. Pemberton. It is omitted in
the recent dispensatories.

Powder of Chalk, Compound, is prepared, according to
the Lond. Ph. by rubbing separately half a pound of prepared
chalk, four ounces of cinnamon bark, tormentil root, and
acacia gum, of each three ounces, and half an ounce of
long pepper, to a fine powder, and then mixing them.
This preparation containing a larger proportion of aro-
matics than the compound powder of carbonate of lime,
above mentioned, and the addition of the tormentil root, is
better adapted for checking diarrhea connected with acidity
of the prime viile, than that of Edinburgh, which is a
simple but grateful antacid. The dose is from grs. v to
3j, given in the form of mixture rubbed up with mucil-
age and diffused water.

Powder of Chalk with Opium, Compound, of the L. P.
is prepared by mixing fix ounces and a half of compound
powder of chalk, with four scruples of hard opium pow-
dered. The addition of opium renders it more proper for
diarrhea than the former, and as the quantity of opium is
small, one grain only being contained in two scruples of the
powder, this is an useful opiate powder for children, when
affected with the irritative diarrhea of teething. The dose
is from 2j to 3j for adults.

Powder of Cinnamon, Compound, is prepared, according
to the L. P. by rubbing together two ounces of cinnamon
bark, one ounce and a half of cardamom seeds, one ounce
of ginger-root, and half an ounce of long pepper, to a
very fine powder. See Aromatic Powder, infra.

Powder of Contraervia, Compound, is prepared by mixing
five ounces of contrayerva root powdered with a pound
and a half of prepared shells. (See Contraervia.)
This powder is stimulant and sedative; and is given with
advantage in typhoid fevers, the malignant exanthema, the
finking flage of dysentery ; and in atomic gout. The dose
is from grs. x to grs. xi, given either diffused in simple
water, or rubbed up with mucilage and mint water.

Powder, Cornacine. See ConnaCine.

Powder, Diuretic, is made by pounding together four
ounces of gum arabic, and one ounce of purified nitre. If
the whole be divided into twenty-four doses, one may be
taken three times a-day, with considerable benefit, during
the first flage of the venereal diseace. Buchan.

Powder, Emetic. See Emetic, and Powder of Ipecac-
uanba.

Powder, Gascoign's. See Gascoign, and Bezawiric
Powder.

Powders, Gout, by Dr. Dover, and lord Portland.
See Dover's Powder, Gout, and Powder of Ipecacuanha and
Opium, infra.

Powder, or Pulvis Guttae. See Guttete Pulvis.

Powder of burnt Hartshorn, Pulvis corne cervini ulii, is
formed, according to the D. P., by burning pieces of
hartshorn until they become white, and then reducing them
to fine powder.

Powder of burnt Hartshorn with Opium, is prepared, ac-
cording to the L. P., by mixing a drachm of hard opium
powdered; an ounce of hartshorn burnt and prepared; and
an ounce of cochineal powder. See Hart's Horn.

Powder, Opiae, of E. P., is formed by rubbing together,
to a fine powder, one part of opium, and nine parts of
prepared carbonate of lime. Ten grains of either of these
powders contain one grain of opium, and they are intended
for exhibiting opium in very small doses. The substan-
ces that are used for dividing the opium, are of no confence
as to the effect of the remedy; and, therefore, the burnt
hartshorn being more brittle than the chalk, is better fitted
for this purpose.

Powder, Jesuits'. See Cinciona.

Powder of Jalap is prepared, according to the E. P.,
by rubbing together, to a fine powder, one part of jalap
root with two parts of supertartrate of potasfs. The su-
per tartrate serves not only to divide the jalap very minutely,
but to modify its purgative operation. This powder is an
useful purgative in habitual constiveness: it is also very
useful to children with tumid belly, in worm cafes, and in
dropsy. The dose is from 2j to 3j for adults. See Jalap.

Powder of Ipecacuanba, Compound, is prepared, accord-
ing to the L. and D. P., by mixing ipecacuanba root pow-
dered, and hard opium powdered, of each a drachm, with
an ounce of powdered sulphate of potasfs.

Powder of Ipecacuanba and Opium, formerly Dover's
powders, (which see,) is directed by the Edinb. college to be
prepared by rubbing together into a fine powder ipecacuanba
root powdered and opium, of each one part, with eight
parts of sulphate of potasfs. This powder operates as a
powerful sudorific, and is often given, with this intention,
in acute rheumatism, gout, dropsy, dysentery, and in all
cases, whether inflammatory or not, where profuse sweating
is required. The dose is from grs. v to 3j, given diffused
in water, or in the form of bolus, and diffused with plentiful
dilution of tepid fluids, drank some time after taking the
powder, let it should be rejected from the stomach. Ten
grains of this powder contain one grain of opium. See
Dover's Powder.

Powder of Kino, Compound, is formed, according to the
L. P., by rubbing separately into a fine powder, 15 drachms
of kino, half an ounce of cinnamon bark, and one drachm
of hard opium, and then mixing them. This is an allringent
powder, now first introduced into the pharmacopeia; the
proportion of opium it contains is 1 in 20: the dose is
from grs. x to 3j.

Powder of Myrrh, a form of medicine prescribed in the
late London Dispensatory, to supply the place of the
troches of myrrh. It is ordered to be made thus: take of
dried leaves of rue, of dictany of Crete, of myrrh, each
an ounce and a half; of alsa-feitida, fagapenum, Rudia
castor, and opoponax, each an ounce; and beat altogether
into a fine powder. Pemberton.

Powder, Saline Laxative, is prepared of soluble tartar
and cream of tartar, of each one drachm, and of purified
nitre, half a drachm. In fevers, and other inflammatory
disorders, where it is necessary to keep the body gently
open, one of these cooling laxative powders may be taken
in a little gruel, and repeated occasionally. Buchan.

Powder of Scammony, Compound, is prepared, according
to the L. P., by reducing separately into a fine powder
scammony
flacmony gum-resin, and hard extract of jalap, of each two ounces; and ginger-root, half an ounce; and then mixing them. This powder differs materially from the "pulvis e flacmonio compostiis of P. L. 1745," which was then intended to supply the place of the earl of Warwick's powder, and consisted of a mixture of four parts of flacmony, and three of burnt hartthorn. In the E. P. it is directed to be prepared by rubbing together, to a very fine powder, equal parts of flacmony and superfaterrate of potash. These two powders of the L. and E. P. differ very materially in their nature and effect, though they bear the fame name. In the first, the activity of the flacmony is aided by the jalap, as its gripping effect is in some degree mitigated by the ginger. In the second, the superfaterrate of potash renders the operation of the flacmony less violent and less irritating, and yet more certain. The dose of the first is from grs. x to grs. xv; that of the second from grs. x to 3s. They are chiefly used in hydroptic and worm fevers, and to remove mucous obstructions.

Powder of Squill is directed by the D. P. to be prepared by first drying squill roots (bulbs), freed from their membranous integuments, and cut in transverse slices, upon a sieve with a low degree of heat, and then reducing it to powder, which must be preserved in well-stopped glas phials.

Powder of Senna, Compound, of the L. P., is to be prepared by reducing to fine powder half an ounce of flacmony gum-resin separately, and the other ingredients, vis. seven leaves and superfaterrate of potash, of each two ounces, and of ginger-root two drachms, together; and then mixing them. This powder is hydropoet and cathartic; but the bulk of the dose, though it weighs only from 3½ to 5½, renders it inconvenient for use.

Powder of burnt Sponge is prepared, according to the D. P., by cutting a sponge in small pieces, and beating them so as to free it from little flies; then burning it in a covered iron vessel, until it become black and friable, and finally reducing it to powder.

Powder, Steel, is made by pounding together filings of lead and loaf fugar, of each two ounces, and half an ounce of ginger. In obstructions of the menes, and other fevers where feele is proper, a tea-powfouf of this powder may be taken twice a-day. Duchan.

Powder, Stryph. See STYPHIC.

Powder, Suffolk. See SUFFOLK Powder.

Powder of Sulphate of Alum, Compound, formerly called "Stryph powder," is prepared, according to the E. P., by rubbing together, to a fine powder, four parts of fullphate of alum, and one part of kino. This is a powerful astringent, and is sometimes used internally in chronic diarrhea; but it is more generally employed as an external application. The dose is from grs. x to grs. xv, to be taken in a dry flake, because the kino is decomposed by the alum, when a fluid vehicle is employed.

Powder, Sympathetic. See SYMPATHETIC.

Powder of Tragacanth, Compound, is formed, according to the L. P., in the following manner: take of tragacanth powdered, acacia gum powdered, and starch, of each an ounce and a half, and three ounces of refined fugar. Powder the starch and fugar together; then add the tragacanth and acacia gum, and mix the whole. The tragacanth is not reducible to powder without great difficulty. Ten grains of this compound renders a bulk of two fluid ounces of liquid as thick as it can be conveniently taken. The starch, which is insoluble in cold water, might be omitted. This powder is efficaciously used as a demulcent in hectic fever, and to allay the tickling cough of catarrh; in gonorrhoea and strangury, it is given, combined with nitre, and in dysentery, with ipecacuanha powder. The dose is from 3½ to 3ij, mixed in water, or any bland fluid.

Powders, Worm, are formed by well mixing of tin, reduced into a fine powder, an ounce, and of Ethiope mineral, two drachms. Let the whole be divided into six doses: and one of them may be taken in a little syrup, honey, or treacle, twice a-day. After they have been all used, the following anthelmintic purge will be proper.

Powder, Purging Worm, is prepared of powdered rhubarb, a scruple; and of flacmony and calomel, of each five grains. Rub these together in a mortar for a dose. For children the above doses must be lessened, according to their age. If the powder of tin be given alone, its dose may be considerably increased. Dr. Allston gave it to the amount of two ounces in three days, and says, when thus administered, that it proved an excellent anthelmintic. He used to purge his patients both before they took the powder, and afterwards.

Powder of Yellow Bladder-wrack, Pulvis quecus marine, is directed by the D. P. to be formed in the following manner: take of bladder-wrack, in flower, any quantity: let it be dried, and freed from the forbes, then exposed to heat in an iron vessel, or a crucible, to which is adapted a perforated lid, until the vapour ceasing, it becomes obscurly red-hot: reduce the carbonaceous matter which remains to powder. This powder is a mixture of foda and charcoal. The burnt sublince is confided as obdubtruent, and has been exhibited in scrophulous affections, and bronchocele; and Dr. Rusfvel found the mucus of the vehicles an excellent resolvent when externally applied to scrophulous swellings.

Powder for the Hair, is flour of wheat, or beans, well sifted and prepared, to give it an agreeable odour.

That in which farb-grounds are mixed is much used.

See STARCH.

Powder, Fulminating. See Pulvis Fulminans.

Powder, Gun. See GUNPOWDER.

Powder-Cart, in Artillery, a two-wheel carriage, covered with an angular roof of boards; and to prevent the powder from being damp, a tarred canvas is put over the roof. On each side are lockers to hold shot, in proportion to the quantity of powder, which is generally four barrels.

Powder-Chests, in the Sea Language, are small boxes filled with gumpowder, pebbles, old nails, or splinters of iron, fastened occasionally on the decks and sides of a ship, which they set fire to, when the ship is boarded by an enemy, and soon make all clear before them. These cases are usually from twelve to eighteen inches in length, and about eight or ten in breadth, having their outer, or upper part, terminating in an edge. They are nailed to several places of the quarter, the quarter-deck, and bulk-head of the waist, having a train of powder, which communicates with the inner apartment of the ship, so as to be fixed at pleasure to annoy the enemy. Falconer.

Powder-Flasks, in Artillery, are most commonly made of horn, of any convenient size and figure, to carry powder for priming of cannon: this is their chief use in armies.

Sometimes they are so made as to have a measure for the charge of the piece at top, but this is of more use to gentlemen in fowling, &c. than to soldiers, who have the charges of their piece put into cartridges, which they bite off, and first prime, and then load.

Powder-Magazine. See Magazine.

Powder-Mill. See Mill, and Gunpowder.
POW

Powder, Room, in a Ship, that part of the hold in which the powder is stowed. See Magazine.

Powder of Projection. See Projection.

Powders, Fluf. See Flux.

Powderings, in Buildings, a term sometimes used for devices serving to fill up vacant spaces, in carved works; as also in escutcheons, writings, &c.

Powderings, in Heraldry. See Ferr.

POWELL's Creek, in Geography, a river of America, in the state of Tennessee, which rises in Powell's mountain, runs S.W., and enters Clinch river, through its N. bank, 38 miles N.E. of Knoxville: it is said to be navigable in boats 100 miles. America has also other creeks of the same name; one in Virginia, which runs into James river, N. lat. 37° 13'. W. long. 77° 21'; and another in Pennsylvania, which runs into the Susquehannah, N. lat. 40° 23'. W. long. 77° 1'.

POWELL's Key, a small island among the Bahamas. N. lat. 26° 49'. W. long. 77° 30'.

POWELL's Point, a cape on the coast of North Carolina, at the entrance into Albemarle found. N. lat. 36° 1'. W. long. 76° 4'.—Alfo, a cape of Virginia, in James river. N. lat. 37° 2'. W. long. 76° 24'.

POWELL's Valley, a district of America, which lies between Powell and Cumberland mountains, between 80 and 90 miles in length, and from 10 to 18 wide, and which is almost equally divided between Virginia and Tennessee. The soil is easily cultivated, some parts of it being of the best quality. The water is good and plentiful, and the air is salubrious. It produces grain, corn, grass, flax, hemp, fruit-trees, &c. and the Tennessee part yields cotton. It is furnished with good stone quarries, and good timber for building, and has a good outlet for boats by means of Powell's river, which is well stocked with fish. About the middle of the valley is a natural bridge, over a small creek, formed by three regular arches, 50 feet long, 40 high, and 20 wide.

POWELL, DAVID, in Biography, an ancient antiquary, was born in Derbyshire about the year 1552, and was educated at Oxford, where he took his degree of D. D. He died in 1590, and was buried in the church of Ruabon, in Denbighshire, of which he was vicar. He published "Caradoc's Hiftory of Wales in 1584;" "Annotationes in Itinerarium Cambriam Scrip per Giraldum;" "De Britannica Hiftoria recte intelligenda."

POWELL, WILLIAM SAMUEL, was born at Colchester in 1717, and educated at St. John's college, Cambridge, of which he became successively fellow and master. In 1766 he obtained the archdeaconry of Colchester, and other prebendaries. Dr. Powell published a famous sermon on subscription to the articles, and other discourses. The doctor contended that young persons might subscribe on the authority of others; which, says Mr. Archdeacon Blackburne, might be liable to the reprobation which was made to biphop Pierce, by a poor man, who was required to attend to the contents of the book of Common Prayer, at the time of the infamous Bartholomew act. The man begged first to read it; "You have already read it," replied the prelate, "by the mouth of the convocation, which is your representative."—"If that be the cafe," said the man, "let it suffice for me to affent to it by the mouth of the convocation." Blackburne's Works, vols. v. and vii.

POW, LIONEL, author of one of the Tracts in the celebrated musical MS. of Waltham Holy-Crofts, in Essex; which upon the supposition of the monasteries, became the property of the venerable Tallys, whose name appears in his own hand-writing on the back of the leaf. Morley seems to have consulted this MS., but to whom it belonged after the death of Tallys does not appear till the reign of king William, when it was among the books of Mr. Powle, speaker of the house of commons. From him it went to lord Somers; and then to sir Joseph Jekyll, at the sale of whose library by auction, it was purchased by a country organist, who in gratitude for some benefits received, presented it to the late James Weft, esq. president of the Royal Society, and it is now in the possession of the marquis of Lansdown. It contains nine tracts on music, seven of which are in Latin, and two in very old English. That by Lionel Powle is the eighth. It is a short tractate in English, which, besides the obfolute words, orthography, and shape of the letters, has several other internal marks of confiderable antiquity: such as a mixture of Saxon letters; an oblique stroke instead of a dot over the letter i; and the frequency and kind of abbreviations. Though this effay will afford no information of importance to a musician of the present times, except that which will gratify self-complacency, by discovering to him that the author knew less than subsequent improvements in the art of music have enabled him to know himself; yet, as it seems to be the most ancient musical tract that has been written, or at least preferred, in our vernacular tongue, we shall give a quotation from it, not only to shew the state of our music, but our language at the time it was written, which was, probably, during the reign of Edward III.

"This tract is continued upon the gamme for hem that will be fyngers, or makers, or techers. For the ferth thing of alle ye muft kno how many cordis of difcant the be. As olde men fyagen, and as men fyng now-a-dayses, ther be nine; but whofeo wil fyng mannerli and musikeli, he may not lepe to the fyfteenth in no manner of difcant; for it longeth to no manny's voyes, and fo ther be but eyght accordis after the difcant now ufed. And whofoever will be a maker, he may ufe no mo than eyght, and fo ther be but eyght fro unioon unto the thrytenth. But for the quattubril fyghte ther be nine accordis of difcant, the unioon, thyr, fyff, fyff, eyght, eyght, tenth, twelfth, thrytenth, and fyfteenth, of the which nyne accordis fyve be perfyte and fower be imperfecte. The fyve perfyte be the unioon, fyff, eyght, twelfth, and fyfteenth; the fower imperfecte be the thyr, fyff, tenth, and thrytenth: alfo thou maifte afcedere and defcedere wyth alle maner of cordis excepte two accordis perfyte of one kynde, as two unioons, two fyffs, two eyghts, two twelfths, two fyfteenth, wyth none of thefh thou maifte neyther afcedere, neyther defcedere; but thou maifte refpeete thefe accordis togeder, and medle hem wel, as I fhall enform thee. Ferth thou fhall modele with a thyr a fyff, wyth a fyff an eyghth, wyth an eyghth a tenth, wyth a tenth a twelfth, wyth a fyfteenth a thrytenth; under the which nyne accordis three fyghtes be conteyned, the mene fyght, the trebl fyght, and the quattubril fyght; and others alfo of the nyne accordis how thou shalt hem ymagyn ye betwene the playn-fong and the difcant here foloath the enamele. First to enforme a chylde in hyss couterpoynt, he muift ymagyn hyss unioon the eyghth note fro the playn-fong, benette hyss thyr; the fyffh note benette hyss fyffh; the fowrth benette his fyffh; the thyrde note benette his eyghth, even wyth the playn fong; his tenth and thyrde note aboue, his twelfth the fyffh note aboue, his thryteth the fyffh aboue, his fyfteenth the eyghth note aboue the playn-fong."
mind being daily informed, by the senses, of the alterations of the simple ideas of things without, and reflecting on what passes within itself, and observing a constant change of its ideas, sometimes by the impressions of outward objects upon the senses, and sometimes by the determinations of its own choice; and concluding, from what it has so constantly observed to have been, that the like changes will for the future be made in the same things, by the same agents, and by the like ways; considers, in one thing the possibility of having any of its simple ideas changed; and in another, the possibility of making that change; and so comes by that idea which we call power. Thus we say, fire has a power to melt gold, and make it fluid; and gold has a power to be melted.

Power, thus considered, is twofold; viz. as able to make, or able to receive, any change; the one may be called active, the other passive power.

Of passive power, all sensible things abundantly furnish us with ideas; nor have we of active power fewer instances; since whatever change is observed, the mind must suppose a power somewhere able to make that change.

Yet, if we attentively consider it, bodies, by our senses, do not afford us so clear and distinct an idea of active power, as we have from reflection on the operations of our minds; for all power relating to action, and there being but two sorts of action, viz. thinking and motion, it may be considered whence we have the clearest ideas of the powers which produce those actions.

Of thinking, body affords us no idea at all; it is only from reflection that we have that: neither have we from body any idea of the beginning of motion. A body, at rest, affords us no idea of any active power to move; and when it is set in motion itself, that motion is rather a passion than an action in it. The idea of the beginning of motion, we have only by reflection on what passes in ourselves; where we find by experience, that, barely by willing it, we can move the parts of our bodies, which before were at rest.

We find in ourselves a power to begin or forbear, continue or end, several actions of our minds and motions of our bodies, barely by a thought or preference of the mind. This power which the mind has, thus to order the consideration of any idea, or the forbearing to consider it, or to prefer the motion of any part of the body to its rest, and vice versa, in any particular instance, is what we call the will. And the actual exercise of that power, is that which we call motion, or willing.

The forbearance or performance of that action, consequent to such an order or command of the mind, is called voluntary; and whatsoever action is performed without such a thought of the mind, is called involuntary.

The power of perception, is what we call the understanding.

Perception, which we make the act of understanding, is of three sorts: the perception of ideas in our minds; the perception of the signification of signs; and the perception of the agreement or disagreement of any distinct ideas.

These powers of the mind, viz. those of perceiving, and preferring, are usually called by another name; and the ordinary way of speaking is, that the understanding and will are two faculties or powers of the mind. A word proper enough, if used so as not to breed any confusion in men's thoughts, by being suppos'd, as there is room to suppose it has been, to express some real beings in the soul, that perform those actions of understanding and will.
been already discussed, as far as our limits will allow, under the article Cause.

Power, as others have defined it, is that quality or attribute of any being which produces change in the nature, properties, or circumstances of things. Thus we say, clay becomes hard and wax soft by the power of heat; a bee is said to have power to build a cell, a bird to make a nest, and a man to construct a ship or house, &c. But a question here occurs, whether beings that have no will or understanding may have active power? In the solution of this question, we can derive little satisfaction from the consideration of the events that are observed in the course of nature. We perceive innumerable changes, and we know that these changes must be produced by the active power of some agent; but we neither perceive the agents nor the power, but merely the change. Whether the things be active, or merely passive, is not easily discovered; and indeed it concerns us little to know the real efficient, whether it be matter or mind, whether of a superior or inferior order.

According to Mr. Locke, the only clear notion or idea we have of active power is deduced from the power which we find in ourselves to give certain motions to our bodies, or a certain direction to our thoughts; and this power in ourselves can be brought into action only by willing or volition. Hence it must follow, that if we had not will, and that degree of understanding which will necessarily implies, we could exert no active power, and consequently could have none; for power that cannot be exerted is no power; and it follows also, that the active power, of which only we can have any distinct conception, can be only in beings that have understanding and will.

Upon the whole, Dr. Reid thinks it most probable, that such beings only as have some degree of understanding and will, can possess active powers; and that inanimate beings must be merely passive, and have no real activity. Nothing we perceive without us affords any good ground for ascribing active power to any inanimate being; and every thing we can discover in our own constitution leads us to think that active power cannot be exerted without will and intelligence. But if we restrict active power to a subject endowed with will and intelligence, what shall we say of the powers, ascribed by philosophers to matter:—the powers of corpuscular attraction, magnetism, electricity, gravitation, and others? In reply to this inquiry, it should be considered, that the ambiguity of the words cause, agency, active power, &c. has led many to misunderstand them, who used in natural philosophy, in a wrong sense, and in a sense which is neither necessary for establishing the true principles of natural philosophy, nor was ever meant by the most enlightened in that science. When philosophers attribute active powers to matter, they teach us, at the same time, that matter is a substance altogether inert and merely passive, and that gravitation, attraction, and repulsion, &c. which they ascribe to it, are not inherent in its nature, but impressed upon it by some external cause, which they do not pretend to know, or to be able to explain. Although on some occasions philosophers speak the language of the vulgar, they think differently from the vulgar, and in order to avoid affectation and ostentation, and to render themselves intelligible, they confound to use the common phraseology. The word power, therefore, when applied to inanimate substances, like the term principle, &c., is a term invented to express the unknown cause of known effects which are reducible to certain laws. It is difficult to ascertain, says an ingenious writer, whether powers are, properly speaking, attributes of inanimate substances. To allow that they are seems to imply, that power may exist without an agent, and that beings may act where they do not exist. This absurdity follows, if, e.g. gravitation is supposed to be a power inherent in matter, by which bodies act upon each other at immense distances. But, on the contrary, to deny, that powers may be attributes of inanimate substances, leads to the conclusion, that nothing exists in the universe but God and his energies, which coincides with pantheism, and even tends to atheism.

In all languages, action is attributed to many things that are known and allowed to be merely passive; as when we say, the wind blows, the rivers flow, the flowers rage, &c. Every body which undergoes any change, must in that change be either active or passive; and the change is always expressed in language, either by an active or a passive verb; nor is there any verb, expressing a change, which does not imply either action or passion. The thing either changes, or it is changed. But in language, when an external cause of the change is not obvious, the change is always imputed to the thing changed, as if it were animated, and had active power to produce the change in itself. So we say, the moon changes, the fun rises and goes down. Thus active verbs, as Dr. Reid has observed, in illustrating the observation at large, are very often applied, and active power imputed to things, which a little advance in knowledge and experience teaches us to be merely passive. To sum up this part of the argument: we see in the theatre of nature innumerable effects, which require an agent endowed with active power, but the agent is behind the scene. Whether he be the supreme cause alone, or a subordinate cause or causes; and if subordinate causes be employed by the Almighty, what their nature, their number, their different offices may be, are things hid, for wise reafons without doubt, from the human eye. It is only in human actions, that may be inspected for praise or blame, that it is necessary for us to know who is the agent, and in this, nature has given us all the light that is necessary for our conduct. Every man is conscious of a power to determine, in things which he conceives to depend upon his determination. This observation leads us to consider power, in a more peculiar and distinguishing sense, an attribute of mind; whether we allow it to belong to inanimate substances or not. To the negative in this question we feel ourselves much inclined, as the least objectionable, though it is not without its difficulties. As an attribute of mind, power may be defined the power of carrying into effect the determinations of the will. Those who maintain that power is an attribute of the human mind, argue, 1. From conceit and observation. I will to walk, to speak, to write; the bodily organs insantly obey; and I am as conscious that I perform the action, as that I form the volition. Other agents possess a similar power. 2. It is affirmed, that we have a conception of power, though we cannot satisfactorily define it. Those who deny that power is an attribute of the mind, contend 1. That we have no consciousnefs of its existence. We are merely conscious, they say, of volition and the effect produced: that which we call a consciousnefs of power being nothing more than a belief that the effect will follow the volition. 2. They further argue, that our total ignorance of the manner in which muscular motion is produced, proves that the mind is not the efficient and proper cause of this wonderful effect. Locke's Essay on the Human Understanding. Reid's Essays. Stewart's Elements. Bellam's Elements. See Cause, Liberty, Necessity, Mental Philosophy, Understanding, Votition, Voluntary, Will.
Power. in Arithmetic, the product of a number, or other quantity multiplied into itself.

Thus the product of the number 3, multiplied by itself, viz. 9, is the second power of 3; the factor of 9, multiplied by three, viz. 27, is the third power; and the product of 27, again multiplied by 3, viz. 81, is the fourth power; and so on to infinity. In respect of these higher powers, the first number, 3, is called the root, or first power.

The second power is called the square; with respect to which, 3 is the square root.

The third power, 27, is called the cube; with respect to which, 3 is the cube root.

The fourth power, 81, is called the biquadrate, or quadrato-quadratum; with respect to which, 3 is the biquadrate root.

The number which shows how often the root is multiplied into itself, to form the power, or how oft the power is to be divided by its root, to come at the root, is called the exponent or index of the power.

The moderns, after Des Cartes, are contented to distinguish most of their powers by the exponents; as first, second, third, &c.

The particular names of the several powers were introduced by the Arabs, viz. square, cube, quadrato-quadratum or biquadrate, cubicus, duodecim, fquare of the cube, second fquare, quadrato-quadrato-quadratum, cube of the cube, square of the biquadrate, third fquare, &c.

The names given by Diophantus, followed by Vieta and Oughtred, are the fide or root, square, cube, quadra-to-quadra-tum, quadrato-cubus, cubicus, quadrato-quadra-tum, quadrato-cubus-cubicus, cubicus-cubicus, &c.

The characters with which the several powers are denoted both in the Arabic and Cartesian notation, are as follow:

Hence to raise a quantity to a given power or dignity, is the same as to find the factor arising upon its being multiplied a given number of times into itself; e. gr. to raise 2 to the 3d power, is the same as to find the factor 8; whose factors are 2, 2, 2. This operation is called involution; which see.

Powers of the same degree are to one another, in the ratio of the roots, as manifold as their exponent contains units: thus, squares are in a duplicate ratio; cubes in a triplicate ratio; quadrato-quadrata, or fourth powers, in a quadruplicate ratio. See RATIO.

The powers of proportional quantities are also proportional to one another.

Power. Arithmetical, is used by Mr. Machin for composite numbers or quantities, whose factors are in arithmetical progression. See Dr. Martin’s Abridg. Phil. Trans. vol. viii. p. 78.

Mr. Machin uses a particular notation for quantities of this kind. The quantity expressed by this notation has a double index; that at the head of the root at the right hand, but separated by a hook to distinguish it from the common index, denotes the number of factors; and that above, within the hook on the left hand, denotes the common difference of the factors proceeding in a decreasing or increasing arithmetical progression.

\[
\frac{a(m)}{2^c}
\]

Thus the quantity \(n + a\) denotes by its index \(m\) on the right hand, that it is a composite quantity, consisting of \(m\) factors as there are units in the number \(n\), and the index \(c\) above on the left, denotes the common difference of the factors decreasing in an arithmetical progression, if it be positive; or increasing, if it be negative; and fo signifies, in the common notation, the common number or quantity, \(n + a, n + a - a, n + a - 2a, &c\).

For example, \(n + 5\) is \(= n + 5, n + 3, n + 1, n - 1, n - 3, n - 5,\) consisting of six factors, whose common difference is 2. After the same manner, \(n + 4, (1 = n + 4, n + 2, n + 2, n - 4, n + 5,\) consisting of five factors. According to which method, it will easily appear, that if \(a\) be an integer, \(\frac{2a}{2(a + 2)}\) will be \(n - n - 1, n - 9, n - 1, n - 2, n - 3, n - 4, n - 5,\) continued to such a number of double factors as are expressed by \(a + 1\) or half the index, which in this case is an even number. Thus also \(n + 2a\) will be equal to \(n + 4, n + 2, n + 1, n - 1, n - 2, n - 3, n - 4, n - 5,\) containing six factors. So \(\frac{6}{2(6 + 1)} = 6, 5, 4, 3, 2, 1,\) and the like for others.

If the common difference \(a\) be a unit, it is omitted: thus \(\frac{6}{2(6 + 1)} = 6, 5, 4, 3, 2, 1,\) and the like for others.

If the common difference \(a\) be nothing, the hook is omitted, and it becomes the fame with the geometrical power. Thus \(n + a = n + a\), according to the common notation.

The learned author above quoted applies this doctrine of arithmetical powers to the investigation of the principal rule in the method of fluxions, and its inverse, which is that if the ordinate \(y = m x^n + 1\), then will the area, or rather the form of the quantity for the area, be \(n^z\); or vice versâ, that if the area be \(n^z\), the ordinate will be \(m x^n + 1\); on which occasion he observes, that the symbol \(z\), considered as a component part of the rectangle \(z\), may bear a plain interpretation, viz. that it is the measure according to which the quantity \(z\) is measured. See Fluxion.

From a given power to extract the root, or side, is the same as to find a number, e. gr. 2, which multiplied any number of times, e. gr. twice, produces the given power, e. gr. the 3d power, or 8. This operation is called Evolution, and Extraction of Roots; which see.

To multiply or divide any power by another of the same root. I. For multiplication, add the exponents of the factors; the sum is the exponent of the factor. Thus:

\[
\text{Factors} \begin{cases} x^x, y^y, z^z \\ x^x, y^y, a^a \\ x^x, y^y, a^{a+r} \end{cases}
\]

\[
\text{Prod.} \begin{cases} x^x, y^y, z^z \\ x^x, y^y, a^a \\ x^x, y^y, a^{a+r} \end{cases}
\]

For
2. For division, subtract the exponent of the power of the divisor, from the exponent of the dividend; the remainder is the exponent of the quotient. Thus:

Divid. \( x^i \) \( \left( x \right)^{m-n} \) \( y^n \) \( \alpha^m \) \( a^{-t} \) \( \beta^n \) \( \alpha^{m-t} \)
Divid. \( x^i \) \( \frac{x^n}{\alpha} \) \( \frac{y^n}{\beta} \) \( \frac{\alpha^m}{\alpha^{-t}} \) \( \frac{\beta^n}{\beta} \) \( \frac{x^n}{\alpha} \) \( \frac{\alpha^{m-t}}{\alpha^{-t}} \)

M. de la Hire gives us a very odd property common to all powers: M. Carre had observed with regard to the number 6, that all the natural cubic numbers, 8, 27, 64, 125, whose root is less than 6, being divided by 6, the remainder of the division is the root itself; and if they be gone further, 216, the cube of 6, being divided by 6, leaves no remainder; but the divisor 6 itself the root. Again, 343, the cube of 7, being divided by 6, leaves 1; which, added to the divisor 6, makes 7 the root, &c. M. de la Hire, on considering this, has found that all numbers, raised to any power whatever, have divisors, which have the same effect with regard thereto, that 6 has with regard to cubic numbers.

For the finding of these divisors, he discovered the following general rule:

If the exponent of the power of a number be even, \( i.e. \) if the number be raised to the 2d, 4th, 6th power, &c., it must be divided by 2; the remainder of the division, in case there be any, added to 2, or to a multiple of 2, gives the root of this number, corresponding to its power, \( i.e. \) the 2d, 6th, &c. root.

If the exponent of the power be an uneven number, \( i.e. \) if the number be raised to the 3d, 5th, 7th, &c. power; the double of the exponent will be the divisor, which has the property mentioned.

Thus it is found in 6, double of 3, the exponent of the power of all the cubes; thus, also, 16 is the divisor of all numbers raised to the 5th power, &c.

If any power of a quantity be divided by a greater power of the same quantity, the quotient must be negative. For the rule for dividing any power of a quantity by another power of the same quantity, is to subtract the exponent of the divisor from the exponent of the dividend, and make the difference the exponent of the quotient.

For instance, \( \frac{a^i}{a^t} = a^{i-t} = a^2 \); and \( a^n a^t = a^{n-t} \).

Hence if \( n \) be greater than \( m \), the exponent \( m - n \) must be negative.

Thus if \( n = m + n \), then \( a^n a^t = a^{n-t} = a^{m-n} \).

It is obvious that \( \frac{a}{a} = a^{0} \). But \( \frac{a}{a} = 1 \); and therefore \( a^0 = 1 \). In like manner \( \frac{1}{a} = a^{-1} = a^0 \); \( \frac{1}{a} = a^{-1} \), so that the quantities \( a, 1, \frac{1}{a}, \frac{1}{a^2}, \frac{1}{a^3}, \frac{1}{a^4}, \ldots \), &c. may be expressed thus, \( a^i, a^0, a^{-1}, a^{-2}, \ldots \), &c. This change of expression is often of great use in the computation of fluxions and infinite series.

When the quantity to be raised to any power is positive, all its powers must be positive. And when the radical quantity is negative, yet all its powers, whose exponents are even numbers, must be positive. For \(-x \) gives \( -x \) the power then can only be negative, when the exponent is an odd number. Thus the powers of \(-a = a + a, a + a, a, a, a, \ldots \) are positive; the powers whose exponents are 2, 4, 6, &c. are negative; the powers whose exponents are 1, 3, 5, &c. are negative. Maclaur. Algebra. p. 37, 38.

Hence if a power have a negative sign, no root of it, denominated by an even number, can be assigned; since no quantity multiplied into itself an even number of times can give a negative product. Thus the square root of \(-a a \) or \( -a a \) cannot be assigned, and is what mathematicians call an impossible, or an imaginary quantity or root. See Root.

Observe, that every power has as many roots, real and imaginary, as there are units in the exponent of the power. This holds true of unity itself. Maclaur. Algebra. p. 128.

**POWER.**

*Power, Imperfett,* in Algebra, is used for a power that has a fractional exponent; thus \( \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \ldots \), &c. are imperfect powers. Maclaur. Algebra. p. 44.

These are otherwise expressed by placing the given power within the radical sign \( \sqrt{v} \), and placing above the radical sign the number that denominates what kind of root is required.

Thus \( a^\frac{2}{3} = \sqrt[3]{a^2} \); \( a^\frac{1}{2} = \sqrt{a} \); \( a^\frac{m}{n} = \sqrt[n]{a^m} \).

These imperfect powers are also called surds; which fee. The powers of numbers have several curious and remarkable properties, the most important of which are as follow:

1. The difference of any two equal powers of different numbers is divisible by the difference of their roots; that is, \( \frac{x^n - y^n}{x - y} = 1 \) an integer, or \( x^n - y^n = M (x - y) \), where the abridged expression \( M (x - y) \) signifies an integral multiple of \( x - y \).

2. The difference of the two equal powers is always divisible by the sum of their roots, when the exponent of the power is an even number; that is, \( \frac{x^{m+n} - y^{m+n}}{x + y} = 1 \) an integer, or \( x^{n+1} + y^{n+1} = M (x + y) \).

3. The sum of two equal odd powers of different numbers is always divisible by the sum of their roots; that is, \( \frac{x^{m+n} + y^{m+n}}{x + y} = 1 \) an integer, or \( x^{n+1} + y^{n+1} = M (x + y) \).

And in all these cases it may be demonstrated, that when \( x \) and \( y \) are prime to each other, the sum, or differences of the powers as above stated, are divisible only once by their respective divisors, unless those divisors are equal to the respective powers, or to some multiple of them.

By means of the above propositions, we are also enabled to ascertain the divisors of the sum or difference of two unequal powers of the same root, \( \sqrt{v} \).

\( (x^n - x^m) = M (x^n - x^m) \), and \( M (x + 1) \),
when \( n = m \) is even, or of the form \( 2n \), for 
\( (x^n - x^m) = x^n (x^{m-n} - 1) \).

And since \( m = n \) is of the form \( 2n \), \( (x^{n+1} - 1) \) is divisible both by \( x + 1 \) and \( x - 1 \), by prop. 1 and 2.

Again, if \( n = u \) odd, or of the form \( 2n + 1 \), then,
\( (x^n - x^m) = M (x + 1) \).

And \( (x^n + x^m) = M (x + 1) \).
For \( x^n - x^m = x^m (x^{n-m} - 1) \).
And \( x^n + x^m = x^m (x^{n-m} + 1) \).

And since by the supposition \( m - n \) is odd, or of the form \( 2n' + 1 \), it follows from prop. 1 and 3, that in the first case we have,
\[
(x^{m+n-1}) = M (x - 1)
\]
And in the second case,
\[
(x^{m+n+1}) = M (x + 1).
\]

4. Neither the sum nor the difference of two powers, higher than the square, can produce a complete power of the same denomination; that is, \( x^n \pm y^n = z^n \) is always impossible, either in integers or fractions, if \( n \) is greater than \( 2 \).

This is one of Fermat's propositions mentioned by him, but without its demonstration, in the marginal notes of his edition of Diophantus. The impossibility of some partial cases have since been demonstrated by Euler, and other modern analysts: viz. it has been found impossible in the case of \( n = 3 \), and \( n = 4 \); but beyond this, the truth of the proposition rests only on the assertion of Fermat, and it would be, therefore, highly interesting to see a complete demonstration of this property. Mr. Barlow, in his Theory of Numbers, has attempted this, but failed in his conclusion, by referring to a proposition which did not apply. He has, however, made a considerable advance towards it, by proving that if there are any cases in which the equation \( x^n \pm y^n = z^n \) be possible, \( n \) being a prime number, it must necessarily happen that \( x \equiv y \equiv z \equiv \pm 1 \), and \( y + z \), are all three complete \( n \)th powers; or two of them complete \( n \)th powers, and the other \( n \) times such a power. These limitations are sufficient to indicate the impossibility of the equation; but something farther is necessary for the complete demonstration.

5. If \( m \) be a prime number, and \( x \) any number not divisible by \( m \), then the remainder arising from the division of \( x \) by \( m \), will be the same as that from the division of \( x^n \) by \( m \); that is, \( \frac{x}{m} \) and \( \frac{x^n}{m} \), will both leave the same remainder.

From the above proposition is readily deduced the following, which is also another of Fermat's propositions, first demonstrated by Lagrange, viz.

6. If \( m \) be a prime number, and \( n \) any number not divisible by \( m \), then will the formula \( x^{n-m} - 1 \) be divisible by \( m \).

This is a very important proposition in the theory of numbers, being that on which depend many of the most elegant and interesting properties connected with this subject.

7. From this property we readily draw the following propositions for the forms of the different powers of numbers, and which are frequently very useful in determining \( a \) priori whether a proposed number be a complete power or not, without the trouble of extracting it, viz.

Since \( x^{n-m} - 1 \) is always divisible by \( m \), under the limitation of the proposition; therefore, \( x^{n-m} \) is of the form \( am + 1 \), and consequently every power, whose exponent plus 1 is a prime number, as \( (m) \), will be of the form \( am \) or \( am + 1 \); and thus we may ascertain the forms of many of the higher powers: thus,

\[ x^1 \] is of the form \( 5m \) or \( 5m + 1 \).
\[ x^2 \] is of the form \( 7m \) or \( 7m + 1 \).
\[ x^3 \] is of the form \( 11m \) or \( 11m + 1 \).
\[ x^4 \] is of the form \( 13m \) or \( 13m + 1 \).

Again, since \( m \) is a prime number, if it be greater than 2 it is an odd number, and consequently \( m - 1 \) is an even number; and therefore,

\[ x^{m-1} - 1 = \left( x^m + 1 \right) \left( x^2 - 1 \right) \]

And since this product is divisible by \( m \), and \( m \) is a prime number, one of these factors is divisible by \( m \), and consequently \( x^m - 1 \), when divided by \( m \), must leave either \( 1 \), or \( m-1 \), for a remainder; that is, \( x^m \) is of one of the forms \( am \), or \( am + 1 \). And hence, again, we derive the forms of many other of the higher powers: thus,

\[ x^5 \] is of the form \( 7m \) or \( 7m + 1 \).
\[ x^6 \] is of the form \( 11m \) or \( 11m + 1 \).
\[ x^7 \] is of the form \( 13m \) or \( 13m + 1 \).
\[ x^8 \] is of the form \( 17m \) or \( 17m + 1 \).
\[ x^9 \] is of the form \( 19m \) or \( 19m + 1 \).
\[ x^{10} \] is of the form \( 23m \) or \( 23m + 1 \).
&c. &c. &c.

The only power under 12 excluded from these formulæ is 7, because neither 7 + 1 nor 2 · 7 + 1 is a prime number.

8. All prime powers divided by double their exponent, will leave for remainders the same numbers as their several roots, when divided by the same double exponent. Hence we see why all 5th powers terminate with the same digit as the roots of those powers.

9. The \( n \)th differences of any consecutively \( n \)th powers is a constant quantity, and equal to the product \( 1 \cdot 2 \cdot 3 \cdot 4 \cdot &c. \cdot n \). That is, the second difference of consecutive squares is \( 1 \cdot 2 \).

The third differences of consecutive cubes is \( 1 \cdot 2 \cdot 3 \).

The fourth differences of consecutive 4th powers is \( 1 \cdot 2 \cdot 3 \cdot 4 \). &c.

This property is readily demonstrated for any particular power; but under the general index \( n \), it is attended with some difficulty; the proof is generally made to depend upon the following property, which is not easily demonstrated, viz. that the product \( 1 \cdot 2 \cdot 3 \cdot 4 \cdot &c. \cdot n = n! = (n - 1) \cdot (n - 2) \cdot &c. \cdot 1 \cdot 2 \cdot 3 \).

There, however, is a very ingenious demonstration of it, depending only upon first principles, given by S. Burke, etc. in vol. ix. of the Transactions of the Irish Academy.

We might have added here many other curious properties of numerical powers, but we prefer subjoining the following table of the first 10 powers of all numbers from 1 to 100, which is remarkably useful in a variety of arithmetical operations; and for farther information relating to the properties of powers, their divisors, forms, &c. we must refer the reader to Legendre's Élémens de la Théorie des Nombres, to Gauss's Disquisitiones Arithmeticae; and to Barlow's Elementary Treatise on the Theory of Numbers. See also vol. ix. of the Trans. Irish Acad.
The first Ten Powers from 1 to 100.

Powra


Power, in Mechanics, denotes a force, which, being applied to a machine, tends to produce motion; whether it does actually produce it or not.

In the former case it is called a moving power; in the latter, a sustaining power.

If the power be a man, or a brute, it is called an animate power; if the air, water, fire, gravity, or elasticity, an inanimate power.

Power, Attractive. See Attractive.

Power, Confining. See Confining.

Power, Repelling. See Repelling.

Power is also used for any of the six simple machines, viz., the lever, balance, screw, axis in peristichion, wedges, and pulleys; which are particularly called the Mechanic powers, which fee.

See also each power under its proper article, Lever, Balance, &c.

Power, Maintaining, or Maintaining power, in Horology, is that extraneous force which is applied in a clock or watch to maintain or perpetuate the natural vibrations of a pendulum, or oscillations of a balance, which would otherwise cease to act, by reason of friction in the mechanism, and the resistance opposed by the air to the parts in motion.

This power, in the larger clocks, is usually a suspended weight, but in the portable clocks and watches, it is a spring, coiled in a metallic box, which actuates the wheelwork, by gradually unbending itself; in the former of these cases, the weight is suspended by a cord, or chain, that is coiled round a cylinder when wound up, which cylinder, being of uniform diameter throughout its length, is acted on by the cord, when lifted at the interior end, by a similar force in every situation; and, therefore, imparts through the train, that is connected with its great wheel, variable impulses to the escapement-wheel, at every vibration of the pendulum; which pendulum receives therefrom such a flight push, as is just sufficient to restore the momentum that it lost from friction and resistance of the air; and thus the uniform motion of the pendulum is perpetuated, or would be perpetuated, if no impediment from dirt, from the thickening of oil, or from wear, &c., were to interfere with the regularity of its action. But when a spring is substituted for a weight, its agency is not uniform, without some mechanical correction to equalize it; this correction is effected by the fusée, which we have already explained in its proper place, but which is seldom so completely proportioned to the varying forces of the opening spring, as to be at all times equal to a weight suspended from an uniform cylinder. Hence have originated various escapements in horological machines, either to correct or to obviate the inequalities of the maintaining power, after it has been modified by transmutation through the train of wheelwork, that is necessary both for limiting its quantity, and lengthening the time of its action.

The whole quantity of maintaining power that is expended in a given time, when a weight is used, is the product of the weight into its deficient, in inches and parts, from its situation at the commencement of action, and therefore the slower the fall is, the greater must be the weight, and vice verfa, when a given quantity is necessary for maintaining the vibrations in an undiminished state for the requisite duration. Hence a clock may be made to go at one winding, any length of time, from a day to a year, or more; but the most usual time, and perhaps as unobjectionable as any, is something more than a week, for which a weight of from ten to twelve pounds is sufficient, with an ordinary cylinder and double cord. In general, an excess of maintaining power is injurious to the natural motion of a pendulum or balance; but as different escapements require different degrees of power to produce the requisite effect, it would not be an easy matter to calculate the exact quantity that would be best in all cases, even if the same power were requisite in all flats of foulness of the machine. The best rule in practice is to adopt that weight which experience has pointed out as adequate to its purpose, and if, on trial, a little addition or diminution of the power is found to bring the vibration to the most desirable length; the weight so changed will be proper to make choice of. In those particular escapements which are called isochronal, an increase or diminution of the power, though they affect the total length of the vibration, will not alter the time; and, therefore, with respect to them, the exact quantity of power is not of so much importance as in other escapements, provided it be sufficient, under all circumstances, to make the total vibration exceed the arc of escapement, so as to prevent quiescence. In those escapements which are denominated remontoir, the maintaining power does not itself act on the escapement-wheel, but serves only to raise a pair of small weights, or to wind up a couple of small springs, that become substitutes for the maintaining power, by giving their small alternate impulses at each vibration or oscillation, without variation in the intensity of each impulse, which is a great improvement in the art of clock-making and watch-making, particularly where the escapement is of the detached description; for whatever irregularities might arise from the transmutation of the modified power, through the train, in different flats of the weather, or of foulness, these irregularities, not influencing the effective forces derived from the secondary weights or springs alone, do not affect the pendulum or balance, that is actuated solely by one or other of these invariable powers, though these powers are under the agency of the maintaining power themselves, at certain intervals, more or less distant.

It has been asserted, that if the weight of a pendulum-bob be increased inerterely as the square of the arc of vibration is diminished, and vice verfa, the maintaining power must remain the same, but the experiments of F. Derthoud, as reported in his 14th chap. of his "Essai sur l'Horlogerie," prove that this is far from being the case in practice, and that no theory, which has yet been proposed, is competent to the calculation of the exact maintaining power, that shall make a given pendulum move in a given arc, with all the variety of escapements; it appears, however, to be agreed on, that a heavy bob, moving in a small arc, with a comparatively small maintaining power, is most conducive to invariable regulation in a clock; but that in a watch, a large arc of oscillation is necessary, in order to obtain sufficient momentum. See Escapement.

Power, in Optics. The power of a glass is used by some for the dilution of the convexity from its solar focus.

Power, Commensurable in. See Commensurable.

Power, of the County. See Poissy Comitate.

Power, in the Feudal Jurisprudence, a right which the lord has to resume to his seigneurial rights held of him, when the vassal has alienated it, upon reimbursing the money given for it, with legal costs.

The lord is to exercise his power over the fee within a year after he has notice of the fall; otherwise he losses it. The word is also used for the right a lord has to seize a dependent fee, to compel the payment of all dues, services, &c.

Powers, Patentes, are also used among the fathers, &c., for the sixth order in the hierarchy of angels, reckoning from seraphim.

Thence they suppose to be the spirits who bridge and restrain the power of the devils; preside over inferior caufes; and prevent
prevent contrary qualities from disturbing the economy of the world. See Angel and Hierarchy.

Power, Balance of; in Political Economy, denotes such a disposition of things in a single state, or among different nations, that no power is able absolutely to predominate, or to preferice laws to others. The first means for preserving this balance or equilibrium would be that no power should be much superior to the others, and that all, or at least the greater part, should be nearly equal in force. This project is attributed to Henry IV.; but it could not be executed without injustice and violence. Besides, if equality had been established, how could it be always supported by lawful means? Commerce, industry, military virtues, would soon put an end to it. The right of inheriting sovereignties, even in favour of women and their descendants, so absurdly settled, and yet if settled, would overthrow this system. It is more natural, easy, and just, to have recourse to the means of forming confederacies for making head against the most powerful, and hindering him from dictating law. This, till the distraction and confusion of the last 20 or 30 years (1813), has been observed by the sovereigns of Europe. They consider the two principal powers, which on that very account are naturally rivals, as defined to be checks on each other, and unite with the weakest, so like so many weights thrown into the lightest scale, for keeping one in equilibrium with the other. The house of Austria was long the preponderating power, but of late times France has taken her turn. England, the opulence and fleets of which have had a great influence, without alarming any state with regard to its liberty, has had in the common course of things the glory of holding this political balance. It has been watchful to keep it in equilibrium, which is really a very wise and just policy, and will be ever highly valuable, whilst the means it makes use of are only alliances, confederacies, and others equally lawful. Confederacies would be a sure way of preserving the equilibrium, and supporting the liberty of nations, if all princes thoroughly understood their true interests, and regulated all their flews for the good of the state. But great powers are too successful in gaining over partizans and allies, who blindly surrender themselves to their views. Dazzled by the lull of a present advantage, seduced by their avarice, deceived by wicked ministers, how many princes become the tools of a power, which at one time or other may swallow up either themselves or their successors? Thus the falsest way, when a favourable opportunity offers, and it can be done with justice, is to weaken him who infringes upon the equilibrium; and by every honest method hinder his acquiring too formidable a degree of power. For this purpose the interested nations should be especially attentive not to suffer him to aggrandize himself by arms, and this they may always do with justice. For if this prince makes an unjust war, every one has a right to succour the oppressed. If he makes a just war, neutral nations may interfere as mediators for an accommodation, induce the weaker side to offer a just satisfaction with reasonable terms, and not permit it to fall under the weight of the conqueror. On the offer of equitable conditions to the prince who makes even the most just war, he has all that he can demand. The justice of his cause never gives him a right of absolutely reducing his enemy, unless when this extremity becomes necessary to his safety; or in the want of any other means of indemnifying him for the injury he has received. But this is not the case in the present instance, as the interposing nations can in another manner procure him just satisfaction, and assurance of safety. If this formidable power should plainly entertain designs of oppression and conquest, and manifest its views by making preparations or other motions, the neighbouring nations have an unquestionable right to prevent it; but if the fate of war declares on their side, they have a further right to avail themselves of this happy opportunity for weakening and reducing a power too contrary to the equilibrium, and dangerous to the common liberty. This right of nations is still more evident against a sovereign, who from a precipitate and running to arms without reason, or even so much as plausible pretences, is continually disturbing the public tranquility.

Mr. Hume observes, that in all the politics of Greece, the anxiety with regard to the balance of power, is apparent, or expressly pointed out to us by the ancient historians. Thucydides (lib. i.) represents the league which was formed against Athens, and which produced the Peloponnesian war, as entirely owing to this principle. And after the decline of Athens, when the Thebans and Macedonians disputed for sovereignty, we find, that the Athenians (as well as many other republics) always threw themselves into the lighter scale, and endeavoured to preserve the balance. They supported thebes against Sparta, till the great victory gained by Epaminondas at Leuctra; after which they immediately went over to the conquered, from generosity as they pretended, but in reality from their jealousy of the conquerors. Upon the first rise of the Macedonian power, Demosthenes immediately discovered the danger, founded the alarm throughout all Greece, and at last assembled that confederacy under the banneis of Athens, which fought the great and decisive battle of Cheronaea. However, if we attentively consider the state of Greece and the character of its inhabitants, we shall perceive that the balance of power was of itself sufficiently secured in that country, and that it was unnecessary to guard it with that caution which may be requisite in other nations and ages. The Persian monarch was, with regard to his force, a petty prince compared with the Grecian republics, and therefore it behoved him from views of safety to interefl himself in their quarrels, and to support the weaker side in every contest; and thus the fate of the Persian empire was prolonged for near a century. The successors of Alexander manifested great jealousy concerning the balance of power; and their jealousy was founded on true politics and prudence, and preferred distinct for several ages the partition made after the death of that famous conqueror. In subsequent times we find, that as the Eastern princes considered the Greeks and Macedonians as poiffeling the only real military force with which they had any intercourse, they kept always a watchful eye over that part of the world.

It has been supposed, however, that the ancients were entirely ignorant of the balance of power; and this opinion seems to have been formed from an attention to the Roman history more than the Grecian. As to the Romans, it must be allowed, that they never met with any such general combination or confederacy against them as might naturally have been expected from their rapid conquests and declared ambition, but they were allowed peaceably to subdue their neighbours, one after another, till they extended their dominion over the whole known world. Upon Hannibal's invasion of the Roman state, a crisis occurred, which ought to have roused the attention of all civilized nations. Nevertheless, though this was in reality a contest for universal empire, no prince or state seems to have been in the least alarmed about the event or issue of the quarrel. The only prince in the Roman history, who seems to have understood the balance of power, is Hiero, king of Syracuse. Although the ally of Rome, he affliated the Carthaginians, esteeming it requisite, as Polybius says (lib. i. cap. 83.) both in order to retain his own dominions in Sicily, and to preserve the Roman friendship, that Carthage should be safe; left by its fall the remaining power should be able, without contrai or opposition, to execute every purpose and undertaking. And here he acted, says the same writer.
POW

with great wisdom and prudence. For that is never on any account to be overlooked; nor ought such a force ever to be thrown into one hand, as to incapacitate the neighbouring states from defending their rights against it. Here, says Mr. Hume, the rife of modern politics is pointed out in express terms. In short, as he proceeds, the maxim of preserving the balance of power is founded so much on common sense and obvious reasoning, that it is impossible it could have altogether escaped antiquity, where we find in other particulars so many marks of deep penetration and discernment. If it was not so generally known and acknowledged as at present, it had, at least, an influence on all the wiser and more experienced princes and politicians, and, indeed, even at present, however generally known and acknowledged among speculative reasoners, it has not, in practice, an authority much more extensive among those who govern the world. After the fall of the Roman empire, the form of government, established by the Northern conquerors, incapacitated them, in a great measure, for farther conquests, and long maintained each state within its proper boundaries. But when vainglory and the feudal militia were abolished, mankind were anew alarmed by the danger of universal monarchy from the union of so many kingdoms and principalities in the person of the emperor Charles. The power of the house of Austria succeeded; but its dominions, though extensive, were divided, and supported by riches, derived chiefly from mines of gold and silver; and it was therefore more likely to decay from internal defects than to overthrow the bulwarks raised against it. In less than a century it funk, and was succeeded by a new power, more formidable to the liberties of Europe, possessing the advantage of the former without its defects, excepting only a share of that spirit of bigotry and persecution with which the house of Austria long continued to be infatuated. Another power has lately springing up in France, and having risen from a small beginning to an enormous and gigantic size, so that like a large colossus it was bestriding the whole of Europe, it became necessary to form a general confederacy against it, the exertions of which have been attended with signal successes, and not only prognosticated but produced a favourable issue at the present moment (1814). Against this ambitious power, extending the observations of Mr. Hume to our own times, Great Britain holds the foremost, and she still maintains her station, in conjunction with other very powerful and active allies. Besides her advantages of riches and situation, her people are animated with a strong national spirit, and are so fully capable of the blessings of their government, that we may hope their vigour will never languish in its necessary and just cause. The errors of Great Britain have more frequently proceeded from a laudable excess of ardour, than from a blamable deficiency. Hence it has happened, that our debates in defence of our allies, in our opposition to French power, has, on some occasions, led them to reckon upon our force as upon their own, and expecting to carry on war at our expense, they have refused reasonable terms of accommodation. Besides, we are such true combatants, that, when once engaged, we lose all concern for ourselves and our popularity, and consider only how we may most effectually annoy the enemy. Vattel’s Law of Nations, b. iii. chap. 5. Hume’s Essay, vol. i. pt. 2. cff. 7. See BALANCE of the Constitution, Balance of Power, and War.

POWER of Attorney, in Commerce, an instrument or deed by which a person is authorized to act for another, either generally, or in any specific transaction. By this instrument, a merchant resident abroad empowers and authorizes his agent to accept or negotiate bills of exchange, and to make contracts in the name and upon the responsibility of his principal. A power of attorney is, in its nature, revocable, and its revocation may also be either general or special. See ATTORNEY and LETTER of ATTORNEY.

POWERSCOURT, in Geography, a village of the county of Wicklow, Ireland, near which are the romantic scenes of the Dargle and Waterfall, much frequented by parties from Dublin, and visited by every traveller in Ireland, whose object is to view the beauties of nature. Near it is the seat of that honour to his country, the Rt. Hon. H. Grattan. Powerscourt is 103 miles from Dublin.

POWHATAN, a county of Virginia, containing 8672 inhabitants. It is bounded N. by James river, which separates it from Goochland, and S. by Amelia county.—Also, the ancient name of James river, in Virginia.

POWICSVISKO, a town of the duky of Warsaw; 13 miles W. of Gienfa.

POWIS LAND, or Powys Land, in Geography, one of the three districts or territories, anciently called kingdoms, into which Wales was divided by Rodericus Magnus, king of Wales, about A.D. 870; the other two territories were Gwynedd, or North Wales, and Deheubarth or South Wales. In each of these he ordained a princey seat or court; that of Gwynedd was Aberfraw in the isle of Mon, or Anglesey; that of Deheubarth, called in Latin Demetia, Caermarthen, whence it was afterwards removed to Dynefieur, at the distance of about eight miles; and that of Powys Land, Pengwern, called Y Mywthig, and in English Shrewsbury, whence it was removed to Mathrafael in Powys land. This kingdom, sometimes called Mathrafal, was divided into Powys Padre, containing five cantrefs and 13 commotes, and Powys Wenywyyn, containing five cantrefs and 12 commotes. To the kingdom of Mathrafael belonged the land between Wye and Severn, containing four cantrefs and 13 commotes. See WALES.

POWLLAMYA, Pulomaya, and Poculami, in Mythology, names of the Hindoo goddesses Indrani, comfort of Indra. See those articles.

POWNAI, in Geography, a flourishing township of America, in Bennington county, and S.W. corner of the state of Vermont, containing 1655 inhabitants. Mount Belcher, a portion of which is within this town, stands partly in three of the Rates, viz. New York, Vermont, and Massachusetts. Mount Anthony, also one of the most remarkable mountains in Vermont, lies between this and Bennington. Housack river winds beautifully through the S. part of this town.—Also, a town of Cumberland county, in the district of Maine, containing 872 inhabitants.

POWNAL’s Island, an island near the E. coast of Labrador. N. lat. 57° 10'. W. long. 61° 15'.

POWNULL, Thomas, in Biography, a miscellaneous writer, was born in 1722, and educated at Lincoln. He went to America in 1753, and was appointed governor of New Jersey, and afterwards of Massachusetts. In 1760 he removed to the government of South Carolina. After his return from America, he became comptroller-general of the expenditure and accounts of the extraordinary of the army in Germany. He served in three parliaments; after which he retired wholly from public business, and died at Bath in 1805. His works are “Memoirs on Drainage and Navigation,” “Letter to Adam Smith on Several Points treated of in his Enquiry into the Wealth of Nations.” “Topographical Description of North America,” “Treatise on Antiquities;” “Memoir addressed to the Sovereigns of America;” “The Rights, Interest, and Duties of Government, as concerning the Affairs of the East Indies;” “Intellectual Physics;” “An Essay concerning the Nature of Being;” “A Treatise on Old Age;” and other pieces.

POWOW, in Geography, a small river of America, in Essex county, Massachusetts, which rises in Kingdon, New Amsterdam, and takes the name of the Thames in the English Channel.
POY

Hampshire, and runs into Merrimack river, seven miles from the sea, between the sound of Salisbury and Amhurst. It is navigable a mile from its mouth, and many vessels are built upon its banks.

POWTER, or English Powter, the name of a peculiar species of pigeon, called by Moore the colomba gutturosa Anglica. See COLUMBA.

It was first bred in England, and is of a mixed breed, between what is called the horfeman and the cropper. It is a very beautiful species, and is valued for its length of legs and body, neatness of crop, and slendernefs in girth, added to the beauty of its feathers. This species is often eighteen, sometimes twenty inches long from the end of the bill to the extremity of the tail; its legs, from the upper joint of the thigh to the toe-nail, are sometimes seven inches; the crop is large and round, especially toward the back, filling also behind, and making almost a perfectly orbicular figure. They are either blue-pied, black-pied, red-pied, or yellow-pied; the last color is most valued. See PIGEON.

POWTER, Pi Ri fian, a species of pigeon called by Moore colomba gutturosa Parisi Icum. This is a yellow-legged pigeon, produced between those two kinds, known by the names of the cropper and the horfeman, according to the number of times that the young are bred over from the cropper. They are distinguished by the name of the first, second, or third breed.

These are a very agile and nimble pigeon; and by their continually flying up and down about the dove-house, are apt to bring in other stray pigeons; which cannot find their houses. They are observed to breed often, and take great care of their young ones. See PIGEON.

POWZOLS, in Geography, a town of France, in the department of the Herault; 18 miles N.E. of Baziers.

POX, in Medicine, the plural of pock, which signifies a pululita or large vehicle, prominent upon the skin. Whence the term is applied to several diseafes, in which different punctular and vesicular eruptions appear on the skin; such as the French pox, great pox, or pox simply, (signifying the venereal disease); the small-pox; chicken-pox; swine-pox; &c.

POX. Chicken. See VARICELLA.

POX, French. See LUES VENEREÆ.

POX. Small. See SMALL-POX.

POX, Swine. See VARICELLA.

POY AIS, in Geography, a town of Mexico, in the province of Honduras, on the W. side of Black river; 55 miles S. of Cape Cameron, which forms the N. point of the entrance of the river into the sea of Honduras.

POYAMONY, a town of Hindoostan, in the Carnatic; 11 miles W.N.W. of Trichinopoly.

POYANG, a lake of China, in the province of Kiang-6, the largest collection of waters within the Chinese dominions. It lies in the midst of a great extent of flat and swampy land; and for some miles on every side of it, the face of the country is a wild and morally waste, covered with reeds and rushes, and entirely inundated for a part of the year. Not a village is to be seen, nor any traces of habitations, except here and there a mean solitarv hut for the residence of a fisherman, accession sometimes only by a boat. These wretched beings subsist by fishing, and by raising vegetables on hurdles of bamboo refting upon marshes, or floating upon the surface of the water. This lake and the adjacent country may be literally termed the common fewer of China. Rivers flow into it from most points of the compass; several canals have been formed from it, and inclosed within high banks for the security of vessels in the season of tempests and inundations. The billows of the lake rise occasionally to such a height as to render it, in the opinion of the Chinese mariners, no less dangerous than the sea. In the lake are numerous islands in the midst of the surface of the water, and covered with terrible dwellings, the abodes of fishermen. The Poyang, which is said to be about 200 miles in circumference, after having collected the waters of several rivers, empties itself into the Yang-tfe-kiang, and contributes in no small degree to the magnitude of that river. The adjacent country, consisting of swampy ground to the E. and S. of the lake, is distributed into fishing ponds, in which each proprietor breeds and fattens his fish, of which some are a small species like sprats, which dried and salted, become an object of commerce throughout the empire. Water-fowl are also plentiful in this part of the country, and form a part of its resources. The city Nang-kiang is situated on the banks of this lake. Stanton's Emb. vol. ii.

POYERA, or PETRI GRANDE, a town of Africa, in the district of Asa, on the Gold coast.

POYESEIE, a town of Lithuania, on the Nienen; 61 miles S.E. of Kowce.

POYNINGS, Sir Edward, in Biography, a gentleman of Kent, was sent by Henry VII. to Ireland, which he governed with courage and prudence; the object of his mission was to quell the partizans of the house of York, and to reduce the natives to subjection. He was not supported by forces sufficient for that enterprize. The Irish, by flying into their woods and mountains, eluded his efforts. But he summoned a parliament at Dublin, in which he was more successful, and passed that memorable statute, which for more than three centuries was referred to by the name of Poyning's law, and which established the authority of the English government in Ireland. By this statute, all the former laws of England were made to be of force in Ireland; and no bill could be introduced into the Irish parliament, unless it had previously received the function of the privy council of England. The Union (which see) in 1800 has changed the whole system of government. In the reign of Henry VIII. Poyning was made privy councilor, and appointed governor of Tonrany. Hume and Rapin.

POYNING'S ACTS, a set of statutes enacted in the 10 Hen. VII. one of which (cap. 4.) in order to restrain the power as well of the deputy as the Irish parliament, provides, 1. That before any parliament be summoned or held, the chief governor and council of Ireland shall certify to the king, under the great seal of Ireland, the considerations and causes of it, and the articles of the acts proposed to be passed in it. 2. That after the king in his council of England, shall have considered, approved, or altered the said acts or any of them, and certified them back under the great seal of England, and shall have given licence to summon and hold a parliament, then the same shall be summoned and held; and in it the said acts so certified, and no other, shall be proposed, received, or rejected. But it was afterwards provided by 3 & 4 Pf. & M. cap. 4. that any new propositions might be certified to England in the usual forms, even after the summons, and during the session of parliament. By this means, however, there was nothing left to the parliament.
PZO

liment in Ireland, but a bare negative or power of rejecting, not of proposing or altering any law. But the usage has since been, that bills were often framed in either house under the denomination of 4 heads for a bill or bills, and in that shape they were offered to the consideration of the lord-lieutenant and privy council; who, upon such parliamentary intimation, or otherwise upon the application of private persons, received and transmitted such heads, or rejected them, without any transmission to England. And with regard to Pynnings' law in particular, it could not be repealed or frustrated, unless the bill for that purpose, before which they were certified to England, were approved by both the houses. Irish law, 1 Eliz. law. 5, cap. 38.

It was also enacted by another of Pynnings' laws (cap. 22.) that all acts of parliament, before made in England, should be of force within the realm of Ireland. But by the same rule that no laws made in England, between king John's time and Pynnings' law, were then binding in Ireland, it followed that no acts of the English parliament, made since the 10 Hen. VII. did bind the people of Ireland, unless specially named or included under general words.

These laws took their name, as we have before observed, from Sir Edward Pynnings, who was lord-deputy at the time when they were enacted; before which time, the original method of passing statutes in Ireland was nearly the same as in England, the chief governors holding parliaments at his pleasure, which enacted such laws as they thought proper.

With respect to the dependent state of Ireland, it was declared by 6 Geo. I. cap. 5, that the kingdom of Ireland ought to be subordinate to, and dependent upon, the imperial crown of Great Britain, as being inseparably united to it; and that the king's majesty, with the consent of the lords and commons of Great Britain in parliament, hath power to make laws to bind the people of Ireland. But this act was repealed in 1782; and a new state of things has taken place since the Union; which sec.

Poyo, in Geography, a town of Spain, in Galicia; 21 miles S.E. of Lugo.

Poyssis, a town of Sweden; 22 miles N.N.E. of Abo.

Poyucar, a town of Brazil; 21 miles S. of Fernando de Noronha.

Pozegi, a town of Ruffia, in the government of Pliska; 28 miles S.S.W. of Toglnetta.

Pozoblancó, a town of Spain, in the province of Cordova; 28 miles N. of Cordova.

Pozon, one of the smaller Philippine islands, near the W. coast of Leyta. N. lat. 10° 43'. E. long. 124° 24'.

Pozorubio, a town of Spain, in New Catlle; 28 miles S.S.W. of Huelva.

Pozzi, Anna, in Biography, an Italian female singer, who arrived home in the autumn of 1776, as succesor to the Gabrielli; but through young, handsome, and possessed of a voice uncommonly clear, firm, and powerful, her want of experience, both as a singer and actress, rendered her reception not very flattering: after so celebrated a performer as Gabrielli, though the public had never been in good humour with her during her whole residence in England, nor, we think, ever rendered justice to her talents. Before the season was far advanced, the Pozzi was superseded by Mrs. Davis; and after this degradation, she generally appeared as second woman, in which character she was always thought as superior to the fingers of that rank as any of the first women to whom she was obliged to give the pal, were to herself. She left England in 1781; and the spirit and brilliancy of her voice, with more experience, soon rendered her one of the first and most admired singers in Italy; where, by the year 1784, she had sung as first woman in all the great theatres, till she had worked her way to Naples, which is regarded as the post of honour for singers. But alas! the enjoyed this station only a short time; for she was seized by a fever, which carried her off, in the flower of her age, from the summit of vocal glory.

Pozzi, in Geography, a town of Naples, in the province of Otranto; 3 miles S.W. of Oria.

POZZO MARICHIO, a town of Naples, in the province of Bari; 19 miles S.S.W. of Conversano.

POZZO NEGRO, a town on the E. coast of the island of Foratventura.

POZZO Nuovo, a town of Naples, in Lavoria; 9 miles N.W. of Naples.

POZZO Roffo, a town of Naples, in the province of Bari; 9 miles S.W. of Andria.

POZZOZIANA, or Pizzolana, in Natural History, a kind of substance formed of volcanic ashes, more or less compacted together, and so called from Pozzuolo, and lulvis Puteolanus, from Puteoli, situated near mount Vesuvius, from which these ashes are ejected, and in the vicinity of which it abounds. It occurs of various colours, white, red, or black, reddish or reddish-brown, grey or greyish-black; that of Naples is generally grey; that of Civita Vecchia is more generally reddish or reddish-brown. The red variety is the proper pizzolina; the black and the white forts are called in Italy "lapillo," or "rapillo." The ashes which overwhelmed Pompeii now form an immense bed of white pizzolina. The surface of this substance is rough, uneven, and of a baked appearance. It comes to us in pieces, from the size of a nut to that of an egg. It is wholly indistinct of internal lustre and transparancy. It is easily fragile, and its fracture is uneven or earthy, and porous; commonly filled with particles of pumice, quartz, scoria, &c. Hardness, 3. Very brittle. Sp. gravity from 2.570, which is that of the black, to 2.785, rarely 2.8. Its smell is earthy. It is not diffusible in cold water; but in boiling water it gradually deposits a fine earth. It does not effervesce with acids. Heated, it assumes a darker colour, and easily melts into a black flag, or with borax into a yellowish-green glaze. Before it is heated, it is magnetic, but not afterwards. By Mr. Bergman's analysis, it contains from 55 to 60 per cent. of silicious, 19 to 20 of argillaceous earth, 5 or 6 of calcareous earth, and from 15 to 20 of iron. When mixed with a small proportion of lime it quickly hardens; and this induration takes place even under water. This fugglar property proceeds, as Mr. Kirwan supposes, from the magnetic state of the iron it contains; for this iron, being unoxidated, vitally divided, and dispersed through the whole mass, and thus offering a large surface, quickly decomposes the water with which it is mixed, when made into mortar, and forms a hard substance analogous to the peculiar iron ore, as it does in the iron tubes, in which water is decomposed, in the experiments of M. Lavoisier and Dr. Priestley; for in these the iron swells and increases in bulk; and so does pizzulana, when formed into mortar, as we learn from Higgins on "Cements." One principal use of lime seems to be to heat the water, as while it is hot, it cannot pervade the caked argill that invests the ferruginous particles; yet in time even cold water may pervade it, and produce hardnes; and hence, as M. Dolomieu has observed, lavas become harder when moistened. If the mortar be long exposed to the atmosphere, fixed air, as well as pure air, will unite to the iron, rust will be produced, and the mortar will not then harden, as Dr. Higgins has noticed. Clay, over which lava has flowed, is frequently converted into pizzulana; but volcanic scoria never afford it; either because they are much calcined, or retain sulphur, or its acid. (Kirwan.) The
The ancients were well acquainted with this substance and its properties; and among them its principal use, as it has been also in modern times, was that of mixing it with their cements for buildings funk into the sea. As it hardens and petrifles in water, it is of particular service in making moles, and other buildings, in maritime places. See Vitruvius, Pliny, de Lorme, &c. who set a great value on it. See Calexius Cements. See also Lava.

POZZOLE, in Geography, a town of France, in the department of Marsan; 5 miles S.E. of Alexandria.

POZZOLENO, a town of Italy, in the department of the Benaco; 5 miles S.E. of Defenzano.

POZZUOLO, anciently Puteoli, (which see), a town of Naples, in the province of Lavara, situated on a gulf of the Mediterranean, to which it gives name. For the supposed origin and ancient history of this town, we refer to Puteoli. Having suffered much, both from wars and earthquakes, it is reduced to a poor condition, though still furnishing many remains of its ancient magnificence and splendour. Its cathedral church was built from the temple of Jupiter, in the highest part of the city, and was constructed of large blocks of marble, and in a manner so solid, that it has maintained its existence notwithstanding the depredations of war, earthquakes, and time. It is of the Corinthian order, and was dedicated to Augustus, under the name of Jupiter, by Calpurnius Piso, a Roman knight, as appears by an inscription on the front of it. It contains also two parish churches, eight convents, and about 10,000 inhabitants; near it are Solfatara and the Campi Phlegraei, which are distant six miles W. from Naples.

In the square of this town stands a beautiful marble pedestal with jaffo-relieves on its pannels, representing the fourteen cities of Asia Minor, which had been destroyed by an earthquake, and rebuilt by Tiberius. It supported a statue of that emperor, erected by the fame cities, as a monument of their gratitude. Each city is represented by a figure bearing in its hand some characteristic emblem. The most striking monuments of Pozzulo (Puteoli) are the remains of the temple of Jupiter Scapis, and those of the mole that formed the port. The former stands in the precincts of the town, partly in a garden, and partly in the barracks, surrounded by new buildings. Its form is nearly square, about 130 feet long, and somewhat less in breadth. It was inclosed in a court, divided into small apartments, several of which still exist. Three of the four columns of the portico are standing, and the fourth lies extended on the pavement; they are of marble, and its roof is supported by sixteen pillars: the pedestal remains. Some beautiful statues have been found buried in the earth under the ruins, and many fine fragments of capitals, cornices, and sculptured pieces still remain, scattered around in the midst of dirt and rubbish.

Several piles of the mole still stand unbroken. They are sunk in deep water, and once supported arches, parts of which remain in a shattered state, notwithstanding the waves. When it was erected, it is not known. Antoninus, however, repaired it, when damaged or thrown down by the fury of the waves. Its solidity and durability are owing, in a great degree, to the quality of the cement, made of Pozzolana sand, which hardens under water, and acquires the strength and concretion of marble. The arches bear the name of Caligula, and are supposed by the people of the town to be the remains of the bridge which that prince, in one of his fits of phrenzy, threw over the bay from Puteoli to Baiae or Baalis. But it is needless to inform the learned reader, that Caligula's bridge was like that of Xerxes, which he intended to imitate, a temporary bridge erected upon boats, formed only of wood, and carried from the extremity of the mole to the opposite coast. In length, solidity, and duration, it probably surpassed its model, as it did also in extravagance and inutility.

PRAASPA, in Ancient Geography, a town of Asia, in Media, which had the title of royal, according to Dion Cassius. Plutarch gives it the name of "Phraortus," and says that Marc Antony made himself master of it.

PRABAT, in Geography, a town of Siam, seated on a river, which runs into the Mecon, remarkable for a relic of superlition, from which the place derived its name: but in the Bali or Palli language denoting a foot, and pra any thing worthy of veneration or respect. This relic is the print of a man's foot upon a rock, thirteen or fourteen inches deep, and five or six times its usual size. The Siamese adore this velfige, and believe that brute animals repair hither for the same purpose, when no perfon is present. The king renders homage once a-year to this miraculous impression, for which purpose he visits it with great pomp and parade; and it has been covered with a plate of gold, within a chapel constructed for this purpose. The Talapous pretend that it was made by Sommona Kodom, who at the time had one foot here, while the other rested in Lanka or Ceylon, although the whole gulf of Beugal lies between both places. They also record that by the pressure of his foot, he made the mountain flat and level, which was before elevated to a great height; 20 miles N. of Louwo.

PRAHBA, in Hindu Mythology, is comfort of Surya, or the sun. The name means splendour or brightness. She is sometimes called Chaya, or shade; and fables relate, as a reason for this, that unable to bear the intensity of Surya's beam, the affirmed the form of shade. In this form he became impregnated, and after a hundred years was delivered of a male child, who became regent of the planet Saturn, under the name of Sanj. (See that article.) This poetical allegory may refer to the phenomenon of the luminous and dark appearances of the remote planet. Prabha is also a name of the goddess Parvati; brightness being her property as Luma, or the moon. (See Parvati.) Vitalia, who is the sun, has a similar name, being sometimes called Prabha.

PRACA, in Ancient Geography, a town of Asia, in Cilicia, near Seleucia.

PRACELS, in Geography. See Paracels.

PRACHATITZ, or Pracum, a town of Bohemia, and capital of a circle of the same name, which circle borders on Bavaria and Austria, is full of mountains furnishing many precious stones besides some gold and silver, and contains 38 towns, great and small. The town is 66 miles S. of Prague. N. lat. 49° 1'. E. long. 13° 33'.

PRACTICAL Arithmetic, Geometry, Mathematicks, Music, Philology. See the subjacentive.

PRACTICE, in Arithmetick, Practica Italica, or Italian Ufages, certain compendious ways of working the rule of proportion, or golden-rule; especially where the first term is 1, or unity.

They were thus called from their expediting of practice, and business: and because first introduced by the merchants and negociants of Italy.

The most useful of these practices are as follow: 1. Since the use of the rule of three is to find a fourth proportional to three given numbers, divide the first and second, or first and third, by some common number (if that can be done exactly), and work with the quotients in their stead; as in the following example:

Price of 3lb. is 9s. What is the price of 7lb?

\[ \frac{3}{1} \times \frac{7}{3} = \frac{21}{3} = 7 \]

Price
Price of 14 lb. is 26s. What is the price of 7 lb?

7) 2 —

facit 13s.

2. If the first term be 1, and the second an aliquot part of a pound, thilling, or penny, divide the third by the aliquot part: the quotient is the answer.

Note. To find the aliquot part, those who cannot do it otherwise, may see the table of aliquot parts of a pound, under the article ALIQUOT.

E. gr. If one ell 10s. What cob 957 ells?

facit 478d. 10s.

3. If the first or third number be 1, the other not exceeding large, and the middle term a compound, i.e. consisting of several denominations, it may be wrought without reduction, thus:

Price of 1 lb. is 3s. 8d. 3d. What is the price of 3 lb?

facit 18s. 7d. 3d.

For four farthings making a penny, five times three farthings make 3d: 3d.; and twelve-pence making 1s., five times eight-pence make 3s. 4d., which, with 3d. from the place of farthings, makes 3s. 7d. Lastly, five times three thillings make 15s., and with the three thillings from the place of pence, 18s. The price required, therefore, is 18s. 7d. 3d.

4. If the middle term be not an aliquot, but an aliquant part, resolve the aliquant part into its aliquot parts, divide the middle term by the several aliquots; the sum of the quotients is the answer. To find the aliquant parts contained in an aliquant, see the table of aliquant parts of a pound, under the article ALIQUANT.

For an instance of this rule.

If 1 ell 15s. What cob 124 ells?

facit. 93d.

5. If the first or second term be 1, and in the former case, the second or third, in the latter the first, be resolvable into factors, the whole operation may be performed in the mind, without writing down any figures; as in the following example:

Price of 1 lb. is 24s. What is the price of 20 lb?

facit 480s.—24s.

6. Where one of the given numbers is 1, we have several compendious figures to save multiplication and division.

E. gr. If 9 lb. cob 20s. What does 1 lb. cob?

It is obvious the sum required is had by adding to the tenth part of 20s. viz. 2s. the ninth part of the tenth, viz. 2s. 1d., and 1/2 of a penny; the answer, therefore, is 2s. 2d. and 1/2.

Again, if 5 lb. cob 64s. What cob 1 lb.?

Since 5 is half of 10, the double of the tenth part of the given price, viz. 12s. 9d. and 2/3 is the sum required.

Again, if 1 lb. cob 18d. What will 19 lb. cob?

Since 19 = 20 - 1, from the given price doubled, and increased by a cipher, viz. 360; subtract the simple 18; the remainder is 342 = 28d. 6d. the sum required.

7. If two terms of the same denomination differ by an unit, we have a peculiar kind of compound, which will be clear from the following examples: e. gr. if 5 lb. cob 30s. What will 4 lb. cob? Since the price of 4 lb. is one-fifth part short of that of 5 lb. divide the given price 30s. by 5; the quotient 6 being subtracted from the dividend, the remainder, viz. 24s. is the sum required.

Again, if 8 lb. cob 24s. What cob 9 lb.?

Since the price of 9 lb. exceeds that of eight by one-eighth part, divide the given price 24s. by 8, and add the quotient 3 to the dividend: the sum 27 is the answer.

8. Sometimes one may use several of these compendies, or practices, in the same question. E. gr. If 100 lb. cob 30s. 4d. What cob 50 lb.

facit 7s. 4d.

PRACTORES, Ἱππακράντα, among the Athenians, officers appointed to receive the money due to the city from fines laid upon criminals.

PRADA, in Geography, a town of Italy, in the department of Amona; five miles N. of Faenza.—Alfo, a town of Italy, in the department of the Serio; seven miles N.E. of Bergamo.

PRADAKSHINA, in Mythology, a reverential ceremony, fo called by the Hindus, purporting a circumambulation. It is performed by keeping with closed palms the right hand toward the honoured object, and the face inclined that way. A pupil in this manner occasionally salutes his Guru, or spiritual preceptor, or his parents, by several times thus walking slowly round them. It is not unusual to see Brahmins and others circumambulating a temple, or a tree, especially of that species called in Europe the Ficus religiosa, in India pippala. Sometimes this is done with the right hand in a bag, holding a rosary. It is thought to aid abidrak contemplation, and is performed in silence, and called sap. (See that article.) Females also frequently perform this ceremony of pradakshina around a tree, or a linga; the latter especially, if it be in view of a temple, by propitiating a generative deity. (See Partiha.) It is in the latter cases continued for a considerable time, an hour perhaps, or more, usually at dawn of day, with a quickened pace, and frequently. Certain prayers are mentally recited during the ceremony. It is common to see one of the above-mentioned trees majestically spreading its arms over the roof of an extremely neat and clean house of a Brahman. Around the temple, for two or three yards each way, a mound of earth is often raised three or four feet, with perpendicular sides of brick or stone. This forms a terrace, on which perhaps is placed a linga (see LINGA), or an image, or shrub, according to the feel of the individual. The terrace is frequently smeared over with cow-dung, thinned with water to the consistance of paint, which is a very cool and cleanly application, and keeps away fleas and other insects. Mats or carpets spread on the terrace afford seats for reading or contemplation, or repose. To keep this place neat and in proper order is the province of the females of the family, who at day-break decorate the linga, &c. with chaplets of flowers, water the holy shrub, &c., or perform the pradakshina at the foot of the terrace, around which a path is usually made, and kept very clean, like the top of the terrace, which is called chakura.

PRADANOZ, in Geography, a town of Spain, in the province of Leon; 60 miles E. of Leon.
PRADELLES, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy; 17 miles S. of Le Puy. The place contains 1,197, and the canton 6,508 inhabitants, on a territory of 240 square miles, in 15 communes.

PRADES, a town of France, and principal place of a district, in the department of the Eastern Pyrenees, situated on the river Têt; 23 miles W.S.W. of Perpignan. The place contains 2,332, and the canton 5,184 inhabitants, on a territory of 295 square miles, in 23 communes. Lat. 42° 37'. Long. 2° 56'.—Allo, a town of Spain, in the province of Catalonia, near which is a magnificent abbey, where the ancient Kings of Aragon were interred; 12 miles N.W. of Manresa.

PRAO, a town of Portugal, in the province of Entre Duero e Minho; 2 miles N.W. of Braga.—Allo, a town of Spain, in Afturia; 32 miles N.E. of Oviedo.

PRAO, El, a town of Spain, in Castile; 27 miles W.S.W. of Madrid.

PRAOYAMNA, in Mythology, is an avatar or incarnation of Kama, the Hindoo cupid. (See KAMA.) Among a people so addicted to poetry as the Hindoos, we may reasonably expect a great deal of embellishment and extravagance in the amatory line. Such expectations are fully realized by an examination of their writings. The pretty fable of the god of love being reduced from a corporeal form to a mental effuence by a flash of fire from Siva's central eye, is very often alluded to. Kama met this fate in punishment of his presumption for伤口ing the angry god with one of his flowery arrows: but relenting, on the intercession of Parvati, he confided the afflicted Reti, widow of Kama, in the assurance that she should regain her husband, when he should be born again on earth, as Pradyamna, son of Krishna. (See Krishna.) Reti meanwhile was reduced to mental fervorite with a tyrant or demon, named Sambara, and her lamentations on her wretched fate fill a whole book in a poem, called the Birth of Kumara, by Kalidas, the author of Sakoontala. The promy of Siva was in due time fulfilled. Pradyamna, soon after his birth, was seized by the tyrant, put in a chest and thrown into the sea, where it was swallowed by a fish, which was caught and purveyed for his table. It fell to the lot of Reti to open the fish, and finding the chest and its contents, the nurtured the infant in private, and educated him, until he had attained maturity, and strength to destroy the malignant Sambara. The youth had before considered Reti as his mother; but their minds being now irradilated, their maya or delusion being dispelled, see Maya, the prophetic promise of Mahadeva was remembered, and the god of love was reunited to the goddess of pleasure.

P.R.E., a Latin preposition, literally signifying before; it is used in composition with several words in our language, to denote the relation of priority.

Of late, our writers, in Latin words anglicised, for *prae,* (prie, pri) usuall write *pré*; restringing the Latin orthography to words that are still Latin, or used as such. Hence, for such words beginning with *prae,* as are not found here, see *Præ.*

P.R.E.BIUM, a name used by medical authors to express a dose of any thing, or the quantity of medicine to be exhibited at one time.

P.R.E.CIÆ, among the Romans, the name with *Præelemitatores*; which see.

P.R.E.CIPE, in Law. See *Preeipe.*

P.R.E.CIPE in capite, a writ illuming out of the chancery, for a tenant holding of the king in capite; viz. in chief, as of his crown. *Vol. XXVIII.*

P.R.E.CLAMITATORES, among the Romans, officers that went along the streets of Rome before the *flamen dialis,* to oblige all people to give over their work on public holidays; for if the flamen saw any one at work, the service of the gods could not be performed.

P.R.E.CLAVIUM, among the Romans, was used to signify the pretexta.

P.R.E.CO, among the Romans, the public crier, an officer whose business it was in the assemblies of the people to call the Classics and centuries according to their order, and to order silence to be kept in the temples during the time of sacrificing.

The allusion of the praeo, or public crier, was used on many other occasions, as at public sales or auctions, funerals, games, in courts of justice, or public things loll, &c. See *Cres.*

P.R.E.COCIA MALA, in Botany. See *Aphrodit.*

P.R.E.COINISSUS, in Natural History, the name given by Ludovicus Dulcis, and other writers of his time, to a gem famous for its imaginary virtues: it is described to have been of the nature of the faphrite, but somewhat approaching to the colour of the chaledony: this seems to make it the leucofapphirus of other authors.

P.R.E.CORDIA, in Anatomy. See *Preeordia.*

P.R.E.CRETUR æ, among the Romans. See Prefecture.

P.R.E.FERICULUM, among the Romans, a vase with a large prominent mouth, used in the sacrifices of *Ops.*

P.R.E.FIERUM, a word used by chemical writers to express the anterior part of a furnace, by which the coals, or fuel are put in, and the ashes taken out.

P.R.E.FICE, among the Romans, were mourning women hired to attend funeral solemnities; where they prayed the deceased, made a lamentation, beat their breasts, and distorted their faces, to excite others to mourn.

P.R.E.FINE, or Præme Fine, in Law, that fine which upon fining out the writ of covenant on levying fines of lands, is paid before the time is past. This is a noble for every five marks of land fixed for, i.e. one-twelfth of the annual value. See *Post-fine.*

P.R.E.LUDIUM, Lat. See *Preelude.*

P.R.E.MIUM. See *Premium.*

P.R.E.MORSUS, in Botany. See *Radix* and *Root.*

P.R.E.NOTION, is used by lord Bacon for breaking of an endlesse search, which he observes to be one of the principal parts of the art of memory. For when one endeavours to call any thing to mind, without some previous notion or perception of what is sought for, the mind exerts itself and strives in an endlesse manner, but if it hath any short notion before hand, the infinity of the search is presently cut off, and the mind hunts wiser home, as in an inclosure. Thus verfe is easier remembered than prose; because if we flick at any word in a verfe, we have a previous notion that it is such a word as must fland in a verfe. Hence also, order is a manifest help to memory; for here is a previous notion that the thing sought for must be agreeable to order. Bacon's Works Abr. vol. i. p. 136. and vol. ii. p. 473. See *Prenotion,* and *Common Notions.*

P.R.E.PPOSITUS Sacri Cubiculi, among the Romans, an officer who was to take care of the emperor's bed-chamber. His office was the same with that of our lord chamberlain, and he had the privilege of marching next to the captain of the horse-guards.

P.R.E.SALTO, among the Romans, an appellation given to the chief director of the *falli.*

P.R.E.SALTO, among the Romans, an appellation given to the chief director of the *falli.*

P.R.E.SALTOR, among the Romans, an appellation given to the chief director of the *falli.*

P.R.E.SALTO, among the Romans, an appellation given to the chief director of the *falli.*

P.R.ESEP'TA, a word used by authors to express the sockets of the teeth.
PRÆSICIA, in Antiquity, those parts of the intrails of sacrifices which were cut off, and offered to the gods.

PRÆSUL, among the Romans, the name of a chief of the falis, or priets of Mars. He was so called a praefidendo; i.e., dancing at the head of the falis.

PÆTORIUS, Michael, in Biography, an ecclesiastic in the Romish church, born at Creutzberg, in Thuringia; and one of the most voluminous writers on music, and composer, in Germany. In 1596, he was the forty-eighth of fifty-three ordinaries appointed to examine the organ newly erected in the castle church at Groningen, in North Holland. His great theoretical work was entitled "Synagnasmus Mucicum," which was designed to be extended to four vols. quarto; but he only published three. They contained a kind of history of the progress of ecclesiastical music, from its beginning, to the author's own time. Walther has given the contents of each chapter of the three volumes; in which we find that the author had not confined his enquiries to ecclesiastical music, but of secular music gives the names of the fancied inventors of instruments and melodies; not forgetting the medicinal, or miraculous powers of the music of the ancients.

We fancy the work was not received by the public in a manner which the author expected. In the dedication of the first volume the author complains of his fatigues and trouble, and never published the fourth.

Many of his compositions have fallen into our hands, which, having feared, we found to be dry, and totally devoid of genius, though correct in harmony. If ever they may be said to have lived, they have been too long plunged in Lethe, as to be now dead beyond all the power of resuscitation.

PRAG, in Geography, a town of the duchy of Wurzburg; 3 miles N. of Killingen.

PRAGA, or PRAGUE, a town of the duchy of Warfaw, on the Vltava, which separates it from Warfaw, of which it is the faubourg.

PRAGELAS, a town of France, in the department of the Po, ceded by France to the king of Sardina, at the peace of Utrecht; 9 miles from Sufa.

PRAGERHOF, a town of the duchy of Stivia; 4 miles E. of Windisch Weilirzit.

PRAGMATIC SANCTION, in the Civil Law, is defined, by Hottoman, a reprimand, or anwer of the sovereign; delivered, by advice of his council, to some college, order, or body of people, upon their consulting him in some cafe of their community.

The word is formed from the Greek πράγμα, negotiwm, bujimis. It is sometimes also called absolutely, pragnaticum, πραγματικόν.

The like answer given to any particular person, is called simly referant, referantum.

The term pragmatic sanction is chiefly used, among the modern writers, for that famous ordinance of Charles VII. of France, drawn up at Bourges, with the consent of the most eminent prelates and grandees of the nation assembled at that place, and published in 1438, containing a regulation of ecclesiastical discipline, conformable to the canons of the council of Basil; and since used by the Gallican church, as a barrier against the enterprizes and encroachments of the court of Rome.

The scope of the pragmatic sanction, which consisted of twenty-three articles, was to regulate the form of elections made by the clergy, to restore to every church its privilege of chusing its bishop, and to every monastery that of electing its abbot or prior; to declare the collations to belong to ordinaries, the prevention alone referred to establish prebends; to align a third of the benefices to graduates; and to abolish reservations, annates, and other like grievances.

The pragmatic of St. Lewis in 1268, consisting of six articles, was similar to this in its chief design. The edict of Bourges, in 1438, was drawn up in concert with the fathers of the council of Basil, and the articles it contains were taken from the decrees of that council; though they were admitted by the Gallican church with certain modifications, which the nature of the times and the manners of the nation rendered expedient. See this edict published at large in Har. Concil. tom. viii. p. 1490.

Pope Pius II. obtained an abrogation of this sanction from Louis XI., on which occasion the court of Rome, transported with joy, dragged the pragmatic through the streets, whipping it all the way, as Xerxes anciently did the Hellepont; and the king obtained for himself and his successors the title of Moiff Christian.

But the parliament opposed this abrogation with a great deal of vigour, and refused its consent to the lait. Lewis also perceiving that he had been deluded into this measure by the treacherous inflammations of Geoffroy, bishop of Arras, whom the pope had bribed with a cardinal's cap, and large promises of a more lucrative kind, took not for pains to have it executed, but published, on the contrary, new edicts against the pecuniary pretensions and extortions of the court of Rome. So that, in spite of all the efforts of Rome, the sanction still held in force, till the concordat held between pope Leo X. and Francis I. in 1517, when the pragmatic sanction was abolished, and the king was invested with the privilege of nominating to bishoprics and vacant benefices.

The parliament of Paris again opposed the innovation, and refused to confirm the concordat; and was not brought to give its consent at last, till after repeated orders of the king; together with a secret resolution taken always to judge conformably to the tenor of the pragmatic sanction.

PRAGMATIONAL, PRAGMATICUS, a term sometimes used in the same sense as practical, mechanical, or problematical.

Sestius, in his Hydrostatical Elements, calls certain of his mechanical or practical experiments, which he undertakes to instruct his reader how to make, by the name of pragmatical examples: and, in the like sense, is the word sometimes used by other naturalists.

PRAGSTAAAL, in Geography, a town of Austria; 9 miles S. of Grein.

PRAGUE, a city and capital of Bohemia, situated in the circus of Schlan, and almost in the centre of the kingdom. Its fortifications are of little importance; its houses, generally of three stories, are built of stone; it has broader streets, though fewer flatly palaces, than Vienna. The number of its churches and chapels is reckoned to be 92, and it has about 40 cloisters. The population of Prague is not duly proportioned to its extent, as it contains only about 79,500 Christians, 9000 Jews, and 8000 in garrison; nor is its commerce considerable, and its inhabitants chiefly subsist on the brewing of beer, independently of some few arts and handicraft trades. Prague confines properly of three towns, each of which has its peculiar magistrate: viz, the Old and New Towns, lying the E. side of the Mulda, and Small-side, on the W. side of that river. The Old Town, like ancient, is called Small-side, but older than the New Town, was first founded in the year 795, and from its ancient citadel called "Wichterid," and the "Great Town," by way of distinction from the lesser side or Town. The New Town, or "Neufstadt," was founded by Charles IV. in the year 1348, and called "Karl." or "Karl-
“Karlstadt,” having the same privileges with the Old Town. This surrounds the Old Town for a considerable compass, and has broad and straight streets, with 2500 houses. The Small-side, or Leffer Town, is united with the preceding by a stone bridge, erected over the Mulda, and being the oldest, first bore the name of Prague. Prague is the see of an archbishopric. It is besides our purpose to recount the contelis in which for several centuries it has taken part. Without the Strahov gate, at no great distance from the cky, is situated the eminence, called the “White Mountain,” and rendered remarkable by the battle fought there in 1620, which terminated unhappily on the side of the Palfgrave, and crowned Frederick king of Bohemia. Prague has an university, which was founded in 1347. N. lat. 50° 51’. E. long. 13° 28’.

PRAGWALD, a town of the duchy of Stria; 6 miles W. of Cilley.

PRAHEC, a town of France, in the department of the Two Sevres, and chief place of a canton, in the district of Niort; 6 miles S.E. of Niort. The place contains 7444, and the canton 4900 inhabitants, on a territory of 1624 kilomètres, in 9 communes.

PRAIRIE de Rocher, La, or the Rock Meadow, a settlement in the Indiana territory, on the E. side of the Menilippi, on a stream which enters into this river, 12 miles to the S. 15 miles N.W. of Kafkalkas village, and 6 miles by E. of fort Chartres. Between 30 and 40 years ago it contained 100 white inhabitants, and 80 negroes.

PRAIRE, La, a populous though small village, with narrow dirty streets, on the river St. Lawrence in Canada; 18 miles N. of St. John. N. lat. 45° 32’. W. long. 73° 15’.

PRAISSAS, a town of France, in the department of the Lot and Garnone; 10 miles S.E. of Tonneins.

PRAKRITI, in Hindoo Mythology, is a personification of crude nature, or chaos. It is detailed at great length in the Hindoo theogonies how the divine being, after creating the triumviri, proceeded to the formation of Prakriti, who under different forms and names is the consort of the triad or trimurti. 1. As Saraswati, she is the consort of Brahma, the patroness of learning, the goddess of eloquence, and inventress of the lyre. 2. As Sri, or Lakshmi, she is the beloved of Vishnu, the goddess of abundance and fertility. 3. As Surya or Parvati, she is the companion of Shiva, and the vaquisher of the giants. These were produced by the volition of the deity. In the Sri Purana it is added, that with Prakriti, a male being called Parvata was created. Prakriti is described as of perfect beauty, with eight arms. They are afterwards called Narayana and Narayani, whence proceeded the elements of created nature, earth, fire, water, &c. From the navel of Narayana a lotos issued, bearing Brahma in its calyx; and from Narayani sprung Vishnu, and Lakshmi and Parvati, and Savita; the latter a name of the sun; but here apparently the fame as Saraswati. We shall here, however, enter no further on these fables, which require a lengthened and connected detail to render them at all consistent or comprehensible. A reference to the several articles in this work, under the names mentioned above, may perhaps furnish a clue to some of the natural phenomena veiled in these allegories.

PRAM, or PRAPE, a fort of lighter used in Holland and the ports of the Baltic sea, to carry the cargo of a merchant ship along-side, in order to land her, or bring it ashore.

PRAVMION, in Natural History, the name of one of the fennel, and from all the others as to make properly a peculiar genus of fennel. It is called by

many of the ancients morio or morion, and by our lapiaries the black agate.

It is a stone of a very great concealed beauty. Our lapiaries, who know it by the name of the black agate, are very indeterminate in the application of that name, calling not only this, but every black stone capable of a good polish, by the same name, and never looking for its great character, its hidden colour. It is found in the shape of our common flints and pebbles, but seldom larger than an egg; it appears, on a slight inspection, to be of a fine deep black, but held up against the sun, or the light of a candle, it discloses itself to be of a fine brown red, without the least admixture of any other colour. It is most frequently a purplish tinge, like the amethyst, but is at times found of all the degrees of red, from the pale flower colour of the hyacinth to the deep red of the carbuncle. It is of great hardness, and capable of an elegant polish.

It is produced only in the East Indies; and we sometimes have it thence among other stones, but it is not much regarded with us. The Romans were fond of it for engraving on, as we find by Pliny, and by a much more undeniable proof, many of the valuable antiques being cut on it.

PRAMNOS, a name given by the ancients to a fort of auriferous wine, which looked of a black colour till held up against the light, and then appeared of a deep purple: it is recommended by Hippocrates in hemorrhages.

PRAMPRAM, in Geography, a town of Africa, on the Gold Coast. N. lat. 5° 50’. W. long. 7° 45’.

PRANDNETZ, a town of Prussia, in the palatinate of Culm; nine miles E. of Thorn.

PRANSAUR, a town of Bengal; 10 miles S. of Dinagepour.

PRAPREDSHOFF, a town of the duchy of Carniola; three miles W.N.W. of Weixelburg.

PRAE, in Mineralogy. See Quartz, Gems, and Prasis.

PRASIN, in Geography, a town of Istria; 14 miles N.N.E. of Pedena.

PRASINUM VIHIDE, a word used by the ancients for verdigris.

PRASON. The ancient Greek writers have expressed three very different plants by this name.

The most common signification of the word is the common marvium, or horchord. It is in many places used also to signify the leek, and often for that sort of marjoram which we call origanum onitc, or pot-marjoram. Pliny describes this plant, and says that it was called origanum and prasis, and had the appearance of hyflop.

Hesychius tells us, that the sea-weeds of the fucus and alga kinds, the sea-oaks, and sea-wracks, are called by some of the Greek writers prasia; and Theophrastus in one part of his works seems to have given this name to those substances.

The ancients having used the word prasia in this sense, explains a passage in Galen which cannot otherwise be well understood, that is, where he calls the esopreum marium, prasiaeides, like the prasia.

Dioscorides had called it fucoides, like the sea-fucus, and he was very well understood; but Galen coming after him, and expressing his sense by the word prasaides, which was supposed to signify resembling leeks, or horchord, or origanum, his readers were perplexed to find out what alliance the epithet he had chosen to use could have, either to the plant, or to the epithet of Dioscorides; but when it is found that prasia signifies the same as fucus, the whole is very intelligible.

PRASIS,
PRASIS, a word used by some authors to express what they call green chalk, an earth used by the painters, and known among us by the name of the terre verte.

PRAS lumin, in Botany, a name adopted from Dioscorides, though there is little probability of his ψηφος being our plant, except so far as it is reported to have some affinity to Horehound or to Marjoram, and our's is a ringent flower, found wild in Greece and other parts of the south of Europe. Linn. Gen. 302. Schreb. 398. Willd. Sp. Pl. v. 3. 1759. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. Juli. 1717. Lamarck Illistr. t. 516. Gaertn. t. 66.—Claus and order, Didynamia Gymnofermata. Nat. Ord. Verticillatae, Linn. Labiate, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell- shaped, turbinate, erect, two-lipped; upper lip broadest, divided half way down into three acute segments; lower rather smaller, cleft. Cor. of one petal, ringent; its upper lip erect, ovate, concave, slightly margined; lower broadest, three-cleft, reflexed, the middle segment largest. Stam. Filaments four, awl-shaped, rather distant, preflled close to the upper lip, but not so long, two of them shorter than the others; anthers oblong, lateral. PfiJl. Germen four-cleft; style thread-shaped, agreeing with the lamens in length and situation; stigma in two acute segments, one of which is shorter than the other. Peric. Seeds four, roundish, in the bottom of the calyx, each pulp under the skin.

Eff. Ch. Seeds four, with a pulpy coat.

1. P. major. Great Spanish Hedge-nettle. Linn. Sp. Pl. 838. Willd. n. 1. Ait. n. 1. Sin. Fl. Grec. Sibth. t. 584, unpublished. (Teucrium fruticans, ampio et albo flore, italicum; Barrel. 1c. t. 895.)—Leaves ovate-oblong, ferrated.—Native of Italy, Sicily, Barbary, and the Levant. It flowers in our greenhouse from the early spring to the end of summer, and is easily kept, as well as propagated by cuttings without difficulty, but there is nothing in its appearance to excite popular admiration. The stem is shrubby, branched and spreading. Leaves on short stalks, opposite, smooth, dark-green, an inch or more in length. Flower axillary, solitary, opposite, white, spotted in the mouth with purple. Fruit dark violet, juicy, like four berries, some of which are often abortive.

2. P. minor. Small Sicilian Hedge-nettle. Linn. Sp. Pl. 838. Willd. n. 2. Ait. n. 2.—Leaves ovate, with two notches at each side. Native of Sicily, where it was noticed by Cupani. This species finds a place in Mr. Alton's work, but seems to be no where figured, nor is it supposed to be more than a small variety of the foregoing, with fewer notches in the leaves. Cupani's description of the flowers betrays no distinction whatever. Linnaeus however seems to have, at some time or other, confounded another plant with this, but not perhaps in any of his descriptions. The P. major bears the name of σπονδυλον among the modern inhabitants of Zante; which from its resemblance to ψηφος, softened, as usual in modern Greek, at the beginning of the word, and combined with ψηφος a plant, countenances the Linnaean adaptation of the generic name.

PRASIS, in Gardening, contains plants of the low, shrub- by, exotic, evergreen kinds, of which the species cultivated are, the great Spanish hedge-nettle (P. major); and the small hedge-nettle (P. minor).

Method of Culture.—These plants may be increased by seeds and cuttings. The seeds should be sown on a bed of light mould, in the early spring season, as about April, the plants being afterwards kept clear from weeds, and placed in the situations where they are to remain, or in pots, to be gradually hardened as they advance in growth.

The cuttings should be taken from such plants as are strong, and where the thoots are short and good, and if a joint of the former year's wood be taken to each of them, they succeed better. They should be planted out either in a shady border or in pots in the latter part of the spring season, as about the end of April. When the plants have flourished root enough in the borders, they should be removed into the situations where they are to remain, and those in pots into separate ones. Those in pots should be placed under a frame during the winter, or in the greenhouse, where they can have plenty of free air when the season is dry. They only require to be screened from severe frosts. When planted in the open ground they should have a dry poor soil and sheltered situation. These plants afford much ornament in the greenhouse collections, and among other evergreen shrubs of the more hardy kinds.

PRASIS, in Natural History, the name of a gem much approaching to the nature of the emerald, but of a coarser green, and wanting its hardness, and having in its green a cast of yellow.

It is the flake which the ancients called prafites; and when of a greater than ordinary admixture of yellow, the chry- soprasus, and of which the gem distinguished by later au- thors under the name of smeragloprasus, is only one of the varieties.

The prafus, even in its most perfect state, is much less beautiful than most of the other gems; it is found of various sizes, and not unfrequently considerably large: it is seldom met with smaller than a pea; from that to the size of a horde bean is its more usual standard, from this to the size of a nutmeg it is more rarely found; and the larger specimens are coarser and less frequent than these. It is of various figures, but is never found in a columnar or crytal-like form; this is declaring against the sense of our dealers in gems, indeed, who frequently buy and sell columns of the shape of sprig crytal; under the name of the smeragloprasus; but these are all truly no other than crystals tinged to a coarser and dead green, and without any mixture of yellow; so that they are more properly pseudonarageth, or baltard emeralds, than any thing of the prafus kind. See Gems and Quartz.

P R A S L A U K E N, in Geography, a town of Prussian Lithuania, on the Rominte; eight miles S.S.E. of Gumbinnen.

P R A S L I N, an island in the Indian sea, lofty, mountainous, and covered with trees. Mr. Lewis, commander of the Eagle, one of the Hon. East India Company's cruisers from Bombay, landed here in the year 1771, and found a flag-flaat erected by the French on a rock, but the flag was blown away; the arms of the king of France were cut on a sheet of lead, and set in a small place built of brick and mortar, in token of possession, with the date 1768. Port Prassin, on the N. side of the lands of the Arsacides, (see Arsacides,) in S. lat. 70° 25', E. long. from Paris 155° 32', was discovered and entered by M. de Saurive, Oct. 12, 1799. The inhabitants of the islands that form this port are represented as being generally of the Negro kind, with black woolly hair, flat noses, and thick lips. Mr. Lewis found on the island which he visited plenty of cocoanut trees, and land-tortoises, but neither tents nor appearance of inhabitants. The harbour seemed to be a good one, and well sheltered by small islands from all winds.

P R A S L I N, a town of France, in the department of the Aube; nine miles S.W. of Bar-sur-Seine.
PRAISONISI, a small island near the N. E. coast of the island of Samos.—Allo, two rocky islets in the Grecian Archipelago, near the S. coast of Myconia.

PRASHYLLUM, in Botany, from ψευδος, a lie, and φυλλον, a leaf, because of the tubular and tapering form of the solitary leaf in every known species, resembling the foliage of a leek. Brown Prodr. Nov. Holl. v. i. 317.

Efl. Ch. Calyx ringlet; upper leaf in front, vaulitet. Petals inequilateral. Lip ascending, undivided, flabellate, without a spur. Column deeply divided; its lateral segments membranous. Anther in front, parallel to the stigmas, permanent, with approximated cells. Masses of pollen in two each cell, powdery, attached by their points to the stigmas.

This genus is said by its author to be very nearly akin to Granichis, as well as to Genoplophium. He describes twelve species, natives of the caff and south parts of New Holland; all smooth herbaceous plants, growing on the ground. Their bulbs are undivided. Stem bearing one or two short leafing scales and one leaf, but no bracteas. The leaf is cylindrical, tubular, sometimes short, with a very long leafing base. Flowers spiked, among the small bell of this tribe, of various colours. Some have the lateral segments of the column, which Mr. Brown regards as abortive filaments, entire at the summit; others have those parts cloven. In the former case the anther is without a point: in the latter it has a sort of beak. All the species were seen by this acute botanist in a living state, and appear to have been described by no other writer.

PRAGRAMDET, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 61° 21'. E. long. 17° 10'.

PRASOE, or PRASOE, a sea-port of Denmark, with a good harbour in a bay of the Baltic, on the S. E. coast of the island of Zealand; 35 miles S. of Copenhagen. N. lat. 55° 10'. E. long. 12° 6'.

PRESTERGADEN, a town of Sweden, in Warmeland; seven miles N. E. of Carlstadt.

PRA, a town of France, in the department of the North Coasts; eight miles S. E. of Lianon.

PFATAS, a cluster of islands in the Chinese sea, arranged in a circular form, and about 60 miles in circumference. N. lat. 19° 32'. E. long. 165° 43'. One of these islands, called "Prata," is of considerable extent, being 18 miles from N. to S., according to captain King, but he was not able to ascertain its western limits. Its N. E. extremity was in N. lat. 20° 55'. E. long. 117°; and its S. W. extremity in N. lat. 20° 45'. E. long. 115° 44'.

PRATENSIS, in Biography. See Josquin.

PRATICA, in Geography, a town of Italy, in Campagna di Roma; eight miles S. W. of Albano.

PRATIQUE, or Pratique, in Commerce, a negotiation, or communication of commerce, which a merchant-vehicle obtains in the ports it arrives in, and the countries it discovers.

The word is French, and signifies, literally, pratique. Hence, to obtain pratique, is to obtain a liberty to frequent a port, to go afloat, to buy and sell, &c.

In the European ports of the Mediterranean sea, it implies a free commercial intercourse with the inhabitants of the country, after a limited quarantine has been performed, in conformance of a voyage to Barbary or Turkey.

Pratique is particularly used for a licence to traffic, granted to the master of a ship in the ports of Italy, upon a bill of health; that is, a certificate that the place whence he came is not annoyed with any infectious disease.

PRATO, in Geography, a town of Italy, in the department of the Serio; 10 miles E. N. E. of Bergamo.—Allo, a town of Etruria; five miles N. E. of Florence.

PRATS DE MOLLO, a town of France, in the department of the Eastern Pyrenees, and chief place of a canton, in the district of Ceret; constructed in the form of an amphitheatre, irregularly built. In its vicinity are mines of copper mixed with silver; 12 miles W. S. W. of Ceret. The place contains 3190, and the canton 5954 inhabitants, on a territory of 285 kilometres, in five communes.

Prats del Rey, a town of Spain, in Catalonia; nine miles W. of Manresa.

PRAVIS, a town of Spain, in Afturia, on a river of the same name.—Allo, a river of Spain, which passes by Oviedo, &c. and runs into the sea; 10 miles N. from the town of Pravis.

PRAUL POINT, a cape of England, on the S. coast of Devonshire, in the English channel; five miles S. W. of Start Point.

PRAUSKA, a town of the duchy of Warfaw; 30 miles S. of Siradìa.

PRAUSNI, Teutsch, a town of Bohemia, in the circle of Koninggratz; four miles S. of Trautcnau.

PRAUSNITZ, or Prussiek, a town of Silefia, in the principality of Trachenberg; six miles S. of Trachenberg. N. lat. 51° 21'. E. long. 16° 58'.

PRAUST, a town of Pomerelia; seven miles S. of Dantzic.

PRAUTHY, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Langres. The place contains 654, and the canton 9532 inhabitants, on a territory of 272 1/2 kilometres, in 25 communes.

PRAWD. See Cancer and Squilla, family Palaemon.

PRAXAGORAS, in Biography, a physician, born in the island of Cos, and the son of Nearchus. He was of the family of the Aclepides, and one of the last of them who supported the medical reputation of the line. He was contemporary with Diocles. He studied anatomy, and especially the dissection of the brutes, and left some works on the subject, which are now lost, and of which Galen spake with some contempt. Nevertheless, his reputation attracted the celebrated anatomists Philotimus, Philonicus, and Herothus to his school. Some fragments of his medical doctrines, however, which are preserved by Calius Aurelianus, seem to confirm the opinion which Galen maintained of his skill. See Le Clerc. Hist. de la Med.

PRAXEANS, in Ecclesiastical History, a sect of heretics, so called from their author, Praxes.

This heretarchy was of Asia, and lived in the second century. He was at first a disciple of Montanus, but quitted him, and soon after set up a sect of his own: teaching, that there was no plurality of persons in the Godhead; and that it was the Father himself that suffered on the cross; which sentiment was afterwards adopted by the Monarchists, Sarbellians, and Patrisphalians.

PRAXITELES, in Biography, a celebrated sculptor of antiquity, was born in Greece Magna, and flourished about the year 364 B. C. He excelled particularly in the working of marble, and was the author of some of the most famous statues noticed by ancient writers; among these were two of Venus, one clothed and the other naked. The first was purchased by the Coans, who preferred it as the most decent.
PRA

PRA

PRA

decent. The Cnidians took the other, which was so exquisitely beautiful, that many persons took a voyage to the island for the sole purpose of seeing it. Praxiteles was deeply enamoured of the famous courtezan Phryne, of whom he made several statues, one of which was erected at Delphi. Many of his performances were in the Ceramicus at Athens, among the rest, the statues of Harmodius and Aristogiton, which Xerxes carried away, and Alexander afterwards restored. Many were extant at a later period in Rome. His most noted works were in marble, but he cast many statues in metal, which, as well as those of marble, were greatly admired. He had a son, Cephisodorus, who inherited his skill and fame.

PRAYA, in Geography. See PORTO-PRAYA.

PRAYA, a sea-port town of the island of Tercera, situated on a plain, near the gulf, defended by walls and bastions; containing a church, four convents, three hospitals, and about 5000 inhabitants.—Alfo, a town of the island of Gratiofia, one of the Azores.—Alfo, a town of Africa, on the Slave Coast, in the kingdom of Ardra, situated on the sea-coast, at the bottom of a bay; 32 miles N.E. of Grand Popo.

PRAYER, in Theology, denotes a serious and solemn address of our minds to the Deity, as the fountain of being and happiness, and the parent and governor of the world. The chief parts which it includes are, acknowledgment of our dependence, and of the divine perfections and sovereignty: thankfulness for the mercies we have received; a penitential confession of what we have done amiss; and offering up our desires of favour and happiness for ourselves and others.

Divines distinguish three kinds of prayer:

Vocal, which is clothed in words and sounds to be uttered with the mouth. Mental, which is only formed or conceived in the mind, and not delivered in words. Ejusatory, which is a short, sudden flight, without studied, order, or method.

Mythic divines, again, distinguish prayer into actio and piafice.

Among us, prayer is most frequently considered under the divisions of preconceived and extemporary.

Under the first come all the forms, whether public or private, by which the mind is directed in the order, manner, expression, &c. of its petitions. See Piafice.

The second is that where the mind is left to itself, its own conduct, both as to matter, manner, words, &c.

The Romanists also prefer prayers to saints; the Virgin, the angel Gabriel, &c.

We conceive that we shall not deviate from the general plan and design of this work, by availing ourselves of the opportunity that here occurs, of introducing some observations on the duty and efficacy of prayer, with brief replies to the more common objections that are urged against the obligation or utility of this duty.

It has been remarked in general, that it is the usual practice of mankind, when some of them wish to obtain any thing of others, to recur to intreaty. This universal practice must be natural; and it seems probable, says archdeacon Paley, that God, as our supreme governor, should expect that towards himself, which, by a natural impulse, or by the irresistible order of our constitution, he has promised us to pay to every other being on whom we depend. The same observation is applicable to thanksgiving. Besides, it has been often said, and as generally acknowledged, that prayer is necessary to keep up in men's minds a sense of God's agency in the universe, and of their own dependence upon him. But after all, the duty of prayer depends upon its
unqualified for any:—might not that prince, I say, although he proceeded upon no other considerations than the strict rectitude and expediency of the measure, grant a favour or pardon to this man, which he did not grant to another, who was too proud, too lazy, or too busy, too indifferent whether he received it or not, or too insensible of the sovereign's absolute power to give or to withhold it, ever to ask for it; or even to the philosopher, who, from an opinion of the fruitlessness of all addresses to a prince of the character which he had formed to himself, refused in his own example, and encouraged in others, all outward returns of gratitude, acknowledgments of duty, or application to the sovereign's mercy or bounty; the disuse of which (being affections do not long subsist which are never expressed) was followed by a decay of loyalty and zeal among his subjects, and threatened to end in a forgetfulness of his rights, and a contempt of his authority? These, together with other allignable considerations, and some perhaps inestimable, and even inconceivable by the perrons upon whom his will was to be exercised, might pafs in the mind of the prince, and move his counsels; whilst nothing, in the mean time, dwelt in the petitioner's thoughts but a sense of his own grief and wants; of the power and goodnecfs from which alone he was to look for relief; and of his obligation to endeavour, by future obedience, to render that perfon propitious to his happiness, in whose hands, and at the disposal of whose mercy, he found himself to be."

Our author obferves, that the objection to prayer supposes that a being perfectly wise must be necessarily immoveable, which supposition is altogether unwarrantable, as inexcusable is not any part of perfect wisdom; and it also affumes as a principle, that there is one, and only one mode of action for the behoof, and that the divine will is necessarily determined and confined to that mode; both which positions preffume a knowledge of universal nature, much beyond what we are capable of attaining.

Another evidence of the inefficacy of prayer is deduced from its want of the confirmation of experience. Concerning this appeal to experience, it will be sufficient to remark, that if prayer were suffered to disturb the order of second causes appointed in the universe too much, or to produce its effect with the same regularity that they do, it would introduce a change in human affairs, which, in some respects, will be evidently for the worse. If the efficacy of prayer were fo conitant and obfervable as to be relied upon before hand, the conduct of mankind would, in proportion to that reliance, become careless and disordered. Men would depend upon their praying instead of labour for the supply of their wants, and recur to prayer for the reformation of their health, instead of moderating their passions, or abating from those pleasures, which in many cafes are productive of dif-cafe. Upon the whole, we may observe, that our prayers may possibly, in many instances, be efficacious, and yet our experience of their efficacy be dubious and obscure. This obscurity and ambiguity may probably be necessary to the happiness and safety of human life.

Some persons, who would not with altogether to exclude prayer, object to the mode of it that is often adopted, and to many of the subjects that form a part of public worship, or of private devotion. To pray for particular favours explicitly, is, as they say, to dictate to divine, wisdom and goodness; to intercede for others, especially for whole communities and empires, is still worse: because we thus presume that we have such an intercessor with the Deity, as to be able, by our applications, to bend the most important of his counsels, and that the happiness of others as individuals, or in the aggregate, is to depend upon this intercessor and our choice. To this kind of objection it will be sufficient to reply, that our prayers for ourselves or others, as far as they concern ourselves and temporal interest, should be expressed with great humility and entire resignation to the divine will, and that under this limitation they are highly reasonable and proper; and they are conformable to that general plan of providence, which renders one man the instrument of happiness or misery to another. "Why may we not be afflicted by the prayers of other men, who are behelden for our support to their labour? Why may not our happiness be made in some cases to depend upon the intercession, as it certainly does in many upon the good offices of our neighbours? The happiness and misery of great numbers we fee oftentimes at the disposal of one man's choice, or liable to be much affected by his conduct; what greater difficulty is there in supposing, that the prayers of an individual may avert a calamity from multitudes, or be accepted to the benefit of whole communities?"

If we recur to the authority of divine revelation, this will confirm the conjectures and deductions furnished by natural religion, and afford us direct and positive evidence of the efficacy of prayer. The scriptures not only affirm the propriety of prayer in general, but supply us with precepts or examples, which justify some topics and modes of prayer that have been thought exceptional. Concerning the duty and efficacy of prayer in general, we may refer to Matt. vii. 11. Luke, xxi. 36. Rom. xii. 12. Phil. iv. 6. 1 Thess. v. 17. 1 Tim. ii. 18. Examples of prayer for particular favours by name occur in 2 Cor. xii. 8. 1 Thess. iii. 10. Directions to pray for national or public blessings may be found in Psalm cxiii. 6. Zech. x. 1. 1 Tim. ii. 1, 2, 3. Examples of intercession, and exhortations to intercede for others, are recorded in Exod. xxxii. 11. Acts, xii. 5. Rom. i. 9. xv. 30. James, v. 16. Moreover, declarations and examples authorizing the repetition of unsuccessful prayers may be found in Luke, xviii. 1. Matt. xxvi. 44. 2 Cor. xii. 8.

The reformed churches of Christendom, adhering to their only infallible guide, have laid aside prayers for the dead, because they are not authorized by any precept or precedent found in scripture. For the same reason they properly reject the invocation of saints; and also because such invocations suppose in the saints whom they address a knowledge, which can perceive what paffes in different regions of the earth at the same time: and they deem it too much to take it for granted, without the smallest intimation of such a thing in scripture, that any created being possesses a faculty little short of that omniscience and omnipresence which they ascribe to the Deity.

Private prayer, which is recommended by its own propriety, and by advantages not attainable in any form of religious communion, receives a superior sanction from the authority and example of Christ. Matt. vi. 6. xiv. 23.

The peculiar use of family prayer, as a branch of domestic piety, confines its influence upon servants, and the young members of a family, who may be less disposed than others of maturer years and greater reflection to avail themselves of the exercise of private devotion, and whose attention is not so easily commanded in public worship.

The duty and advantages of public worship require a more distinct consideration, and a more ample discussion, for which we refer to Public Worship. On the subject of this article, see Paley's Principles of Moral and Political Philosophy, vol. ii. ch. 2. Price's Differtations, diff. ii. Leckham's Sermon on Prayer.

PRAYER, Common. See Common Prayer and Liturgy. PRAYERS of forty Hours. See Hours.
PRAYERS, in *Mythology*, were, according to Hesiod, Jupiter’s daughters, mournful fitters, who were repulsed oftener than they were heard. Homer, in the speech of Phoenix to Achilles (II. I. 9), gives the following description of them:

“Prayers are Jove’s daughters, of celestial race; 
Lame are their feet, and wrinkled is their face; 
With humble men and with dejected eyes, 
Confiant they follow where Injustice flies: 
Injustice swift, erect, and unconfined, 
Swipes the wide earth, and tramples o’er mankind, 
While Prayers, to heal her wrongs, move slow behind. 
Who bears these daughters of almighty Jove, 
For him they meditate to the throne above; 
When man rejects the humble suit they make, 
The fire revenges for the daughter’s fake; 
From Jove commission’d, fierce Injustice then 
Defends, to punish unrelenting men.”

The mythologists give several explications of this allegory: but it requires no great penetration to find out that Homer calls Prayers lame, because they come not always just after the injury that occasions them; that they are wrinkled and have downcast eyes, to denote how apt men are to defer repentance, and how humble at last, when they want to make their peace with the offended party.

**PREAMBOCCO**, a town of Italy, in the Veronese; 13 miles N.W. of Verona.

**Preaching**, in *Theology*, the declaration, or proclamation, of the word of God, in public, by a person authorized, and in a place appointed for the purpose.

The word is derived from the Hebrew *parashah*, *expatium*, *be expounded*.

Anciently none but bishops were allowed to preach; now, not only priests, but deacons, are qualified.

Any person may preach, whatever be his mental talents and acquirements, who is legally qualified for the exercise of this office, either according to the constitution of the established church, or under the act of toleration. But the honourable, acceptable, and useful discharge of the office of preaching, so as to prevent the office itself from sinking into profane and contemptible use, religion from suffering reproach, and the end of preaching, which is to make men wiser, better, and happier, from being defeated, requires a variety of qualifications, that cannot be attained in an age, when miracles have ceased, and when a spirit of general inquiry prevails, without previous study. It is deplorable that the preacher, like the physician, should possess a fund of general knowledge; nor is it indelible, that he should be well acquainted with those subjects that immediately pertain to his profession. Without a considerable degree of this kind of knowledge, whatever popularity of a particular kind he may acquire, he is not likely to gain permanent reputation among persons of reflection and judgment, or to promote the mental and moral improvement of his auditors. Different situations, however, admit of the exercise of different talents, and preachers, undistinguished by literary, scientific, or even theological acquirements, have been eminently useful in impressing the heart, and regulating the practice, without communicating any great degree of information to the understanding. At the same time, it ought never to be forgotten, that, as Dr. Blair says, “the understanding must always be applied to in the first place, in order to make a lasting impression on the heart; and he who would work on men’s passions, or influence their practice, without first giving them just principles, and enlightening their minds, is no better than a mere declamer. He may raise transient emotions, or kindle a passing ardour; but can produce no solid or lasting effect.” Nevertheless, it should also be remembered, “that all the preacher’s instructions are to be of the practical kind; and that perusing must ever be the ultimate object. It is not to diffuse some abstruse point, that he ascends the pulpit; it is not to illustrate some metaphysical truth, or to inform men of something which they never heard before; but it is to make them better men; it is, at once, to give them clear views and perceptive impressions of religious truth. The eloquence of the pulpit, then, must be popular eloquence. One of the first qualities of preaching is to be popular; not in the sense of accommodation to the humour and prejudices of the people (which tends only to make a preacher contemptible), but, in the true sense of the word, calculated to make impressions on the people; to strike and to please their hearts. I scruple not, therefore, to assert, that the abstract and philosophical manner of preaching, however it may have been sometimes admired, is formed upon a very faulty idea, and deviates widely from the just plan of pulpit eloquence. Rational, indeed, a preacher ought always to be; he must give his audience clear ideas on every subject; and entertain them with ease, not with found. But to be an accurate reasoner will be small praise if he be not a perspicuous speaker also.”

A preacher, who would deliver a perspicuous oration, must himself be a good man. A well-known and approved character for piety and virtue will very much contribute to his success. As no man, on any subject, can be truly eloquent, who does not utter the “true voices able profound,” who does not speak the language of his own conviction and his own feelings, this circumstance is supremely requisite in preaching. Here, “it is of the utmost consequence that the speaker firmly believe both the truth and the importance of those principles which he inculcates on others; and, not only that he believes them speculatively, but have a lively and fervent feeling of them. This will always give an earnestness and strength, a fervour of piety to his exhortations, superior in its effects to all the arts of studied eloquence; and without it, the elegance of art will seldom be able to conceal the mere declamer. A spirit of true piety would prove the most effectual guard against those errors which preachers are apt to commit. It would make their discourses solid, cogent, and useful; it would prevent those frivolous and effeminate harangues, which have no other aim than merely to make a parade of speech, and amuse an audience.”

The chief characteristics of the eloquence fitted for the pulpit, as distinguished from other kinds of public speaking, appear to be two; gravity and warmth. The terrify nature of the subject belonging to the pulpit requires their immediate exercise. Unless these qualities are united, it is impossible to make a good preacher, and an earnest desire that they make full impression on the hearts of his hearers.” Blair’s Lectures, vol. ii.

For further particulars relating to the subject of preaching.
see Elocution (Elocution of the Pulpit), ORATION, PUBLIC SPEAKING, and SERMON.

Bishop Wilkins has delivered the art of preaching, in a treatise called Ecclesiastics, or the Preacher.

The religious of the order of St. Dominic assume the quality of preaching-brothers, friars-predicant, or predicants.

PREADAMITE, PREADAMITITES, a denomination given to the inhabitants of the earth; conceived, by some people, to have lived before Adam.

Pereyra, in 1655, published a book to evince the reality of Preadamites; by which he gained a considerable number of profelytes to the opinion; but the answer of Demares, professor of theology at Groningen, published the year following, put a stop to its progress; though Pereyra made a reply.

His system was this; the Jews call Adamites, and suppose them to have issued from Adam; and gives the title Preadamites to the Gentiles, whom he supposes to have been a long time before Adam.

But this being expressly contrary to the first words of Genesis, Pereyra had recourse to the fabulous antiquities of the Egyptians and Chaldeans, and to some of the idle rabbin; who imagined there had been another world before that described by Moses.

He was apprehended by the inquirers in Flanders, and very roughly used, though in the service of the Dauphin. But he appealed from their sentence to Rome, whither he went in the time of Alexander VII., and where he printed a retraction of his book of Preadamites.

PREAMBLES, in Law, the beginning of an act of parliament, &c. serving, as it were, for a key to open the intent of the makers of the act, and the mischief intended to be prevented or remedied thereby.

PREAUNDENCE. See PRECEDENCE.

PREBEND, PREBENDARY, the portion which a prebendary receives for his maintenance out of the estate of a cathedral, or collegiate church.

The term prebend is usually confounded with canonicate, or canonica; yet there is a real difference. A prebend is properly a right which an ecclesiastic has in a cathedral, or collegiate church, where he officiates, to receive certain ecclesiastical revenues, and to enjoy certain dues, either in money or in kind (so called a prebenda, q. d. afforded or allowed him; not a prebenda auxilium, or confilium episcopi); whereas canonica is a mere title, or spiritual quality, which a person enjoys independent of any pretation, or any temporal revenue; so that the prebend may subsist without the canon icy; but the canonicate is inseparable from the prebend.

For it is not to the prebend that the right of suffrage, and other spiritual rights are annexed, but to the canonicate; and when the prebend is joined to the canonicate, it becomes spiritual by virtue of the canonicate to which it is attached.

Anciently the pope created canons with the right of having place in the choir, a deliberative voice in the chapter, and an expectation of the first prebend that should become vacant; but this was prohibited by the council of Trent: yet the pope still confers the canonicate without any prebend, when he would confer a dignity in a church, for the obtaining of which it is required the candidate be a canon.

This they call a canonicate ad effectum, and sometimes a jura ventorum, which is no more than an empty title, conferred purely to qualify a man for a dignity restrained to the capacity of canon.

Originally the prebend was only a livery, or portion of things necessary to life, given daily; at present the rents and profits of the church are divided into fixed portions, called prebenda, which are enjoyed independently. Of common right the bishop is patron of all the prebends, because the possessions were derived from him. In such case, he prefers to them by collation, which is the same thing with institution, as no prebend is made; but if a prebend be in the gift of a layman, the patron prefers to the bishop, who instituted in like manner as to another benefice; and then the dean and chapter induce them, that is, after some ceremonies, place them in a stall in the cathedral church to which they belong; by which they are said to have a place in the choir. Some prebends are donnatic. At Westminster, the king collates by patent, and by virtue thereof the prebendary takes possession without institution or induction; and the king, at this day, is patron of most of the great prebends.

Prebends are either simple, or with dignity. The latter are such as, beside their prebends, have some jurisdiction annexed to them.

No person may hold more than one prebend in the same church; and if a prebendary accepteth of a deanery, his prebend is void by cession, the acceptance of a deanery being underfoot to be in the same church. So if he is made a bishop, the king presents to his prebend.

Neither prebendaries nor canons appear to have any cure of souls; and therefore a prebend and a parochial benefice are not incompatible, but both may be held together, without a dispensation; nor is it who takes a title to a prebend thereby obliged, by 13 Eliz. cap. 12, to subscribe or read the thirty-nine articles.

No part of the revenue of the church of Canterbury is allowed to any prebend in particular, except the annual stipend of 17l. 6s. 8d., which by the 16th chapter of the statutes is to be paid to every prebendary "pro corpore pre bendario fixe." The residue of the revenue is the joint property of the dean and chapter, as being an aggregate body; and no member has a right to any part of it.

PREBENDARY, PREBENDARIUS, an ecclesiastic who enjoys a prebend.

Prebendaries and canons of cathedral and collegiate churches have this in common, that they have each a portion of the revenues of the church for their subsistence; the one under the title of prebenda, prebend; the other under the title of canonic or canonicate; and have each places and voices in the chapter; but they differ in this, that the latter receives his portion or prebend in consideration of his officiating and serving in the church; but the latter without any such consideration, merely by his being received into the cathedral or college, per a signaturam sili in choro, et locum in capitolo.

Prebendaries and canons are bound to preach in their turns, or provide proper substutes. By 28 Hen. VIII, cap. 11, the profits of a prebend, during the vacation, shall go to the succesor, towards the payment of his fruits.

A prebendary leaving a house, by death or cession, out of repair, shall himself or by his executors be liable to a fine of dilapidation, though it was not annexed to the prebendal stall.

No prebendaries nor canons in cathedral or collegiate churches, having one or more benefits with cure (and not being residentiaries in the same cathedral or collegiate churches), shall, under colour of their said prebends, absent themselves from their benefits with cure, above the space of one month in the year, unless it be for some urgent cause, and certain time, to be allowed by the bishop. And such of the said canons and prebendaries, as by the ordinances of the cathedral or collegiate churches do hold bound to be resident in the same, shall so among themselves proportion the times of the year, as that some of them shall always be personally resident there; and all such residentiaries shall, after the days of their residency, appointed by their local statutes or customs expired, presently repair to their benefices or some one of them, or to some other charge according to the space thereof...
where the law requireth their presence, there to discharge
their duties according to the laws in that cause provided.
And the bishop of the diocese shall see the same to be duly
performed and put in execution. Car. 44.

PREBENDARY, Goldin of Hereford, called also prebenda-
rias episcopi, is one of the twenty-eight minor prebendaries,
who has, ex officio, the first canon's place that falls.

He was anciently confess of the bishop and cathedral,
and had the alterations ; on which account he was called the
golden prebendary.

PRECEARIE, or Preece, in our Ancient Law Books,
days-works, which the tenants of certain manors are bound
to give their lords in harvest-time.

These in some places are corruptly called bind-days, for
biden-days, from the Saxon, bidlan, to pray.

Magna Precaria was a great or general reapings-day.
The lord of the manor of Harrow, in Middlesex, had,
21 Ric. II. a custom, that by summons of his bailiff on a
general reap-day, then called magna precaria, the tenants
should do one hundred and ninety-nine days work for him;
every tenant that had a chimney lending a man.

PRECARIOUS, in Commerce, an appellation given to
a kind of trade carried on between two nations at war, by
the intervention of a third at peace with them both.

Thus the English held a precarious commerce with the
Spaniards by means of the Portuguese; when the two
former nations being at war, the third lent its vessels, its
colours, and name, to continue their trade.

Precarious Jurisdiction, is applied to a fund or flock,
of which a person has not the full propriety, whereof he cannot
dispose absolutely, and which is mort of it borrowed.

PRECATORIUS, in Church History, a sort of heretics,
who, under the pretence of praying always, refused to work.

PRECE PARIUM, in Law, the continuance of a suit
by consent of both parties.

PRECEDENCE, PRECEDECY, or Precedency, a place
of honour which a person is entitled to in companies; either
fitting, or walking.

With regard to the order of precedence, it may be ob-
erved in general, that persons of every degree of honour
or dignity take place according to the seniority of their
creation, and not of years, unless they are descended of the
blood-royal; in which case they have place of all others of
the same degree.

Precedency is either of courtsey, or de jure, of right.
The former is that which is due to age, or estate, &c.
which is regulated by custom and civility.

The latter is settled by authority, and where broken in
upon, gives an action at law.

Here we may observe, that the younger sons of the pre-
ceeding rank take place from the eldest son of the next me-
diate; viz. the younger sons of dukes from the eldest sons
of earls; the youngest sons of earls from the eldest sons of
barons. The whole chain of precedence is founded upon
this gradation, and thus settled by act of parliament. (31
Hen. VIII. cap. 11. A.D. 1539.) By subsequent alter-
ations, all the sons of viceroys and barons are allowed to
precede baronets; and the eldest sons and daughters of
baronets have place given them before the eldest sons and
daughters of all knights, of what degree or order foever,
though superior to that of a baronet; these being but tem-
porary dignities, whereas that of baronets is hereditary;
and the younger sons of baronets are to have place next
after the eldest sons of knights. There are also some great
officers of state, who take place, although they are not
noblemen, above the nobility of higher degree; and there
are some persons, who, on account of their dignities in the
church, degrees in the universities, and offices in court, officers
in the state or army, although they are neither knights nor
gentlemen born, that nevertheless take place among them.

Thus, all colonels and field-officers, who are honourable.
As also the master of the ordnance, quarter-master general,
doctors of divinity, law, physic, and music; deans, chan-
celloirs, prebendaries, heads of colleges in universities, and
fercants at law, are, by courtsey, allowed place before ordi-
nary esquires. And all bachelors in divinity, law, physic,
and medicine; masters of arts; barristers in the courts of;
lieutenant-colonels, majors, captains, and other commissioned
military officers; and various patent officers in the king's
honour, may equal, if not precede, any gentleman that
has none of these qualifications.

In towns corporate, the inhabitants of cities are preferred to the
hundred, and those who have borne magistracy to all others.
It has been also determined in the earl marshal's court of honour,
that all who have been lord mayors of London, shall have
where take place of all knights-bachelors, because they have
been the king's lieutenants.

The rules of precedence in England may be reduced to
the following table: in which, those marked * are entitled to
the rank here allotted them, by statute 31 Hen. VIII.
c. 10; those marked †, by statute 1 W. & M. c. 21; those
marked ‡, by letters patent 9, 10, &c. 14 Jac. I. which fee
in Seld. tit. of hon. ii. § 46. and ii. 11. 3. those marked §,
by ancient usage and established custom; for which see
(among others) Camden's Britannia, tit. ordines. Mille's
catalogue of honour, ed. 1610. and Chamberlayne's prentice
state of England, b. iii. ch. 3.

Table of Precedence.

* The king's children and grand-children.
* —— brethren.
* —— uncles.
* ——— nephews.
* Archbishop of Canterbury.
* Lord chancellor or keeper, if a baron.
* Archbishop of York.
* Lord treasurer.
* Lord president of the council if barons.
* Lord privy seal.
* Lord great chamberlain. But see private list. 1 G. 1. c. 3.
* Lord high constable.
* Lord marshall.
* Lord admiral.
* Lord steward of the household.
* Lord chamberlain of the house-
hold.
* Dukes.
* Marquesses.
‡ Dukes' elder sons.
‡ Earls.
‡ Marquesses' elder sons.
‡ Dukes' younger sons.
‡ Viscounts.
‡ Earls' elder sons.
‡ Marquesses' younger sons.
‡ Secretary of state, if a bishop.
‡ Bishop of London.
‡ ——— Durham.
‡ ——— Winchester.
‡ Bishops.
‡ Secretary of state, if a baron.
‡ Barons.
‡ Speaker of the house of commons.
‡ Lords commissioners of the great seal.
‡ Viscounts' elder sons.
Earls’ younger sons.
Barons’ eldest sons.
Knights of the Garter.
Privy counsellors.
Chancellor of the exchequer.
Chancellor of the duchy.
Chief justice of the king’s bench.
Matter of the rolls.
Chief justice of the common pleas.
Chief baron of the exchequer.
Judges, and barons of the coif.
Knightsbannerets, royal.
Vicounts’ younger sons.
Barons’ younger sons.
Baronets.
Knights bannerets.
Knights of the Bath.
Knights bachelors.
Baronets’ eldest sons.
Knights’ eldest sons.
Baronets’ younger sons.
Knights’ younger sons.
Colonels.
Serjeants at law.
Doctors.
Esquires.
Gentlemen.
Yeomen.
Tradesmen.
Artificers.
Labourers.

The ladies take place, or precedence, according to the degree of quality of their husbands.

With regard to the precedence among women, we may observe, that women, before marriage, have precedence by their father; with this difference between them and the male children, that the same precedence is due to all the daughters that belong to the eldest. By marriage, a woman partakes of her husband’s dignities; but none of the wife’s dignities can come, by marriage, to her husband, but are to descend to her next heir. If a woman has precedence by creation or birth, she retains the same, though she marry an inferior; but if a woman nobly born marry any nobleman, as a baron, she shall take place according to the degree of her husband only, though she be a duke’s daughter. A woman, privileged by marriage with one of noble degree, shall retain the privilege due to her by her husband, though he should be degraded by forfeiture, &c. The wife of the eldest son of any degree takes place of the daughters of the same degree, who have always place immediately after the wives of such eldest sons, and both of them take place of the younger sons of the preceding degree. And this rule holds, not only in comparing degrees, but also families of the same degree among themselves. The precedence among women is as follows.

The queen and princess of Wales; princesses and duchesses of the blood; duchesses; wives of the eldest sons and daughters of dukes of the blood; marchionesses; wives of the eldest sons and daughters of dukes; countesses; wives of the eldest sons and daughters of marquisses; wives of the youngest sons of dukes; vicountesses; wives of the eldest sons, and daughters of earls; wives of the younger sons of marquisses; baronesses; wives of the eldest sons, and daughters of vicounts; wives of the younger sons of earls; wives of the eldest sons and daughters of barons; wives of the younger sons of vicounts; wives of the younger sons of barons; wives of baronets; wives of the knights of the Garter; of the Bath; and of knight-bachelors; wives of the eldest sons and daughters of baronets; wives of the eldest sons and daughters of knights of the Garter; wives of the eldest sons and daughters of knights of the Bath; wives of the eldest sons and daughters of knights-bachelors; wives of the younger sons of baronets; wives of esquires by creation; of esquires by office; of gentlemen; daughters of esquires; of gentlemen; wives of citizens; of burgesses, &c. The wives of privy-counsellors, judges, &c. are to take the same place as their husbands do. For the precedence and pre-attendance among barristers in the English courts, see Counsel.

PRECEDENT, in Law, frequently denotes an original, authentic instrument, or writing; serving as a form to draw others by.

Hence precedent books, &c. full of draughts of deeds, conveyances, &c. for attorneys.

PRECEDE. See Condition.

PRECEDE. PRECEDOR, PRECEDEOR, a dignitary in cathedral churches, popularly called the chanter, or master of the choir. The precentor is called, from the Latin prece, and cano; because he is supposed to lead the choir, and sing before the rest.

PRECEP'T, PRECEPTUM, in Law, a command in writing, sent by a chief justice, justice of peace, or other like officer, for the bringing of a perfon, record, or other matter, before him.

Precept is also used for the command, or incitement, whereby one man urges upon another to commit felony, theft, &c. Bracton speaks of three diversities of offending in murder; viz. preceptio, foris, confilium.

Preceptio, is the initiation used beforehand; foris, the affilltance in the fact; consilium, the advice given either before or after.

PRECEPTORY, PRECEP'TORIA, Commandry; a kind of benefice held by the more eminent among the ancient Knights Templars, who were created by the grand master, with the title of preceptors Templi, i.e. masters of the Temple.

Stephens, De jurid. lib. iv. says, the preceptories were only a kind of cells, all subordinate to their principal mansion, the Temple in London.

Of these preceptories, Dugdale says, he finds fifteen recorded, as anciently belonging to the Templars in England, viz. Crefling Temple, Balhal, Shengay, Newland, Yevley, Witham, Temple Bruere, Willington, Rotherley, Ovington, Temple-Combe, Trebig, Ribitaine, Mount St. John, Temple-Newfin, and Temple-Hurt. But there were more. See Commandry.

PRECES. See Precaies.

PRES CE, or PRI MELP, or PRIMELIA, is the denomination of an imperial prerogative, by which the emperor exercises, and hath immemorially exercised, a right of naming to the first prebend that becomes vacant after his accession, in every church of the empire. This right was also exercised by the crown of England in the reign of Edward I. and probably gave rise to the royal corodies. See Corody and Option.

PRECESSION, PRECESSION, in Astronomy, a term applied to the equinoxes, which by a very slow inelastic motion, change their place, going backward or westward, i.e. in antecedentia, as astronomers call it, or contrary to the order of the signs.

It is shewn, in the new astronomy, that the pole, the filices, the equinoxes, and all the other points of the ecliptic, have a retrograde motion; and are continually moving from east to west, or from Aries towards Pices, &c. by means of which the equinoctial points are carried farther and farther back, among the preceding signs of the stars at the rate of about fifty seconds each year, which retrograde motion is called the precessio, recession, or retrocession of the equinoxes.

Hence, as the fixed stars remain immovable, and the
equinoxes go backward, the stars will seem to move more and more easterly with respect to them; whence the longitudes of the stars, which are reckoned from the first point of Aries, or the vernal equinox, are continually increasing.

Hence it is, that the interval of time between any equinox and that fame equinox, in the following revolution of the earth (which astronomers call the tropical year) is some minutes shorter than the sidereal year, or the period in which the earth revolvs from one point of her orbit to the fame point again; and, because the retrograde motion of the equinoctial points thus advances during the time of every equinox a little sooner than it would otherwise have happened, this phenomenon is called the "precession of the equinoxes."

Hence it is that the constellations have all changed the places assigned them by the ancient astronomers: in the time of Hipparchus, and the eldest astronomers, the equinoctial points were fixed to the first stars of Aries and Libra; but the signs are now no longer in the same points; and the stars which were then in conjunction with the sun when he was in the equinox, are now a whole sign, or thirty degrees, to the east of it: thus the first star of Aries is now in the portion of the ecliptic, called Taurus; and the first star of Taurus now resides in Gemini. Taurus and Gemini are advanced into Cancer, &c.

The equinoxes will have made their revolution westward, and will be returned up to Aries again; and the constellations will have made their eastward, and will again fall into their former places with regard to the equinoxes, in 25,816 years, according to Tycho; in 25,920, according to Riccioli; and in 24,899, according to Caffini.

These phenomena may be clearly understood by a view of Plate XIX. Astronom., fig. 7. Let NZSVL be the earth, SON its axis produced to the flary heavens, and terminating in A, the present north pole of the heavens, which is vertical to N, the north pole of the earth. Let E O Q be the equator. T = Z the tropic of Cancer; and V T = T the tropic of Capricorn; V O Z the ecliptic, and BO its axis, both of which are immovable among the stars. But, as the equinoctial points recede in the ecliptic, the earth's axis SON is in motion upon the earth's centre O; in such a manner as to describe the double cone NOQ and S O R, round the axis of the ecliptic BO, in the time that the equinoctial points move quite round the ecliptic, which is 25,920 years; and in that length of time, the north pole of the earth's axis produced, describes the circle ABCDA in the flary heavens, round the pole of the ecliptic, which keeps immoveable in the centre of that circle. The earth's axis being about 23° 30' inclined to the axis of the ecliptic, the circle ABCDA described by the north pole of the earth's axis produced to A, is 47 degrees in diameter, or double the inclination of the earth's axis. In consequence of this, the point A, which at present is the north pole of the heavens, and near to a star of the second magnitude in the tail of the constellation called the Little Bear, must be deserted by the earth's axis; which moving backwards a degree every 72 years, will be directed towards the star or point B in 6480 years hence, and in double of that time, or 12,960 years, it will be directed towards the star or point C; which will then be the north pole of the heavens, although it is at present 83 degrees south of the zenith of London L. The present position of the equator E O Q will then be changed into O Q, the tropic of Cancer T = Z into V = N, and the tropic of Capricorn V = T into N Z; as is evident by the figure. The sun in the same part of the heavens where he is now over the earthly tropic of Capricorn, and makes the shortest days and longest nights in the northern hemisphere, will then be over the earthly tropic of Cancer, and make the days longest and nights shortest. So that it will require 12,960 years yet more, or 25,920 from the then present time, to bring the north pole N quite round, so as to be directed towards that point of the heavens which is vertical to it at present. And then, and not till then, the same stars which at present describe the equator, tropics, and polar circles, &c. by the earth's diurnal motion, will describe them over again.

The ancients, and even some among the moderns, have taken the equinoxes to be immoveable; and ascribed that change of distance of the stars from it, to a real motion of the orb of the fixed stars, which they supposed to have a slow revolution about the poles of the ecliptic; so that all the stars perform their circuits in the ecliptic, or its parallels, in the space of 25,920 years; after which they should all return again to their former places.

This period the ancients called the Platonic or great year; and imagined, that at its completion every thing would begin as at first; and all things come round in the same order as they have already done.

The physical cause of the precession of the equinoxes, Sir Isaac Newton demonstrates, arises from the broad or spheroideal oblate figure of the earth; which itself arises from the earth's revolution around its axis; for as more matter is accumulated in round the equatorial parts than anywhere else on the earth, the sun and moon, by attracting this redundance of matter, bring the equator sooner under than any other return towards it, than if there was no such accumulation.

In order further to illustrate the operation of this cause, and to discern its effect, we should consider how the action of the sun produces the retrograde motion of the nodes of the moon; as it will follow, from the same principles, that if a planet revolved about the earth near to its surface, the plane of the equator, its nodes would also go backward, though with a slower motion than those of the moon, in proportion as its distance from the centre of the earth was less than that of the moon. Suppose the number of such planets to be increased till they touch each other, and form a ring in the equator, and the nodes of this ring would go backward in the same manner as the nodes of the orbit of any one planet revolving there. Suppose then this ring to adhere to the earth, and its nodes would still go backward, but with a much slower motion, because the ring must move the whole earth, to which it is supposed to adhere. The elevation of the equatorial parts of the earth has the same effect as such a ring would have, excepting only that the motion of the nodes of the equator, or of the equinoctial points, is slower, because the accumulated parts of the earth, above a spherical figure, are diffused over its surface, and have a less effect than if they were all collected in the place of the equator, in the form of a ring. The moon has a greater force on this ring than the sun, on account of her less distance from the earth; and they both contribute to produce the retrograde motion of the equinoctial points; the motion, however, produced by both is so slow, that those points will not finish a revolution in less than above 25,000 years. Sir Isaac Newton has determined the quantity of this motion from its causes, and finds it, as deduced from the theory, to be consonant with the observations of astronomers. We shall here add, that there is another effect of the action of the sun and moon on this ring, which is too small to be sensible in astronomical observations; their action on the ring makes its inclination to the ecliptic to decrease and increase, by turns, twice every year.

Allowing the case to be as above stated, and since the plane of the moon's orbit is at one time above ten degrees more inclined to the plane of the equator than at another, it is reasonable to conclude, that the part of the whole annual precession, which arises from her action, must in different years be varied in its quantity; whereas the plane of the ecliptic,
The quantity above stated would be the precession of the equinoxes, arising from the attraction of the sun, if the earth were a solid of an uniform density, and the ratio of the diameters as 229:230; but professor Vince has shown, that, if the greatest nutation of the earth's axis be rightly stated, the precession is only about 14''; which differences between the theory, and what is deduced from observation, must arise, either from the fluidity of the earth's surface, an increase of density towards the centre, or the ratio of the diameters being different from that which is here assumed; or probably from all the causes conjointly. This regreion of the equinoxes, caused by the plane of the equator moving backwards upon the ecliptic, must necessarily cause the poles of the earth to describe circles about the poles of the ecliptic, in a direction contrary to the order of the signs, setting aside the effect of nutation. Our author, having ascertained the precession, shews how to find the corresponding nutation. If we take the whole precession for the time the fun is moving from the equinox to the tropic, to be 4th of 14'', the nutation at the tropic = 1'', which is the greatest nutation arising from the force of the fun. If y be supposed to denote an arc described by the sun in the ecliptic, to a radius equal to unity, whilst a point of the equator describes an arc about its axis in an indefinitely small given time, which may also represent its velocity, the nutation from the time the sun leaves the equinox = \( \frac{y}{r} - \frac{y}{r} \times \text{col.} 2 \), and at 45'' from the equinoxes, the inclination is the mean, it varying half a second each way from thence. Hence, at the equinoxes, the nutation = \( \frac{y}{r} \), and at the tropic, the nutation = \( -\frac{y}{r} \) from the mean inclination; and the nutation at any time from the mean inclination = \( \frac{y}{r} \times \text{col.} 2 \). The equation of the precession is greatest in the middle point between the equinox and tropic, and is there = \( 17'' \frac{1}{4} \); and it is to be subtracted from the first and third quadrants of the ecliptic, and added in the second and fourth. It appears that the inequality of the precession, and the nutation, may be represented, by supposing the pole of the equator to describe a circle of 1'' diameter about the mean pole every half year; and therefore the apparent distance of every star from the pole of the equator, will be subject to a variation of 1'' twice in a year from this cause.

The inequality of the precession of the equinoxes, and the nutation of the earth's axis, arising from the attraction of the moon in different situations of its nodes, was discovered, as we have already suggested, by Dr. Bradley. Dr. Bradley communicated his observations to Mr. Maclaurin, who soon after sent him a table of the annual precession and the corresponding nutation, in the various situations of the moon's nodes. These were calculated upon the supposition that the pole of the equator, during a period of the moon's nodes, moved round in the periphery of a circle of 19'' diameter, having the centre 23'' 29' from the pole of the ecliptic, that circle having an angular motion of 50'' about the same pole. The north pole of the equator was conceived to be in that part of the small circle which is farthest from the north pole of the ecliptic, when the moon's ascending node is in the beginning of Aries; and the opposite point of it, when the same node is in the beginning of Libra. But Dr. Bradley afterwards observed, that the calculations would agree better with observations, if the true pole of the equator described an ellipse instead of a circle, whose minor axis is about 16'', and lying parallel to the ecliptic. This is confirmed by theory. From all the observations of Dr. Bradley, Dr. Maitclay fixed the whole nutation at 19''. In the table computed by professor Vince, it is affirmed at 19''. We shall here remark, that sir Isaac Newton had taken notice of the nutation of the earth's axis; and Mr. Flamsteed, in his Hlst. Ccl. vol. iii. p. 113, informs...
forms us that he attempted to discover its quantity, but
found his instruments not sufficiently accurate for the
purpose. Some hints relating to it have been found by M. de la
Lande in the MSS. of Roemer. But though the motion
of the earth's axis had been so long suspected, the discovery
of the caufe and quantity of it was referved for Dr. Bradley.
See Nutation, Light, and Stars.

Mr. T. Simpson, in his "Miscellaneous Tracts," has shown
how to find the preceflion during a revolution of the moon's
node, and his method, which is pronounced to be as simple as the
subject will admit of, is adopted by professor Vince. Hence
it appears, that the whole quantity of motion during half a
revolution of the node from γ : the corresponding quantity of
preceflion : 10 : 174 very nearly. If the moon's orbit
coincides with the ecliptic, the effect of the moon
would be to that of the fun, in the ratio of their denfities ;
therefore the mean preceflion of the moon : that from the fun
in a compound ratio of 0.988 : 1, and of the denfity of the
moon : the denfity of the fun : consequently the denfity of the
moon : denfity of the fun : the preceflion from the fun :
preceflion from the fun x 0.988. If the annual preceflion
arising from the fun be taken = 21" 6', and the whole preceflion = 50'
then the part arising from the action of the moon
will be 28" 54', hence the denfity of the moon : the
denfity of the fun : 28" 54' : 21" 6' x 0.988 = 20" 8'
which ratio does not agree with the proportion deduced from
the tides, or with the accurate observations of Dr. Bradley.
The beat method, says Vince, of getting this point, is from
the greatest nutation. The nutation, during half a revolu-
tion of the moon's node from Aries, Dr. Maskelyne fixed
at 19".1, and it may be assumed at 19" ; hence 10 : 174 ::
19° = 174 x 19°
10 the preceflion from the moon during that
time, which we may take equal to 9.31 years; hence the
mean preceflion from the moon in one year = 174 x 19°
10 x 9.31
therefore, if we take the whole preceflion in a year to be 504°,
we have 504 = 174 x 19°
10 x 9.31
for the part of the preceflion arising from the fun.
Hence, the denfity of the moon : the denfity of the fun ::
174 x 19° : 10 x 9.31 x 504° = 174 x 19°
10 x 9.31
0.988 :: 2.44 : 1. Consequently, the part of the preceflion arising
from the action of the moon is = 35° 39", and that of the
fun = 14° 36", and the greatest equation of the preceflion
arising from the moon = 174°.7.

The following table shows the mean preceflion of the
equinoctial points in longitude for complete years.

PREGHAC, in Geography, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Bazas; 6 miles S.W. of Bazas. The place contains 2664, and the canton 7496 inhabitants, on a territory of 255 kilometres.

PRECIÉ, in Botany, the twenty-first among the natural orders of Linneus, consisting of Primula, Androcles, Diapensia, Areata, Dodendanum, Cortyta, Soldanella and Lycastema; to which is subjoined, in a separate section, Limosella; and in a third division, with a mark of doubt, Merynther, Hottotania and Stomus. See Lysimachea.

PREIGNÉ, in Geography, a town of France, in the department of the Sarthe; 4 miles W.N.W. of La Flèche.

PRESIGNY le Grand. See Presigny le Grand.

PREIOUS, or Precious-value. See Gem.

PRECIPÉ, or Precipé, in Law, a species of original writ, called optional, which command the defendant to do the thing required, or else the reason wherefore he hath not done it. The use of this writ is where something certain is demanded by the plaintiff, which is in the power of the defendant himself to perform; as to restore the possession of land, to pay a certain liquidated debt, to perform a specific covenant, to render an account, and the like; in all which cases, the writ is drawn up in form of a precipe or command to do thus, or else cause to the contrary; giving the defendant his choice, to defend or not defend the suit. This writ is distinguished from the peremptory writ, called 

Precipé, or Precipé, is also a name given to a writ of covenant, the foundation of which is a supposéd agreement or covenant, that one party shall convey lands to the other; on the breach of which agreement, action of covenant is brought by the party to whom the land is to be conveyed or affrued, who thus commences an action or suit at law against the other.

Precipé, or Precipé quod reddat, a writ of great diversity, both as to form and use, extending in common to all writs of right, as to other writs of entry and possession.

It is sometimes called a writ of right close, as when it issues out of the court of chancery close; sometimes a writ of right patent, as when it issues out of chancery patent, or open, to any lord's court, for any of his tenants deposed, against his deforcer.

Precipé in Capite. See Precipé.

PRECIPITANT. Precipitants, in Chemistry, a term applied to any liquor, which, being poured on a diffolution, separates what is there dissolved, and makes it precipitate, i.e. fall to the bottom of the vessel.

Precipitant is also used, in Medicine, for a remedy, which separates and precipitates any heterogeneous matter contained in the mafs of blood; and by this means abates any irregular fermentations, efhervescences, of the like diforders, which the matter had excited.

Among the number of precipitants are ranked hartshorn, crabs' eyes, ivory, bezouard, banks of oak and guaiacum, iron, quinquina, chalk, &c.

Precipitate, Precipitatus, in Chemistry, a substance, which, having been diffolved in a proper menstruum, is again separated from its diffolvent, and thrown down to the bottom of the vessel, by the pouring in of some other liquor.

When a body is decomposed by means of an intermediate substance, and a precipitate is formed by this decomposition, this precipitate can be effected only by the intermediate substance uniting with one of the component matters of that body; and consequentely a new compound is always formed in these operations. Sometimes the separated matter, being no longer soluble, becomes fusible, and falls as a precipitate, while the new compound remains dissolved. In other instances, the separated substance remains dissolved, while the new combination, not being soluble, is precipitated. This depends on the nature of the substances which act upon one another in these operations: but we may easily perceive, that the precipitates of the former kind are simple, and those of the latter are compound. Earth and metals, when separated from acids by means of alkalies, or other metals, are simple precipitates, and when separated from acids by other acids, they are compound. See Precipitation.

Precipitates, Metallic. See Precipitation, in Affaying.

Precipitate of Gold by Tin, &c. See Gold, &c.

Precipitate, White, Red, and Per fe, are all oxys, or fafts of mercury. See Mercury.

Precipitation, Precipitatio, a process in chemistry, which, in its most extensive sense, is applicable to all chemical decompositions made by an intermediate substance; or, to all operations in which two bodies are diffoluted by employing a third body, which has the property of uniting with one of these, and thereby of separating the other; so that every precipitation is effected by means of the affinity of a precipitant much stronger than that of the precipitate with the substance from which it is separated. In a more confined sense, precipitation is a kind of separation, whereby a body, diffolved and suspended in any menstruous liquor, is detached from it, and falls down to the bottom of the vessel.

Precipitation, in its more extended sense, comprehending any visible separation of any substanse or compound, from its clear solution, whether it sinks or swims, and whether it be crystallized or pulverulent, forms one of the great operations of chemistry, and is directly opposed to that of solution. Till the late experiments of Berthollet on the subject of affinity (see Affinity), all chemists seem to have coincided with Bergman, who maintained, that in cases where a compound was decomposed by the superior affinity of one of its elements for a third substance, there was a total transfer of the base from the substance of the weaker to that of the stronger affinity; and hence originated the term a single elective affinity, which was made use of to signify, that if to the compound A. B. a body C. was added, polleaded of a superior attraction for A., than B. has, A. would, by election or choice, as it were, quit B. entirely, and form with C. a new compound, A. C., to the exclusion of B. Berthollet has shown, in his valuable elays on chemical affinity, and on chemical latices, how philosophers have been led to deduce the supposing order of affinities from the circumstances of precipitation. These changes, which, according to the theory of Bergman, were supposing to be produced by the predominance of certain affinities over others, are ascribed by Berthollet to those circumstances which influence attraction and limit combination. If four affinities, for example, be presented to each other, two of which have a greater tendency to cohesion than the other two, so as to form by their union an insoluble compound, instead of one compound being formed by
by the union of the four, in which the affinities are balanced, 
this will be averted by the force of cohesion, and the two 
which form the infoluble compound will unite, and be sepa-
rated by precipitation or crystallization, leaving the other 
two in combination in the fluid which has been the medium 
of action. "If even these four substances were previously 
in the reverse binary combinations, on presenting them to 
each other, the affinities within the sphere of action must be 
reciprocally exerted; and the same extraneous forces will 
cause an exchange of principles, or the phenomena which 
have been ascribed to elective affinities will be produced." 
To avoid the term elective attraction, Bergman denominates 
cafes of this kind complex affinity. The explanation of 
fingle elective attraction, or where three substances are pre-
fented to each other, is precisely the same; the union which 
takes place between two of them being determined by the 
tendency to cohesion, or the disposition of the combination 
of two of them to form a compound of little solubility. 
The proportion also of the substances presented to each 
other considerably influences these combinations; and the 
changes produced by the decomposition are scarcely ever 
complete; especially where the force of cohesion has not 
been powerfully exerted, so as to render the effect of quanti-
ty imperceptible. Elastocity likewise has a considerable 
influence in determining decompositions where the application 
of heat is necessary; and, according to Berthollet, the 
decomposition of a compound body, of which one of the in-
gredients has a great tendency to assume the elastic form, is 
to be ascribed to the disposition it has to escape from its com-
bination, when aided by the intervention of even a weaker 
affinity. 
In complex affinities the same cause determines the union 
of substances disputed to assume the elatic form, and sepa-
rates them as a volatile compound. "If, therefore," says 
he, "it be desired to know the result of the exposure of two 
alts to the action of heat, it is only necessary to consider 
which of the two bases, and which of the two acids have 
the greater volatility, if there be a difference: for the more 
volatile base and acid will escape and enter into combination, 
and the fixed base and fixed acid will remain behind, and 
combine with one another." 
There are two principal kinds of precipitates which have 
been distinguished by chemistry, one where to a com-
 pound compounded of an acid and a bafe, each highly 
soluble in water, another acid is added, which has a greater 
affinity with the bafe, and forms with it a compound less 
soluble than the first. In this case the precipitation (which 
is sometimes crystallized, sometimes otherwise) is composed 
of the acid last added, in proportions that vary but little. 
As, for example, when sulphuric acid is added to a saturated 
solution of nitrate of potash, a crystallized precipitate of 
fulphate of potash is added, the proportions of which scarcely 
vary in any circumstances, though the actual quantity of 
precipitate is determined by the quantity of water and of 
sulphuric acid present. 
Another kind of precipitate is that which has unusually 
supposed to be simple, and takes place when to a compound 
of an acid and a base insoluble (or nearly so) in water, an 
alum or soluble earth is added, which, by elective affinity, 
unites with the acid, and displays the former base; and 
this latter, now suppos'd to be uncombined and insoluble in 
the quantity of liquid present, falls to the bottom. This 
kind of precipitation is constantly resorted to when we wish 
to obtain the simple earths, as in adding an alum to a solu-
tion of alum, in order to precipitate the alumine, to Epfom 
salt to precipitate magnesia, &c. But the precipitate in all 
such cases is not (as has been usually supposed) the simple 
earth, but it always retains, after the first operation, a small 
and variable portion of the acid with which it was before 
combined. Thus if the alumine, however well edulcorated, 
be redissolved in muriatic acid, and a salt of barytes added, 
there will be a sensible precipitate of sulphate of barytes. This 
retent of acid is variable, and may be reduced to an infinible 
quantity, if not absolutely taken away, by subsequent digestion 
in very concentrated alkali. Such precipitations, therefore, 
are not affected merely by simple affinity, but by a division 
of the acid into two portions, one of which, and by much 
the largest, goes to the alkali, and the other remains with 
the earth, and accompanies it in its precipitation. Even 
when no precipitation occurs, the acid may be proved 
to distribute itself in this manner, for, as Bergman has re-
marked, if a calcareous salt is dissolved in fifty times its 
weight of water, and an excess of potash or soda is added, 
no precipitation takes place, so that the acid continues in 
part to act upon the lime, and renders it soluble in a much 
less quantity of water than the lime alone would require 
for solution. 
It may be affirmed, therefore, as a general principle, and 
one which is of great importance in the explanation of 
chemical decomposition, that where a salt is composed of 
an acid and a base, insoluble or little soluble by itself, the 
decomposition effected by any soluble base is the result not 
of a simple but a compound action, in which, on the one 
hand, the decomposing base unites with more or less of the 
acid and remains in solution, whilst the other base renews 
its insolubility by the separation of part of its acid, and 
forms a precipitate with the remainder. This will be 
found to apply still more strikingly in the formation of 
metallic precipitates, and of those salts which (like the 
sub-sulphate of mercury or turbith) were formerly taken 
for simple oxys, but are now found to be salts with excess 
of oxyd. 
Chemical affinity is, in many cases, determined by precip-
itation; but a contradiction in the mode of applying this 
principle has been well pointed out by Berthollet. 
The orders of affinity which the several bases have for 
the acids is usually determined by adding any base to a 
known combination of an acid and another base, and if the 
latter base is precipitated, it has been inferred that its 
affinity for the acid is less than that of the other base. 
Thus, when lime is precipitated by adding potash to muriate 
of lime, it is inferred that potash has a stronger affinity 
for muriatic acid than lime, and hence the preference in 
the order of affinity has been given to the most soluble bases. 
But, on the other hand, the respective affinities of the acids 
has been determined in the contrary way, as for example, 
when oxalic acid is added to muriate of lime a precipitate of 
oxalat of lime is produced, whence the superior affinity of 
the oxalic acid over the muriatic for lime has been deduced. 
Thus, in these cases, the preference in affinity has been 
given to those acids which have the most disposition to 
form insoluble combinations. 
But many infiuences may be given to shew that the phe-
omena of precipitation are distinct from those of chemical 
affinity, so that the resulting insolubility or force of cohesion 
which produces precipitations is sometimes superadded to 
the simple force of affinity, and at other times opposed to 
it, and ought in strictness to be always considered as a dif-
tinct principle. 
Precipitation, in Asaying, is the separation of any 
part of a compound body, while melting in the fire, or 
when cooling, is from the rest of the mass, in such 
a manner that it sinks to the bottom, while the remainder 
continues at top, and makes the surface. The heavy part 
thus
Precipitation.

Thus precipitated from the reit is called the regulus of that body.

This is an operation which almost always requires the addition of such ingredients, as serve to take away the mutual connection and coherence of the parts of the body to be separated; that is, such as have a membranous virtue, and keep others in a state of diffolution. For instance, the regulus part of antimony, and mineral sulphur, difolve each other mutually, and constitute crude antimony; nor can they be separated from each other by fire alone, without destroying the regulus; but if you add iron, copper, silver, &c. which are more thoroughly penetrated by sulphur, and are thus reduced to the state of ore, then the regulus of antimony is freed of its sulphur, and sinks to the bottom, as it is heavier than the additional bodies, when joined to the sulphur.

Such a precipitation by fusion happens in vitrifications, scoriifications, and coppers, while one part of the body turns into dross, or scoria, and the other metallic part, if there be any, keeping still its metallic form, is collected at the bottom of the fpherical vessel. Therefore silver and gold, which are hardly subject to a perfect vitrification, constantly remain and themselves in their own form; and on this account, though they were in ever so small a quantity in a coppers, they always show themselves very clearly to the eye when the scoria are absorbed: whereas so fo small a regulus of the other metals would have been as if it were buried and hidden under so great a quantity of scoria.

Nor is precipitation by fusion lefs necessary to obtain almofl all the other metals, which, on this account, are called lefs perfect, unless perhaps you except a very small quantity of native metal, which nevertheless can scarcely be properly called pure. Besides, they are all to be had either in form of earth, or that of a solid ore. In the first case, you may make a glafs by a bare fusion; in the second, if the sulphur and arsenic, which, together with the metallic part, constitute an ore, are difpersed in roasting, the ore, destitute of the oily phlogiston, (fays Cramer,) becomes glafs in a pure fire, which glafs may be mixed with unmetallic stones and earths; but by adding a phlogiston or inflammable principle to it, this metallic glafs is again reduced to its metallic form; and so long as it keeps under this form, it cannot be united with the glafs of the other species, but sinks to the bottom of it, except only a very small quantity of it, which is detained by the claminales of the glafs. The precipitating body in this case, therefore, is truly the phlogiston, or inflammable principle: any body that takes away the connection, by the removal of which a precipitation is made, is properly called the precipitating body.

Precipitation of solid bodies from fluid menftruum is performed either by extracting, or evaporating over a gentle fire the difolving menftruum out of the difolved fixed body, or by adding fuch a body, as is greedily difolved by that menftruum; as if one metal difolved by an acid is precipitated by another metal, or by an alkaline falt; for instance, filver difolved in aqua fortis is precipitated by copper, copper by iron, iron by zinc, and all metals and femi-metals, either partly or entirely, by pot-afhes, volatile and urinous falis.

A precipitation is also made by pouring on a solution {such} things as either cannot difolve the body in hand, whether alone, or joined to a menftruum that contains the said body; or difolve it in another manner; or in a lefer quantity than if the menftruum had been pure. In the first cafe, a total precipitation is performed, as may be feen in the precipitation of filver out of aqua fortis, by means of spirit of falt. In the fecond, a great deturbation and precipitation is made; but a fecond folution foon follows, as it happens when iron being difolved in aqua fortis, you add to it, in a proper manner, a liquor perfectly free from alkaline fixed falt; but then there remains usually a certain part, which is not perfectly difolved a fecond time. In the third cafe, there is but a partial precipitation made. You have an inclination of this, if mercury difolved in aqua fortis, and the menftruum thoroughly faturated with it, is precipitated either by common falt, or falt ammoniac, or by their acid spirit. A precipitation is also sometimes made only by adding a large quantity of fair water to dillee; fuch is that made on the regulus of antimony difolved in spirit of common falt, or in aqua regia, when a large quantity of cold water is poured on this folution; for these menftrua do not difolve this femi-metal, unlefs concentrated.

All these precipitations are promoted greatly by a gentle heat, by means of which the precipitating body enters more easily into the menftruum, and a confiderable quantity of water is next neceffary to diflute with, except in the precipitations of the firft kind; for moft commonly the more concentrated diffolutions assume the confidence of a paste, fo soon as the precipitating body is added to them, which hinders this from mixing equally with the folution. Cramer.

The metal of every metallic folution in any acid is always in the flate of an oxyd, fo that the folution muft contain at leat three fubstances, viz. the acid, the metal, and oxygen united with the metal.

A metallic folution may be decomposed, and its metallic part precipitated, either in the regulus flate or in an oxyd, and these two methods, which have each been adopted in the analysis of metallic bodies, require to be considered separately.

When a carbonated alkali is added to a metallic folution, the precipitate is a carbonated oxyd of the metal, and, like the other carbonates, effervesces on the addition of a stronger acid. But when a pure alkali is added only to faturatation, the precipitate is, in fome infinaces, nearly a pure oxyd, but in the greater number is an oxyd retaining a small portion of the acid with which it was united. This acid, however, is not fufficient to render it soluble, and it may be generally entirely taken away by fubfequent difgellation in a concentrated fixed alkali, provided the oxyd is not soluble therein.

The firft action of alkaliics, therefore, on their metallic folutions, is to cause an unequall division of the acid, the greater part of which unites with the alkali, and the remainder falls down along with the oxyd now rendered infoluble. If the ammoniac or the alkali employed, there is also in general a partition of the alkali, and the precipitate is a quadruple compound, of the metal, the oxyd united with it, and a small portion of the acid, and of the ammoniac, and the folution contains the greater part of the acid, of the alkali, and often a small part of the metallic oxyd sufficient to be very fensitive to the tafle, and to chemical tests. According to Plouf, lime alfo, when used as a precipitant, enters in a small proportion into the folution.

Metallic folutions sometimes yield precipitates on the mere addition of water, by the fimple diftribution of the constituents into two portions, a fubtle and an infoluble one, the former of which has an excess of acid, and the latter of oxyd. Thus, when the clear nitrate of bismuth is diluted with water, a white precipitate falls down, which is chiefly oxyd of bismuth, and the supernatant liquor contains an excess of acid, and a small portion of metal which may be separated by evaporation, or by an alkali. In like manner,
manner, if fulphuric acid and mercury are treated together, fulphureous acid is given out, and the white mass that remains is an uniform acid sulphate, which deliquesces into a dense solution. But if hot water be added, the turbid, or yellow sub-sulphate of mercury is precipitated, and the solution contains an acid sulphate. Even the first turbid may be further decomposed by a fresh affusion of hot water, dividing it into a turbid still more loaded with oxyd, and an acid solution.

These, and many other facts which might be adduced, illustrate the general law of decomposition by precipitation, and the constant tendency of metallic salts to divide into two compounds, each containing of both the constituents of the salt, but distributed in unequal proportions. These phenomena are rendered still more complex by the addition of new substances, most of which, being dissolved under the respective metals, a repetition in this place would be needless.

The second species of metallic precipitates are those in which the metal appears in its reguline form. This takes place when one metal is precipitated by another, as when a piece of iron is immersed in a solutin of copper, and also when phosphorus is kept for some time in certain metallic solutions.

Before the discovery of oxygen, and of the oxydation of metals being neccessary to their solution in acids, the precipitation of one metal by another was supposed to be produced by simple elective attraction, and the respective affinities of the metals for the acids was put down in the order of the precipitations which they produced. But this explanation, though true in general, does not explain a number of apparent anomalies in metallic precipitation, so that we must take into consideration the force of other agents and other affinities.

The order of the precipitation of one metal by another is the following, among those that have been the most accurately examined,* viz. zinc, iron, lead, tin, copper, silver, mercury, gold; that is to say, zinc precipitates all the other metals; iron precipitates all but zinc; lead all but zinc and iron, &c.

But sometimes the precipitation fails with solutions in one acid, though it succeeds with others; thus zinc separates iron in the metallic state from muriate of iron, but only as an oxyd from the nitrate. A small excess of acid is necessary to begin the process in all cases.

During this operation, the following affinities must act; namely, that of the precipitant (or metal by which the separation is effected) for the oxygen of the metal already dissolved; that of the oxyd thus produced, for the acid of the solution; and to this Berthollet adds, that of the two metals for each other when in the reguline state. The sum of these affinities must overcome that which exists between the constituent parts of the metallic salt intended to be decomposed.

It is possible, therefore, that no precipitation may take place even when the metal added has a greater affinity for oxygen than that already dissolved, if the oxyd of the former metal has a less affinity for the acid than the oxyd of the latter has. And, on the other hand, a precipitation may be effected, even if the precipitant has less affinity for oxygen than the metal already dissolved, provided its oxyd has a greater affinity for the acid. In this latter case, however, there must be a considerable excess of acid present in order to begin the oxydation of the precipitant. Thus, again, it is explained why a precipitation will take place with the solution in one acid, and not in the other, since the acids themselves differ considerably in their affinity for the same metallic oxyd, so that in the first cafe, this affinity may surpass that of the same acid for the metallic oxyd already dissolved, and in the second may fall short of it.

Still, however, (as Berthollet remarks,) if the only active affinities in these cases were those of the metals for oxygen and the oxyds for acids, it is not probable that the reduction of the metal with affinities was the weakest, would be complete, but in all probability there would be only an unequal partition of the acid and oxygen, so as to produce the more oxygenated salts of one metal, and the less oxygenated salts of the other metal, which would be agreeable to the usual mode of action in similar cases. Hence it becomes necessary to recur to the well-known affinity which exists between the metals themselves, and many facts shew that this is concerned in these processes.

For example, when a plate of polished copper is dipped into a solution of nitrated mercury, it is instantly whitened by the mercury precipitated upon its surface; but this metal is not merely deposited upon the copper, but amalgamated with it, so that it cannot be scraped or rubbed off, but can only be separated by fire. Here, then, the affinity of the mercury for the copper must act forcibly in causing its separation from the nitric acid which held it in solution. In like manner when copper is immersed in a solution of silver, the precipitated metal is not pure silver, but an alloy, containing a very small portion of copper. As this mutual affinity existing between the metals varies according to the metal employed, this also explains why iron (for example) precipitates silver from its solution with much more difficulty than copper, though iron has a much stronger affinity for oxygen than copper (as is proved by the precipitation of copper by iron), for the affinity between silver and copper is much stronger than between silver and iron.

As, then, metallic precipitates are in fact alloys (though often with such a small proportion of the precipitant as to be scarcely sensible), it is necessary that the combination of the metals must be made when both are in solution, for we can conceive of no other method by which two solid metals (copper and iron for example) should be alloyed in a common temperature. The whole process, therefore, must be the following, taking the above metals as instances; a portion of the iron must first be oxydized and dissolved in the acid, and by this it disoxydizes, and precipitates in the metallic form an equivalent portion of the copper, during which time the dissolved iron must divide itself into two very unequal portions, of which by far the largest part remains in solution, but the remainder must return to the metallic state to unite with the copper, and to be precipitated along with it. This complicated action must take place even from the first, for how else can the union of the two metals be accounted for? and till less can it be explained without this supposition, as the precipitation proceeds, when the surface in contact with every fresh stratum of precipitate is no longer iron, but an alloy of copper and iron, almost approaching to pure copper.

This leads us also to consider what is the affinity that determines the place to which the precipitates attach themselves. In the first instance, that is, when a surface of pure iron is exposed to the cuprous solution, the precipitate may be supposed to attach itself to the iron rather than to fall down loose in the vessel on account of the affinity existing between iron and copper alloyed with a little iron; but after the surface of the iron bar is covered, each successive stratum of precipitate attaches itself, not to the iron (for this is covered), but to the surface of the precipitate already formed, that is to say, to a substance of exactly the same composition.
composition as itself. In this latter case, therefore, the same kind of affinity acts as when a saline solution during crystallization deposits its crystals on the portion of salt already separated, rather than on a naked surface. The adhesion in this instance, however, is very slight, and readily broken. The proportion of the precipitant which enters into the alloy is probably greater in the first stratum of precipitate than in the subsequent ones; thus when copper is separated by iron, the part immediately in contact with the iron is visibly browner than the rest, owing probably to a larger admixture of iron.

It has been mentioned that phosphorus will separate some metals from their solutions in the reguine state. These are particularly gold, silver, mercury, and copper. If a dike of clean new-melted phosphorus is immersed in an acidulated solution of sulphate of copper, in a day or two it becomes beautifully spangled with little knobs of bright metallic copper, which gradually increase to a thick crust, after which, if the dike is put into boiling water, the phosphorus will melt out, and leave a delicate hollow cylinder of copper. In this case, however, as in the former, the precipitate is not pure copper, but an alloy of copper with phosphorus, or a phosphuret, in which, however, the quantity of phosphorus is extremely small, and the solution contains phosphoric acid. When phosphorus is introduced into a solution of mercury, only part of this metal assumes the metallic form, and the rest is oxidized combined with phosphorus and phosphoric acid.

From what has been observed above, it is obvious that the method of recovering one metal from its solution by the addition of another, which is so often referred to in analysis, requires considerable precaution, is liable to many inaccuracies, and can only be employed with propriety in certain cases. The circumstances which forbid its use, or render it inconvenient, are the following. 1st. Where the salt formed by the union of the precipitant in the acid is insoluble in water, and will not mix with the precipitated metal, from which it cannot be readily separated, as when sulphate of copper is decomposed by lead, antimony, or mercury, for the sulphates of these metals are little soluble in water: or, 2dly, where the newly formed salt would be decomposed by the water, as when any nitrate solution is precipitated by bismuth: or, 3dly, when the whole of the new oxyd formed by the transfer of oxygen from the precipitated metal to the precipitant cannot be dissolved by the acid precipent, as when nitrate of copper is decomposed by lead, in which case the precipitate will be very largely alloyed by the precipitant: or, 4thly, when the affinities of the precipitant are such as more easily to decompose the acid than to absorb the oxygen of the metal already dissolved, as when nitrate of copper is decomposed by zinc, in which case the precipitate is partly reguline and partly oxydized: and, 5thly, when the affinities between the two metals are so strong that the precipitate is largely alloyed with the precipitant, as when a solution of silver is decomposed by mercury.

Of these five cases, the third is probably that which much more contributes to produce a large alloy of the precipitated metal than even the affinity existing between the two metals; thus Vanquel found that 50 grs. of copper, diffused in nitric acid, even with excess of acid, required no less than 216 grs. of lead for its complete separation, and the precipitate, instead of weighing only 50 grs., amounted to 128 grs. of which, therefore, 50 were copper, and 78 were lead. Yet these two metals have but little affinity for each other. This inconvenience is corrected, though not entirely removed, by adding a considerable excess of acid. See Aikin's Diet. art. Precipitate.

Precipit, q. d. precipitate, formed from precipium, principal, in the French Jurisprudence, an advantage belonging to any one, in a thing to be divided, or a portion taken off, and set by, in his favour, before the division made.

In noble position, the eldest has always the principal fief, or manor for his precipit, in which view, the precipit coincides with the right of primogeniture.

Precision, Precipitio, in the Schools, the same with abstraction.

Precision, in Writing, denotes such a brevity as confines in saying nothing superfluous, and omitting nothing that is necessary. In this sense it is opposed to a tedious prolixity on the one hand, and an obscure conciseness on the other. See Style.

Preckol, in Geography, a town of Prussia, in Samland, on the Minia; 10 miles S.S.E. of Memel.

Preconisation, a proposition, or declaration, which the cardinal patron makes in the confistory at Rome, of a person nominated by some prince to a prelature, by virtue of letters of which he is the bearer; which the pope complying with, gives his collation.

The date of the bulls is dispatched on the same day with the preconisation.

Precontract, Precursor, a contract made before or prior to another; chiefly used in relation to marriages.

Precurdion, or Precedion, in Anatomy, a word of rather indefinite import, applied more or less largely to the region of the stomach and heart.

Precursor, a person who goes before any one to notify his coming. The term is peculiarly applied to St. John Baptist, who is styled the precursof of Jesus Christ, from what is said of him by St. Luke, "Thou, child, shalt go before the face of the Lord to prepare his way."

Precy-sur-Tille, in Geography, a town of France, in the department of the Côte-d'Or, and chief place of a canton, in the district of Samur; 7 miles S. of Samur. The place contains 629, and the canton 8350 inhabitants, on a territory of 2374 kilometres, in 26 communes.

Preda, La, a town of Italy, in the department of the Panaro; 18 miles W.S.W. of Modena.

Preda di Marignone, a town of Sardinia; 33 miles N.E. of Castello Aragonese.

Preda de St. Vominis, a town of Sardinia; 25 miles N.E. of Castello Aragonese.

Predecessor, a person who has preceded another in the same office or employment. See Ancestor.

Predestiarian, in Etymological History, a person who adheres to the doctrine of absolute predetermination.

St. Augustin is considered as the founder of the sect of Predeterminians, he being the first of the fathers that has set forth the doctrine in such express terms; though the Jansenists and Jutes are still greatly divided about the real doctrine of St. Augustin, in this article, each interpreting it consistently with their own scheme.

Father Sirmond contends for an ancient sect of Predeterminians, or Predeftinatians, contemporary with St. Augustin himself, and who had their rise in Africa, in the monastery of Adrumetum, from a misunderstanding of St. Augustin's doctrine. Hence they were led to the notion, that God not only predetermines the wicked to eternal punishment, but also to the guilt and transgression for which they are punished: and that thus both the good...
and bad actions of all men were determined from eternity by a
divine decree, and fixed by an inevitable necessity.

It is added, that the opinion spread thence throughout
the Gauls, where one of them, a priest named Lucidus, was
condemned by Paulinus, Bishop of Rhegios, and his sentence
was confirmed by two councils.

However, the existence of this Pre-destination belief has been
denied by many learned men, particularly the president
Mauguin, and considered as an invention of the Semipe-
lagiens, designed to decry the followers of Augustin, by
attributing to him unjustly this dangerous and pernicious
error. Nor does it appear, though there might have been
persons who embraced the Pre-determinist opinions, that the
abettors of them ever formed themselves into a sect.

The doctrine was again broached in the ninth century,
by Godeschalkus, a Benedictine; who, as Hucemi, in a
letter to pope Nicolas, says, maintained with the ancient
Pre-determinists, who had been already anathematized, that
God pre-determined some to eternal life, and others to eternal
death; that God did not will all people to be saved; that
Jesu Christ did not die for all, but only the elect, or those
that are saved, &c.

This doctrine was again condemned in a synod held at
Mentz, A.D. 848, and by a council at Quircy, A.D.
849, in consequence of which Godeschalkus was treated
with the utmost barbarity, and compelled to burn with his
own hands the justification of his opinion, which he had
presented to the council at Mentz. He was then cast into
prison, where he died in the year 868 or 869, maintaining
with his last breath the doctrine for which he had suffered.

The decrees of the former council were confirmed in a
new council which met at Quircy, A.D. 853; but they
were declared null by a council assembled at Valence,
A.D. 855, and the decrees of this council were confirmed
by the council of Langres in the year 859, and in 860 by
the council of Touli.

This controversy was revived in the 16th century by
Calvin, who maintained that the everlasting condition of
mankind in a future world was determined from eternity;
and that God, in pre-determining from all eternity one part
of mankind to everlasting happiness, and another to endless
misery, was led to make this distinction by no other motive
than his own good pleasure and free will. This opinion
was, in a very short time, propagated through all the re-
formed churches, by the writings of Calvin, and by the
ministry of his disciples, and, in some places, was infected
in the national creeds and confessions: and thus made a
public article of faith.

The unhappy controversy, which took its rise from this
doctrine, was opened at Strasburg in the year 1566, by
Jerome Zanchi, an Italian ecclesiastic, who was particu-
larly attached to the sentiments of Calvin, and carried
on in a manner that contributed very much to exasperate
the partisans and foment the discord of the contending
parties.

The Pre-destination opinions have been maintained by
considerable numbers, both in Popish and Protestant coun-
tries: and in our own country in particular, they have had
many zealous advocates.

We shall here observe, that they have undergone a kind
of relaxation by those who have been denominated Baxterians,
for an account of whose tenets, see that article.

PREDESTINATION, PREDEMETINATION, in Theology,
a judgment, or decree of God, by which he has resolved,
from all eternity, to save a certain number of persons, hence
named elect

Others define predestination, a decree to give faith in
Jesu Christ to a certain number of men, and to leave the
rest to their own malice and hardness of heart.

According to the Calvinistical scheme, the reason of
God's pre-determining some to everlasting life is not founded
in a foresight of their faith and obedience, considered as
independent upon any communication of grace from him,
but is to be referred to his sovereign mercy and free grace;
nevertheless, it is also maintained on this scheme, that the
means are decreed as well as the end, and that God purporses
to save none but such as by his grace he shall prepare for
salvation by sanctification.

The Remonstrants define predestination more laxly and
generally, the decree of saving believers, and damning un-
believers.

Some represent the election and predestination spoken of
in scripture, as relative only to nations, and not to particular
persons.

The greatest difficulties with which the modern theology
is eluded, turn on the article of predestination: both the
Romish and reformed churches are divided about it; the
Lutherans speak of it with horror; the Calvinists contend
for it with the greatest zeal; the Molinists and Jesuits
preach it down as a most dangerous doctrine; the Janenists
affert it as an article of faith; the Armenians, Remonstrants,
and Pelagians, are all avowed enemies of predestination.

Those strenuous patrons of Janenism, the Portroyalists,
teach, that God pre-determinates those who he foresees will
co-operate with his grace to the end. Dupin adds, that
men do not fall into sin because not pre-determined; but
they are not pre-determined, because God foresees their sins.

See Election and Reprobation.

Predestination is also used for a concatenation of
several causes appointed by Providence: in virtue of which,
things are brought to pass by a fatal necessity, contrary to
all appearances, and in spite of all opposition. See Fate,
Necessity, and Leibnitzian Philosophy.

The Turks are great Pre-determinists; they esteem the
flighty accident predetermined, and on this account, are
much more daring in battle, and run greater risks of their
lives than they would otherwise do.

PREDETERMINATION, PREDEMETINATION, in
Philosophy and Theology. The schoolmen call that concur-
rence of God which makes men act, and determines them
in all their actions, both good and evil, physical prede-
termination, or premotion.

Divines hold, that God hath no part in fin, inasmuch as
he only affords his concurrence to the physical part of
human action, not to the moral part.

Physical predestination, or premotion, if there be any
such thing, is that action of God by which he excites a
second cause to act; or by which, antecedently to all opera-
tions of the creature, or before it could operate in con-
sequence either of the order of nature or reason, he really
and effectually moves, and occasions it to produce all its
actions; that is, whatever the creature does or acts is
really done and acted by the agency of God on the creature,
who is all the time passive. So that, without such prede-
termination of God, all creatures must remain in an eternal
state of inactivity; and with such predestination it is
impossible but they should do what they are thus put upon
doing.

It is strongly controverted, whether or no such a physical
predestination be necessary to the action of natural
causes: the Scotists maintain the negative; urging, that
all natural causes are of their own nature determined to a

PREDESTINATION, PREDEMETINATION, in Theology,
a judgment, or decree of God, by which he has resolved,
from all eternity, to save a certain number of persons, hence
named elect
certain action; whence it should seem needless to call in a
new predetermination of God, e.g., to fire, to make it
warm the hand. For if an object be, by the course of
divine Providence, applied to fire; what need a second ap-
plication of the fire to make it warm the object applied
thereto? since beings are not to be multiplied unnee-
cessarily.

And such predetermination some philosophers hold still
lefs requisite to produce the acts of the will: at least, say
they, the human mind must be allowed the common power
and privilege of a second cause, and therefore be entitled
to produce its own acts, as well as other strictly natural
agents.

The Thomists, on the other hand, stand up strenuously
for the phycical predetermination: one of their principal
arguments is drawn from the subordination of second causes
to the first. Where there are several subordinate agents,
say they, the lower agents do not act, unless first moved
and determined thereto by the first; this being the very ef-
ference of subordination.

Again, the like they argue from the dominion of God
over all its creatures: it is of the essence of dominion, say
they, to apply and direct things subject thereto, to its own
operations; and this, if the dominion be only moral, mo-
raliy; but if it be also physical, physically. And that this
is the case in respect of God and his creatures, is confessed.
See Liberty and Necessity.

PREDIAL Tithes, Decima Predicales, are tithes paid
of things which grow from the ground only, as corn, grass,
and wood. See Tithes.

PREDIATORY DEBT. See Debt.
PREDICABLE, PREDICATUB, in Logio, a general
quality, or epithet, which may be predicated of, or applied
to, several subjects.

Thus animal is predicable both of man and beast; man is
predicable of Peter and James; triangle is predicable of a
hundre different kinds of figures, as right-angled, scalene,
isosceles, &c.

The schoolmen reduce the predicable to five classes; viz.
genus, species, proprium, differentia, and accident; under one
or other of which all that can be predicated of any subject is
included.

A predicable is also called universalis logico, as having
respect to other particular, and inferior or subject things:
thus animal is an universal, with regard to man and beast.
It is called a logical universal, to distinguish it from a me-
taphysical one, which is a common being considered in itself,
and therefore denominated universal in esse: whereas the
logical one is only universal as to our conception and ap-
lication.

Among the schoolmen, predicabile is usually defined num, opium
predicari de multis unioce, & divisi: or, somewhat
more clearly, a predicabile is a nature which may be pre-
dicated univocally of all things to which it is common, and
which, as it is individually multiplied in all its subordinates,
may be aptly predicated of them all.

Thus, when the appellation of virtue is attributed to jus-
tice, prudence, temperance, fortitude, charity, &c. the
name reason may be given why each is distinguished by such
name, as being all founded in a mediocrity, and being agree-
able to right reason, which is the character of virtue.

Hence, if there be several things called by some common
name, but the reason of such name is not the same in all, but
different: these do not come under the name of predicables.
As in the instance, canis, dog, which is both applied to a
domestic animal, distinguished by its barking; to a con-
stellation of the heavens; and to a fsh.

The way by which the mind comes to form such predic-
cables, or universals, is this: among those things which fall
under our observation, we see some characters and prop-
esties common to several, and others peculiar to each;
what we find common, we consider apart, and thus we form
an universal equally applicable to all. See Universal.

PREDICABLY, PREDICABLE, is used in the
schools in opposition to predicamentally. Thus, matter is
said to be united to form predically, or per accidens, to ex-
clude the notion of a predicamental accident.

PREDICAMENT, PREDICAMENTUM, in Logio, a
class or order of beings, or substiances, ranged according to
their natures, called also category, and sometimes categoriea.
See Category.

The word predicamentum was first introduced by Boe-
thusius, in lieu of the Greek προδικατος: and is used among
the school-writers with a good deal of latitude and variety: for
it either signifies the act of predicking, or the common pre-
dicament itself; or the genus or basis of any category; or the
collection of several common predicaments disposed in a
certain order; which last is its more usual acceptance.

Hence some define predicament, a series of predicates
traced from the genus, or highest term, through all the in-
ferior genera and species. Thus, a series of subsistance drawn
from subsistance through body, living, animal, man, to Peter,
is called the predicament of subsistance.

The usual definition among logicians is, that predicament
is a natural order or scheme, of some most general or univer-
sal thing, and of all that is contained under the same,
that is, all the subordinate genera, species, and individuals.

The properties of a predicament, ex parte rerum, i.e. of
the term or word by which the predicament or predicamental
series is denoted, the logicians hold, are, that it be one,
simple, precise, and connatural.

"Vox una, & simplex, rebus concinna locandis."

The conditions requisite ex parte rei, or of the thing to be
ranged in a predicament, are contained in the following verle:

"Entia per se, finita, realia, tota;"

i.e. it must be a positive being, in exclusion of non-entities,
negations, privations, impossibilities, &c.; and a being per
se, to exclude accidental things, factitious things, &c.; and
finite, that is, of a limited nature and extent, to ex-
clude God, and other transcendentals: real, since its in-
tention is for the better and more commodious disposing of
things in their places, to be the more distinctly known and
conceived; and whole, or complete, as not being in the
relation of a competent part, or as only necessary to
some other.

PREDICAMENT, Pos. See Post Predicament.
PREDICAMENTAL Accident. See Accident.
PREDICATE, PREDICATUM, in Logio, that part of
a proposition which affirms or denies something of the sub-
ject. Thus, in God made the world; made the world is the
predicate, and God is the subject.

A predicate, say the schoolmen, is properly a name pre-
dicable or spoken of another, as its subject: as man, in the
proposition, Peter is a man.

It is a celebrated rule or law of predicates, that nothing
is esteemed to be absolutely spoken or affirmed of another,
unless it be affirmed thereof in such a manner, or by such an
affirmation, as wants nothing either in the subject, predicate,
or copula, to make it true.

This also is noted properly of a predicate, that it contains,
in some measure, its own subject; thus metal contains gold, copper, iron, &c. of which it is predicated.

The word predicate is sometimes used indifferently with attribute; but the more accurate writers make a distinction. Every predicate is indeed an attribute, since whatever is predicated of a thing, is attributed to it; so, if animated be predicated of man, it is also attributed to him; but every attribute is not a predicate; thus, soul, learning, &c. are attributed to man, but not predicated of him.

**PREDICATING** is properly the act of affirming or denying somewhat of something. *As, Man is not a stone: body is a substance.* The thing thus predicated is called predicate.

In the doctrine of universalis, or predicables, to predicate is to speak or declare a thing truly, directly, and affirmatively. Thus man is predicated of several, i.e. it is truly and directly affirmed that the several are men, as when I say, *Socrates is man, Plato is man, Aristotle is man, &c.*

The things predicated of others are reducible to three classes: *genera,* as animal, of man, &c.; *species,* as whites, of a fwan, &c.; and *qualities,* of things of equal extent, as species, differences, proprium, &c.

The schoolmen distinguished several ways of predicking, as,
1. *In quod tantum,* which is to predicate essentially, both as to the thing and the manner, as *justice is a virtue.*
2. *In quod tantum,* which is to predicate accidentally, both as to the thing and the manner, as *Peter is learned.* And, 3. *In quod quid,* or *in quod propter quid,* which is to predicate both essentially and accidentally, as *man is rational.*

**PREDICTION.** *Praedicitio,* divination, prophecy, or foretelling what is to come, either by divine revelation, by art and human invention, or by conjecture. See Divination and Prophecy.

**PRE DIERE.** LUC ANTONIO, of Bologna, in Biography, a musical composer in the service of the court of Vienna, where he spent almost the whole of his life, returning to his own country merely to die. He is regarded as one of the best composers of his school, one of those who best united the ancient and the modern. He was endowed with a fertile imagination, and great variety of expression. The emperor Charles VI. had an affection for him, and had great pleasure in his conversation, which is so small praise; as that, since, with all his faults of ambition, had excellent moral principles, and was an acute and refined judge of music and dramatic poetry, Prediere first set many of Apolito Zenos operas for his imperial majesty, between the years 1711 and 1729, and one oratorio of Mufalphan, "Hacce, fique del Redentore."

**PREDMOUTH Point,** in Geography, a cape in the English channel, on the coast of Cornwall, on the west side of the entrance of Towy harbour.

**PREDOMINANT,** *Pradominans,* that which prevails, appears most, or has some superiority or ascendency over another thing.

**PREDTIEGISKOI,** in Geography, a town of Ruflia, in the government of Vologda; 48 miles S.W. of Ultring.

**PREDY,** in Nautical Language, signifying the same as ready. Thus, *perdy the fish,* or *perdy the ordinance,* is as much as to make things ready for a fight. *Perdy the hold,* is to lay or fly everything there in its due order and proper place.

**PRE-EMPTION,** *Preemptio,* a privilege anciently allowed the king's purveyor, of having the choice and first buying of corn, and other provisions, for the king's house, at an appointed value, and both without content of the owner.

In those early times the king's household, as well as those of inferior lords, were supported by specific tenders of corn, and other victuals, from the tenants of the respective demesnes; and there was also a continual market kept at the palace gate, to furnish viands for the royal use. (4 Inft. 273.) This answered all purposes, in those ages of simplicity, so long as the king's court continued in any certain place. But when it removed from one part of the kingdom to another, it was necessary to fend purveyors before-hand, to get together a sufficient quantity of provisions and other necessaries for the household; and left an unusual demand would raise them to an exorbitant price, the powers before mentioned were vested in those purveyors; who, in process of time, greatly abused their authority, and became a great oppression to the subject, though of little advantage to the crown. By degrees the powers of purveyance declined; and were particularly abolished in Sweden by Guiliavus Adolphus, towards the beginning of the 17th century. And with us in England, having fallen into disuse, during the suspension of monarchy, they were taken away by the flat. 12 Car. II. c. 24.

The parliament, in part of recconempence, settled on Charles, his heirs, and successors, for ever, the hereditary excise of 15d. per barrel on all beer and ale sold in the kingdom, and a proportionate sum for certain other liquors. See Excise and Revenue.

**PREENING,** in Natural History, the action of birds cleaning, composing, and dreading their feathers, to enable them to glide more easily through the air.

For their use herein, nature has given them an admirable piece of furniture; viz. two peculiar glands, which secrete an unction matter into an oil-bag, perforated; of which the bird, on occasion, draws it with his bill.

**PRE-ESTABLISHED HARMONY.** See Harmony.

**PREETZE,** in Geography, a town of the duchy of Holstein, 43 miles N.E. of Hamburg.

**PRE-EXISTENCE, ** *Pre-existentia,* the state of a thing actually in being before another.

The ancient Pythagoreans and Platonists all asserted the pre-existence of human souls, i.e. that they were in being before they were joined to our bodies.

Origen also held the eternal pre-existence of souls.

The orthodox believe, that God created the world out of nothing; and not of a pre-existent matter.

Some heretics have held mankind pre-existent to Adam. (See Pre-Adamite.) Divines of various descriptions maintain the pre-existence of Christ, in opposition to those who have appropriated to themselves the appellation of Unitarians. See that article.

**PREFACE.** *Prepatio,* formed from *pre* and *pari* *g. d. to speak before,* an advertisement in the beginning of a book, to inform the reader of the design, order, method, &c. observed in it; of what is necessary to receive its full effect, and facilitate the understanding of it.

There is no part of writing that requires more art and address, or which fewer authors succeed in than prefaces.

Prefacing is, in effect, a particular species of writing, and has its peculiar character and taste to distinguish it from all others. It is neither argumentation, discourse, narration, nor apology.

**PREFACE of the Mafs.** The Romanists call that part of their mass, which precedes the confection, and which is to be rehearsed in a peculiar tone, *precess.*

The use of prefaces in the church, they contend, is very ancient; and conjecture, from some passages of St. Cyprian, &c. that it was in use in the time of the apostles.

The preface to the mass anciently had, and still has, very different names in different churches. In the Gothic, or Gallican
Gallican rite, it is called immolation; in the Mozarabic rite, illusion; anciently among the French, it was called constillation; in the Roman church alone it is called preñatio, preñar.

PRECEPT, PRECEPTUS, in ancient Rome, was one of their chief magistrates, who governed in the absence of the kings, consuls, and emperors.

His power was somewhat different at different times; but was always greatest under the emperors. His principal care was the government and administration of the city of Rome.

He took cognizance of all crimes committed in the city, and within an hundred miles thereof. He judged capitally and finally, no appeal lying from him; and even by the sixti-second Novel, he presided in the senate, taking place before all the patricii and confulars, &c.

He had the superintendence of the provisions, policy, buildings, and navigation.

There is still a preñet in modern Rome, who is a kind of governor, differing little from the ancient preñetus, except that his authority only extends to forty miles round the city, whereas that of the preñet of ancient Rome reached one hundred miles round. With the empire, the preñet of the city had declined to a municipal officer; yet he still exercised, in the last appeal, the civil and criminal jurisdiction; and a drawn sword, which he received from the successors of Otho, was the mode of his investiture, and the emblem of his functions. The dignity was confined to the noble families of Rome; the choice of the people was ratified by the pope; but a triple oath of fidelity must have often embarrassed the preñet in the conflict of adverse duties. A servant, in whom they poñessed but a third share, was disfranished by the independent Romans. At length, however, they conferred, without reluctance, to the restoration of the preñet. About fifty years after this event (A. D. 1209-1216) Innocent III., delivered himself and the Romans from this badge of foreign dominion; he invested the preñet with a banner instead of a sword, and absolved him from all dependences of oaths or service to the German emperors. In this place an ecclesiastic, a preñet or future cardinal, was named by the pope to the civil government of Rome; but his jurisdicti onboard, as we have said, has been reduced to a narrow compass; and in the days of freedom, the right or exercise was derived from the senate and people. About thirty-eight years after the foundation of Conñantinople, a similar magistrature was named in that rising metropolis, for the same uses, and with the same powers.

PREFEET OF THE PRETORIUM, PREFEETUS PRETORII, OR PREFEETUS PRORII, was the chief or leader of the preñetorians, or cohorts defined for the emperor's guard.

The preñetor legion, according to Dion, consisted of ten thousand men. Suetonius refers the institution of preñetorius preñorii to Augustus. It is added, that he was usually taken from among the Roman knights.

By the favour of the emperors, his authority grew very considerable; insomuch, that he became the arbiter and supreme judge of all affairs.

As the government degenerated into a military despotism, the preñetor preñet, who in his reign had been a simple captain of the guards, was placed, not only at the head of the army, but of the finances, and even of the law. In every department of administration, he represented the person, and exercised the authority of the emperor. The first preñet, who enjoyed and abused this immense power, was Plautianus, the favourite minister of Severus. After his fall, the celebrated Paminus was appointed to the execution of this office. From the reign of Severus to that of Dio-

cletian, the guards and palace, the laws and the finances, the armies and the provinces, were entrusted to their superintendence; and, like the vixiers of the East, they held with one hand the seal, and with the other the flannel of the empire.

To reduce this extravagant authority, Conñantine, conformably to the plan of government instituted by Diocletian, divided the preñetor of the preñtorium into four preñetorii; and each of these he again subdivided into civil and military departments; though the name was only referred to him who was invested with the civil authority; and that of commodi belli given him who had the command of the cohorts. See COUNT.

The four preñetorii of Conñantine, which had before been assigned to four princes, were the following. 1. That of the East, whose preñet extended his ample jurisdiction into the three parts of the globe which were subject to the Romans, from the cataracts of the Nile to the banks of the Phasis, and from the mountains of Thrace to the frontiers of Persia. 2. The preñetor of Illyrium once comprehended under his authority the important provinces of Pannonia, Dacia, Macedonia and Greece. 3. The power of the preñetor of Italy extended beyond the country from which he derived his title, over the additional territory of Rhettia, as far as the banks of the Danube, over the dependent islands of the Mediterranean, and over that part of the continent of Africa, which lies between the confines of Cyrene and those of Tingitania. 4. The preñetor of the Gauls comprehended under that denomination the hundred provinces of Britain and Spain; and his authority was obeyed from the wall of Antoninus to the foot of mount Atlas.

Thus the office of preñetor of the preñtorium, which in its origin, and till the time of Conñantine, was military, and succeeded to that of magister equitum, now commenced a purely civil magistrature; and at length became the prime dignity of the empire.

The succeeding emperors, following Conñantine's division, divided the empire into four preñetorii, as into four dioceses; viz. the Gauls, Illyria, Italy, and the East. See Dioñese.

The provinces of which these dioceses consisted, had their particular governors; at the head of whom was the preñetor, who, though he had not the command of the army, yet had the power of the sword, decided ultimately of all causes, and had all the marks and honours of sovereignty.

Although the preñetorii had been deprived of all military command, the civil functions which they exercised over so many subject nations, were adequate to the ambition and abilities of the most consummate ministers. To their wisdom was committed the supreme administration of justice and of the finances, the former including the protection of citizens who were obedient to the laws, which in a state of peace is the distinguishing duty of the sovereign, and the latter, which pertains to the duty of the people, and comprehends the constitution of such a fabric of their property as is required for the exences of the state. The coin, the highways, the posts, the granaries, the manufactures; whatever could interest the public prosperity, was moderated by the authority of the preñetori. As the immediate representatives of the imperial majesty, they were empowered to explain, to enforce, and, on some occasions, to modity, the general edicts by their discretionary proclamations. They watched over the conduct of the provincial governors, removed the negligent, and inflicted punishments on the guilty. From all the inferior juridictions an appeal in every matter of importance, either civil or criminal, might be brought before the tribunal of the preñetor; but his
sentence was not final and absolute; and the emperors themselves refused to admit any complaints against the judgment or the integrity of a magistrate whom they honoured with such unbounded confidence. His appointments were suitable to his dignity; and if avarice was his ruling passion, he enjoyed frequent opportunities of collecting a rich harvest of fees, prebends and perquisites. Although the emperors no longer dreaded the ambition of their prefects, they were attentive to counterbalance the power of this great office by the uncertainty of its duration. From their superior importance and dignity, Rome and Constantinople were alone excepted from the jurisdiction of the pretorian prefects.

Julianus created a fifth prefect of the pretorium for the government of Egypt or Africa, which had been torn off from the diocese of the East by the invasion of the Vandals during the empire of that prince, and allowed him a salary of 100 pounds of gold.

Under Augustinus, the officer sent to govern Egypt with a proconsular authority, was called prefectus Augustalis. There were also several other officers distinguished by this appellation: such as prefectus aerarii, ordained by Augustinus to supervise and regulate the public fund, which he raised for the maintenance of the army; the prefectus alae, appointed by the Roman confid to govern each principal division of the army; the prefectus clavis, or admiral; the prefectus fabrum, who had the care of the arms, and of every thing that related to military expeditions; the prefectus frumenti, appointed by Augustinus to inspect and regulate the distribution of corn among the common people; the prefectus militum, to which clafs belonged three different officers, viz. the prefect of a cohort, of a camp, and of a legion; the prefectus sigillum, appointed by Augustinus to command the soldiers who watched the city, and whose business was to take cognizance of thieves, incendiaries, idle vagrants, &c. and to punish all petty misdemeanours that were thought too trivial to fall under the notice of the prefect of the city, &c.

Prefect of the Sacred Chamber. See Prefectus.

Prefectures, or Prefecture, were certain towns of Italy, whole inhabitants had the title of Roman citizens; but were allowed to enjoy neither their own laws nor magistrates, being governed by annual prefects sent from Rome. These were generally such places as were either suspected, or had some way or other incurred the displeasure of the Roman state; this being accounted the hardest condition that was imposed on any people of Italy.

Prefix, in Grammar, denotes letters or syllables prefixed to words; these are common in the Hebrew, and opposed to affixes.

Nouns that are formed from verbs, by the prefixion or addition of ferville letters, are distinguished by the technical name of "Hebemantic," because the letters which compose the word "HEBEMANTIC," are employed in their formation. To these might be added the letter g. See Serviae.

Pregadi, in Hijlory, a denomination given to the senate of Venice, in which resides the whole authority of the republic.

At its first institution it was composed of sixty senators, to whom sixty more have been added.

Prégartin, in Geography, a town of Austria; eight miles N.E. of Steyrmsg.

Preel, a river of Prussia, formed by the union of the Inler and Angerar, which, falling into Welau, Taptan, Königberg, &c., runs into the Frisch Haff, five miles below Königberg; N. lat. 54° 42'. E. long. 26° 27'.

Pregnancy, the state of a woman who has conceived, or is with child. See Gestation, Conception, and Breeding.

From the original use of the word pregnant, is derived the act of impregnating, in its more general application. See Generation, Flower, and Seed.

Pregnancy, Plana and Trial of, in Law. See Jury of Matrons, and Reprive.

Pregnant. Negative Pregnant, in Law. See Negative.

Pregnitz, in Geography. See Pognitz.

Prenuas, a river of Brazil, which runs into the Atlantic, S. lat. 2° 26'. W. long. 44° 26'.

Pregunzwola, a town of Italy, in the Trevisan; four miles S. of Trevigio.

Prehnite, in Mineralogy, a stone of the flicate genus, and quartz family, which has been denoted by various names; being called by some green stone, and by others emerald, pru- fum, or chryso-pru-fum, and also sappar, chrysolite, and zeo-lite of the Cape. Its colour is apple-green, or greenish-grey, of various degrees of intensity. Its external surface, 2. Its internal use, &c. of the nearly kind. Its transparency, 3-2. This stone is found both amorphous and crystallized; the former presents either a foliated or striated texture, and the crystallized forms either low, small, compressed, flat, quadrangular prisms, or tables, and fome with truncated angles, and heaped together, or in groups. The principal fracture is foliated, feldom striated; the crosf fracture uneven and fine-grained; its hardness from 9 to 10; brittle; its specific gravity 2.9425. Explofed to the blow-pipe, it swells and foams when heated to redness more than zeolites do, and melts into a brown enamel, smooth on the outside, but fpongy and porous underneath. Of the usual fluxes borax is the most effectual; with alkalies it forms only an enamel, but microcomical falt forces it into an opalescent glafs.

By the analysis of Mr. Klaproth, it contains 0.383 3 files, 0.183 33 argill, 0.0566 iron, and 0.01830 water and air.

By that of Mr. Haffenzrat, 0.50 0 4 argill, 0.233 33 1, 0.049 iron, 0.009 water, and 0.009 magnesia.

This stone was first found near the Cape of Good Hope, by Capt. Phrenn, and hence Mr. Werner called it prehnite. It has been lately discovered near Dumbarton in Scotland, and it has also been found in Dauphiné.

In colour, texture, and intumescence, it resembles zeolites, but differs in hardness, specific gravity, colour, relation to fluxes; and also in constitution, for it contains iron; neither does it gelatinize with acids as zeolites do. On the other hand, it differs from those by its fracture, intumescence when heated, greater fusibility, and the porosity of its enamel. Hence Mr. Werner justly considers it as a particular species, but nearly allied to zeolite. Kirwan's Elen. vol. 1. See Gems.

Preis, Joachim Frederic, in Biography, Swidish ambassador at the Hague, was born in 1665, at Dorpt, in Ethimia, being the youngest of sixteen children. Having received a good education, partly at home, and partly at the royal school at Rigia, he was fitted for public life. In 1689 he repaired to Stockholm, and was prented to Charles XI., who gave him reason to hope that he should soon be employed in some public capacity. Encouraged by this prospect, he determined to travel, in order that he might improve himself by a more extensive acquaintance with mankind. After pausing some time in Germany, Holland, and England, he went to Paris in 1695, where he turned his attention entirely to diplomatic affairs, and entered into the service of Palatinii, the Swedii ambassador at the French court, affilling in the duties of the office without any regard to
to emolument. In 1703, when Palmquist was appointed by Charles XII. envoy-extraordinary to the Hague, Preis accompanied him thither as secretary, and on Palmquist's being promoted to be chancellor of the court in 1715, he was acknowledged by the states-general as charge d'affaires, without obtaining special letters of credence. The misfortunes into which Sweden had fallen at this period, rendered his situation exceedingly critical and delicate, being often obliged to act according to the circumstances of the moment, without orders or instructions. The arrest of baron Goertz in Holland, contrary to the law of nations, threw Preis into a confiderable dilemma, nevertheless he conducted himself so much address, that he obtained the release of Goertz, though he thereby excited the displeasure of the Dutch minister, who did all in his power to induce Charles XII. to recall him. The attempt did not succeed, the king returning for answer, that "he found his services still necessary." Peter the Great, when at Amsterdam, was desirous to engage Preis in his service, as being a native of Lithuania, and with this view signified that he wished to have a conference with him; but, to the czar's great astonishment, he declined his visit and offer. On the death of Charles XII., this statesman was treated with the same respect by his successor queen Ulric Eleonora, who in 1719 appointed him her confidential and general, and in the year following he was confirmed in that quality by king Frederic. In the year 1745 he received letters patent of nobility; in 1748 he was created a knight of the Polar Star; and in 1756 was raised to the rank of baron. He died in the year 1759, having served his country, under five different sovereigns, for seventy years, of which he had been employed fifty-seven in the republic of the United States. Baron Preis composed a found judgement, added to great penetration. He was of a serious disposition, but easy in his manners, and could readily adapt his behaviour to that of the persons with whom he was in company. Till a late period in life he applied to business with indefatigable exertion, and his vigilance was directed to every object connected with the department to which he belonged. In his public and private actions, he was guided by the principles of religion, and the integrity of his heart was manifested in every act of his life. He was greatly attached to literary pursuits, and courted the society of learned men, whatever might be their condition, and the hurry of business seldom prevented him from devoting some part of his time to study. His own works were numerous, of which the following may be noticed: "Lettre d'un Ami à Dantzic à un Ami à Amsterdam," 1714. "Seconde Lettre d'un Ami à Dantzic à un Ami à Amsterdam," ou l'on montre que la pretendue Liberté de Navigation, et de Commerce, sur les Villes Suédoises occupées par les Russes, est mal fondée," "Lettre de M. N. N. a une Peronne de Diftinction qui lui demande ses Sentimens sur les Impriques qui ont paru au Sujet de l'Arret du Comte de Gyllemborg et Baron de Goertz, Ministres du Roi de Suede," Gen. Biogr. PREISEGG, in Geography, a town of Aulria; 18 miles S.S.W. of Styre. PREISENDORE, a town of Bavaria, in the bishopric of Bamberg; three miles S. of Bamberg.

PREDICATE. A fallacious notion or opinion of any thing, conceived without a due previous examination thereof.

Prejudice, q. d. pre-judgment, does not import a judgment merely as prior to another in respect of time, but as being prior thereto in respect of knowledge, or of sufficient attention to the thing; the preposition per expressing an anticipation, not so much of time, as of knowledge and due attention.

Hence prejudice is also called among the schoolmen anteposition, et praeventa cognitio, a preconceived opinion, &c.

Prejudices which lead to wrong judgments, or which are causes of error, may be considered as disruptors of the understanding; the investigation and statement of which may serve to point out appropriate and effectual remedies. Lord Bacon, in his fifth book "De Augmentis Scientiarum," and more fully in his "Novum Organum," has distributed them into four classes, under apppellations that are somewhat fanciful; viz. "idola tribus," "idola specus," "idola fori," and "idola theatrici." To every bias of the understanding, by which a man may be mired in judging, or drawn into error, he gives the name of an idol; the propriety of which may be illustrated and evinced by considering, that the understanding, in its natural and befit state, pays its homage only to truth; and the causes of error are regarded by him as so many false deities, who receive the homage that is due only to truth.

The first class comprehends the "idola tribus," which betid the whole human species, so that every man is in danger from them; such are exemplified in the following instances:

1. Men are prone to be led too much by authority in their opinions; and when this bias commences with an indifference about truth, its operation will be the more powerful.
2. Another general prejudice rises from a disposition to measure things less known, and less familiar, by those that are better known, and more familiar. This is the foundation of analogical reaoning, to which we are naturally prone, and to which indeed we owe a great part of our knowledge; at the same time it ought to be considered, that the bias of human nature is to judge from too light analogies.
3. Men are often led into error by the love of simplicity, which directs them to reduce things to few principles, and to conceive a greater simplicity in nature than there really is.
4. One of the most copious sources of error in philosophy, is the misapplication of our noblest intellectual power, which is that of invention, to purposes for which it is incompetent.
5. In avoiding one extreme, men are very apt to rush into the opposite.
6. Men's judgments are often perverted by their affections and passions.

The second class of idols, according to lord Bacon, are the "idola specus"; these are prejudices which have their origin, not from the constitution of human nature, but from something peculiar to the individual. Conceiving the mind of every man to resemble a cave, which has its particular form, and manner of being enlightened, and which, from these circumstances, often gives false colours, and a delusive appearance to objects that are from it, lord Bacon gives the name of "idola specus" to those prejudices which arise from the particular way in which a man has been trained, from his being addicted to some particular profession, or from something particular in the turn of his mind.

The "idola fori" are the fallacies arising from the imperfections and the abuse of language, which is an instrument of thought, as well as the communication of all thoughts.

The fourth class of prejudices are the "idola theatrici," by which are meant prejudices arising from the fictions or sects, in which we have been trained, or which we have adopted. See Reid's Essays on the Intellectual Powers of Man, eff. vi.

PREJUDICIAL ACTION. See Action.

PRELATION, from pralatus, of pra, before, and frato, 1 hear,
PREMIERE VUE, a small island on the N. coast of New Georgia, on the land of the Arfakides, discovered by M. Surville in 1769. S. lat. 7° 15'; E. long. 157° 17'.

PREMIERS. See Primeiras.

PREMISES, PREMISE, PREMISES, Premises, in Logic, the two first propositions of a syllogism.

When a syllogism is in form, the two premises being granted, the conclusion cannot be denied. The premises, says Chauvin, are properly the parts of the antecedent of an argument, when complex; and are called premisse, because premised to the conclusion.

Thus in the argument, every man is an animal; Peter is a man, therefore Peter is an animal: the propositions, every man, &c. and Peter, &c. are the premises.

Premises are the principles of our reasonings; as being clear, evident, and demonstrative propositions, from the relations of which to one another we draw or infer new truths, propositions, &c.

The premises are either equal, where neither suffices alone for drawing a conclusion, as in the instance above; or unequal, the one major, greater, from which alone the conclusion is drawn; the other minor, or less, which only ever serves in applying the antecedent to the consequent.

In the common practice of the schools, however, every syllogism, or formal argument, of what kind soever, is said to have a major and a minor, how equal soever the premises may be.

PREMISES, in Law, the lands, &c. mentioned in the preamble or beginning of a deed, lease, conveyance, or the like.

The premises of a deed (which see) may be used to set forth the number and names of the parties, with their additions or titles. They also contain the recital, if any, of such deeds, agreements, or matters of fact, as are necessary to explain the reasons upon which the present transaction is founded; and herein is also fet down the consideration upon which the deed is made. And then follows the certainty of the grantor, grantee, and thing granted.

PREMIUM, or PREMIUM, literally denotes a reward or recompense.

Among merchants it is taken for that sum of money; viz. $8 or 10 per cent. &c. which is given to an insurer, for insuring the safe return of any ship or merchandise.

In a policy of insurance, the insurers bind themselves to the insured for the true performance of their contract, and confess themselves paid the consideration or premium by the insured, after the rate specified. In practice, however, the premium is not always paid, when the policy is underwritten. Insurances are generally effected by the intervention of brokers, and open accounts are usually kept between them and the underwriters, in which they make themselves debtors for all premiums. By the usage of trade, the insurer is to look to the agent who is employed to effect the policy for his premium. Sometimes the credit is given to the insured himself.

If there be no express agreement, it would seem that the agent or broker is prima facie liable. Perhaps in such case an action would lie against either, unless the principal has paid the premium to the agent; in which case, the writers on this subject are of opinion that the agent alone is responsible. But whichever is liable, the insurer may recover the premium, and "indebitatus assumpsit" will lie for it, notwithstanding the formal acknowledgment of the receipt of it in the policy, which is not inferred there as conclusive evidence of the actual payment of the premium, but to preclude the necessity of proving it in case of loss. The payment
ment or non-payment of the premium can, therefore, have no effect on the insurance. Every insurer may inflict on being paid the premium before he subscribes the policy; but having once subscribed it, and given credit for the premium, to whom being of no consequence, he shall not afterwards be at liberty, when a loss has happened, to object the want of consideration for his promise. There is no fixed rule for ascertaining the premium in any case. This must always depend on the agreement of the parties; and therefore the premium, whatever it may be, is always reputed to be just and fair, if there be no fraud or surmise on either side. If the nature of the risk be fairly and fully declared by the insured, the insurer can never dispute the payment of a loss, on the ground of the smallness of the premium.

The premium paid by the insured, and the risk which the insurer takes upon himself, are correlative, the mutual operation of which constitutes the essence of the contract of insurance. The insurer shall not be liable to the risk, without receiving the premium; nor shall he retain the premium, which was the price of the risk, if, in fact, he runs no risk at all. In such cases he is bound, upon principles of moral honesty and justice, to refund it; and the law implies a debt, "quaeri ex contractu," and gives the insured an action against the insurer to recover the premium. The cases in which the insured shall be entitled to a return of premium are reduced, by fference Marshall, to the following heads: viz. where the contract is void ab initio; where the risk has not been commenced; upon the performance of certain stipulations; and where the deduction of one-half per cent. shall be allowed.

The contract may be void for want of interest, which may be either total, as where the insured has nothing on board the ship, or partial, as where he has an interest in the thing insured, but not to the amount stated in the policy. Upon a wager-policy, which since the Stat.19 Geo. II. c. 37. is illegal and void, the insurer cannot recover back the premium, at least after the risk is run. Yet, before the risk is run, and while the contract is executory, the insurer may recover back the premium. If the contract be void, as being a re-insurance within the statute 19 Geo. II. c. 37. and 4. there shall be no return of premium. The case is the same, if the insurer could have been called upon to pay the sum insured. Captors likewise having insurable interest in their prize before condemnation, if they infure, shall not have a return of premium, though it should afterwards be adjudged no prize. Although an insurance to protect a trading with the enemy is void, yet the insured shall not recover back his premium. Where the policy is void, and no fraud is imputable to the plaintiff, he is entitled to a return of premium; and when the plaintiff is entitled to a return of premium, he may claim a verdict for it, even after the jury have delivered their verdict for the defendant, on the principal question; but the court will not, on setting aside a verdict for a loss, substitute a verdict for the premium. If the policy be void, on account of fraud on the part of the insurer, the premium shall be returned; but whether the insurer be bound to return the premium, in a case where fraud has been committed by the insured, is a question that has occasioned some doubt and difference of opinion. The court of chancery, however, has in one instance ordered a return of premium, where the policy was declared void for fraud committed by the insured. The same doctrine has been adopted in a court of law. Nevertheless, the courts of law, under the sanction of lord Mansfield, have held a contrary doctrine.

With regard to the second head, where the risk has not been commenced, foreign authors maintain, that the insurer cannot, by his own act, disaffirm the contract, and demand a return of premium; excepting only the case, in which it becomes impossible for the insurer to ship the goods, or to cause the ship to proceed on her voyage. In Holland and France the law is different; and in England it is a general rule, that if the risk be not begun, whatever be the cause, the premium shall be returned; but where the voyage and premium are divisible, and any part be not commenced, the premium for that part shall be returned. But if the risk be entire, and be once commenced, it is a general rule that there shall be no return of premium.

The third head relates to the performance of some stipulation. If part of the premium is to be returned upon the performance of some stipulation, as in case of a ship's failing with convoy, this shall be returned, though the insurer be obliged to pay a partial loss.

With regard to the fourth head it is observed, that, as the insurer can never, by his own act, discharge himself from the contract, it seems reasonable that, where the insured thinks proper to put a stop to the adventure, and prevent the risk from ever commencing, he should make some compensation to the insurer for his trouble and disappointment; it is, therefore, the general custom, in all the maritime countries of Europe, to allow him to retain one-half per cent. This, according to Emerigon and Le Guidon, is a consideration to the insurer for his trouble in forming the policy, and making the proper entry in his books. This is allowed to the insurer, where the contract is void for some radical defect, provided this was unknown to him when he entered into the contract. But if he was informed of the fault, or must have known it before he subscribed the policy; as if he were to insure a ship or goods, when he hears of their safe arrival, or seaman's wages, or contraband goods, knowing them to be such, he could have no claim to this allowance. Pothier holds, that if the contract becomes void, not by the act of the insured, but by some cause which he could not prevent or control, the insurer shall not be entitled to the half per cent. Emerigon, on the contrary, maintains that in all cases where the policy becomes void, without any fraud on the part of the insurer, he shall have this allowance. Marshall's Treatise on the Law of Insurance, London, 1802. See Policy.

Premia, is also used, in the money and paper-trade, for what is given for a thing above par.

Thus lottery-tickets, &c. are said to bear so much, e. gr. 10s. or 20s. premium, when they are sold for so much beyond the prime cost, at which the government infused them.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, slightly two-lobed, permanent; the upper segment emarginate. Cor. of one petal, irregular, tubular; limb four-cleft, obtuse; its two upper segments shorter, erect; the others spreading. Stam. Filaments four, erect, of inconsiderable length, the two lowermost shorter; anthers roundish. Pfl. Germin roundish; style cylindrical, shorter; stigma clavate. Peric. Berry rather globular, of four cells. Seeds solitary, bony; rounded at one side, angular at the other.

A tropical genus of shrubs, with opposite, simple, entire or somewhat serrated, smooth or downy, fleshy leaves, whose scent, especially in a dried state, is compared by Mr. Brown to that of *Chenopodium album*. The flowers are small, terminal; the branches of their cymose panicles opposite and forked. Corolla whitish.

Linnaeus describes two species.

P. *integrifolia*. Linn. Mant. 252. (Cornuti corymbosa; Burm. Ind. 132. t. 41. f. 1. Polium hirtum; Rumph. Amb. v. 3. 208. t. 134.)—Leaves elliptical, entire, smooth. Native of the East Indies. Perhaps a variety of the following. Linn.

To these Willdenow adds,

P. *tomentosa*. Willd. n. 2. (Cornutis corymbosa; Lamarck Dict. v. 1. 54.)—Leaves ovate, pointed, entire, downy beneath. Native of the East Indies. Branches yellowish; downy when young. Leaves remarkably pointed. Cyme downy, dense. Bracteas very minute.

Mr. Brown adds five more species, all found in the tropical part of New Holland, and differing from each other in the shape or downiness of their leaves, or in the denseness of their inflorescence. These species are named *obtusifolia*, *attenuata*, *media*, *ovata*, *acuminata*, and *cordata*.

**PREMONSTRANTES**, or **PREMONSTRATENSIUS**, a religious order of regular canons instituted in 1120, by S. Norbert; and thence also called *Norbertines*.

The first monastery of this order was built by Norbert, in the Isle of France, three leagues to the west of *Laon*; and by him called *Praemonstere*, *Praemonstratum*, whence the order itself was denominated; though, as to the occasion of that name, the writers of that order are divided. At first, the religious of this order were so poor, that they had only a single afs, which served to carry the wood they cut down every morning, and lent to *Laon* in order to purchase bread. But in a short time they received so many donations, and built so many monasteries, that, thirty years after the foundation of this order, they had above a hundred abbeys in France and Germany; and in process of time, the order so increased, that it had monasteries in all parts of Christendom, amounting to one thousand abbeys, three hundred provostships, a vast number of priories, and five hundred nunneries. But their number is now greatly diminished. The rule they followed was that of St. *Aulxin*, with some slight alterations, and an addition of certain severe laws, whose authority did not long survive their ancient founder.

The order was approved by *Honorsius II.* in 1126, and again by several succeeding popes. At first the abstinence from flesh was rigidly observed. In 1235, *Innocent IV.* complained of its being neglected, to a general chapter. In 1288, their general, *William*, procured leave of *Pope Nicholas IV.* for those of the order to eat flesh on journeys. In 1466, *Pius II.* granted them a general permission to eat meat, excepting from Septuagesima to Easter.

The religious of this order are clothed in white, with a scapulary before the cacock. Out of doors they wear a white cloak and white hat; within, a little cassock; and at church, a surplice, &c.

In the first monasteries built by *Norbert*, there was one for men, and another for women, only separated by a wall. In 1317, by a decree of a general chapter, this practice was prohibited, and the women removed out of those already built, to a greater distance from those of the men.

The **Praemonstratenes**, or monks of *Premontre*, vulgarly called white canons, came first into England A.D. 1146. Their first monastery, called New-houste, was erected in Lincolnshire, by Peter de *Salutis*, and dedicated to St. *Martins*. In the Reign of *Edward I.* this order had twenty-seven monasteries in England. *They had in England a conservator of their privileges, but were nevertheless often visited by their superiors at *Premontre*, and continued under their jurisdiction till the year 1512, when they were exempted from it by the bull of pope *Julius II.*, confirmed by *king Henry VIII.*; and the superiority of all the houses of this order in England and Wales was given to the abbots of *Welbeck* in *Nottinghamshire*. It is said there were about thirty-five houses of this order.

**PREMOTION**, **PREMOTIO**, in *Schools*, the action of God co-operating with the creature, and determining him to act. See **PREDETERMINATION**.

**PREM'SKAIA**, in Geography, a river of Russia, which runs into the Kama, 32 miles W. of *Gerdin*, in the government of *Perm*.

**PREMSTOLLEN**, a town of the duchy of *Stiria*; 5 miles S.S.W. of *Gratz*.

**PREMUNIENTES**, in *Law*, writs formerly dispatched to each bishop to call them to parliament, warning them to bring with them the deans and archdeacons, one proctor for each chapter, and two for the clergy of his diocese.

**PREMUNIRE**, **PREMUNIRE**, a term used for an offence, for a writ granted thereupon, and for the punishment thereof.

The word is a corruption of the Latin *pramenere*, q. d. to forewarn, or bid the offender take care; of which a reason may be drawn from the words of the statute 27 Edw. III. cap. 1. and the form of the writ, "Premunire facias praefatum populum, & J. R. procuratorem, & c. quad tum coram nobis."

In order to understand properly the occasion and origin of *premunire*, it will be necessary to trace out briefly the rise and progress of the papal usurpations in England. The conversion of the Saxons in this country to the profession of *Christianity*, after they had driven the Christians of the ancient Britifh church to the remotest corners of our island, was effected by *Angulfin the monk*, and other missionaries from the court of Rome; and this naturally introduced some few of the papal usurpations in point of faith and doctrine; but we read of no civil authority claimed by the pope in these kingdoms, till the era of the Norman conquest, when the reigning pontiff, having favoured *William* in his projected invasion, by blessing his hoit, and confecrating his banners, took that opportunity of elaborating his spiritual encroachments, which the policy of the conqueror allowed, in order more effectually to humble the Saxon clergy and aggrandize his Norman prelates. Hence his legates *a latere* were introduced into England to hear and determine ecclesiastical causes; and in the reign of
of Henry I. he assumed the disposal of most of the bishoprics, abbeys, and other ecclesiastical benefices, by mandates or bulls, called *expenditive graces*, and *provisions*, before they became void; in the reign of King Stephen, appeals to the court of Rome were established; under Henry II. the pope claimed exemption of clerks from the secular power; and in the time of King John, Pope Innocent III. obtained a renunciation of his crown to the pope, and compelled him to accept his kingdom from the pope's donation, holding it as a vassal of the holy see, at the annual rent of a thousand marks. Many circumstances concurred, and many contrivances were made use of to extend and establish the papal power in this kingdom.

King Edward I., a wise and magnanimous prince, let himself in earnest to shake off this servile yoke; and in the thirty-fifth year of his reign was made the first statute against papal provisions, which, according to Sir Edward Coke, is the foundation of all the subsequent statutes of praemunire.

In the weak reign of Edward II. the pope again endeavoured to encroach, but the parliament resolutely withstood him: and in the reign of Edw. III. several penal laws were enacted against provisors; 25 Edw. III. stat. 6. 27 Edw. III. stat. 1. cap. 1. 38 Edw. III. stat. 1. cap. 4. and stat. 2. cap. 1, 2, 3, 4. which ordained, that the court of Rome should preterit or collate to no bishopric or living in England; and that whoever disturbed any patron in the presentation to a living by virtue of a papal provision, such provisor should pay fine and ransom to the king at his will, and be imprisoned till he renounced such provision; and the fame punishment was inflicted on such as cited the king, or any of his subjects, to answer in the court of Rome. And when the holy see refented these proceedings, and pope Urban V. attempted to revive the vaflagage and annual rent to which King John had subjected his kingdom, it was unanimously agreed by all the estates of the realm in parliament assembled, (40 Edw. III.) that King John's donation was null and void, being without the concurrence of parliament, and contrary to his coronation oath; and all the temporal nobility and commons engaged, that if the pope should endeavour by process or otherwise to maintain these usurpations, they would refit him with all their power.

In the reign of Richard II. it was found necessary to strengthen these laws, and, therefore, it was enacted by stat. 3 Ric. II. cap. 3. and 7 Ric. II. cap. 12. first, that no alien should be capable of letting his benefice to farm; and, afterwards, that no alien should be capable of being presented to any ecclesiastical preferment, under the penalty of the statute of provisors. By the statute 12 Ric. II. cap. 15. all liegenmen of the king, accepting of a living by any foreign provision, are put out of the king's protection, and the benefice made void. To which the statute 13 Ric. II. cap. 2. ft. 2. adds banishment and forfeiture of lands and goods; and by cap. 3. of the same statute, any person bringing over any citation or excommunication from beyond sea, on account of the execution of the foregoing statutes of provisors, shall be imprisoned, forfeit his goods and lands, and moreover suffer pain of life and member.

In the writ for the execution of all these statutes, the words *praemunire facias*, being used to command a citation of the party, have denominated, in common speech, not only the writ, but the offence itself of maintaining the papal power, by the name of praemunire. And, accordingly, the next statute, 16 Ric. II. cap. 5. usually called the statute of praemunire, and generally referred to by all subsequent statutes, enacteth, that whoever procures at Rome, or elsewhere, any translations, processes, excommunications, bulls, instruments, or other things which touch the king, against him, his crown and realm, and all persons aiding therein, shall be put out of the king's protection, their lands and goods forfeited to the king's use, and they shall be attached by their bodies to answer to the king and his council; or process of *praemunire facias* shall be made out against them, as in other cases of provisors. By the statute 2 Hen. IV. cap. 3. all persons who accept any provision from the pope, to be exempt from canonical obedience to their proper ordinary, are also subjected to the penalties of praemunire; and this is the last of our ancient statutes touching this offense.

Such is the original meaning of the offense, which we call praemunire; viz. introducing a foreign power into this land, and creating *imperium in imperio*, by paying that obedience to papal process, which constitutionally belonged to the king alone, long before the reformation in the reign of Henry VIII.; at which time the penalties of praemunire were indeed extended to more papal abuses than before; as the kingdom then entirely renounced the authority of the see of Rome, though not all the corrupted doctrines of the Roman church. And, therefore, by the several statutes of 24 Hen. VIII. cap. 12. and 25 Hen. VIII. cap. 19. and 21. to appeal to Rome from any of the king's courts; to sue to Rome for any licence or dispensation; or to obey any process from thence, are made liable to the pains of praemunire. And, in order to restore to the king in effect the nomination of vacant bishoprics, and yet keep up the established forms, it is enacted by statute 27 Hen. VIII. cap. 20. that if the dean and chapter refuse to elect the person named by the king, or any archbishop or bishop to confirm or consecrate him, they shall fall within the penalties of the statutes of praemunire. Also, by stat. 5 Eliz. cap. 1. to refuse the oath of supremacy will incur the pains of praemunire; and to defend the pope's jurisdiction in this realm is a praemunire for the first offence, and high treason for the second. So, too, by statute 13 Eliz. cap. 2. to import any *Agnes Dei*, crofles, beads, or other superfluous things, pretended to be hallowed by the bishop of Rome, and tender the same to be used; or to receive the same with such intent, and not discover the offender; or if a justice of the peace, knowing thereof, shall not within fourteen days declare it to a privy-counsellor; they all incur a praemunire.

Further, to contribute to the maintenance of a Jesuit's college, or any popish seminary whatever, beyond sea; or any person in the same; or to contribute to the maintenance of a Jesuit or Popish priest in England; is by statute 27 Eliz. cap. 2. made liable to the penalties of praemunire.

Thus far, says judge Blackstone, the penalties of praemunire seem to have kept within the bounds of their original intitution, viz. the deprecating the power of the pope; but it was afterwards thought fit to apply those penalties to other heinous offences. Thus, 1. By the statute 1 & 2 Phil. & Mary, cap. 8. to molest the poffessors of abbey lands granted by parliament to Henry VIII. and Edward VI. is a praemunire. 2. So likewise is the offence of acting as a broker or agent in any ufurious contract, where above 10 per cent. interest is taken, by statute 13 Eliz. cap. 10. 3. To obtain any lay of proceedings, other than by arrest of judgment, or writ of error, in any suit for a monopoly, is likewise a praemunire, by statute 21 Jac. I. cap. 3. 4. To obtain an exclusive patent for the
fole making or importation of gunpowder or arms, or to hinder others from importing them, is also a praemunire by two statutes; the one 16 Car. I. cap. 21, the other 1 Jac. II. cap. 8, 5. On the abolition, by statute 12 Car. II. cap. 24, of purveyance, and the prerogative of pre-emption, or taking any victual, beasts, or goods for the king’s use, at a staled price, without consent of the proprietor, the exertion of any such power for the future was declared to incur the penalties of praemunire. 6. To affert, maliciously and advisedly, by speaking or writing, that both or either house of parliament have a legislative authority without the king, is declared a praemunire by statute 13 Car. II. cap. 1, 7. By the habeas corpus act also, 31 Car. II. cap. 2, it is a praemunire, and incapable of the king’s pardon, besides other heavy penalties, to send any subject of this realm a prisoner into parts beyond the seas. 8. By the statute 1 W. & M. flat. 1, cap. 8, persons of eighteen years of age refusing to take the new oaths of allegiance, as well as supremacy, upon tender of the proper magistrate, are subject to the penalties of a praemunire; and by flat. 7 & 8 W. III. cap. 24, serjeants, counsellors, proctors, attorneys, and all officers of courts, practising without having taken the oaths of allegiance and supremacy, and subscribing the declaration against popery, are guilty of a praemunire, whether the oaths be tendered or no. 9. By the statute 6 Ann. cap. 7, to affert maliciously and directly, by preaching, teaching, or advising preaching, that the then pretended prince of Wales, or any person other than according to the acts of settlement and union, hath any right to the throne of these kingdoms; or that the king and parliament cannot make laws to limit the defects of the crown; such preaching, teaching, or advising preaching is a praemunire; as writing, printing, or publishing the same doctrines amount to high treason. 10. By statute 6 Ann. cap. 23, if the assembly of peers of Scotland, convened to elect their sixteen representatives in the British parliament, shall presume to treat of any other matter than only the election, they incur the penalties of a praemunire. 11. The statute 6 Geo. I. cap. 18, the year after the infamous South Sea project had beggared half the nation, makes all unwarrantable undertakings by unlawful subscriptions, then commonly known by the name of bubbles, subject to the penalties of a praemunire. 12. The statute 12 Geo. III. c. 11, subjects to the penalties of the statute of praemunire all such as knowingly and wilfully feolemnize, affit, or are present at, any forbidden marriage of such of the descendants of the body of king George II. as are by that act prohibited to contract瞄mony without the consent of the crown.

The punishment of praemunire is thus summed up by Sir Edward Coke, that, from the conviction, the defendant shall be out of the king’s protection, and his lauds and tenements, goods and chattels, forfeited to the king; and that his body shall remain in prison at the king’s pleasure, or (as other authorities have it) during life. (1 Blunt. 199.) And fo odious, adds the fame author, was this offence of praemunire, that a man who was attainted of the same might have been slain by any other man without danger of law; because it was provided by law (flat. 25 Edw. III. flat. 5, cap. 22.) that any man might do to him as to the king’s enemy; and any man may lawfully kill an enemy. But to obviate such mistaken and savage notions, the statute 5 Eliz. cap. 1, provides, that it shall not be lawful to kill any person attainted in a praemunire, any law, statute, opinion, or exposition of law to the contrary notwithstanding. However, such delinquent, though protected as a part of the public from public wrongs, can bring no action for private injury, how atrocious soever; being fo far out of the protection of the law, that it will not guard his civil rights, nor remedy any grievance which he, as an individual, may suffer. And no man, knowing him to be guilty, can with safety give him comfort, aid, or relief. 1 Hawk. P. C. § 5. Blackft. Comm. book iv. cap. 8.

PRAEMUNIRE is now chiefly used for the punishment appointed by the statutes above-mentioned. Thus, when it is said a man for an offence shall incur a praemunire, it is meant he shall incur the penalty appointed by the statute 16 Ric. II., commonly called the statute of praemunire. It is observed, however, to the honour of our courts of law, that prosecutions for a praemunire are unheard of in them. The only influence of one to be found is in the State Trials; when the penalties of a praemunire were inflicted on some perons for refusing to take the oath of allegiance in the reign of Charles II. 2 Hargr. State Tr. 263.

Gen. Ch. Common Calyx cylindrical, smooth, its scales equal in number to the florets, with a few unequal, very short, scales at its base. Cor. compound, of a nearly simple circle of florets, which are from five to eight, or more, all perfect and equal, each of one ligulate, abrupt, four-toothed petal. Stam. Filaments five, capillary, very short; anthers united into a cylindrical tube. Pfi. Germin nearly ovate; style thread-shaped, longer than the stamens; stigma cloven, reflexed. Peric. none, except the cylindrical calyx, very slightly contracted at its mouth. Seeds solitary to each floret, heart-shaped. Down capillary, moist, feellite. Recept. naked.

Seven species of Prenanthus are mentioned in the Sp. Pl. of Linnaeus, and one in his Monitiffa. Wildenow has augmented the number to thirty-three, partly from new discoveries, and partly by removing hither certain plants, which Linnaeus and others had referred either to Lactuea, Hieracium, or Crepis. How far he may be right in some of these inferences, we have not sufficient materials to judge by; but with respect to Crepis pulchra, see Engl. Bot. t. 2325; we cannot help differing from his opinion. Michaux and Pursh have added six species to those known to Wildenow, and the latter has corrected him in one or two cases.—Six species occur in the Hortus Kewensis. The following will give an idea of the genus.

P. purpurascens. Purple-flowered Prenanthus. Linn. Sp. Pl. 1211. Wildl. n. 5. Ait. n. 1. Jacq. Auflr. t. 317. (Souschus sylvaticus; Ger. Em. 294.)—Florets four or five. Leaves oblong-lanceolate, toothed; glaucous beneath; heart-shaped and clasping the stem at their base. Native of groves and thickets in Germany, Switzerland, and Italy, flowering in July and August, and making an elegant appearance amongst alpine bulhes. The root is perennial. Stem erect, round, slender, leafy, two or three feet high, paniced, many-flowered. Leaves alternate, horizontal, from three to five inches long, very smooth. Flowers very numerous, cream or purplish, drooping, on slender stalks.

P. alba.
PRENATION, PRENOTION, or Prenotio, a notice or piece of knowledge preceding some other, in respect of time.

Such is the knowledge of the antecedent; which must precede that of the conclusion. See Common Notions, and PRENATION.

PRENPERG, in Geography, a town of Austria; 13 miles E.S.E. of Glaggntz.

PRESNDOFS, a town of the principality of Querfurt; two miles N. of Dalmha.

PRENZLOW, an independent town of the Ucker Mark of Brandenburg, and capital of the country; also, the chief seat of the court of justice. It is large and well built, with straight and broad streets, seated on a fruitful plain on the lake and river Ucker. It is divided into the Old and New, and its corporation derives considerable revenues from the city mills, its several farms, and large woods. The judge of the numerous French colony established in this town is invested with authority over all the French colonies in the Ucker Mark. Its three convents have been alienated; but its six churches have divine service regularly performed in them. Here is a good Latin school; and the place itself carries on a very large trade in corn, cattle, and tobacco: for the salt it is particularly noted, and also for its manufacture of cloth: 48 miles N.N.E. of Berlin. N. lat. 53° 17'. E. long. 13° 53'.

PREOBRASZENIJA, or Island of Transfiguration, an island in the North Pacific ocean, about 150 miles from the S. coast of Russia. N. lat. 58° 30'. E. long. 175° 14'.

PREOBRASZENSKI, a town of Russia, in the government of Upha; 92 miles E. of Orenburg.

PREPACH, a town of the duchy of Würzburg; five miles S.S.E. of Gerolzhofen.

PREPARANTA, or Preparantia Vafa, in Anatomy, the seminal vesicles; being two arteries, and as many veins of the testicles; thus called by the ancients, from an opinion that the seed began to be prepared in them. See SPERMATIC Vesicles, and GENERATION.

PREPARATION, PREPARATIO, Apparatus, in Mathematics, makes one of the parts or branches of a demonstration.

If it be a proposition in geometry that is to be demonstrated, the preparation consists in certain lines to be drawn in the figure: if a proposition in arithmetic, in some computation to be made: to come the more easily at the demonstration.

PREPARATION, in Chemistry and Pharmacy, is applied to the several manners of managing the materia medica, and of disposing it to serve the several purposes.

There are various preparations of mercury, antimony, and other drugs, to purify them, sublimate, calcine, edulcorate them, &c.

PREPARATIONS, in Anatomy, parts of animal bodies prepared and preserved in various ways, in order to exhibit their natural or disordered structure or appearances, in short any facts illustrating their organization, economy, habits, natural changes, pathology, &c.

The knowledge of anatomy is subservient to various purposes, both of pleasure and utility. By investigating the structure of our organs, and the relations of the different parts of the mechanism, and comparing these with what we see of the living actions, we arrive at the most satisfactory knowledge that can be obtained of the latter. These subjects, and the inferences which they lead to, independently of their connection with the various branches of medical science, form as interesting a study to the philosopher as any depart-
Department of nature. But the utility of these studies is placed in a much more important light, when we view their bearings on the healing art, and their tendency to illustrate every thing connected with the preservation and restoration of health, to the right understanding of which they are indispensable. An examination of bodies in various states of disease lays the foundation of pathology. It is an important object of this science to ascertain how the structure of our organs is altered by accident or disease, and what symptoms denote these alterations; we are thus enabled to determine during life, how parts which are not visible are affected, and to decide on the chances of restoration. To the surgical operator an acquaintance with the form and relative position of parts is principally useful.

Deletion of recent bodies is the chief method of learning anatomy, as it teaches us the organs in the condition most nearly approaching to that of life. Individuals of both sexes and of all ages must be carefully examined, as they exhibit varieties of considerable importance in physiology and pathology. Immediately after death, animal bodies become subject to the chemical changes, which result from the affinities between them, and the surrounding elements. Hence alterations occur, which must be carefully disfiguished from the natural living appearances. Our inferences from the subjects ordinarily employed for dissection must therefore be corrected by the occasional opportunities of examining the human subject, or animals while still warm. It would be useless to enter here into practical directions for the conduct of dissections, which the indiscernible labours of the dissecting room will supply in a few days: skilled hands can we go through detailed instructions for the exposure of the individual parts, for this would be only repeating what we have already said in the various anatomical articles of the Cyclopaedia. We refer on these points to the works of Lieutaud, Bell, Maygrier, Marjolin, and others, enumerated at the end of the present article.

But the labours of the anatomist are not confined to the simple dissection of recent bodies. When he has prepared parts, of which the dissection is difficult and tedious, he preserves them in spirits of wine, which alters them to slightly, that they still exhibit most of the facts that are to be learned from their recent dissection. He fills the vessels with fluids of different kinds, and is thus enabled to ascertain points concerning minute structure, which would otherwise escape notice. He employs mixtures of wax, rosin, tallow, &c. to fill the blood-vessels; these being thrown in warm, become firm when cold, and thus enable him more easily to trace the various ramifications. When the parts are dissected and dried, the course of the vessels is rendered apparent. Such preparations, thoroughly dried and varnished, last for a great length of time. Parts again are often dried and preserved in oil of turpentine. Quicksilver is frequently employed as an injection, and penetrates into the minutest vessels; these preparations are usually dried, and have a beautiful appearance when preserved in oil of turpentine.

When coloured mixtures of wax and rosin are injected into the vessels or cavities of any organ, and the soft parts are destroyed by immersion in the muriatic or nitric acids, complete casts of the tubes or hollows are procured. Immersion in dilute acids, and other chemical menstrua, long maceration in water, boiling, &c. are all occasionally employed as auxiliary modes of unravelling the texture of parts, or determining their distinguishing characters.

The use of acids is particularly important with respect to the bones: it removes their earthy particles, leaving the animal matter and vascular structure behind.

Delicate animal textures are rendered firm by rectified spirits of wine, which is the best means of accomplishing the purpose. It renders the brain perfectly hard. But it has always the inconvenience of making transparent organs opaque. Solutions of corrosive sublimate, or alum, and mixtures of acid with water, have similar effects, but these substances destroy the edge of the knife, and render the spirits, in which the part is afterwards preserved, turbid.

The bones are preferably merely immersing them in water, until all the soft parts are rotten, and then exposing them to the sun and air to bleach. The means just enumerated are employed for the purpose of discovering and exposing the structure of the body, and for preparing parts when thus prepared.

The art is still more important in reference to morbid anatomy, because the opportunities of finding diseascs are comparatively rare; and no demonstrations of morbid anatomy could be given without a collection of parts thus preferred.

For the detailed instructions concerning the manner of performing the processes just enumerated, we refer to the various publications, of which a catalogue is subjoined, and particularly to the more modern ones.

Lyter, Cauter anatomicus, hoc est methodus brevis, facilis, et perplicie artificioso et comprehendo humana corpora incendii. Hafniae, 1653, 8vo.

Bartholin, Administrationum anatomicarum specimen; subjoined to the third edition of the work of Lyter, Frankfort, 1679, 8vo.

Taffini, Administrationes anatomicas, Paris, 1673; 12mo.

Albinus, Oratio, que ad veram vnum, ad fabricae corporis humani cognitionem dext. Leid. 1721, 4to.

Cafiohohm, Methodus sectandi mucosus, et methodus secandic viicera. Haile, 1740, 8vo.

Lietuad, Eliafs anatomicas, 8vo.

Sue, Anthropotomist, or l'art d'injecter, de disobluer, d'enbamer, et conferver les parties du corps humain. Paris, 1765, 12mo.

Pole, Anatomical Instructor; or an illustration of the modern and most approved methods of preparing and preserving the different parts of the human body, and of quadrupeds, by injection, corruption, maceration, dilution, articulation, modelling, &c. London, 1790, 8vo.

Dumeril, Eliafs sui les moyens de perfectionner et d'étudier l'art de l'anatomiste. Paris, 1805, 8vo.

Maygrier, Manuel de l'anatomiste, ou traité méthodique et raisonné de la manière de préparer toute les parties de l'anatomie. Paris, 1811, 8vo.

Marjolin, Manuel d'anatomie, contenant l'exposition des méthodes les plus avantageuses à suivre pour disdiquer, injecter, conférer les parties qui composent le corps de l'homme, et pour procéder à l'ouverture et à l'examen des cadavres; ouvrage spécialement défini à servir de guide aux élèves, qui doivent faire un étude approfondie de l'anatomie; vol. i. Paris, 1812, 8vo.

C. Bell's System of Dissections; explaining the anatomy of the human body, the manner of displaying the parts, and their varieties in disease, Folio, with plates.

C. Bell's System of Dissections, &c. &c.; pointing out to the student the objects most worthy his attention during a course of dissections. 2 vols. 12mo.

Preparation of Dicards, in Medicine. Roulieau has made a long article of this term unnecessarily: to prepare a discord, is its being a concord to the preceding note or found; and resolving a discord, is its being succeeded by a concord. But an example in notes will be the best explanation of these rules. See Counterpoint; Composition, and explanatory plates.
PRE

PREPOSITION. Preposition, in Grammar, one of the parts of speech or discourse.

The preposition is an indeclinable particle, which yet serves to govern the nouns that follow it. Such are, per, pro, proprius, in, ad, through, from, by, &c.

These are called prepositions, because praeposito, placed before the nouns they govern.

F. Fuller does not allow the preposition to be a part of speech, but merely a modificative of a part of speech; viz. of the nouns; serving only to modify or circumstantiate it. See MODIFICATIVE.

The ingenious Mr. Harris ranges the preposition under the class of connectives, and defines it a part of speech devoid of itself of signification, but so formed as to unite two words that are significant, and that refuse to unite or coalesce of themselves. Those connectives which join sentences, are called conjunctions. Hermes, book ii. chap. 3.

One great use (says bishop Lowth, Int. to Eng. Gram. p. 114.) of prepositions in English, is to express those relations, which in some languages are chiefly marked by cafes, or the different endings of the noun.

Prepositions are also prefixed to words in such manner as to coalesce with them, and to become a part of them. There are also certain particles, which are thus employed in composition of words, yet cannot stand by themselves in construction; which are called indeffporable prepositions; as a, &c.

Prepositus VILLAE is sometimes used for the chief officer of the king, in a town, manor, or village.

In ancient records, the prepositus villa was no more than the bailiff of the lord of the manor.

Prepositus villa is sometimes also used, in later writers, for the constable of a town, or petty constable.

Prepositus Ecclesie. See CHURCH-YOE.

Quatuor homines Praeposito, in Crompton, &c. denote four men of each town, who are to appear before the justices of the forest in their circuit.

Prepuce, or Preputium, in Anatomy, the foreskin, is the loofe doubling of integuments covering the glans of the penis and of the clitoris. See GENERATION.

Prepuce, Dissected of, in Surgery. See PHIMOSIS, PARAPHIMOSIS, &c.

Prerav, or Prerow, in Geography, one of the most ancient towns of Moravia, and capital of a circle to which it gives name, containing about 300 houses; 13 miles S.E. of Olmutz. N. lat. 42° 32'. E. long. 17° 25'.

Prerogative, Prerogativa, a privilege, or pre-eminence, which one person has over another.

The word is borrowed from the appellation of a century in ancient Rome, which gave the first vote, or suffrage, in the comitia, or assemblies for the election of magistrates; qualis prerogati; because first asked, or their suffrage first required.

Their vote was called annum prerogativum, because the rest usually gave their votes the same way.

Prerogative of the King, Prerogativa Regis, is that power, pre-eminence, and privilege, which the king hath over and above all other persons, and out of the ordinary course of the common law, in right of his regal dignity. The king's prerogatives are either direct or incidental: the direct are such positive substantial parts of the royal character and authority, as are rooted in any spring from the king's political person, considered merely by itself, without reference to any other extrinsic circumstance; as the right of sending ambassadors, of creating peers, and of making war or peace. But such prerogatives as are incidental, bear always
a relation to something else, distinct from the king's person, and are indeed only exceptions, in favour of the crown, to those general rules that are established for the rest of the community; such as, that no colts shall be recovered against the king, that the king can never be a joint-tenant, and that his debt shall be preferred before a debt to any of his subjects, &c. &c. The sublimate direct prerogatives are of three kinds; being such as regard, first, the king's royal character; secondly, his royal authority; and, lastly, his royal income. See King and Revenue.

It is one of the principal bulwarks of civil liberty, or of the British constitution, that the king's prerogative is limited by bounds so certain and notorious, that it is impossible he should ever exceed them, without the consent of the people, on the one hand; or without, on the other, a violation of that original contract, which in all states implicitly, and in our most expressly, subsists between the prince and the subject. And it is one of the most manifest proofs of that genuine freedom, which is the boast of this age and country, that the limits of the king's prerogative may be examined and discovert with decency and respect, without offence and danger. This was formerly reckoned among the ancena imperia: and queen Elizabeth directed both parliaments to abstain from discoursing of matters of State and maintained, both in person and by her ministers, that this august assembly ought not to deal, to judge, or sit in judgment, with her majesty's prerogative royal. And king James I. more than once laid it down in his speeches, that as it is atheism and blasphemy to create a creature to dispute what the Deity may do, so it is presumption and pedantry in a subject to dispute what a king may do in the height of his power. Good Christians, he adds, will be content with God's will, as it will be revealed in his word; and good subjects will rest in the king's will, as it will be revealed in his law. King James's Works, 557. 531.

Praecogative. Contempts against the King's. See Contempts.

Praecogative. Copyrights, are acts by parliament, proclamations, and orders of council, liturgies, and books and books of divine service, and grammars, and other compositions, compiled or translated at the expense of the crown, translation of the Bible. &c.

Praecogative Court. See Court of Praecogative.

Praecogative. Felonies and Misdemeanors against the King's are those that relate to the coin, not amounting to treason, against the king's council (see Privy-council), and those incurred by foreign service, by imbezling the king's armour or warlike stores (see Imbezle), and by desertion from the king's army or navy, which, by the standing laws of the land, and particularly by 18 Hen. VI. cap. 19, and 5 Eliz. cap. 5, is made felony, but not without benefit of clergy. But by 2 & 3 Edw. VI. cap. 2, clergy is taken away from such defectors, and the offence is made triable by the juries oft every shire. The same statutes punish other inferior military offences with fines, imprisonments, and other penalties. See Deserted, and Mutiny.

Praecogative Property. See Property.

Presa, in the Italian Muses, is in general a character which flews when and where a performer in concert is to begin to sing or play; but, in particular, in fugues or canons it is thus marked + over the note at which the second part, which is to follow or imitate the first, must begin. If the mark be repeated a second time, it is to shew the place where the third part must begin to imitate the second; and so on through all the parts.

It is in fugues and canons a signal for the several parts to begin, after the subject is led off. At present, in catches, and canoni cibis written in one line, this is done by numbers, or by this signo, "\n
Presa, Praeseagium, an augury, or sign of something to come.

The Romans judged of future events by certain signs, which their superstitious, or the artifice of their priests, had invented. Their most celebrated prefigurations were founded on the flight of birds, or the entrails of victims. All night-birds palled for birds of ill preage.

M. Simon, (t. 1. Acad. Belles Lettres, p. 54.) reduces preages to seven kinds: viz. casual words, which were divine voices, when their author was unknown, and human voices when it was known who pronounced them; the flartings of some parts of the body, chiefly of the eyes, the eyebrows, and the heart; the tingling of the ear, and those imaginary sounds, which were sometimes heard; sneezings in the morning, which were not good omens (see OMENS), whilst those in the afternoon were favourable; the accidental encounter of certain persons and certain animals, which prefigured either good or evil; and names of good or bad portent; so that those who regarded preages were very superstitious in observing, that the first soldiers they enlisted, the children who served at the sacrifices, those who performed the dedication of a temple, should have lucky names, and they had an aversion to those which importued any thing fair or delightful. See Prophecy. See also Augurs, Auspices, and Aruspices.

Presburg, or Poseg, in Geography, a free and royal town of Hungary, and capital of the kingdom; pleasantly and salubriously situated on the N. side of the Danube, at the foot of a mountain on which is a castle. In the cathedral, from the time of king Ferdinand I., the kings of Hungary have been crowned. From the year 1723 the diets have been held here, the first having been assembled by the king Sigismund in 1411. This has also been the residence of the council of the king's lieutenant, of the treasurer's office for Hungary, of the archbishop of Gran, and likewise a chapter of 14 regular canons, a college with a gymnasium and church, besides three other convents and churches, a Protestant school, and a Lutheran church. The city is badly built; the houses, properly so called, do not exceed 200, and its fortifications consist merely of a double wall and moat. The suburbs are spacious and handfome, and contain four convents with churches, and two hospitals. The peace of Presburg, as it has been called, between France and Austria, was signed here on the 26th of December, 1805; 23 miles E.S.E. of Vienna. N. lat. 48° 10'. E. long. 17° 15'.

Presby, in Ornithology, a name used by many of the ancient naturalists for the regular crisflatus, or golden crowned wren. See Motacilla Regula.

Presbyta, in Optics, a term applied to perons in whom the configuration of the crystalline of the eye is too flat, so that they see difficult things clearly; but those near at hand confusedly.

The reason is, that, in near objects, the visual rays passing the retina before they unite, there can be no dissimilitudes, since the distinct hue falls too far off beyond the retina.

This defect is helped only with convex glasses or spectacles, which will make the rays converge sooner, and if they are well fitted, fall exactly on the retina.

The word is formed from the Greek, πρόθυναι, worth, because old people are naturally subject to this defect; time, and
and the friction of the eye-lids, &c. gradually wearing the ball flat.

Presbytæ are opposed to myopes, in whom the crystalline is too round.

If the distance between the retina and the crystalline be too small, the person will likewise be a presbytæ. See Eye and Vision.

PREBISHTER, or PREBISHVIA, from πρεσβυτήριον, old, defective light from flatness of the cornea; an infirmity, to which old persons are particularly subject.

PREBUSER, a priest, or person in priest’s orders.

He is thus called from the Greek πρεσβύτευρος, elder, of πρεσβύτεων, old, because, anciently, none were ordained but such as were advanced in years.

The great dispute between the retainers to the Geneva and the Roman discipline is, about the sacraments or difference of presbyters and bishops in the times of the apostles.

Those who confut Acts, xx. 17, 18. Phil. ii. 1. Tit. i. 5, 7, and 1 Tim. iii. 1. may perhaps be led to conclude, that these titles were applied to the same persons.

The learned bishop Uther expressly says, "I have ever declared my opinion to be, that episcopus & presbyter gradus tantum different, non ordine;" and consequently, that in places where bishops cannot be had, the ordination by presbyters stands valid.

And being asked by his majesty at the place of Wight, "Whether he found in antiquity, that presbyters alone ordained any?" he replied, "Yes; and that he could shew his majesty more; even where presbyters alone successively ordained bishops;" and instanced in Jerom’s words (Epist. ad Evagrium) of the presbyters of Alexandria chusing and making their own bishops from the days of Mark, till Heraclius and Dionysius. Baxter’s Life, p. 206.

This was the constant sense of our first reformers, Cranmer, Pilkington, Jewel, Grindal, Whitgift, Bancroft, &c.

Bishop Burnet expressly says: “As for the notion of distinct offices of bishop and presbyter, I confess it is not so clear to me; and therefore, since I look upon the sacramental actions as the highest of sacred performances, I cannot but acknowledge those who are empowered for them must be of the highest office in the church.” Vind. of the Church of Scotland, p. 336. See Bishop.

PREBISHTERIANS, a denomination comprehending a very considerable number of persons in Great Britain; but very differently applied in England and Scotland. The English presbyterians do not materially differ from the independents with regard to church-government and discipline, and mode of worship; but they generally allow a greater latitude of religious sentiments and communion in their churches. The application, in this restricted use of it, implies no attachment to the authority of synods, presbyteries, or ecclesiastical assemblies composed of deputies from different churches, any more than to episcopacy and the ecclesiastical hierarchy; and, therefore, according to its original use, it is improperly applied to many who are now distinguished by it, and who form a very respectable class of non-conformists, or protestant dissenters in this kingdom. See Independents.

But the presbyterians, properly so called, and with whom the former agree in some particulars, admit, in general, and allowing for that latitude of sentiment, which will ever be the result of unrestrained and liberal enquiry, the doctrinal articles of the church of England; their chief difference lies in the point of discipline, viz. who shall appoint the governors of the church, and what subordination there shall, or shall not, be between them.

The presbyterians allow of no hierarchy, no subordination in the persons of their ministers; bishops and priests they maintain, in the times of the apostles, were the same; and therefore, though they allow episcopacy, as now settled in the church of England, to be very ancient, yet they deny it to be true divinely.

In lieu of a series of ministers one over another, in quality of priests, bishops, and archbishops, their polity consists in a series of assemblies or synods. Thus every minister is to be obedient to the clergy under which he lives; and that clafs to a synod, provincial, classical, or ecclesiastical.

The power of ordination, with them, refides in a clafs; and none are admitted to administer the sacrament, but those ordained by the imposition of hands of other ministers.

They make use of deacons to take care of their poor; and, in the government of the church they call in lay elders; whence their name: from the Greek πρεσβυτήριον, signifying senior, elder. See Presbytery.

This is now the established discipline of the church of Scotland, where it was introduced as soon as it began to assume a regular form, about the year 1560. Calvin, whose decisions were received among the protestants of that age, with incredible submission, was the patron and reformer of this scheme of ecclesiasticall policy. The church of Geneva, formed under his eye, and by his direction, was esteemed, the most perfect model of government; and Knox, who, during his residence in that city, had studied and admired it, warmly recommended it to the imitation of his countrymen. But on the first introduction of this system, he did not think it expedient to depart altogether from the ancient form; instead of bishops he proposed to establish ten or twelve superintendents in different parts of the kingdom, who were empowered to inspect the life and doctrine of the other clergy, to predicate in the inferior judicatories of the church, and to perform several other parts of the episcopal function; their jurisdiction, however, extended to sacred things only; they claimed no seat in parliament, and pretended no right to the dignity or revenues of the former bishops. The number of the inferior clergy was, at this time, very small; and in a few places only were formed into regular classes or societies. In order to give greater strength and confidence to the presbyterian plan, Knox, with the assistance of his brethren, composed, in 1561, the first book of discipline, which contains the model or platform of the intended policy. However, though the general assembly in the year 1566 had approved of the Geneva discipline, the parliament did not confirm the votes of the assembly, nor formally deprive the bishops of their power; but all church affairs from that time were managed by presbyteries, and general assemblies. In the year 1574 they voted the bishops to be only pallors of one parish; in 1577 they ordained that all bishops should be called by their own names; and in the next year they voted the name of a bishop to be a grievance. In 1580 the general assembly, with one voice, declared dioecesan episcopacy to be unscriptural and unlawful. In the same year king James, with his family, and the whole nation, subscribed a confession of faith, with a solemn league and covenant annexed, obliging themselves to maintain and defend the protestant doctrine and presbyterian government. In the year 1584 the bishops were restored by parliament to some parts of their ancient dignity. In 1587 the king conferred an act to take away bishops’ lands, and annex them to the crown; and in 1590 it was ordained, that all who bore office in the kirk, or should hereafter do so, should subscribe to the book of discipline. In 1592, all acts of parliament in favour of popery and episcopacy were annulled; and an
act passed for establishing the presbyterian government, its general assemblies, provincial synods, presbyteries, and kirk sessions, with all the different branches of their discipline and jurisdiction, in the most ample manner. This act was again confirmed in 1593 and 1594. King James, during the latter years of his administration in Scotland, revived the name and office of bishops; but they possessed no ecclesiastical jurisdiction or pre-eminence; their revenues were inconsiderable, and they were scarcely distinguished by any thing but by their seat in parliament, and by being the object of the clergy's jealousy, and the people's hatred. The king, delighted with the splendid and authority which the English bishops enjoyed, and eager to effect an union in ecclesiastical policy, resolved to bring both churches to an exact conformity with each other. Three Scotsmen were consecrated bishops at London, from whom their brethren were commanded to receive orders. Ceremonies unknown in Scotland were imposed; and though the clergy, left obsequious than the nobles, boldly opposed these innovations, James, long practised and well skilled in the arts of managing them, obtained at length their compliance. But Charles I. a superfluous prince, unacquainted with the genius of the Scots, imprudent and precipitate in all the measures he pursued in that kingdom, professed too eagerly the reception of the English liturgy, and indirectly attempting a refumption of church-lands, kindled the flames of civil war; and the people being left at liberty to indulge their own wills, the episcopal church was overturned, and the presbyterian government and discipline were re-established with new vigour. Together with monarchy, episcopacy was restored in Scotland. The avarice of the nation, however, was in- surmountable, and it subsisted with difficulty. At the Revolution, the inclinations of the people were thought worthy the attention of the legislature, the presbyterian government was again established (see Convocation), and being ratified by the union, is still maintained in that kingdom. The abuse of church power in the beginning of the reign of James I. obliged many learned ministers and their followers to leave the kingdom, and retire to Amsterdam, Rotterdam, the Hague, Leyden, Utrecht, and other places of the Low Countries, where English churches were erected after the presbyterian model, and maintained by the states according to treaty with queen Elizabeth, as the French and Dutch churches were in England. The first presbyterian church in England was established at Wandsworth, near London, in 1572; and others were afterwards erected in neighbouring counties. After the commencement of the troubles in the reign of Charles I., propositions for establishing presbyterian government in England were made in the treaty of Uxbridge, A.D. 1645; and so zealous were the advocates for it, that many of them maintained the divine right of it. This opinion of its origin was carried in the assembly of divines, but negatived in the house of commons. This form of church government was established, by way of probation, in 1646; though not without considerable opposition and clamour. In the year 1648, an ordinance for more effectually settling the presbyterian government, without limitation of time, received the sanction of both houses, under the title of a form of church government, to be used in the churches of England and Ireland. Under the commonwealth, in 1649, the Presbyterian government was declared by the house to be the established government; it continued, though at a low ebb, under the protectorate of Oliver Cromwell, who was more favourably inclined to the independents, and to the Restoration of Charles II., an event in which the presbyterians and army, under the direction of general Monk, concurred. At this period episcopacy was re-established; the imprudent zeal of the presbyterians was forgotten, and they suffered in common with others who disapproved the hierarchy, and who incurred conformity to the established articles of doctrine and discipline, till they were in some measure relieved by the act of Toleration, which has been modified, with considerable improvements, favourable to religious liberty, during the present reign. See Toleration, Presbyterianism, Presbyterianism, an assembly of the order of presbyters, or priests, with laity, for the exercise of church-discipline. The kirk, or church, of Scotland, is divided into sixty-nine presbyteries, each consisting of a number of parishes, not exceeding twenty-four, nor less than twelve. The ministers of these parishes, with one ruling elder, chosen half-yearly, out of every kirk-session, constitute a presbytery; who, meeting in their chief town, whence the presbytery is denominated, choose a moderator, or, more properly, a prolocutor, who must be a minister, half-yearly. They determine all appeals from kirk-sessions, i.e. from the several parochial assemblies; but can try nothing at the first instance cognizable before a kirk-session. They compose all differences between ministers and people; for which end, they hold presbyterial visitations in each parish, where they examine the registers of the kirk-sessions, &c. They enquire into repairs of churches; fee that the glebe, &c. suffer no dilapidations; appoint schools in the parishes; and see that the funds be not misapplied. They alone can exclude from the communion; license probationers; suspend, depose, and, in effect, determine all ecclesiastical matters within their district. From the presbytery there lies an appeal, in all cases, to provincial synods. Presbytery, Presbyterianism, is sometimes also used for the choir of a church, because anciently appropriated to the presbyters. In opposition to the nave or body of the church, which was for the people. Preschiff, in Geography, a town of Persia, in Farshian; 18 miles S. of Schiras. Presciano, a town of Naples, in Principato Citra; 20 miles E.S.E. of Salerno. Prescience, in Theology, predestination, or fore-knowledge; that knowledge which God has of things to come. The doctrine of predestination, as some divines understand it, is founded on the preface of God, and on the supposition of all futurity's being present to him. Human reason can scarcely reconcile the preface of God with the free-agency of man; hence some have been led to deny the divine preface, and others to maintain the doctrine of necessity. See Liberty and Necessity. Prescot, in Geography, a market-town and parish in the hundred of West-Derby, and county palatine of Lancaster, England. The town is situated on the great road from London to Liverpool, by Warrington, at the distance of 198 miles N.W. from the metropolis; and six miles E. from Liverpool. It consists principally of one long, straggling street, seated upon high ground, in the midst of numerous collieries, some of which extend under the town itself. The church is a large and spacious structure, with a lofty steeple, which constitutes a prominent object of view from all the low parts of this county, and of Cheshire, for an extent of many miles. Here is a bedside, a meeting-house, appropriated to the worship of dissenters; also a free-school, and several almshouses. The market day is Tuesday, weekly; and there are three fairs during the year. The principal manufacture carried on here is the making of watch-tools, for which
which the town has been celebrated for upwards of a century. The drawing of pinion wire originated at Prefcot, and is carried as far as to fifty drawings. (See Wire.) Here are made small files, confidered to be the best in the world, and also various component parts of watches.

According to the parliamentary returns of 1811, Prefcot town contained 770 houses, and a population of 3675 persons; and the remainder of the parifh, including the townships of Bold, Croton, Cuerdley, Ditton, Ecclefeaton, Parr, Penketh, Rainford, Rambill, Great-Sankey, Sutton, Whitton, Widnes, Appleton, and Windle, 2867 houses, and 16,000 inhabitants. At Ravenhead, clofe to St. Helens, which Dr. Aikin, in his "Decription of the country round Manchefter," says, "has of late years rifen from a fmall village to be a well-built and populous market-town," is an extensive manufactory of plate glafs. This was first eftablifhed in 1773, under the authority of an act of parliament, incorporating the proprietors; but that concern having failed in 1794, a new company was incorporated the fame year, which has been hitherto eminently fucceffful. Caft plate glafs, also concave and convex mirrors, are now made here, of fizes and qualities equal, or superior, to any imported from the continent. Of the former, fome have been made to measure 199 inches by 69; and of the latter many are manufactured 36 inches in diameter. In these extenfive works, which cover nearly thirty acres of ground, and are inclosed by a wall, upwards of 500 persons are constantly employed in the various proccfes of melting, caften, blowing, polishing, &c. The room, or hall, in which the glaffes are caft, is 230 feet long, by 78 broad; and has its roof entirely supported by pointed arches refting upon the fide walls as abutments. Near this manufactory is one for fmelting and refining copper ore, brought from Paris mountain in Angleley; and within the township of St. Helens is another for fimilar purpofes.

Within the township of Sutton, in this vicinity, is found an excellent clay, made ufe of for making sugar moulds, and coarfe earthen-ware; and within the township of Rainford, about five miles to the north, is a good clay for making crucibles and fine bricks. Coal is abundant throughout the whole extent of this parifh, and frequently lies under beds of iron-ore, which appear at one time to have been wrought, as on fome particular fpofts, beds of coke, or cinders, are difcovered feveral feet deep. The tradition of the country is, that they indicate the fites of iron-works altogether by the Danes during their occupation of this district.

The chief feat in the neighbourhood of Prefcot is Knowley-park, the property and principal residence of the earl of Derby. The house stands upon elevated ground, and consists of two divisions, one conftituted of stone and the other of brick. The stone division, which has two round towers attached to it, is said to have been built by Thomas, the first earl of Derby, about the year 1480, but there can be little doubt of the greater antiquity of part of it; and indeed, in the history of the house of Stanley, the nobleman above-mentioned is spoken of only as having re- 

Prescription, Prescriptio, in Law, a right or title acquired by ufe and time.

Prescription is a fort of title introduced for affuring the property of effects in favour of persons who have possessed them a certain time; and to keep off any who would diquifit them, or recover the thing poiffed, after the term fixed by the laws.

Tourrel calls prescription a penalty imposed, by the laws, upon negligence; and adds, that poiffleffors, who have no other title to plead but prescription, are only legal ufurpers.

In effect, however, the law of prescription does not punish the indolence of proprietors, but only interprets their filence for their confent; prefuming, that a man who neglects to afford his right for a long feries of years, gives it up.

There are fome of the lawyers who doubt, whether time and unjust prescription be any legitimate means of acquiring. Others, more favourable, call it the patronibus of mankind; as being a general prefumption, under which the law will have men live in peace.

In the common law, prescription is ufually underftood of a poiffelion from time immemorial, or beyond the memory of man; as, when my ancestors, or his whom I have an estate, have enjoyed and ufed it all the time whereof any memory remains.

But in the civil law, and even in our common law, there are prescriptions of a much shorter date; prescription of forty years excludes all actions whatever. Reform. Leg. Ecclef.

The definction between cuftom (which fee) and prescription is this: that cuftom is properly a local ufeage, and not annexed to any perfon; fuch as, a cuftom in the manor of Dale that lands hall defend to the youngfon; prescription is merely a perfonal ufeage; as that Sempronius and his ancestors, or fome whole estate he hath, have ufed time and mind to have fuch an advantage or privilege. (Co. Litt. 115.) All prescription must be either in a man and his ancestors, or in a man, and fome whole estate he hath, which laft is called prefcribining in a que eftale. And formerly a man might, by the common law, have prefcribed for a right which had been enjoyed by his ancestors or predeceffors at any diftance of time, though his or their enjoyment of it had been fufpended for an indefinite feries of years. But by the Statute of limitations, 32 Hen. VIII. c. 2, it is enacted, that no perfon fhall make any prefcription by the feifin or poiffelion of his ancestor or predeceffor, unlefs fuch feifin or poiffelion hath been within three-score years next before fuch prefcription be made. This title of prefcription was well known in the Roman law by the name of usucaptio; fo called, becaufe a man, that gains a title by prefcription, may be faid ufu rem capere.

As to the ferval fpecies of things which may, or may not, be prefcribed for, it may be observed, 1. That nothing but incorporeal hereditaments can be claimed by prefcription; as a right of way, a common, &c. but that no prefcription can give a title to lands, and other corporeal fuflances, of which more certain evidence may be had. 2. A prefcription muft always be laid in him that is tenant of the fee. A tenant for life, for years, at will, or a copy-holder, cannot prefcribe, by reafon of the imbecility of their eftates. (4 Rep. 31, 32.) For, as prefcription is ufeage beyond time of memory, it is absurd that they should pretend to prefcribe, whose eftates commenced within the remembrance of man. 3. A prefcription cannot be for a thing which cannot be railed by grant. 4. What is to arife by matter of record cannot be prefcribed for, but muft be claimed by grant, entered on record; fuch as the royal franchises of deodands, felon's goods, &c. But the franchises of treasure-trove, waifs, cftrays, and the like, may be claimed by prefcription;
preference; for they arise from private contingencies, and not from any matter of record. (Co. Litt. 114.)
5. Among things incorporeal, which may be claimed by preference, a distinction must be made with regard to the manner of preferring; that is, whether a man shall preferable in a que eflate, or in himself and his ancestors. For if a man prefers in a que eflate (that is, in himself, and those whose estate he holds) nothing is claimable by this preference, but such things as are incident, appendant, or appurtenant to lands; but if he prefers in himself and his ancestors, he may prefer for any thing whatever that lies in grant; not only things that are appurtenant, but also such as may be in gross. (Litt. § 183. Finch. l. 104.) 6. Estates gained by prescription are not of course decedible to the heirs general, like other purchased estates, but are an exception to the rule. Blackl. Comm. book ii. ch. 17.

The custom of Paris allows of a prescription of ten years, if the parties be present; and of twenty, if absent; in favour of peaceable possesseurs of an inheritance, if they have any title, however contested; and of thirty years, in favour of those who possess without any title at all.

In Normandy, a prescription of forty years peaceable possession is equivalent to a title to immoveables; and for moveables, and personal actions, a prescription of thirty years suffices.

In Roman countries, prescription does not avail against the church, if short of a hundred years. In France, prescription of twenty years is admitted against all crimes, except duelling, which was excluded by a declaration of the year 1679. In matters of adultery, five years suffice; i.e. provided there have been a discontinuance of prosecution all that time.

By our statutes, a judge or clerk convicted of false entering pleas, &c. may be fined within two years; but those elapsed, he prefers against the punishment of the statute.

The crime of maintenance or embracery, whereby perjury is committed by a jury, must be prosecuted within six days; or otherwise the parties prefer.

There is no preferring against a man’s lord; no prescription avails to take off any servitude or tenure; a title is always required there.

The author of the History of the Inquisition observes, that no time of prescription avails in matters of heresy; even death itself does not securc the free of the researches of that tremendous court.

Prescription, Corporations by, are those which have ex
cilled as corporations, time wherein the memory of man run
neth not to the contrary; with regard to which the king's contem is presumed. For though the members thereof can shew no legal charter of incorporation, yet in cafes of such high antiquity, the law presumes there was one; and that by the variety of accidents, which a length of time may produce, the charter is lost or destroyed.

Prescription, Modus by. See Modus Deceimandi.

Prescription de non decimando (that is, a claim to be entirely relieved of tithes, and to pay no compensation in lieu of them. Thus the king is discharged by his prerogative from all tithes. (Cro. Eliz. 511.) So a vicar shall pay no tithes to the rector, nor the rector to the vicar, for “eccle
sia decimas non solvit ecclisis.” (Cro. Eliz. 479. 511. Leav. 3. Moor 910.) But these personal privileges (not arising from or being annexed to the land) are personally confined both to the king and the clergy; for their tenant or lessee shall pay tithes, though in their own occupation their lands are not generally titheable. (Ibid. 479.)

generally speaking, it is an established rule, that in the hands “modus de non decimando non valet.” (Ibid. 511.) But spiritual persons or corporations, as monasteries, abbeys, bishops, and the like, were always capable of having their lands totally discharged of tithes, by various ways, (Ibid. 359. Cro. Jac. 508.) as, 1. By real composition: 2. By the pope’s bull of exemption: 3. By unity of possession: 4. As when the rectory of a parish, and lands in the same parish, both belonged to a religious house, those lands were discharged of tithes by this unity of possession: 5. By prescription: having never been liable to tithes, by being always in spiritual lands: 6. By their own order; as the Knights Templars, Ciftercians, and others, whose lands were privileged by the pope with a discharge of tithes. (2 Rep. 44. Seld. tith. c. 13. 2.) Through the abolition of abbey lands by Henry VIII., most of these exemptions from tithes would have fallen with them, and the lands become titheable again, had they not been supported and upheld by the statute 31 Hen. VIII. c. 13, which enacts, that all persons who should come to the possession of the lands of any abbey then dissolved, should hold them free and discharged of tithes, as large and ample a manner as their abbey lands formerly held them. And from this original have sprung all the lands, which, being in royal hands, do at present claim to be tithe-free. For if a man can shew his lands to have been such abbey lands, and also immemorially discharged of tithes by any of the means before-mentioned, this is now a good prescription de non decimando. But what shew both these requisites for abbey lands, without a special ground of discharge, are not discharged of course; neither will any prescription de non decimando avail in total discharge of tithes, unless it relates to such abbey lands. Blackl. Comm. b. 3. See Tithe.

Prescription, in Medicine, the act or art of directing proper remedies for diseases. The word is also applied to the written formula, by which the individual substances are directed to be combined or administered.

The art of prescription is of course the result of a knowledge of the nature of the living body, both in a state of health and diseased; and of an accurate examination of the symptoms of the disease present, together with an acquaintance with the various articles of the materia medica, and with their operation and properties, chemical and vital. The best prescription is that which directs the most active and appropriate medicines, in the simplest manner, and most natural combination. It was formerly the practice of physicians, to unite in one formula the great farrago of drugs, many of them, indeed, very inert in their agency, but many which differed materially in their properties; a practice, by which the operation of the whole was rendered extremely obscure, and the means of discriminating the powers of medicines in a great measure prevented. Simplicity certainly constitutes the chief elegance of prescription, and if at the same time correctness of combination, and a full application of the most active ingredient, be observed, the best ends are obtained. The correctness of combination, however, especially where chemical agencies are introduced, depends upon a knowledge of the affinities which exist between different substances; from the want of which knowledge, it not unfrequently happens, that the substances intended to be administered are neutralised, decomposed, or united in new combinations, and a very different medicine is actually given.

Extemporaneous prescription, in particular, requires an accurate knowledge of these points. Another object, though commonly of secondary importance, requires to be attended to, namely, to render the medicine as agreeable to the palate, as is consistent with its qualities. This is of importance, at
P R E

haft in the medicines directed for children, and for those who possess, either naturally, or in consequence of the disease, a great delicacy of stomach, and at all times when a long course of medicine is absolutely necessary, in order to ensure that it shall be taken. It is scarcely necessary to add, that an accurate knowledge of the doses of all the medicines prescribed, is absolutely requisite for salutary, or even safe prescription.

Prescription, in Theology, was a kind of argument pleaded by Tertullian, in the third century, against erroneous doctors; and which has been urged by Catholics (see Methodists), and others, in more modern times. With regard to this mode of arguing, we may observe, that there is scarcely an article, in which the plea of prescription can be admitted as a satisfactory argument in favour of religious tenets, or articles of faith; unless by prescription be meant, a doctrine's being established in the time and by the authority of the apostles. In all other cases, prescription is no argument at all; it cannot recommend error, and truth hath no need of its support.

Presence, Presentia, a term of relation, used in opposition to absense, and signifying the existence of a person in a certain place; or the state of a person considered as co-existing with another.

In this sense, an obligation is laid to be passed in presence of a notary and witnesses; at the breaking open a seal of a minor, or an absent person, the presence of a substitute is necessary.

The schoolmen hold, that presence, in speaking of bodies, denotes not only a co-existence, but a sort of contact.

They distinguish two kinds of presence; the one virtual, in which one speaks of a spirit, or mind, is said to be present to a body when it acts upon it; the other corporeal, which consists in a physical contact.

The treasurers, &c. of France have what they call a right of presence; a certain sum due on their actual attendance in their offices, to oblige them to be the more affiduous in their function.

A person absent in the service of the king, or a community, is represented as present.

The Roman Catholics believe the real presence of Jesus Christ in the eucharist, both in body and soul. See Transubstantiation.

Present, Presens, in Grammar, the first tense, or inflexion of verbs; expressing the time present, or that which now is.

It is a particular piece of address in eloquence, to make use of the present for a past tense, in order to express a past action with the more force and warmth. Thus, the fleet is no sooner in full sea, than the heavens begin to lower, the winds rise, the waves dash against each other, thunder rolls, and lightning glares on all sides; the ships lose their masts and rudders, and are driven impetuously against the rocks.

Presentation, Presentatio, in the Canon Law, the act of a patron, nominating and offering his clerk to the bishop or collator, to be instituted in a benefice of his gift, which is void.

The word is formed from the ancient phrase, presentare ad ecclesiam; which originally signified the patron's finding or placing a person in a church; and which itself is formed from representare, which, Selden observes, is used in the council of Lateran, and elsewhere, for presentare.

For the difference between presentation and collation, see Collation.

By common law, a deacon, of any age, might be instituted and inducted to a parsonage or vicarage; but it was ordained by 13 Eliz. cap. 12, that no persons under 23 years of age, and in deacon's orders, should be presented to any benefice with cure; and if he were not ordained priest within one year after his induction, he should be ipso facto deprived. And now, by 13 & 14 Car. II. cap. 4, no person is capable of being admitted to any benefice unless he hath been first ordained a priest; and then he is, in the language of the law, a clerk in orders. Any clerk may be presented to a parsonage or vicarage; that is, the patron, to whom the advowson of the church belongs, may offer his clerk to the bishop of the dioce to be instituted. A layman may also be presented, but he must take priest's orders before his admission. As to the right of presentation, this belongs even to an infant, who is heir of a manor to which an advowson is appendant (3 Inst. 156.); and in case of a patron's bankruptcy, the commissioners may fell the advowson. (Gibb. 794.) If the right of presentation is in coparceners, who agree in the same person, they are to join in the act of presentation; otherwise, the eldest shall have the preference, and afterwards the right in their turns; but where the right is in joint-tenants or tenants in common, if there hath been no composition in writing to present by turns, they must join in the presentation. (1 Inst. 156. Gibb. 794.) If one be seised of an advowson in fee, and the church becomes void, the void turn is a chattel; and if the patron dies before he presents, the avoidance doth not go to his heir, but to his executor. (Watf. c. 9.) But if the incumbent of a church be also seised in fee of the advowson of the same church, and dieth, his heir, and not his executors, shall present. In the case of a bishop, who holdeath an advowson in the right of his bishopric, the void turn of a church doth not go to his executor, but the king shall present. (2 Roll's Abr. 345.) If a vicarage becomes void during the vacancy of the parsonage, the patron of the parsonage, and not the executor of the deceased parson, shall present. (Ibid. 346.) If a feem-tenant hath a title to present, the presentation must be by husband and wife in both their names. And though the right of patronage in the wife defendeth to her heir, yet the right of presenting during life belongs to the husband, who is tenant by curtesy. (Gibb. 794. Watf. c. 9.) If a man that is seised of an advowson takes a wife, and dieth, the heir shall have two presentations, and the wife the third. (Watf. c. 9.) In case of a mortgage in fee of a manor, to which an advowson is appendant, although the legal right of presentation is vested in the mortgagee, yet a court of equity will compel the ordinary to institute the clerk of the mortgagee any time before foreclosure. (Str. 403.) But if the advowson itself only is mortgaged, the mortgagee presents. (2 P. Wills. 404.) The king, as patron paramount of all the benefices in England, hath a right to present to all churches not regularly filled by other patrons, whether it happens by lapse, or through incapacity to present, as if the patron be attainted, outlawed, or an alien, or have been guilty of simony, &c. On this ground, the king hath a right to present to all dignities and benefices of the advowson of archbishops and bishops, during the vacation of the respective fees. (Gibb. 763. Watf. c. 9.) And it is said, that this privilege which the king hath of presenting, by reason of the temporalities of a bishopric being in his hands, shall be extended unto such prelatures to which the bishop of common right might present, though by his composition he hath transferred his power unto others. (Watf. c. 9. 2 Roll's Abr. 343.) Upon promotion of any person to a bishopric, the king hath a right to present to such benefices or dignities, as the person was poissified of before such promotion, though the advowson belongeth to a common person. (Gibb. 758. 763.) But by law in Ireland, no person can accept a bishopric
bishops' there, until he hath resigned all the prebendary which he hath in England; which prebendary being void before the acceptance of the bishopric, the king in such case shall lose the presentation. The lord chancellor, or lord keeper of the great seal for the time being, hath right to present to the benefice appertaining to the king, of the yearly value of 20l. or under in the king's books. (Gibb. 764.) For a prebendee to have another benefice, although it be above the value of 2l. a-year in the king's books, is no cause of refusal, for that is at his own peril, and the former benefice only becomes void in such case. God. 271. Watf. c. 20.

It is rule of the canon law, that no person may present himself: in this case, the legal and regular way is to make over the right to some other before the avoidance. Gibb. 794.

The presentation must be tendered to the bishop within a hundred and eighty-two days after the living is vacant, else it lapses to the bishop; and if the bishop do not collate in half a year more, it lapses to the archbishop; and from him, in a like time, to the king; who may play as long as he pleases; for *mendum tempus occurrit regi.* See Lap. 1.

By some customs a lay patron has only four months time to make his presentation in; and if he have presented a person incapable, he may vary it, and make a new presentation within the four months.

It is said that presentation may be made either by word, or by writing. If it be by word, the patron must declare in the presence of the ordinary; if by writing, it is not a deed, but in the nature of a letter missive to the bishop. 1 Inl. 120. 2 Roll. Abr. 353.

Where a corporation aggregate of many doth present, it must be under their common seal (Gibb. 794.); and since the statute of frauds and perjuries, (29 Car. II. cap. 3.) it is necessary that all presentations shall be in writing. Thus also by the several stamp-acts, which enact a stamp-duty of 20l., provided that the benefice, &c. presented to, be of the yearly value of 10l. or upwards in the king's books; but if under that, only 10l.

Presentation may be revoked or varied before admission and institution. But when a clerk is presented, the bishop may refuse him on various accounts; as, 1. If the patron is excommunicate, and remains in contempt forty days. (2 Roll. Abr. 355.) Or, 2. If the clerk be unfit; (Glanv. l. 13. c. 20.) which unfitness is of several kinds. First, with regard to his person; as if he be a bastard, an outlaw, an excommunicate, perjured, guilty of forgeries or simony, under age, or the like. (2 Roll. Abr. 356. 2 Inl. 632. flat 3 Ric. II. c. 3. 7 Ric. II. c. 12.) Secondly, with regard to his faith or morals; as for any particular heresy, or vice that is *malum in se,* but if the bishop only alleges in general terms, as that he is *falsificarius iudicatus,* or objects a fault that is *malum probatium,* merely, as haunting taverns, playing at unlawful games, or the like, it is not good cause of refusal. (5 Ric. 58.) Or, lastly, the clerk may be unfit to discharge the pastoral office for want of learning. In any of which cases the bishop may refuse the clerk. In case the refusal is for hereby, schism, inability of learning, or other matter of ecclesiastical cognizance, there the bishop must give notice to the patron of such cause of refusal, who, being usually a layman, is not supposed to have knowledge of it; else he cannot present by lapse; but if the cause be temporal, there he is not bound to give notice. (2 Inl. 632.) If an action at law be brought by the patron against the bishop for refusing his clerk, the bishop must assign the cause. If the cause be of a temporal nature, and the fact be admitted (as,
cially those given by the clergy, or the flates of a realm, to a king.

They are so called, because given into the hands of a per-
son present; by which they are distinguished from numera,
gifts, which are sent to the party, or delivered by the inter-
vention of a third person.

Thus the eighteenth law, “De verb. signif. Abfentibus
res donari dicitur, numera autem mitti, & praefined
ferri.” There is no accointing the easter princes without
making them fine presents. Kings usually make rich pre-
sefs to embassadors sent to their courts.

PRESENTO, in Geography, a town of Naples, in the
Lavon; 91 miles N.E. of Senza.

PRESEPE, or PRESEPE, in Astronomy, a name given
to three nebulous stars in the breach of the sign Cancer, or
the Crab. Two of them are of the seventh, the third of
the sixth magnitude.

PRESERVATION of Vegetables. This is to be done
several ways in the several kinds, and many more might
certainly be invented, for we are not yet arrived at the per-
fected method of preserving vegetables with their colours,
odours, and all their sensible qualities, as well as their na-
tural form, for a number of years. Fruits may be long pre-
served in spirits of wine, first well saturated with the oils
and tinted parts of those fruits; and many may be tolerably
preferred in perfectly fermented liquors, which generate no
more air. The more solid vegetable substances may be pre-
served by gentle drying in the sun-shade, or other slack heat.
Thus pease or beans may be dried young in a slack oven, in
their proper season, and may afterwards be holed in the
winter, and will eat young and tender, as if just gathered.
The ways of preserving fruit both dry and moist, with
fugar, are now universally known; and there are in the fe-
veral ways many secrets in the hands of particular artifices,
which it would be well to have generally known. See Pre-
servation of Fowers.

PRESERVATIVE, or Preventive, in Medicine, a
remedy or expedient employed by way of precaution, or to
secure a perfon from a disease, which he is in danger of re-
ceiving.

These preservatives have been specially objects of re-
search, during the prevalence of epidemic and contagious
diseases; and many medicines have been declared to posses
specific preservative powers against the plague, and other
fears. But a more enlightened experience has decidedly
exploded these pretended preventives, as possefsed only of
imaginary powers. We are possefsed of no antidote to con-
tagion, which can only be disarmed of its virulence by dilu-
tion with fresh air, or by decomposition by chemical fum-
gations; and all the pretended personal preservatives, such
as camphor, vinegar, &c. are totally ditractible of any fuch
qualities. The bett preservative is a fystem of diet and
regimen, which shal retain the constitution in an equable
state of health, and avoid disturbance to any individual func-
tion or organ; i.e. in other words, a careful avoidance both
of the prejudicial and exciting causes of disease in general:
for under this regular condition of the habit, the particular
cause of disease, that may be prevalent, will have less in-
fluence upon the health. It is important, therefore, to cau-
tion the reader against putting too implicit confidence in
any preventive drug, as to induce him to neglect the tau-
tary measure of self-preservation, to which we have just al-
luded. See Contagion and Epidemic.

Dr. Wenceslaus Dobr. Zenkly de Negro Ponte gives us
an universal preservative against infection in all diseases.

"Whoever," says he, “in conversing with patients of any
kind, would prefer to himself from infection, must, while he
is within the sphere of their effluvia, never swallow his
spittle, but spit it out.” For this author conceives it to be
the spittle that first imbibes the infection.

PRESERVING of Timber. See Timber.
PRESIDIE, in Geography, a town of Naples, in the
province of Otranto; 3 miles W.S.W. of Alessano.

PRESIDENT, or PRESIDENT, an officer created, or elected,
to preside over a company, or assembly; to call in contra-
distinction to the other members, who are termed repre-
sentatives.

It is of some importance to ascertain the powers possefsed
and exercised by the presidents of the Roman provinces.

From Ulpian, a celebrated Roman lawyer, who flourished
in the beginning of the third century, we learn that it was
the duty of a good president to preserve tranquility in his
province, and to hunt diligently after sacrilegious perfons,
robbers, men-stealers, and thieves, and to punish every man
according to his guilt; and he expressly acribes to them the
right of power of the sword for the punishment of male-
factors, and the highest authority in his province next to the
emperor. Hermogenianus says, that governors and pre-
sidents of provinces have the cognizance of all causes, which
belong to the prefeft of the city, or the prefeft of the pre-
torium, and the confuls, and pretors, and other magistrates
at Rome. From these, and other authorities that might be
cited, it appears that the governors of provinces had not
only the power of life and death, but that they were also the
supreme judges in matters of property. Accordingly Pilate
had the power of life and death in Judaea. It was also usual
for the presidents to have a council, consisting of their
friends, and other chief Romans in the province, of whole
advice they availed themselves on particular occasions. We
have many authentic testimonies in behalf of the equity of
the Roman government in general, and of the impartial ad-
ministration of justice by the Roman presidents towards all
the people of their provinces, how much moreover they differed
from each other in matters of religion. Although many of
these presidents were guilty of extortion, and other acts of
injustice, and endeavoured to enrich themselves in the pro-
vinces, yet there seems not to have been any one thing,
which the Romans were more concerned to preserve invio-
lable, than the religion of all the people whom they con-
quered. It is, however, to be lamented that the Romans
afterwards departed from these moderate maxims that di-
rected and governed their conduct, as long as the history of
the Acts of the Apostles reaches. Nero appears to have
been the first emperor that persecuted the Christians; and
his persecution was owing, not so much to the differences
that subsisted between the principles of religion maintained
by the Christians and the Romans, as to his wish to throw
off from himself the odium of having set fire to the city,
with which infamous action he was generally charged.

Lord President of the Council is a great officer of the
crown, who has precedence next after the lord-chancellor
and lord-treasurer; as ancient as the time of king John,
when he was styled confiliarius capitulis.

His office is to attend on the king, to propose business
at the council chamber, and to report to the king the feveral
transactions there. See Privy-Council.

President of the United States of America is the person
in whom the constitution has vested the executive power.
He holds his office during the term of four years, and, to-
together with the vice-president, chosen for the same term, is
elected in the following manner. Each state shall appoint,
as its legislature may direct, a number of electors, equal to
the whole number of senators and representatives to which
the state may be entitled in the congress; but no senator or
representative, or person holding an office of trust or profit under the United States, shall be appointed an elector. The electors meet in their respective states, and vote, by ballot, for two persons, of whom one at least shall not be an inhabitant of the same state with themselves. Having made a list of all the persons voted for, and of the number of votes for each, they sign and certify this list, and transmit it, sealed, to the seat of the government of the United States, directed to the president of the senate. The president, in the presence of the senate and house of representatives, opens all the certificates, and the votes are counted. The person having the greatest number of votes shall be the president, if such number be a majority of the whole number of electors appointed; and if there be more than one who have such majority, and have an equal number of votes, then the house of representatives shall immediately choose, by ballot, one of them for president; and if no person have a majority, then, from the five highest on the list, the said house shall, in like manner, choose the president. But in choosing the president, the votes shall be taken by states, the representative from each state having one vote. A quorum for this purpose shall consist of a member or members from two-thirds of the states, and a majority of all the states shall be necessary to a choice. In every case, after the choice of the president, the person having the greatest number of votes of the electors shall be the vice-president. But if there should remain two or more, who have equal votes, the senate shall choose from them, by ballot, the vice-president.

No person, except a native citizen, or a citizen of the United States at the time of the adoption of the constitution, shall be eligible to the office of president; neither shall any person be eligible to that office, who shall not have attained to the age of thirty-five years, and been fourteen years a resident within the United States. The president shall, at stated times, receive for his services a compensation, to be neither increased nor diminished during the period for which he shall have been elected; and he shall not receive, within that period, any other emolument from the United States, or any of them. Before he enters on the execution of his office, he shall take the following oath or affirmation: "I do solemnly swear (or affirm) that I will faithfully execute the office of president of the United States, and will, to the best of my ability, preserve, protect, and defend the constitution of the United States." As to his powers and duties, he shall be commander-in-chief of the army and navy of the United States, and of the militia of the several states, when called into the actual service of the United States. He may require the opinion, in writing, of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices; and he shall have power to grant reprieves and pardons for offences against the United States, except in cases of impeachment. He shall have power, by and with the advice and consent of the senate, to make treaties, provided two-thirds of the senators present concur; and he shall nominate, and by and with the advice and consent of the senate, shall appoint ambassadors, other public ministers and consuls, judges of the supreme court, and all other officers of the United States, whose appointments are not otherwise provided for, or whose terms of service shall not otherwise be fixed by law. But the congress may, by law, vest the appointment of such inferior officers as they think proper in the president alone, in the courts of law, or in the heads of departments. The president shall have the power to fill up all vacancies that may happen during the recess of the senate, by granting commissions, which shall expire at the end of their next session. He shall, from time to time, give to the congress information of the state of the union, and recommend to their consideration such measures as he shall judge necessary and expedient: he may, on extraordinary occasions, convene both houses, or either of them; and, in case of disagreement between them, with respect to the time of adjournment, he may adjourn them to such time as he shall think proper; he shall receive ambassadors, and other public ministers: he shall take care that the laws be faithfully executed, and shall commission all the officers of the United States.

The president, vice-president, and all civil officers of the United States, shall be removed from office on impeachment for, and conviction of, treason, bribery, or other high crimes and misdemeanors.

PRESIDIAL, a tribunal or bench of judges, formerly established in the several considerable cities of France, to judge ultimately, or in the last resort, of the several causes brought before them, by way of appeal from the inferior judges. The presidials make one company with the officers of the bailliages and seneschales, where they are established.

The edict of 1551 establishes presidials, under these two conditions: first, that they may judge definitely, and without appeal, to the sum of 350 livres, or 10 livres per annum; and, secondly, to the sum of 500 livres, or 20 livres per annum, by provision.

When they judge in the former case, they are obliged to pronounce it with these words, par jugement dernier; in the latter, par jugement presidial.

When they judge finally of appeals from inferior judges, they may not pronounce the sentence or appeal, au moment, void; that form only belonging to the sovereign courts; but are to pronounce simply, that it has been well or ill-judged. To judge presidially and finally, they must at least be levain in number.

PRESIDIO, State di gli, in Geography, a small district or province, situated on the coast of the Mediterranean, in the territory of Etruria, under the dominion of the king of Naples. Its capital is Orbitello.

PRESIDIO DE Cerro, a town of Mexico, in New BItxay; 150 miles N. of Durango.

PRESIDIO de Sanos, a town of New Navarre; 270 miles S.E. of Cafa Grande. N. lat. 30° 9'; W. long. 109° 6'.

PRESIDIO de St. Juan, a town of New Mexico, in the province of New Leon. N. lat. 29° 11'; W. long. 101° 48'.

PRESLE, a town of France, in the department of the Aisne; eight miles E.N.E. of Soissons.

PRESNITZ, a town of Saxony, in Thuringia; two miles S.E. of Camburg.—Allo, a town of Bohemia, in the circle of Saatz; 14 miles N.W. of Saatz.

PRESA, a town of European Turkey, in Macedonia; 11 miles N.N.E. of Akaria.

PRESQUE 1st, a small peninsula, on the S.E. shore of lake Erie, S. of Long Point, on the opposite side of the lake; 15 miles from fort Beauf, and 60 N. by W. from Venango, on Alleghany river. The garrison is upon a commanding point, just opposite to the entrance of the bay. The bay commences 50 yards W. of the old British fort, leaving a vacancy of 600 yards for a military parade and public walk. The town extends three miles along the lake and one mile back. It has the best harbour on the S. side of the lake. N. lat. 43° 44'; W. long. 82° 20'.

PRESQUE Island, an island near the N. coast of lake Ontario. N. lat. 43° 53', W. long. 78°.

PRESQUE Isle, an island in lake Huron. N. lat. 45° 4'; W. long. 83° 40'.—Allo, an island in the river St. Lawrence, Upper
Upper Canada, in Edinburgh, nearly opposite to Hospital island, and above Point au Galope.

Presque Isle Major, an illand in the river St. Lawrence, in front of the township of Matilda, above Point Iroquois.

PRESS, a machine of most extensive use in the mechanic arts, for squeezing or comprefuring any substance very clofe, and alfo to retain the matter under the preifure as long as may be required.

All preffes confift of the following parts: 1st, two flat, smooth tables of wood or metal, between which the substances to be preffed are placed; 2dly, the frame, or cheeks of wood or metal, which unite and retain the two together; and 3dly, the mechanical power, by which the preffure is exerted.

This is generally a screw, or two fcrews, turned by a long lever, or by wheel-work. At other times a rack is employed, and moved by a pinion turned by wheel-work, to give it a great power. Some preffes used for exprreffing of oils are actuated by a wedge driven by a hammer or flamper, (see Oil-Mills) and in others, the preffure is produced by means of a powerful lever, and retained by a rack and click. Of late years the hydrofstatic prefs has been produced, acting by the preffure of water or other fluids in cylinders. We shall now fpeak of the different kinds of preffes.

Screw-preffes are thofe in which the preffure is caufed by means of one or more fcrews; the molt common have a fingle fcrew, formed either of wood or iron, which at its lower end has a globe-head, with four holes through it, for the reception of the end of the lever employed to turn the fcrew; the thread of the fcrew is fitted through a nut, fixed fast in the head of the wood, or iron frame of the prefs. This frame confifts of a lower bed, or horizontal piece, on which the matter to be preffed are laid, two upright cheeks being firmly united with it, and supporting the head, or upper horizontal piece of the prefs, in which the nut of the fcrew is fixed; the lower point of the fcrew is united with the follower, or moving bed of the prefs, and this reft upon the substances to be preffed, and the power of the fcrew forces it down upon it.

A drawing of this prefs, with its lever, and alfo a wind-lass to work it with immense power, will be found in Plate XI. Agriculture, as applied to exprrefs the juice of fruit for cider.

The kind is alfo employed for exprrefsing fome vegetable oils, but generally with iron framing, because of the great ftrength required; for packing cloth, paper, and other goods; alfo in the paper-mills, for flattening and rendering paper-folid; and in the manufacture of woolen cloth, for glazing and fettling a finifh upon the article and its laft flage.

Two elevations of a very good screw-prefs for a paper-mill are given in fig. 6 and 7 of Plate II. Paper-Mill. A A is the bed, formed of an impenetrable beam of oak; and each of the cheeks, B, confifts of a long iron bar b b, (fig. 7.), the ends of which are welded together, fo that it forms a long link, one end of which receives the end of the bed A, and the other the end of a massive iron crofs bar or head D, through which the fcrew, E, is received, and its nut fixed fast therein. The open spaces of the long links or cheeks, b b, are filled up by rails of wood, C, which support the weight of parts of the prefs when it is not in action, but thefe bear nothing, when the prefs has any articles under preffure in it; fhefe articles are laid at H, on the bed, and the follower, G, is preffed upon them by the fcrew, when it is turned by a long lever put through the holes in the fcrew-head F. The fcrews employed for paper preffes are generally formed with fuch coarse threads, and fo rapid a spiral, that the ftrength of the paper is fufficient to force it to run back. To thofe a ratchet-wheel, a, is fixed, and a click, c, (fig. 8.1) is applied to its teeth: to prevent its return, the click is fupported on a bar b d, which moves on a centre at B, but the other end is retained by a catch or lever f g. When the prefs is to be relieved, the end, f, of the catch is driven back; this relieves the bar d b, and the click no longer retaining the ratchet-wheel, the fcrew runs back.

The fcrews for preffes were formerly made of wood, with sharp threads, that is, the worm of the fcrew, if cut aeroes, would make a triangular fecticn, the base thereof abafting upon the cylinder of the fcrew. In this method it was neceflary to have the threads very coarse, to give them fufficient ftrength, and then the power of the fcrew was not fo great as in the modern preffes, where the fcrews are made of iron, and their threads need not be above one-third or fourth the distance of the center, to have the fame ftrength.

Another advantage of the iron fcrew is, that the friction is fo much diminished, that a far greater preffure can be obtained by the fame exertion of the people who work it. The frames of the modern preffes are alfo made of iron, wood being found incapable of refifting the strain of a severe preffure, for any confiderable length of time; as all the fibres, even of the hardeft oak, become separated into ribbands, and then break one at a time, till the whole beam fails.

Another kind of screw-preff consists of two fcrews, which are immovable fixed in the lower board or bed, and palling through holes in the upper board, have nuts upon them, which being turned by a lever, draw the two boards together, and exert a preffure upon any thing placed between them. Sometimes the fcrews pass through the upper board, and are tapped into the lower one; then the fcrews themselves are turned round by a lever put through their heads, instead of turning the nuts. Preffes of this kind, when accurately made, have a communication of wheel-work from one fcrew to the other, fo that both shall turn round together, and cause the two boards of the prefs to advance parallel to each other.

A very ingenious and useful packing preff, invented by Mr. John Peek, was, in 1798, rewarded by the Society of Arts. This machine confifts of two very strong horizontal beams, one at the bottom for the bed, and the other at the top of the preff. These are united by two iron fcrews, which fland in a vertical position, and therefore ferve as cheeks to the preffes. The follower of this prefs is a very strong horizontal beam, having two nuts fitted into it at its ends. Thefes nuts act upon the threads of the two vertical fcrews; and, therefore, it is plain when they are turned round, the follower will rise and fall upon them. The nuts are fo fitted into the follower, as to admit of a circular motion round the fcrews, but are not permitted to rise or fall without the follower, because they have a circular ring or projection in the middle of their length, which is fitted into a proper receptacle in the wood-work. To give them motion, the edges of the circular rings are cut into cogs or teeth, and are turned by means of an endles fcrew for each, fitted at the opposite ends of a horizontal fpindle, which revolves in bearings attached to the follower of the prefs. The fpindle has a winch at each end, by turning which, the two endles fcrews act upon the wheels or teeth of the nuts; and by thus caufing them to turn round with equal velocities, raise or deprefle the follower, always parallel to itself, and also to the head and bottom bed.

The great utility of this prefs confists in its being capable of packing two fets of bales at once; thus anfwering the purpose.
purpofe of two prefses, and with more expedition. It is placed upon the floor of the warehouse in which the packing is to be performed, and behind it a flage is erected, half the height of the whole prefs; then one fet of the bales are made up on the floor, and the other upon the flage. Suppofe the follower raised up above the level of the flage, a bale of goods is placed on the lower bed, and by turning the winches, the follower is forced down upon it, till it is sufficiently prefse: now, while the men below arc tying and making the bale fall, the people on the flage place a bale upon the follower; and it is plain, that when the follower is raised up to relieve the lower package, the upper bale will be comprifed between the follower and the head of the prefs; and while this is making fall, the workmen below get another bale of goods loaded in. By this means no time is ever lost in screwing up or opening the prefs; for it performs work both ways, which is a matter of no small importance in large works, fuch as the East India Company’s warehouses, where fuch a great number of people are employed in packing.

In the Philosophical Transactions for 1781 is an account of a double screw, applied to a prefs, by Mr. W. Hunter. To explain this, we must fuppofe a single screw prefs of the ordinary form, fuch as we have termed Plate XI. Agriculture, or Plate II. Paper Rolls, both the lower end of the screw, which reff upon the follower or prefs, has a feporad screw of finer thread cut upon it. This thread is received into a nut or barrel, which reff upon the prefs. The nut is at liberty to turn round freely upon the prefs, except when it is required to be fationary; and then, by a key, it can be made fast to it. In like manner, the nut or barrel can, at pleafure, be fixed fast to the lower screw by a key put through a hole in both; and in this flate they will of course turn round together. As the nut and lower screw take up some room, the screw is turned by arms fixed in a head, formed on the upper end of it, above the prefs. In the operation of this prefs, the nut or barrel is pinned falt to the lower screw by the key; and the screw being turned by the arms at top, the nut is carried round with it, and the effect is exactly the fame as an ordinary screw prefs. But having by this means given as great a preffure as the single screw is capable of producing, the crofs key which unite the lower screw to the barrel is removed, and is put in fuch a poftion, that it unite the barrel to the prefs, fo as to prevent its turning round upon it. The effect of the prefs now becomes compound, and while the whole screw is carried downwards by the revolution of the great screw, the fine screw at the bottom of it screws down into the barrel or nut, which is attached to the prefs; which is, therefore, carried down a quantity only equal to the difference of the thread of the two screws; and if there are made very nearly alike, the defcent produced by the difference between them will be exceedingly small, and the power exerted upon the articles under preffure will be in proportion to it. Indeed the effect would be the fame, as if a single screw had been employed, having its threads fo fine or clofe together, that the difference between thread and thread is only equal to the difference between the meafures of the threads of the two screws.

For example: Suppofe it was required to produce a strong preffure, with a screw of ten threads in an inch, it is evident that the metallic protuberance, or heft of the screw, could not be quite fo thick as one-twentieth of an inch, and could not, therefore, withftand any confiderable force. By the prefent construction, we may have the thread as strong as can be defired. Thus, if the lighted be a quarter of an inch, the finest screw must have two turns in the inch, and the coarseft two turns in one inch and one-tenth; or, in other words, it would pass over the fame space in ten turns, that the other screw would in eleven.

Upon the invention of the double screw Mr. Nicholson remarks, that from the extreme preffure of a fimple screw, if commonly well made, it may feem scarcely necessary to ufe this contrivance in the meafurement of small quantities. The fine screws ufually is to be met with do not exceed 100 threads in the inch, and few have been made finer than of 200 threads in that space. Let us confider by what threads, of ufual, or even coarse numbers, we could have a difference per turn of above one-thousandth of an inch, and we fhall find that the difference between a thread of 52 and one of 53 in the inch, is the 1056th part of an inch; fo likewise, the difference between the 6th and 611th parts of an inch is the 3660th part.

The Hydroflate or Water Pref, has, for a great number of purpofes, improved the ufe of the screw prefs, over which it poifoncd great advantages, in all cales where a strong preffure is required. This machine was invented by Mr. Joseph Bramah, and its principle has been explained in our article Machinery. See vol. vii.) In plate Pref we have given drawings of one of them, fig. 1. 2 being elevations, taken in opposite directions; A B is the frame, confifting of a piece of cafe iron, e, (fee also fig. 3), and a tube of cafe iron, b, (fee also fig. 4), the two being united by the wrought iron bolts A, B, which muft have fufficient strength to refift the whole force of the prefs, the preffure being produced between the under surface of B, and the upper surface of an iron table or follower, E, F is a ftrong metallic cylinder, in which the rammer or pilton, D, moves. To the upper part of this pilton, the iron table, E, is fixed, by the motion of which upwards, the preffure is communicated to the articles placed upon it. D reprefents a cilinder containing water; within this cilinder is fixed a fmall forcing or injewing pilton, of which b is the pilton rod, and H the lever by which it is worked, a contrivance being introduced for keeping the pilton rod vertical during the working; it confifis of a guide, formed at the top, of the fame standard, K, which fupports the fulcrum or centre pin, g, of the lever H; the rod g, which is part of the pilton rod, slides through the focket; the part, f, of the rod is made open, to admit the lever to pass through it, a link being applied to unite the lever to the rod. I is a counterbalance for the weight of the lever. Fig. 5, is a defcription of the pump, on a larger fcale, to shew its interior ftructure, b reprefenting the lower extremity of the pilton rod; it is surrounded by a collar of leather, s, which is retained in its place by a tube, or perforated screw, r, which admits the passage of the pilton rod b, but which screws the two-cupped leathers with the metal ring, which is interpoled between them, clofe down to a shoulder, in the body of the injewing pump, and thus renders the junction between the injewing pilton b, and its cylinder, water-tight; the upper part of the screw, r, is excavated, to form a receptacle for oil; M M is the barrel, or chamber of the pump, in which the pilton rod does not fit; but the collar of leather s, closely embracing the rod, will have the fame effect of enlarging or diminishing the capacity of the chamber when the rod is moved up and down. In the bottom of the chamber is a fuction valve, N, which allows the water to enter into the barrel from the cilinder, but will not permit it to return in the fame direafion; it is fitted into the upper part of a tube, N, which is screwed into the lower end of the barrel; the valve itself consits
consists of a metallic rod, at one end of which there is a knob turned conical next the stem, so as accurately to fit the conical face of the hole into which it is put; the tail is filed on one side, so that it does not entirely fill the cylindrical hole which it occupies, by which means a passage is afforded for water when the head of the valve is raised. A valve of a similar nature is placed at \( i \), in the upper part of the pump, and being in the passage which conveys the water from the pump, and through the copper pipe, \( e \), to the cylinder, \( F \), it allows the water to pass from the pump to the cylinder, and prevents its returning. At \( k \), fig. 5, is a safety-valve, which is loaded by a fleet-yard and weight, as shewn at \( k \), fig. 1; this keeps the valve shut in the ordinary course of working; but if the pressure should become so great as to endanger the bursting of the pipes, the valve rises, and the water escapes. At \( i \) is a ferew plug, or valve, at which the water is discharged, when the press is to be relieved. When screwed tight, its conical end or point is forced into a corresponding socket, and prevents the escape of the water; but on turning the screw back, the water is permitted to flow back into the cistern. The real situation of this discharging valve is shewn in fig. 1, at \( i \). The cylinder, \( D \), is surrounded by a collar of leather at \( o \); the leather is formed as shewn in fig. 7; being turned up to form a double cup, so that it reenables the cuff of a coat sleeve. When in its place it is kept confined by the copper rings, \( h \), entering the circular channel, or fold, of the leather. This ring has a lodgment in a recess formed within the cylinder \( F \). The leather is kept down by a brass or bell-metal ring, \( m \), which is received into a recess formed round within the cylinder, as shewn in fig. 5. The interior aperture of this ring is adapted to receive the cylinder \( D \), and thus in the cylinder becomes confined in a cell, with the edge of the interior fold applied to the cylinder \( D \), while the edge of the outer fold is in contact with the interior surface of the cylinder \( F \). In this situation the pressure of the water, acting between the folds of the leather, forces its edges into close contact with both, and makes a tight fitting round the cylinder, and as the pressure is increased the leather is applied more closely, so as to prevent leakage under any circumstances. The metal ring, \( m \), is truly turned in the lathe, and the cavity or cell formed for its reception; then to get it into its place, it is divided by a saw into five segments, as shewn in fig. 6. Three of the lines at which it is divided point to the centre, but the other two are parallel to each other, and the ring is put into its place (after the leather and copper rings are introduced), by putting in the four segments separately, and the one with parallel fingers is put in last. The cylinder, \( D \), is then put down in its place, and ready for action. This plan of a divided ring was first used by Mr. Peter Kier, who, since the expiration of Mr. Bramah's patent, has made several hydrotatic presses. In the original construction, the ring or head of the cylinder, which kept down the leather cup, was held down in its place by several screw bolts, but as these had to bear a greater force than the whole power of the press, they were frequently torn out, or strained, so as to cause leakage. The upper part of the cylinder above the ring, \( m \), is filled with tow, or other soft packing, impregnated with sweet oil, which is confined by a thin plate or ring. This packing serves at once to supply the cylinder with oil, and to prevent the admission of any substance which might injure the surface of the piston.

The pipe, \( b \), is made of copper, and its joints are made as shewn in fig. 5. The end of the pipe has a projecting piece folded or screwed upon it, and this fits into a cavity formed in the metal of the pump or cylinder, and it is forcibly pressed into its seat by a perforated ferew \( w \), which ferews into the cavity. The joints are rendered tight by a leather ring or washer, interposed between the end of the pipe and the bottom of the cavity in the cylinder or pump.

The hydrotatic press is not liable to get out of order, but if any extraneous matter attaches itself to either of the valves, their action will necessarily be suspended till it be removed; for this purpose the valves can be taken out. The valve at \( i \) has a screw plug, \( g \), fitted over it, and this regulates the ascent of the valve, or by unferrying the plug the valve can be taken out. To get access to the lower valve, the lower piece, \( N \), of the pump must be unferried. The discharging valve, \( i \), may also be examined by withdrawing its screw.

The operation of the press may be very readily comprehended, by supposing the pump, cylinder, and connecting pipe \( e \), to be filled with water, and that an adequate supply of water is contained in the cistern \( L \). When the handle of the lever, \( H \), is raised, it brings up the piston \( b \), which would leave a vacuum beneath, if the atmosphere did not force the water through the lower, or suction valve, of the pump. The lever being then pressed down, the piston rod, by descending, diminishes the capacity of the pump; this causes the lower valve to shut, and forces the water through the valve \( i \), whence it passes, by the pipe \( b \), into the cavity of the great cylinder \( F \), and raises the piston \( D \), and pressing-table \( E \), together with its load, a distance proportional to the quantity of fluid injected. On the subsequent rise of the piston of the pump, the descent of the upper valve prevents the return of the water, and consequently the fall of the cylinder \( D \). A repetition of the same process injects more water, and the pressure may, in this manner, be carried to a great extent. When it is proposed to relieve the action of the press, the discharge valve, \( i \), must be opened by turning the screw back; the water then escapes out of the press into the cistern \( L \), and consequently the table \( E \), and the cylinder \( D \), depend by their own weight, restoring the engine to its original situation.

The mechanical effect of the hydrotatic press will admit of an easy calculation. For it is known, that if there be a mutual communication between two columns of any fluid, whatever pressure or effort may be exerted on the one, will be transmitted to the other in a ratio proportional to the respective area of each column, consequently the proportion of the area of the injecting pump to that of the cylinder constitutes the hydrotatic power of the press, and the mechanical effort exerted on the injecting pump is transmitted to the cylinder \( D \), an the intervention of the fluid, in a ratio proportional to their comparative areas.

If the diameter of the piston, \( b \), be one quarter of an inch, and that of \( D \) one inch, that is to say, four quarters of an inch, one pound lodged upon the piston rod, \( g \), will be in equilibrio with sixteen pounds lodged upon the table \( E \), the weights of the parts of the engine attached to, and moving with each piston, being respetively included. And if the length of the lever, \( e F \), be fifteen inches, and the distance between the centres of motion, \( e f \), of their action upon the piston rod two inches, one pound at the end of \( H \) will gain an advantage of \( \frac{1}{7} \) times, when compared with that at \( g \).

Instead, therefore, of sixteen pounds, upon the table \( G \), being equal in effect to counterpoise this last action, there will be required upwards of 120 pounds. But a man in this action of pumping, by a downward pressure, can, without difficulty, apply his whole weight, and with great ease one-third, or one-fourth, of his weight, suppose 50 pounds. In this case the pressure will be equivalent to 50 times 120 pounds, or 6000 pounds, that is to say, nearly three tons.
To compare this engine with a screw in theory, we must inquire what fineness of thread, and length of lever, would afford a purchase of 120 to 1. Let us suppose the thread of a screw, substituting in the place of the cylinder D, to be one-tenth of an inch thick, the distance from the top of one thread to the top of the next, will in this case be one-fifth of an inch. This is the space through which the weight must rise in one revolution of the screw; the power, therefore, moves through 120 times that space, namely, twenty-four inches. A lever or radius four inches long will describe a circle somewhat larger than this, and consequently such an engine would, in theory, be equal in power to the hydrostatic engine we have been describing.

But when the subject is viewed practically, the difference between the two machines appears to be very remarkable. All practical men know how very large a part of the force, operating by means of engines, is employed in overcoming friction. Every one is aware of the extreme friction between solids, and the very slight friction which takes place between the parts of fluids. This is seen in the common expedient of oiling the pivots of wheels, and in the very gradual decay of motion in fluid bodies, where solids moving upon each other float at once as soon as the force is diminished to a certain degree. The screw is an organ peculiarly liable to friction, and this friction is always much greater than the whole of the re-acting force, for there are few instances where a screw will return from extreme preffure, when the agency upon the lever is withdrawn. It is also to be considered, that the whole force of the weight or resistance acts directly upon the face of the thread of the screw, at the place where the motion is required to take place. It has not been ascertained in what degree this resistance or friction increases with the weight. In lighter actions the simple ratio has been inferred, but under more severe preffures, the two metallic faces exclude the greater part of the half fluid matter between them, and appear, by the magnitude of their resistance, to be attached to each other by a proof of the nature of cohesive attraction.

Mr. Nicholson, in his Journal, relates the following experiments, which he made with one of Mr. Bramah's small preffures, which he makes for the purpose of copying letters, or writings, in the manner of Mr. Watt (see Copying); it had the same parts which we have described, but the frame made of wood. When employed to press papers, the force applied to the lever of the injecting pump was so slight, that the instrument required no fastening to the table on which it stood; but the effect of the upper bar, B, which was of wood, three inches and a half thick, was such, as bended it out of a straight line upwards of a quarter of an inch, and it appeared that it might have easily been broken by continuing the preffure. With a screw-preff, the screw of which was iron, and nearly of the dimensions above mentioned, excepting that the lever was twelve inches long instead of four inches, and the action on the lever upwards of two hundred weight, applied with a jerk, the effect was nearly the same: he estimated the advantage to be very much in favour of the hydrostatic preff.

In another preff of this kind, the diameter of the great piston was four inches, and of the smaller three-eighths of an inch, and the advantage given by the lever or handle was twelve to one. Above the piston, D, of the great cylinder, was applied a long lever, at one end of which was an axis, and at the other end a large scale to hold weights; it contained twenty two hundred weight. The difference between the axis of motion of this lever, and the part where it acted on the piston, was six inches; and the distance from the same axis to the extremity where the scale was hung, was one hundred and twenty-six inches. Every hundred weight in the scale consequntly pressed upon the piston with a force equal to twenty-one hundred weight, whence the whole preffure was twenty-one tons. It was easy to work the lever briskly with one hand, and each stroke raised the scale nearly one-third of an inch. Forty-seven pounds, hung at the end of the lever, carried it down with a moderate stiHTness of working; but a weight of only forty-three pounds remained in equilibrio, and did not descend. Now as the true weight in theory was thirty-two pounds, as deduced from the dimension of the parts in the manner already done, with regard to the small preff it follows, that less than one-third of the actual power was employed to give velocity, and overcome all friction.

It may be remarked, that the principal frictions in these preffures must be at the circumference of the pistons, and that these do not increase in the simple, but in less than the sub-duplicate ratio of the power. For if the diameter of the great cylinder were double, every thing else remaining unchanged, the surface of its piston, and consequently the power, would be quadrupled, but the friction would be only doubled, and that merely at the leathering of the greater piston D.

As the preffure, in the experiment last mentioned, amounted to forty-seven thousand and forty pounds upon the great piston, of four inches diameter, and sixteen square inches surface, it amounted to two thousand nine hundred and forty upon each round inch; but the medium preffure of the atmosphere on a round inch is nearly twelve pounds, consequently the action was equal to two hundred and forty-five atmospheres, and as each of these correspond with a column of thirty-four feet of fresh water, at a medium the water in the cylinder was preffed in the same manner, as if the whole column had been eight thousand three hundred and thirty feet, or one mile and two-thirds perpendicular height.

Large preffures of this contruction are generally made with two pumps, of one inch and a quarter bore, and a cylinder of seven inches. These have been used in preffing hay and cotton for package, and are very effective in producing a greater condensation on the material, with a much less application of moving power, and consumption of time.

Presses used for expressing of liquors, are of various kinds; some, in most respects, the same with the common preffures, excepting that the under plank is perforated with a great number of holes, to let the juice expressed run through into a tub, or receiver, underneath.

Others have only one preff, or arbor, which passes through the middle of the moveable plank, which is made to descend into a kind of square box, full of holes or all sides; through which the juices flow, in proportion as the arbor is turned; by means of a little lever applied thereto.

Presses used by joiners to keep close the pieces they have glued, especially panuels, &c. of wainscot, is very simple, consisting of four members; viz. two screws, and two pieces of wood, four or five inches square, and two or three feet long; of which the holes at the two ends serve for nuts to two screws.

Presses used by inlayers resembles the joiners' preffes, except that the pieces of wood are thicker, and that only one of them is moveable; the other, which is in form of a treffel, being sustained by two legs, or pillars, joined into it at each end.

This preff serves them for fawing and cleaving the pieces of wood required in marquetry, or inlaid work.
Press, Foundery, is a strong, square frame, containing four pieces of wood, firmly joined together with tenons, &c.

This press is of various sizes, according to the sizes of the moulds; two of them are required to each mould, at the two extremities of which they are placed; so that, by driving wooden wedges between the mould and the sides of the presses, the two parts of the mould, in which the metal is to be run, may be prefixed close together.

Press, Printing. See Printing Press.

Press, Messenger of the. See Messenger.

Press, Auditors of the. See Auditors.

Press, Rolling, is a machine for the taking off prints from copper-plates.

It is much less complex than that of the letter-printers.

See its description and use under the article Rolling-press.

Printing.

Press, in Coining, is one of the machines used in striking of money; differing from the balance, in that it has only one iron rod to give it motion, and press the moulds, or coins; is not charged with lead at its extreme, nor drawn by cordage. See Coinage.

Press, Binders cutting, is a machine used equally by book-binders, stationers, and paletboard-makers; consisting of two large pieces of wood, in form of cheeks, connected by two strong wooden screws; which being turned by an iron bar, draw together, or set asunder, the cheeks, as much as is necessary, for the putting in the books, or paper, to be cut.

The cheeks are placed lengthways on a wooden frame, in form of a shelf, into which the cuttings fall. Aside of the cheeks are two pieces of wood, of the same length with the screws, serving to direct the cheeks, and prevent their opening unequally.

Upon the cheeks the plough moves, to which the cutting-knife is fastened by a screw; which has its key to dismount it, on occasion to be sharpened.

The plough consists of several parts; among the rest, a wooden screw, or worm, which catching within the nuts of the two feet, that sustain it on the cheeks, brings the knife to the book, or paper, which is flattened in the press between two boards. This screw, which is pretty long, has two directories, which refumble those of the screws of the press. To make the plough slide square and even on the cheeks, so that the knife may make an equal paring, that foot of the plough where the knife is not fixed, slides in a kind of groove, fastened along one of the cheeks. Lastly, the knife is a piece of steel, six or seven inches long, flat, thin, and sharp, terminating at one end in a point, like that of a sword, and at the other in a square form, which serves to fell the knife to the plough. See Book-binding.

As the long knives used by us in the cutting of books or papers are apt to jump in the cutting thick books, the Dutch are said to use circular knives with an edge all round; which not only cut more readily, but last longer without grinning.

Press, in the Woollen Manufactury, is a large wooden machine, serving to press cloths, serge, cotton, &c. by which to render them smooth and even, and to give them a gloss.

This machine consists of several members; the principal of which are the cheeks, the nut, and the worm or screw, accompanied with its bar; which serves to turn it round, and make it descend perpendicularly on the middle of a thick wooden plank, under which the fluids to be press'd are placed. The calender is also a kind of press, serving to press or calender linens, silks, &c.

Press, Liberty of the, in Law, consists, says judge Blackstone, in laying no previous restraints upon publications, and not in freedom from censure for criminal matter, when published; and this is essential to the nature of a free state. Every free man has an undoubted right to lay what sentiments he pleaseth before the public; to forbid this is to destroy the freedom of the press; but if he publishes what is improper, mischievous, or illegal, he must take the confluence of his own temerity. To subject the press to the restrictive power of a licensor, as was formerly done, both before and since the revolution, is to subject all freedom of sentiment to the prejudices of one man, and make him the arbitrary and infallible judge of all controverted points in learning, religion, and government. But to punish (as the law does at present) any dangerous or offensive writings, which, when published, shall on a fair and impartial trial be adjudged to be a pernicious tendency, is necessary for the preservation of peace and good order, of government and religion, the only solid foundations of civil liberty.

The art of printing, says the same excellent writer, soon after its introduction, was looked upon (as well in England as in other countries) as merely a matter of trade, and subject to the coercion of the crown. It was, therefore, regulated with us by the king's proclamations, prohibitions, charters of privilege and of licence, and, finally, by the decrees of the court of star-chamber, which limited the number of printers, and of presses, which each should employ, and prohibit new publications, unless previously approved by proper licencors. On the demolition of this odious jurisdiction in 1641, the long parliament of Charles I. after their rupture with that prince, assumed the same power as the star-chamber exercised with respect to the licensing of books; and in 1643, 1647, 1649, and 1652, issued their ordinances for that purpose, founded principally on the star-chamber decree of 1637. In 1662 was passed the statute 13 & 14 Car. II. c. 33, which (with some few alterations) was copied from the parliamentary ordinances. This act expired in 1679, but was revived by Stat. 1 Jac. II. c. 17, and continued till 1692. It was then continued for two years longer by Stat. 4 W. & M. c. 24; but though frequent attempts were made by the government to revive it in the subsequent part of that reign, yet the parliament refused it so strongly, that it finally expired, and the press became properly free in 1694, and has so continued, under certain limitations, ever since.

How far these limitations and restrictions are vindicable on the learned judge's principles and declarations, (ubi infra,) we will not undertake to determine. It will be sufficient for us to observe, that these are inexcusable, who by abusing the liberty of the press and subjecting themselves to the jilt animadversion of the law, contribute to restrain it, no less than others, who by the severity of punishment inflicted on trivial violations of it occasion or justify measures for abridging this glorious privilege of Britons and palladium of the British constitution and liberties.

The learned judge says, that by the liberty of the press, as it existed in his time, "the will of individuals is still left free; the abuse only of that free will is the object of legal punishment." Neither is any restraint hereby laid upon freedom of thought or inquiry; liberty of private sentiment is still left; the disseminating, or making public, of bad sentiments, destractive of the ends of society, is the crime which society corrects. A man (says a fine writer on this subject) may be allowed to keep poisons in his closet, but not publicly to vend them as cordials. And to this we may add, that the only plausible argument heretofore used for the retenning of the just freedom of the press, "that it was
was necessary to prevent the daily abuse of it," will entirely lose its force, when it is thrown (by a feantonal exertion of the lawe) that the pres cannot be abused to any bad purpose, without incurring a suitable punishment; whereas it can never be used to any good end, when under the control of an inspector. So true will it be found, that to confine the licentiousness, is to maintain the liberty, of the presses. Blackl. Comm. book iv.

PRES, in the Manage. A horse is laid to refist, or presses upon the hand, when either through the stiffness of his neck, or from an ardour to run too much a-head, he stretches his head against the horsemans hand, refutes the aid of the hand, and withstands the effects of the bridle.

If your horse is too fiery, and presses upon the hand, endeavour to pacify him by making him go more softly, and pulling him backwards; and if it proceeds from a stiffness of the shoulders and neck, you must supply him with a cavefon, made after the duke of Newcastle's way. See Heavy.

Press is also used for pulling a horse forwards by afflicting him with the calves of your legs, or even spurring him, in order to make him go on.

Press, or Preßing, in Sea-Language. See MANNING the Fleet.

PRESSAS, in Geography, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen. The place contains 14,15, and the canton 9251 inhabitants, on a territory of 137 1/2 kilometres, in 14 communes.

PRESSAT, a town of Bavaria; 19 miles N. of Amberg.

PRESSELUNDS, a town of Norway; 68 miles N. of Christiana.

PRESIGNY, a town of France, in the department of the Upper Maine; 15 miles S.E. of Langres.

PRESIGNY le Grand, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Loches. The place contains 953, and the canton 9000 inhabitants, on a territory of 355 kilometres, in 13 communes.

PRESSING, in the Manufactures, the action of violently squeezing a cloth, fluff, linen, &c. in a press, to render it even, smooth, polished, and glossy.

This, in the linen and linen manufactures, they properly call calendering.

There are two manners of pressing; the one hot, the other cold.

Pressing Cold, Method of. After the fluff has had all its preparations, i.e. has been foured, fullled, and thorn, (see Filling and Sheering,) it is folded square, in equal plats; and a skin of velum, or fine smooth palteboard, is put between each plat. Over the whole is laid a square wooden plank; and in this condition it is put in the press, which is driven tight down by means of the screw turned full upon it, by the hands, afflicted with levers.

After it has lain a sufficient time under the press, they take it out, remove the palteboards or velums, and lay it up to keep. It may be observed, that some do not use a press with a screw in pressing cold, but content themselves with laying the fluff on a firm table, after plaiting and palteboarding it as before; covering the whole with a wooden plank, and loading this with a weight, greater or less, as is judged necessary.

Pressing Hot, Method of. The fluff having received all its preparations, as before, it is sprinkled a little with water, sometimes with gum-water, spurted over it with the mouth; then plaited equally, and between each two plaits are put leaves of palteboard; and between every sixth and seventh plait, as well as over the whole, an iron or brass plate, well heated, in a kind of furnace prepared for the purpose.

This done, it is laid upon the press; and a screw is brought forcibly down upon it, by means of a long iron bar.

Under this press are laid five or six pieces, one over another, at the same time, all furnished with their palteboard and iron plates. When the plates are well cold, they take the fluffs from under the press, remove the palteboards and plates, and titch it a little together, to keep it in the plait.

This manner of pressing woolen fluffs is very pernicious, and was only invented by the manufacturers to cover the defects of the fluffs, and excuse their not giving them all the shavings, dyes, and preparations, that are necessary to render them perfect; accordingly they have been frequently prohibited.

Pressing to Death. See Pain Fort &c. Due.

PRESSION, or Pressure, in the Cartesian Philosophy, an impulsive kind of motion, or rather an endeavour to move, imprefsed on a fluid medium, and propagated through it.

In such a pression the Cartesian suppose the action of light to conffit. (See Light.) And, in the various modifications of this pression, by the surfaces of bodies, on which that medium is thus pressfed, they suppose the various colours to conffit, &c. But Sir I.as Newton has taught us better; for if light, &c. confi! only in a pression, propagated without actual motion, it could not agitate and warm such bodies as reflect and refract it, as we actually find it does; and if it conflated in an infiantaneous motion, or one propagated to all distances in an instant, as such pression happens, there would be required an infinite force to produce that motion every moment, in every lucid particle.

And if light confiled either in pression, or in motion propagated in a fluid medium, whether infiantaneous, or in time, it must follow, that it would inflict itself ad omnium; for pression, or motion, in a fluid medium, cannot be propagated in right lines, beyond any obstacle which shall hinder any part of the motion; but will inflict and diffuse itself, every way, into those parts of the quiescent medium which lie beyond the said obstacle.

Thus the force of gravity tends downward; but the pressure which arises from that force of gravity, tends every way with an equable force; and, with equal ease and force, is propagated in crooked lines as in straight. Waves on the surface of water, while they slide by the sides of any large obstacle, do inflect, dilate, and diflute themselves, by degrees, into the quiescent water lying beyond the obstacle. The waves, pulses, or vibrations of our air, in which sounds confi, do manifeftly inflect themselves, though not so much as the waves of water; for the sound of a bell, or of a cannon, can be heard over a hill, which intercepts the fonsous object from our view; and sounds will be propagated as easily through crooked tubes, as through straight.

But light is never observed to go in curve lines, nor to inflect itself ad omnium; for the fixed stars do immediately disappear on the interoposition of any of the planets; as well as some parts of the suns body, by the interoposition of the Moon, Venus, or Mercury.

Pressure of the Air. See Air.

Most of the effects ascribed to the fuga vacui, are now accounted for from the weight and pressre of the air.

The pressure of the air on the surface of the earth is balan-
The preflure of the air on every square inch on the surface of the earth, is computed to be about fifteen pounds avoidupus. See Atmosphere.

Pressure, Centre of. See Center of Preffure.

Pressure of Fluids. See Fluid.

Pressure Engine is an hydraulic machine, acting by the power of a defending column of water upon the piflon of a cylinder, to give motion to pumps, for raiing water from a different level. In the mountainous districts which dominantly contain rich mineral treasures, falls of water may be often otained at a greater elevation than it is practicable to confruct water-wheels of sufficient size to occupy the whole defcent ; and often the stream is too small to supply a wheel. In these situations the preflure engine is well adapted to produce the greatest effect from the fall, in working pumps, or other machines for draining the mines of water. The fame principle can readily be extended to the raiing of water for supplying towns, gentlemen's houses, &c. ; and universally for raiing water from any depth wherever a fall of water can be procured, particularly in those cafes where the fall is great, that is, where it exceeds 30 or 40 feet. It will not only exceed all other known machines in effect, but in fimplicity, and that whether the quantity of water that is to be applied is great or small.

Machines of this kind, invented by Mr. Denizart, are described in the Machines Approvuees par l'Academie for 1731, vol. v. and by Mr. Genilanes in 1741, vol. vii.; but the earlieft which was put in execution in this country was by Mr. William Weftgarth, who invented the proper expedients to obviate those difficulties which had before attended the practical execution of machines upon this principle in France; he erected a large one at a lead mine of Sir Walter Blacket's, at Coal Cleugh, in Northumberland, in the year 1765. Mr. Weftgarth's machine confisted of a cylinder, provided with a piflon fuspended by a chain from a beam or working lever, from the oppofite end of which the rod of the pump, which was to raiie the water, was fuspended; the working cylinder was made the full height of the column of water which was employed to work the engine, and the working beam was, of course, placed above the top of it, whilst the chain and rod reached down into it; so that the piflon itfelf acted in a chamber or barrel, nearly at the bottom of it; a trough, or ciftern, at the top of the cylinder, was kept constantly supplied by the stream of water, and thus the whole height of the cylinder being filled with water, the preflure of its column always bore upon the piflon. From the lower part of the cylinder was a paffage to permit the water to escape from it, and likewise another paffage by a pipe, communicating from the lower part of the cylinder, beneath the piflon, to the upper part of the fame above the piflon. Both thefe paffages were governed by a fidding valve of very ingenious ftricture, which opened and flut them alternately, but would not allow both to be open at one time. The fidding valve was actuated by an apparatus of levers, very familiar to thofe ufed in the old steam-engines for opening the cocks; and the pump rods were fo loaded as always to have a preponderance to draw the piflon up when the preflure of the water upon it was removed or balanced. Suppose the piflon at the top of its motion, by opening the paffage from the bottom of the cylinder the water escapes from it, and relieves the lower side of the piflon from the preflure of the water, whilst the whole column continues to prefl upon the upper side; in this situation the piflon descends, drawing up a column of water in the pumps at the opposite end of the beam or lever, but on arriving at the bottom of the cylinder, the mechanism shuts the fidding valve, and it closes the paffage at which the water escapes from the cylinder, and at the fame time opens the other in the pipe, which admitting the water from the upper into the lower part of the cylinder, it will prefl equally below the piflon as above it, consequently the forces are balanced, and the counter-weight of the pump rods, at the oppofite end of the beam, will draw up the piflon to the top of its chamber, when the position of the fidding valve is again altered, and it closes the piflon, at the fame time opening the paffage for the water to escape; this makes another stroke, and thus the engine continues to work as long as the fupply of water is kept up. The minutiae of the machine are decribed in the Transactions of the Society of Arts, vol. i.; but the ingenious Mr. Smeaton foon improved it very materially, by enclosing the top of the cylinder with a lid, through which the piflon rod paffes in a collar of leather, and the cylinder is then required to be no higher than convenient for the motion of the piflon within it, the water being introduced to it by a pipe. The construction of Mr. Weftgarth's fidding valve he preferved with very little alteration. In Flute Preffure, we have given drawings of a small engine which Mr. Smeaton erected in Yorkshire, at the feat of lord Irwin, in 1770, to raiie a supply of water for the fervice of the houfe. Figs. 1 and 2 are elevations of the whole engine, and the other figures are enlarged feathers of the fidding valve, which regulates the aflimation of the water into the working cylinder at proper intervals, to caufe the motion.

The pipe, A, which supplies the engine with water is 1.7 of an inch bore; its perpendicular defcent from its mouth or entry at the spring of fupply is 54 feet; and its length 400 feet. The water is conveyed from the engine by a pipe, I, which has a fall or defcent of twelve feet from the engine to the surface of the water in the pit or well into which it delivers; and it has a ftop-cock, which regulates the discharge of the water. This defending column of 66 feet of water is employed in working a pump, D, which throws back part of the water to a retervoir by a pipe, s, in fecimal about 900 feet in length, and 1.5 inch bore. The delivery of this pipe at the top of the retervoir is 80 feet above the engine, consequently 26 feet above the level of the head or spring of fupply. The pipe, A, conducts the water to the pump, D, by one branch, and to the top of the cylinder, C, which works the engine, by the other. The cylinder, C, is of brass, truly bored, and furnished with a solid piflon, whole rod, b, paffes through a clofe fuffling-box in the cylinder lid, where a leafier is packed round it to clofeiy, that no water can leak by it; the upper end of the piflon rod is keyed into a small box, which connects it with an iron rod, fidding through a guide, s, to make it move readily. K is the working-beam, moving round a centre at L; it has an arch head at the outer end, which is a segment of a circle, ftruck from the centre L; the arch receives a chain, by which the piflon-rod, b, is fuspended; and therefore has a vertical motion. E is the pump-rod, jointed to the beam, and moving up and down with it, the forcer of the pump, D, is fixed to it at the lower end, H is a pipe, which forms a communication between the top and bottom of the cylinder; it leads down into a cheft, n, upon which the cylinder is placed, and to which it is open at bottom; the cheft is compofed of plates frewed together, as fhewn by the feathers, figs. 3, 4, and 5, which also explain the construction of the fidding valve contained within the cheft. In these figures, s is a short cyhndrical pipe, fixed across within this cheft, and communicating with the

Vol. XXVIII.
pipe, H, at top, and the pipe I (which conveys the wa-
ter away from the engine) at bottom. This short pipe has a
water-tight division, \( \nu \) (fig. 4) in the middle of it, so
that there is no direct passage through it from H to I; but there are four square holes made in the pipe, at
equal distances round it, above and also below the
division, as shown at figs. 4 and 5. A cylinder or tube of
brasses, \( \tau \), is fitted upon the cyndric pipe, and slides up and
down it, being packed with leather round the edges of the
middle partition, as shown in fig. 4d, so that no water may escape
between the two cylinders. The sliding cylinder, \( \rho \), is just half
the length of the other, and when it is pushed down, as in
the figures, it covers and stops the four holes in the pipe \( \eta \),
which are below the division \( \nu \), and opens the four holes
above the division, allowing a passage from the pipe H
to the bottom of the cylinder \( \zeta \), fig. 1. On the con-
trary, when the slider is pushed up, the upper holes are
closed, and the lower ones opened, making a passage from
the cylinder bottom into I. The sliding valve, \( \rho \), besides
the leather packing which surrounds the partition \( \nu \), has
leather placed at top and bottom of the fixed cylinder \( \zeta \),
at \( \rho \), \( \rho \), and the ends of the slider are pressed upon these
leathers, to make a tight joint when up or down, but the
cylinder fits as tight as it can be made, independent of the
leathers. The sliding valve has a pin projecting from each
side of it, which pins are included between cleats made at
the end of a forked lever \( \nu x \), movable on an axis \( y \), which
passes through the side of the cleat in a collar of leather \( \nu \),
fig. 5, and has a long lever \( \nu \), figs. 1 and 2, fastened upon it.
By moving the upper end of this lever towards the
engine, the sliding valve will be raised up; and by moving
it in a contrary direction, the valve will be pushed down:
\( \nu \) is a small iron rod, jointed to the upper end of the long
lever \( \nu \), one of its ends, and the other is supplied by
hooks from a spindle turning upon pivots, supported by the
framing; this spindle has several levers upon it, similar to
the working gear of a steam-engine, as follows: \( \nu c \) is a
three-armed lever; the arm \( \nu \), has a weight at the end, and is
called the tumbling bob; \( \nu \) and \( \nu \) are two other arms, made
in the fame piece with \( \nu \); these two latter arms strike against
a pin, fixed across in the end of the rod \( \nu \), which is forked, to
adapt the pin and the arms \( \nu \), \( \nu \), to act within the fork; \( \nu \)
are two crooked levers, by which the spindle is moved as
handles; these levers are struck by pins, \( \nu \), fixed in a wooden
rod \( \nu d \), which is jointed to the working-beam \( \nu K \), and moves
up and down with it: \( \nu \) (fig. 2) is a piece of wood fixed to
the upright beams of the frame, having pins projecting
from it, which catch the tumbling bob \( \nu \), and prevent it
moving too far; \( \nu \) is a drop-scock in the main pipe, which
regulates the quantity of water coming to the engine, and
consequently the velocity with which the engine will works.

To describe the operation of the engine, suppose every
thing to be in the position of the figures, and the pipes,
cylinder, and pump, full of water, the sliding valve is down
in the position of fig. 4, and therefore forms a communica-
tion from the top to the bottom of the cylinder; in this
state the pressure of the defending column of fifty-four
feet of water presses equally upon both sides of the pilon
of the cylinder, and therefore has no operation either way,
the communication with the pipe I being stopped, so that
the water cannot escape through it; but the pressure operates
upon the lower surface of the force D of the pump, rising
freely through the lower valve of the pump; this pressure,
being unbalanced, raise up the working beam, and with it
the pilion of the cylinder and the rod \( \varepsilon \). This, as before
mentioned, has pins, \( \iota \), in it, one of which is seen, in fig. 1, to
be just meeting the arm or handle \( \kappa \), which it raises, lifting
the tumbling bob \( \varepsilon \), and turning the axis with all its levers.
When the engine arrives at the top of the stroke, the
ruminating bob presses the vertical point, and falls over on
the other side of the centre; the arm \( \kappa \) now strikes the crofs pin
in the end of the rod \( g \), and by drawing it moves the lever \( \alpha \),
and lifts up the sliding valve; this closes the communication
between the top and bottom of the cylinder, and opens a
passage to the pipe I, permitting the water to pass through
the pipe into the well, and thus get away from the engine.
This removes the preffure of fifty-four feet from beneath
the piston, though it still remains acting at the top of
the piston, and has added to it the twelve feet from the engine
to the bottom of the well, in consequence of this column
being suspended in the pipe I; this unbalanced preffure
causes the pilion to descend, bringing down the end of the
beam \( \kappa \), and pump rod \( E \) with it: the valve in the bottom
of the pump now shuts, and the water in the pump, being
preffed by the forcer, opens the other valve at \( M \), and goes
up the pipe, \( \alpha \), to the refervoir, lifting a column of water
of eighty feet. When the engine gets to the middle of its
stroke, a pin in the other side of the wooden rod \( d \), and
therefore not seen, takes the lever \( \delta \), and forces it down, raising
the tumbling bob \( \varepsilon \), at the same time. By the time the pilion
arrives at the bottom of the cylinder, the tumbling bob is
brought past the vertical position, and suddenly overflies,
by its own weight, into the position of fig. 1. The lever \( \delta \),
now runs against the pin, across the end of the rod \( g \), and
shoves it from the engine, moving the long lever \( \alpha \), of the
sliding valve, and the short lever \( \omega x \), (fig. 3) down, just
in the position of the drawings. This closes the four lower
holes in the fixed cylinder, and prevents the water going
down the pipe I, but at the same instant opens the four upper
holes, forming a communication between the top and
bottom of the cylinder. The preffure of fifty-six feet,
which caused the pilion to descend, is now removed, or
rather balanced, by caufing it to act equal beneath the piston;
and the column of water of fifty-four feet, coming down
the pipe \( \Lambda \), and through the branch, forces open the lower
valve of the pum\( p \), (the valve at \( M \) closing and supporting
the column of eighty feet,) preffes the under side of the
pum\( p \) forcer, and raises it up, as before decribed, moving
the beam and piont with it, there now being an equal preffure,
both above and below the piston, it will be moved up
casly. When the piston arrives at the middle of its stroke,
the preceding operations are repeated; thus the pin in the
rod \( d \), takes the lever \( \delta \), and raises it till it arrives at the top
of its stroke, when it again prusses the vertical position, and
infantly falls over into the position firft described; the lever
\( \delta \), taking the end of the rod \( g \), and pushing it towards the
engine, raifes the sliding valve, opens the passage to the pipe
I, and the whole column of fifty-six feet now preffes upon
the piston, and forces it down as before decribed, overcom-
ing a column of eighty feet upon the pump. Though
the diameter of the pump is larger than that of the cylinder,
this happens from the chain of the pilion acting upon a
much longer lever than the pump. \( P \) and \( N \) are two air-
vefils upon the pipes \( A \) and \( \alpha \), to equalize the action of
the pump, and to prevent the shock which would otherwise
take place when the sliding valve was suddenly shut, and the
motion of the defending water thus checked.

A very complete preffure engine was erected by Mr. Tre-
avitchick at the Druid copper-mine, in Illogan, near Truro,
in Cornwall; it acted with a double power, that is, the preffure
was firft applied to one side of the pilion to force it
up, and then on the other to force it down, in the fame
manner as a double acting steam-engine. It acted by two
sliding valves instead of one, but they were so made that one
opened
opened rather before the other shut, and this, though it waited a small quantity of water, by permitting it to escape, prevented the conclusion of dopping the column of water, which indeed is always in motion.

PREST, a duty in money, paid by the sheriff upon his accounts in the exchequer, for money left, or remaining, in his hands.

The word is French, prêtre; where it signifies ready.

PREST-Money, a sum of money which binds those who receive to be ready at command, at all times appointed; chiefly understood in the lifting of soldiers.

PREST-Salt, in Sea Language, is when a ship carries all the salt she can possibly crowd.

This is sometimes done in giving chase, &c. but it is a dangerous experiment, left the ship overfet, or bring her masts by the board; in which latter case the becomes an easy prey.

PRESTANT, the name of a metal flop in French organs, equal to the principal in our's: being an octave above the open diapason, and an octave below the fifteenth.

PRESTATION-Money, a sum of money paid yearly, by archdeacons, and other dignitaries, to their bishop, to exterior jurisdiction.

PRESTATION, Prebatio, was also anciently used for other payments; " Et quieta sunt de praetatione muragii." Chart. Hen. VII. Sometimes also for pourvoyance.

PRESTEAN, in Geography, a town of the Morea, in the gulf of Corun; 11 miles S.E. of Scardamula.

PRESTEIGNE, or Llan-Andras, a borough and market town in the commw of Dyffryn Teyfeddian, Cantref-y-Clawdd, (now called the hundred of Radnor,) in the county of Radnor, South Wales. It is situated near the south bank of the river Lug, on the confines of the county with Herefordshire, and in the centre of a fertile and well cultivated valley. This town is of considerable antiquity, and is a borough by prescription, but has now lost the privilege, which it formerly enjoyed, of voting as a contributory borough, in the election of a representative to parliament. It still, however, exercises other important rights, and is governed by a bailiff, nominated by the ward of the cantref of Maelienydd, an officer in the appointment of the crown. Richard Martine, the pope's legate in the reign of Richard III., was an extraordinary benefactor to Presteigne, having obtained for the inhabitants many privileges, and among others these of holding a weekly market on Saturday, and fairs three times a year, in May, June, and December, which are continued to this day. The church here is very ancient, and over the great chancel window are sculptured the initials P. L. M. and the date 1244; but the meaning of the letters is unknown. In this church are several old monuments, inscribed with the names of Owen, Price, and Davies; and the walls are adorned with various texts from the scriptures, and with figures of Mofes and Aaron, Time and Death. Here is a free-school, founded, and liberally endowed, by John Beccles, eqq. in the reign of queen Elizabeth, for the benefit of the inhabitants of the township. The great and quarter scissors are held in this town, and the county courts alternately here and at Radnor. Presteigne is now considered the principal town in the county; and seems to be improving both in respectability and population. According to the parliamentary returns of 1811, it contained 2239 houses and 1144 inhabitants.

On a little eminence adjoining the town, called the Warren Walks, formerly stood the castle of Presteigne, of which not a trace remains, nor are any notices of its history recorded. Its site is now occupied by a pavilion, and by a bowling green, presented to the inhabitants by lord Ox-
that there were two perfons in the East under this appellation, agreeably to the preceding account; whilst others consider the Abyssinian Preacher John as a fictitious character. The fact, as Mr. Molheim has stated it, seems to be briefly this. In the fifteenth century, John II. king of Portugal, employed Pedro Covilliano in a laborious enquiry into the real situation of the kingdom of Preacher John. The curious voyager undertook this task; and for information in the matter, travelled with a few companions into Abyssinia; and observing in the emperor of the Abyssinians or Ethiopians many circumstances that resembled the accounts which at that time prevailed in Europe concerning Preacher John, he persuaded himself that he had fulfilled his commission, and found out the resiufence of that extraordinary monarch, who was the object of his researches. His opinion easily gained credit in Europe, which had not yet emerged out of its ignorance and barbarism. But a new light was cast upon this matter in the 17th century, by the publication of several pieces, which the industry of the curious drew forth from their obscurity, and by which a great number of learned men were engaged to abandon the Portuguese opinion, and were convinced that Preacher John reigned in Asia, though they still continued to dispute about the situation of his kingdom, and other particular circumstances. There are, however, some men of the most eminent learning in our times, who maintain, that John was emperor of the Abyssinians, and thus prefer the Portuguese opinion, though (says Molheim) delitute of authentic proofs and testimonies, to the other, though supported by the strongest evidence, and the most unquestionable authorities.

We shall only add, that the death of Preacher John, and the total defeat of his successor by Genghiskan, or Geng•fchan, emperor of the Tartars, gave an unhappy turn to the affairs of the Christians in the northern parts of Asia, towards the close of the 12th century. From this period the Christian cause lost much of its authority and credit in the provinces that had been ruled by Preacher John and his successor David, and continued to decline till, at length, it sunk entirely under the weight of oppression; and was succeeded in some places by the errors of Mahomet, and in others by the superstitions of paganism. In this general account, however, we may except the kingdom of Tangut, the chief residence of Preacher John, in which his posterity, who persevered in the profession of Christianity, maintained, for a long time, a certain seat of tributary dominion, which exhibited, indeed, but a faint shadow of their former grandeur.

See Nestorian.

The name of Preacher, or Prebyter John, (says Mr. Gibbon,) a khan, whose power was vainly magnified by the Nestorian missionaries, and who is said at this time to have received the rites of baptism, and even of ordination, has long annulled the credulity of Europe. In its long progress to Moful, Jerusalem, Rome, &c. the story of Precher John evaporated in a monstrous fable, of which some features have been borrowed from the Lama of Thibet, and were ignorantly transferred by the Portuguese to the emperor of Abyssinia. Yet it is probable that in the 11th and 12th centuries Nestorian Christianity was professed in the lord of the Keraites. The royal convert, as the story fays, was indulged in the use of a portable altar; but he dispatched an ambafador to the patriarch, to inquire how, in the season of Lent, he should abstain from animal food, and how he might celebrate the Eucharift in a defert that produced neither corn nor wine. In their progres by sea and land, the Nestorians entered China by the port of Canton, and the northern residence of Sigan. Unlike the senators of Rome, who assumed with a filnle the characters of priests and augurs, the Mandarins, who affect in public the reason of philosophers, are devoted in private to every mode of popular superstition. They cherish and they confounded the gods of Palestine and of India; but the propagation of Christianity awakened the jealousy of the state, and after a short vicifitude of favour and perfeafion, the foreign fect expired in ignorance and oblivion. Under the reign of the caliphs, the Nestorian church was diffused from China to Jerufalem and Cyprus; and their numbers, with thofe of the Jacobites, were computed to surpass the Greek and Latin communions. Twenty-five metropolitans or archbishops composed their hierarchy, but feveral of these were difpenfed, by the diftance and danger of the war, from the duty of perfonal attendance, on the eafy condition that every fix years they should fetcifily their faith and obedience to the Catholic or patriarch of Babylon, a vague appellation, which has been fucceffively applied to the royal fets of Seleucia, Ctefiphon, and Bagdad. These remote branches are long fince withered, and the old patriarchal trunk is now divided by the Elijahs of Moful, the representatives, almost in lineal defcent, of the genuine and primitive fucceffion, the Jofaphs of Amida, who are reconciled to the church of Rome, and the Simeons of Van or Ormia, whose revolt, at the head of 40,000 families, was promoted in the 16th century by the Sophists of Perfa. The number of 300,000 is allowed for the whole body of the Nestorians, who, under the name of Chaldeans or Afyrians, are confounded with the moft learned, or the moft powerful nation of eaftern antiquity.

Gibbon's Hist. vol. viii.

PRESTESSE, in the Measure, is used to denote the readiness and diligence of a horse in working a measure.

PRESTET, John, in Biography, a French prieft and able mathematician, was born, in the year 1648, at Clalons-sur-Saone, where his father filled the humble post of tipstaff to the bailiff. Being bent when young to Paris, in search of employment, he was taken into the service of the celebrated father Malebranche, who took upon himfelf the task of teaching him the mathematics. The pupil did credit to the master's expectations, and in 1675 he became himself an author, and published the firit edition of his "Elements of the Mathematics," in one volume 4to. This was the firft work of the kind which had appeared in France, and was particularly recommended by the number of curious problems which it contained, for exercising the ingenuity of young mathematicians. In the fame year the author was admitted a member of the congregation of the Oratory, and he afterwards filled the mathematical chair in different feminaries belonging to the society, with great succefs and reputation. In 1689 he published at Paris the second edition of his "Elements," improved and enlarged. He died in 1690. Moreri.

PRESTEWITZ, in Geography, a town of Saxony; 3 miles N.E. of Liebenwerda.

PRESTIMA, a town of Portugal, in the province of Beira; 11 miles N. of Coimbra.

PRESTIMONY, Prelomina, in the Canon Law, a term about which authors are much divided. It is derived a praelatione quotidiana; and is, by some, defined a kind of benefice, served by a single prieft; in which sense, prelomy is the name with a presbyterian chapel.

Others will have prelomy to be the incumbency of a chapel, without any title, or collation; such as are moft of those in castles, where prayers or masses are said; and which are mere oratories unwedowed. Where as, the term is applied, in the Roman church, to certain perpetual offices, bestowed
befeloned on canons, religious, or others, for the faying of masses, by way of augmentation of their livings.

Others, again, will have prelominy to be a leafe, or confeffion of any ecclefeiatical fund, or revenue, belonging to a monastery, to be enjoyed during life.

Du Moulin makes prelominy a profane benefice, which, however, has a perpetual title, and an ecclefeiatical office, with certain revenues attached to it; which the incumbent is allowed to fell, and which may be poifelled without tonfure: such as the lay-churfhwardens of Nôtre Dame.

He adds, that, in propriety, the canoories of chapels are benefits of this nature.

Upon the whole, the most probable opinion feems to be this, that prelominy is a fund or revenue appropriated by the founder for the fubfiftence of a priest, without being erected into any title or benefice, chapel, prebend, or priory; and which is not fubjeft, either to the pope, or to the ordinary; but of which the patron, and thofe who have a right from him, are the collators, and nominat and conferr, pleno jure.

PRESTISSIMO, in the Italian Muft, intimates to perform extremely quick, falletly, and with fury.

PRESTO, Ital. quick. This term written at the beginning of a movement in music, implies the molt rapid and animated mefure of all the five different degrees of quickness; and this rapidity admits of increafe by più prefto, and prestissimo.

PRESTON, in Geography, a borough, market-town, and parifh, in the hundred of Amounderness, and county-palatement of Lancafter, England. The town is placed upon an extremity extending from the river Ribble, at the diftance of 22 miles S. by E. from Lancater, and 216 N.W. by N. from London. It is of great antiquity, having rifen, according to Camden, out of the ruins of Ribchester, or Cocium, a Roman fation, which was fittered some fome higher up the river; but this opinion is only conjectural.

It is probable, however, that it was a town of fome importance previous to the Norman conquest; and it is faid to have derived its name from the number of religious houses it contained during the period of the Saxon dynasty. From Domefday-book the lordship of this place appears to have been held by earl Tolli, brother to king Harold, who loft his crown and life at the celebrated battle of Haling.

Prefton was fift incorporated, by charter, in the reign of Henry II.; and that charter has fince been confirmed and extended by several of his fucceffors. Under that laft granted, the corporation now confifts of a mayor, a recorder, eight aldermen, four under aldermen, seventeen common-councilmen, and a town clerk; and it has the peculiar privilege of holding a guild every twenty years, which is reforted to as a kind of jubilee by the people of fashion and列入 from all the country round. It is held in Auguft, and lafs a month. On the day it begins, the members of the corporation walk in proceffion, followed by the trading companies, under their respective banners, and decorated with the insignia of their professions. Plays, concerts, and other public amufements efliven this period of festivity and joy.

The laft jubilee took place in 1802, being the third which has occurred fince the commencement of the reign of his prefent majefty. This curious custom originated in Saxon times, and is strictly enjoined in all the charters to the corporation, on pain of forfeiting the elective franchise, and their rights as burgoffes. Every perfon, on this occafion, muft renew his freedom within twenty-eight days after profecution is made, or be liable to forfe the fame for ever.

This town returns two representatives to the national councils. It fift enjoyed that privilege in the reign of Ed-ward I.; but after the first year of his fucceffor, it caelfed sending until the reign of Edward VI., fince whose reign its returns have been regular. Party contefts have, perhaps, been as violent here as in any borough in England; indeed, on the occafion of several elections Preston has almost fuffered the fate of a town florned by an enemy. A queftion has been at fife for nearly a century and a half, whether the right of election vested generally in the inhabitants, pot- wallers, or was confined to "the in-burgifie of the laft guild, and thofe admitted fince by copy of court-roll"? This point has been four times defcufed in the house of commons, and each time the decision has been in favour of the inhabitants at large. The chief influence in the borough is that of the earl of Derby, who commonfly returns one member, and the diftinguifh intereft the other. The mayor and two bailiffs are the returning officers, and the voters are eftimated at 600 in number.

Preston, though free, comparatively, from the bullfe of trade and manufacture, is nevertheless opulent and well inhabited; and takes the lead of all the towns in Lancashire, in point of gentility and fashionable reftort. It has more-over the advantage of being the seat of feveral law courts, viz., the borough court; a court of chancery for the duchy of Lancaster; a county court, which fits on Tuesday weekly; a court called the county arrefit; and a fifth for the wapentake; besides the court of quarter fessions, which is held here by adjournment from Lancater on the Thursday of the week after Epiphanie. Hence, as may be supposed, a large proportion of the inhabitants of Preston are engaged in, or connected with, the profeflion of the law.

Markets are held here on Wednesday, Friday, and Saturday, every week, and are extremely well regulated to prevent fellfalling and regrating. Here are likewise three annual fairs, in March, September, and January. Coals are supplied plentifully by means of the Dogfafs and Lancater canals, the former of which communicates with the river Ribble, and the latter paffes clofe to the town. By these canals communications are opened with all the principal rivers in the kingdom.

From its lofty situation, and its proximity to the Irish sea, Preston enjoys a fulbrious and healthful climate. It is a handsome, well-built town, with broad, regular streets, and many good houses; and is rendered gay by feafons and other places of amufement, fuitable to the genteel ftyle of the inhabitants. The earl of Derby has a large modern manfion in it. The principal public buildings are, the parish church, the town-hall, the afembly rooms, the new prisson, and the bridge. The church is a very spacious ftructure, the living of which was formerly appropriated to the college of Leicer, but is now in the patronage of the Hoglton family. There are also feveral chapels of ease, and meeting-houses for different fects of diftinguifhers, but Sectarians are comparatively few in number. The town-hall is a very fubstantial and commodious building, and contains a fine portrait of George III., preferrfed to the corporation by Sir Edward Stanley. The afembly rooms, which are well adapted to their object, were erected at the expence of the earl of Derby. The new prisfon, or penitentiary houfe, is fittuated near the entrance to the town from Chorley, by Walton. It was built at the charge of the hundreds of Lofondale, Amounderness, Blackburn, and Well-Derby, on the Howardian plan, and is exclusively appropriated to prisfons from thole hundreds. Its objeét is faluatory confine-ment and reformation only; each prisfoner has a daily allowance of one pound and a half of bread, with a proportionate quantity of butter, and a few potatoes; and they are per-mitted to exchange what they do not eat for tea and funny;
but all strong liquors are strictly prohibited. The new bridge was built over the Ribble in 1781, in the place of a former one carried away by a flood.

From its relative position Preston has been an important port in the civil commotions of the kingdom, and the scene of various military actions. In the time of the parliametary resistance to Charles I., the royal army, under the duke of Hamilton and Sir Marmaduke Langdale, was defeated here with great slaughter by an inferior force commanded by generals Cromwell and Lambert. Here also the rebel general Forster was routed by the king's troops in 1715; when many pertons in Preston suffered for taking up arms in the cause of the Pretender. In 1745 Prince Charles took possession of this town; and is said to have viewed the country around from the Emin with extraordinary emotions.

The borough of Preston, according to the parliamentary returns of 1811, contains 3624 houes and 17,065 inhabitants. The religious houses recorded to have been founded here since the conquest, are, an hospital, established soon after that event, and a house of Grey friars, erected and endowed by Edmund, earl of Lancaster, fon to Henry I.; but of neither of them do any vestiges remain. About a mile from the town, at Penwortham, was likewise a priory of Benedictine monks, subject to the abbey of Evesham, in Worcestershire. It was founded about the year 1068 by W Australians, and at the dissolution was granted by King Henry VIII. to John Fleetwood.

From Preston a Roman cañefway, or military road, still distinctly visible in places, conducts to Ribchester, once a military station of that people. Its original designation has been a matter of much contention among antiquaries. Camden supposes it to have been the Coccinum of Antoninus, and the Rigodunum of Ptolemy. Horley was of the same opinion as to Coccinum, but inclined to fix Rigodunum at Warrington. Mr. Whitaker, the historian of Manchester, contended that it was Rigorium of Richard of Cirencester; but Dr. Whitaker, who late investigated the subject, appears to have clearly identified it with Coccinum. This antiquary affirms its original establishment to Agricola, and says it was placed with the peculiar judgment which distinguished the encampments and works of that celebrated commander. From the boldness and extent of its ramparts, and also from the number of altars, inscribed stones, earthen vessels, plates of copper, coins, and other relics found here, Ribchester is pre-eminently to have been a station of more than ordinary magnitude and importance. That the Ribble was anciently navigable as high as this place, is proved by the fact of many anchors having been dug up in the vicinity, as well as the hull of a ship, larger than could now be floated above Preston. Contiguous to Ribchester is the parochial church of Street, which originally belonged to a guild or hospital. See Beauties of England and Wales, vol. ix. by John Britton, F.S.A. A Description of the Country from 30 to 40 Miles round Manchester, by John Aikin, M.D., 1795. History, &c. of Whalley, by the Rev. Dr. Whitaker.

Preston, a town of America, in New London county, Connecticut, six or eight miles E. of Norwich, from which it is divided by the Hackett river; incorporated in 1687, and containing two congregational churches, a society of Separatists, and 2834 inhabitants. Alto, a village of Kentucky, on the bank of the Ohio, just below the salt-works.

Preston's Creek, or Wood Creek, a river of Kentucky, which runs into the Ohio, N. lat. 37° 54'. W. long. 86° 46'.

Eff. Ch. Corolla falvex-shaped; its mouth crowned with an annular undivided tube, and five internal scales, alternate with the segments of the limb. Antlers half-prominent, arrow-shaped, cohering with the middle of the stigma, their hind-lobes empty. Germans two. Style one, thread-shaped, dilated at the top. Stigma turbinated, with a small taper point. Nectar a cup of one leaf below the gemm. Follicles . . .

Preston-Pans, in Geography, a burgh of barony, market, and seaport town, in the county of Haddington, or East Lothian, Scotland, is situated on the southern bank of the Frith of Firth, at the distance of eight miles E. from Edinburgh. This place derived its name from the small village of Preston adjoining, and from the salt-works or pans established here by the monks of Newbottle as early as the year 1189. For several centuries it was called Salt-Preston; but in 1617, when the charter for erecting it into a burgh of barony was granted, it had obtained its present appellation. Previous to the union a very considerable foreign trade was carried on here, especially in Dutch and French goods; and even to late as 1719, forty-one foreign cargoes were delivered at this port within twelve months, nineteen of them from vessels belonging to the town. The harbour chiefly used at that period was Port-feaston, a mile to the east, in the parish of Tranent; that belonging to the town at present is Morrison's Haven, which is situated at its western extremity. It was formerly called New Haven, and sometimes Acheon's Haven, from an ancient family of that name, progenitors of the earl of Golspie, in Ireland. This harbour draws twelve feet of water, and is considered one of the safest on the Frith of Firth. A custom-house is established here, the jurisdiction of which extends from the Eiggat-Burn, in Mid Lothian, on the west, to the mouth of the East Lothian Tyne, on the east. Within the collection are thirty-one salt-panns: viz. ten at Cockenzie, four at Preston-Pans, two at Cuttle, four at Wigt-Pans, four and Pinkie-Pans, and six at Duddingston-Pans. The chief imports to this town are the ingredients for the manufactures carried on in it, and in the vicinity; the exports are fish, particularly oysters, flax-ware, bricks, tiles, oil of vitriol, spirit of salt, and Gluefer. About twelve thousand bushels of salt are made here annually. The flax-ware is manufactured partly from the fine clays in the neighbourhood, and partly from clays brought from Devonshire. The white and red lead used in the glazing process is imported from London, Hull, and Newcastle. This branch of business was established here about a century and a half ago; and was probably first derived from the Dutch. How long the smaller manufactories have existedit is not recorded. Here is a market twice a week, on Wednesday and Saturday, chiefly for butcher's meat and other provisions. In 1754, there were in this town no fewer than sixteen brewers, but they are now reduced to a third of that number; two or three of those remaining, however, brew upon a very extensive scale. According to the parliamentary returns of 1811, the parish contains 259 houes, and 1995 inhabitants.

A very
A very singular commercial institution is connected with this town. On the second Tuesday of July, annually, the travelling chapmen, or peddlars, that is, the itinerant sellers of wares, &c., of the three Lothians, meet here and elect some of their number for the purpose of holding courts to enforce the observance of by-laws, to which they bind themselves to give obedience at their admission into the society. They elect on this occasion a provost, or preffes, a deputy-provost, a clerk, a treasurer, fix bailies, and several counsellors. There is one bailie for Preston-Pans and Cockenzie; one for Haddington and North-Berwick; one for Dunbar and Oldhamstocks; one for Musselburgh and Dalkeith; one for Queensberry and Borrowtounness, and one for Linlithgow and Bathgate. After the election they march in a body, preceded by music, to the crofs at Preston, where they drink a few bottles of wine, and then return. In the towns where their booths are erected at fairs, the bailie for that town gets a pledge from each chapman, who is bound to attend a meeting of the whole number at an appointed hour in the evening, or the next morning. Here the behaviour of each during the fair is enquired into. If any of the by-laws have been transgressed, a fine is exacted and paid. If the offence has been gross, they are expelled. The fines are deposited in the hands of the treasurer, and are applied to relieve the widows or families of those members of the society who need supply, and sometimes of such of their number as have been unsuccessful in business. They cannot proceed to an election unless some married member be present; but the preffes is usually chosen from among the unmarried men, it being supposed that bachelors will more readily attend the fairs. When a new member is admitted, he pays a sum to the common fund. No information has been obtained, that can be depended upon, as to the origin of this society, or the circumstances that led to the holding of their annual meetings at Preston, which was the cafe before its fairs were transferred to Preston-Pans. This village and parish is situated to the south of that town, comprehending Northfield and Scaw's-hospital. It is of greater antiquity than Preston-Pans, which indeed was formerly comprehended within the parish of Preston, though now a distinct parish in itself. Scaw's-hospital was originally a family residence, but was converted to its present purpose by the will of the late James Scaw, esq., who died in 1784, and now affords maintenance and education to twenty-four boys. The funds appropriated to the support of this establishment consist of the barony and a great part of the lands of Preston. Here are the ruins of a tower, which formerly constituted part of the family mansion of the Hamiltons of Preston; and here is likewise a market crofs, but so much has Preston decayed, that this relic of its former importance is now situated in a field. It is the property of the peddlars, they having acquired a right to it in the year 1636.

In the open grounds above the village of Preston, was fought, on the 22d of September, A.D. 1745, the "battle of Preston-Pans," in which prince Charles Stewart, commonly called "the Young Chevalier," at the head of his Highland army, completely routed the English forces under the command of general sir John Cope; all the infantry, except about 170, being either killed or taken prisoners. In this action the brave colonel Gardner, disdaining glorious flight, fell on the field of battle, as did likewise captain Brymer, of Lee's regiment, who was the only officer present who had ever seen Highlanders engaged with regular troops, and expressed strong apprehensions of the refuit on the day previous to the battle.

Preston, with Preston-Grange, is situated within the parish of Preston-Pans, and is now distinguished by the name of the Weit Barony. The adjacent grange to the latter place was derived from the grange which the monks of Newbottle settled here. The earl of Hyndford is principal proprietor of the grange lands, and has a seat in the vicinity.

About a mile from Preston-Pans is the village of Tranent, which contains about 1500 inhabitants, and is chiefly remarkable on account of its church, which has the appearance of being "a practical or architectural pun" upon the mysterious doctrine of the Trinity, to the honour of which it is dedicated. It is a building of very high antiquity, but nothing is known of its foundation or history. On the outside it appears to consist of three separate oblong houses, placed parallel to each other; but when entered it is found to consist of only one building. The central portion is somewhat longer at each end than the others, with which it communicates by means of openings in its side-walls, formed by lofty circular arches. The roofs of all the divisions are vaulted and covered with stone, and in the centre of the entire building rises a low, square tower. The windows of this edifice are few and small, and are carefully adequate to afford a dim light to the interior. Beauties of Scotland, vol. i. by Robert Forsyth, 1804. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

PRESTONVILLE, a town of America, in Floyd county, Kentucky, containing 32 inhabitants; its county contains 4353.

PRESTWICK, a town of Scotland, in the county of Ayr, which is a barony of barony, and has a market weekly; three miles N.E. of Ayr.

PREJUMPTION, Presumption, in Law, a supposition, or conjecture, founded on a verisimilitude. Presumption is of three sorts. 1. Violent, which many times is allowed a full proof; as if one be killed in a house, and a man is seen to come out of the house with a bloody sword, and no other person was at that time in the house; this, though but a presumption, is a proof. 2. Probable, arising from such circumstances as usually attend the fact, which has its due weight. 3. Light, or temerarious, which is of no prevalency at all.

In cases of a charter, or feoffment, if all the witnesses to the deed be dead, the violent presumption, that flands for a proof, gives continual and quiet possession. "Stabat presumption, donec probetur in contrarium." Coke on Litt. See Circumstantial Evidence, and Evidence.

Presumption was also anciently used for intrusion. Presumption, Presumption, in Rhetoric, the fame with prolepsis.

PREJUMPTIVE HEIR. See Heir.

PREJUMPTIVE Evidence of Felony. See Evidence.

PREJURA, in Surgery, inflammation of the ends of the fingers from cold; the phlogosis erythema of Cullen.

PRETENCE, in Heraldry. See Inescutcheon, and Escutcheon of Pretence.

PRETENDED, or Pretended Right, in Law, is where one is in possession of lands and tenements, which another, who is out, claims and sues for. Here the pretended right is in him who fo claims, or sues. As to the offence of felling such title, see Ch党史.

PRETER, or Preterit, pretetius, past, in Grammar, an inflexion of verbs, expressing the tense, or time passed. Preter, or preterit, is a general name, that comprehends all the inflexions corresponding to the several tense, or several circumstances and relations of the time past; all which, the Latin, &c. distinguishing by particular inflexions,
or terminations, of the verb; which make the proper notion of tenses. See Tense.

The modern languages, particularly the English, in lieu of different terminations of the verbs themselves, have usually recourse to those of their auxiliaries, and participles.

The preter, or past time, is subdivided, by grammarians, into "preterimperfect," as e. gr. I had, I thought; in the Latin, habebam, cogitabam; in the French, j'avois, je pensais: the "preterperfect," as, I have had, I have thought; habus, cogitavus; j'ai eu, j'ai pensé; and "preterduperfect," as, I had thought, I had had; habueram, cogiteram; j'eus eu, j'eus pensé. The English have properly but two cases, or kinds, of the preter tense; viz. the preter time of the imperfect action; as, I was at supper then, but had not yet done it; and the preter time of the perfect action; as, I had then supped, and it was then done. The preter tense is most often formed of the present tense, by adding ed; as I burned.

The French have a particular case of the preterperfect, which F. Buffier calls the preterite simple, in opposition to the former, called the preterit-composite; others call it the preterit-indefinite, because expressing a thing done indeterminately; as j'avois hier. This answers to the aoristus of the Greeks; and, in the distinction of this from the common preterit, does one of the greatest niceties in the practice of the French language confit.

In the passive voice, the Latins, French, &c. have recourse to participles and auxiliaries, like the English, to form their preter tenses; as, I was loved, amantus eram, j'étais aimé, &c.

Preterit, Preteritus, in the Roman Jurisprudence. Infans pretéritus, is a child of whom the father has forgot to make mention in his testament; which renders it entirely null.

Exhoration of his son is allowed in a father, but never preterition.

Preterition, or Pretermission, in Rhetoric, a figure whereby, in pretending to pass over a thing untouched, we make a summmary mention of it.

I will not say he is valiant, he is learned, he is just, &c.

The most artificial præfixes are those given by way of preterition. See Reticency.

Preternatural Rains. See Rain.

Pretext, or Pretence, a colour, motive, or cause, either real, or apparent.

Pretexta, or Pretexata, a amongst the Romans, was a long white gown, or toga, having a band, or border, of purple, at the bottom.

It was worn by children of quality till the age of puberty, i. e. by boys till seventeen, at which time they laid it aside, and resumed the virile gown. Girls wore it till marriage.

It took its name pretexta, according to Godwin, "quod ei purpura pretexta erat," because guarded about with purple silk.

The pretexta, at first, was a robe of flate, or ceremony, worn only by the chief magistrates, and the priests, nor was it lawful for such who wore this gown to be arraigned, or sentence to pass against them, till it was pulled off. In continuance of time, it was permitted to noblemen's children; and at length, even to all Roman children in general. See Toga.

Preti, Girolamo, in Biography, an Italian poet of the 17th century, was the son of Alexander Preti, a Tufcian, and knight of St. Stephen. He was brought up as a page in the court of Alfonso II., duke of Ferara, and afterwards lived with prince Doria at Genoa. He had been intended for the legal profession, but did not accord with his feelings, and he applied himself entirely to the composition of Italian verse. His works were read, admired, and translated into various languages; but they were suited to the taste of that particular period only, and have long since fallen into neglect. Preti became a favourite at the court of Rome, and was appointed by cardinal Fr. Barberini, his secretary, in a legation to Spain. He died on the journey to Barcelona, in the year 1626, being in the flower of his age. Moreri.

Pretium Sepulchri, in old Law Books, &c. those goods accruing to the church in which a corpse is buried.

In the Irish Canons, lib. xiii. cap. 6. it is ordered, that along with every body that is buried, there go his cow, horse, apparel, and the furniture of his bed; none of which may be disposed of otherwise than for the payment of debts, &c. as being familiar and domesticities of the deceased.

Pretor, Pretor, an eminent magistrate, or minister of justice, in ancient Rome; accordingly we often find a balance on the medals of the pretors.

The title of pretor is derived a praemunio, or, praefer, denoting the superiority of his jurisdiction.

In the first ages of the commonwealth, all the great magistrates were styled pretors; afterwards, the title was bestowed on all the principal officers of the army; at last, pretor became restrained to a particular magistrate.

About the year 386 of Rome, the people soliciting to have one of the consuls always chosen from among themselves, the senators granted it, on condition, that a new magistracy should be erected, to be filled wholly from among the patricians; such was the origin of the pretures, praetura; which, Livy observes, was first discharges by Spurius Furius Camillus, in the year of Rome 387; and whose office was to look to the administration of justice and equity between man and man; much in quality of a lord chief justice, or lord chancellor, or rather both in one.

But business increasing, in proportion as the empire was enlarged, a second pretor was created, A. U. C. 510, to take cognizance of the affairs of foreigners residing at Rome; upon which the former was distinguished by the title of pretor urbanus, or major; and the latter, by that of pretor prergerinus, or minor.

In the year 526 of Rome, when Sicily and Sardinia were reduced into Roman provinces, two more pretors were created to assist the consuls in the government of the provinces; and as many more upon the entire conquest of Spain, A. U. C. 556. Sylla, in the year of the city 672, increased the number to eight; Julius Cæsar, in the year 707, augmented them first till ten, and then to sixteen; under the reign of Augustus there were first ten pretors, and afterwards sixteen; two of whom were called pretores cereales, as being charged with the providing of corn and grain; to which number Claudius added two others, viz. pretores fidei comitissarii. In the Code, lib. i. tit. 39. we find a law of the emperors Valentinian and Marcian, which reduces the pretors to three.

In the time of Justinian, the office of pretor was entirely abolished.

The office of the pretor, or pretor urbanus, was to render justice in the city; and he had a power to interpret the laws, to supply and reform them; and even to make new ones, when the public good required. See Civil Law.

In the Institutes, the edicts of the pretors are called jus honoriuim; whence it should seem they had only the force of laws out of respect to that eminent magistrate; the businesses of the pretor being rather to look to the observation of the old laws than to make new ones. See Edicts.

Some
Some are of opinion, he had not the juri gladii, the power
of the sword; the cognizance of criminal matters being the
special province of the prefect of Rome. See PREFECT.

But others are of another sentiment. In the general, it is
very difficult to fix precisely how far his power extended.

When he walked, he was preceded by fix híders; and
was clothed with the robe called pretexa; he sat in a curule
chair; his tribunal was elevated in form of a semicircle; and
he bore a spear and sword.

His authority, like that of the other magistrates, was very
much weakened and reduced under the emperors. In the
Digest and Code it is a title de officio praetoris.

Pretor was also a title among the Romans, given the
governor of a province, who had served the office of pretor.
Whence provinces governed by pretors, or restrained to
those who had discharged that office, were called pretorian
provinces.

Pretorian Guards, or Band, pretoria cohors,
were the folders of the emperor’s guard; so called, as some
imagine, from their place or station in the palace or court
called pretorium.

They were originally nine or ten thousand men (for Ta-
citus and Dion are not agreed upon the subject), divided
into as many cohorts. Vitellius increased them to sixteen
thousand, and as far as we can learn from inscriptions, they
never afterwards sunk much below that number.

Their institution is owing, as some say, to Scipio Africa-
cus, who first established a company of the bravest men
in his army, selected for the purpose, to be his guard, and
never to fire from his side in battle.

But by others, their institution is derived from Augustus.
That crafty tyrant, says Mr. Gibbon, (Hist. vol. i.), sen-
tible that laws might colour, but that arms alone could
maintain, his usurped dominion, had gradually formed this
powerful body of guards in constant readines to protect his
perfon, to awe the senate, and either to prevent or to crush
the first motions of rebellion. He distinguished these fa-
voured troops by a double pay, and superior privileges; but
as their formidable aspect would at once have alarmed and
irritated the Roman people, three cohorts only were sta-
tioned in the capital, whilst the remainder was dispersed in
the adjacent towns of Italy. But after fifty years of peace
and servitude, Tiberius ventured on a decisive measure,
which for ever rivetted the fettors of his country. Under
the fair pretences of relieving Italy from the heavy burden
of military quarters, and of introducing a stricter discipline
among the guards, he assembled them at Rome, in a per-
manent camp, which was fortified with skilful care, and
placed on a commanding situation, close to the walls of the
city, on the round summits of the Quirinal and Viminal hills.

In the civil war between Vitellius and Vespasian, the pretor-
ian camp was attacked and defended with all the machines
used in the siege of the best fortified cities.

Such formidable servans are always necessary, but often
fart, to the throne of despotism. By thus introducing the
pretorian guards, as it were, into the palace and the senate,
the emperors taught them to perceive their own strength,
and the weakness of the civil government; to view the vices
of their masters with familiar contempt, and to lay aside
that reverential awe, which distance only, and mystery, can
preferve, towards an imaginary power. In the luxurious
idleness of an opulent city, their pride was nourished by the
sense of their irresistible weight; nor was it possible to con-
ceal from them, that the perfon of the sovereign, the autho-
rity of the senate, the public treasurers, and the seat of em-
pire, were in their hands. To divert the pretorian bands
from these dangerous reflections, the finest and best elabo-
Vol. XXVIII.

... rushed princes were obliged to mix blandishments with com-
mands, rewards with punishments, to flatter their pride, in-
dulge their pleasures, comine at their irregularitics, and to
purchase their precarious faith by a liberal donation, which,
from the elevation of Claudius, was exacted as a legal claim,
on the accession of every new emperor. The power which
they afforded by arms, their advocates attempted to justify
by arguments; and maintained that, according to the purest
principles of the constitution, their content was essentially
necessary in the appointment of an emperor. The pretro-
rians, having violated the sanctity of the throne, by the
atrocious murder of Pertinax, disinherited the majesty of it
by their subsequent conduct. Sulpicianus, the emperor’s
father-in-law, and governor of the city, treated with
them for the imperial dignity; but some of the more prud-
ent of the pretorians, apprehending that by a private con-
tract they should not obtain a just price for so valuable a
commodity, ran out upon the ramparts, and loudly pro-
claimed, that the Roman world was to be disposed of to the
bell bidder by public auction. This infamous offer at length
reached the ears of Didius Julianus, a wealthy senator,
March 28th, A.D. 193; and he determined to outbid Sul-
picianus, who was in actual treaty for the crown. The
latter had actually offered a donation of 5000 drachmas
(above 160l.) to each folder; when Julian, eager for the
prize, advanced at once the sum of 6250 drachmas, or up-
wards of 200l. sterling. The bargain was immediately con-
cluded, and he was declared emperor. But the day of his
elevation to the throne was followed by a sleepless night,
during which he probably revolved in his mind his rash folly,
the fate of his virtuous predecessor, and the doubtful as
well as dangerous tenure of an empire, which had been pur-
chased by money, and not acquired by merit. He soon
found himself on the throne of the world without a friend,
and without an adherent. The guards themselves were
affrighted of the prince whom their avarice had induced them
to accept; nor was there a citizen who did not consider his
elevation with horror, as the last insult on the Roman name.

When the Pannonian legions, by which Septimius Severus,
his commander, had been saluted with the names of Au-
gustus, Pertinax, and Emperor, April 13th, A.D. 193, were
advancing towards Rome, Julian found himself reduced to
a state of the utmost distress; and in order to protract his
ruin, implored the venal faith of the pretorians, who,
affrighted of utterly abandoning him, and yet trembling at
the name of the Pannonian legions, put on arms with re-
liance. At length, however, he was defeated even by the
pretorians; and condemned and executed by order of the
senate, June 2, A.D. 193. Before the new emperor entered
Rome, he issued his commands to the pretorian guards,
directing them to wait his arrival on a large plain near the
city, without arms, but in the habits of ceremony, in
which they were accustomed to attend their sovereign.
The haughty troops obeyed his mandate with a contumtion,
which was the effect of their just terrors. A chosen part of
the Illyrian army encompassed them with levelled spears.
Severus mounted the tribunal, and having sternly reproached
them with perfidy and cowardice, disinfamed them with igno-
miny from the trait which they had betrayed, deplored
them of their splendid ornaments, and banished them, on
pain of death, to the distance of 100 miles from the capital.
During the transaction, another detachment had been sent
to seize their arms, occupy their camp, and prevent the
hafty consequences of their despair. The pretorians, who
had murdered their sovereign, and sold the empire, thus re-
ceived the just punishment of their treason.

The next object to which Severus directed his attention
was
was an institution of guards, formed on a new model, and increased to four times the ancient number. The emperor flattered himself that these newly chosen pretorians would be regarded by the legions as the representatives of the whole military body, and that the sudden aid of 50,000 men, so well selected and armed, would for ever crush the hopes of rebellion, and secure the empire to himself and his posterity. The command of these troops was entrusted with an officer, designated the pretorian prefect. See PRE, PRETORIAN.

By the prudent measures of Diocletian, the number of the pretorians was infinitely reduced, their privileges were abolished, and their place was supplied by two faithful legions of Illyricum, who, under the new titles of Jovians and Herculeans, were appointed to perform the service of the imperial guards. The pretorians, having taken a decided and active part with Maximus against Constan-tine, knew that their offences were beyond the reach of mercy; and, therefore, in the battle between these two leaders, fought near Rome, October 28th, A.D. 312, they were animated by revenge and despair. Notwithstanding their repeated efforts, these brave veterans were unable to recover their victory; they obtained, however, an honourable death; and it was observed, that their bodies covered the same ground which had been occupied by their ranks. The pretorian guards, whose numbers and privileges had been restored, and even augmented, by Maxentius, were for ever suppressed by Constantine. Their fortified camp was destroyed, and the few who had escaped the fury of the sword were dispersed among the legions, and banished to the frontiers of the empire, where they might be serviceable, without again becoming dangerous. Gibbon's Hist. vols. i. and ii.

PRETORIUM, PRETORIUM, among the Romans, the place, hall, or court, wherein the pretor of a province lived, and wherein that magistrate sat to administer justice to the people.

There were of these pretoriums in all the cities of the Roman empire. The scripture mentions that of Jerusalem under the name of judgment-hall; and there are still some remains of one at Nîmes, in Languedoc.

Pretorium was also the tent or pavilion of the general of the Roman army; wherein councils of war, &c. were held.

From the time of Augustus, the emperor's tent in the camp was distinguished by the title of pretorium Augustale.

Pretorium was also a place in Rome where the pretorian guards were lodged.

Some will have the pretorium to be properly the tribunal of the praefectus praetorio, or an auditory defined for the rendering of justice in the emperor's palace. See PREFECT and PRETORIAN GUARDS.

This they argue from St. Paul's Epistle to the Philippians; and from this place called pretorium, they will have the guards to have been denominated pretorians, because assembled here for the emperor's safety.

Others will not allow the pretorium to be any tribunal, or seat of justice, but merely the imperial guard-house.

Perizonius has an express dissertation to prove, that the pretorium was no court of justice in St. Paul's time; but the camp or place where the pretorian guards were quartered.

He adds, that the name pretorium was not given to places where justice was administered till a long time after; when the office of the praefectus praetorio was converted into a civil function.

PRETCH, in Geography, a town of Saxony, on the Elbe; 50 miles N.W. of Dresden. N. lat. 57° 42'. E. long. 12° 48'.
PRETTIGAU, a valley of the Helvetian republic, in the Grisons, east of Mayenfold.

PRETTIN, a town of Saxony, on the Elbe; 20 miles S.S.W. of Wittenberg. N. lat. 51° 37'. E. long. 13°.
PRETZ, a town of Germany, in the county of Plun- dentz, near the river Alvens; 3 miles E.N.E. of Plun- dentz.
PRETZCHENDORF, a town of Saxony, in the circle of Erzgebirg; 7 miles E. of Freyberg.
PRETZLAU, a town of Prussia, in Pomerelia; 15 miles E. of Dautzic.

PREVARICATION, PREVARICATIO, in the Civil Law, is when the informer colludes with the defendant, and so makes only a feigned prosecution.

Sylvius, in his comments on Cicero, pro Cluentio, gives us the difference between the three terms, calumniari, pretorians, &c.

PREVARICATION, in our Law, is when a man, falsely and deceitfully seems to undertake a thing, with intention that he may destroy it; e. g. where a lawyer pleads booty, or acts by collusion, &c.

PREVARICATION is also used for a secret abuse committed in the exercise of a public office, or of a comminution given by a private person.

PREVARICATOR, PREVARICATOR, in the University of Cambridge, is a master of arts, chosen at a commencement, to make an ingenious satirical speech, reflecting on the misdemeanors of the principal members. See TERR. Filius.

PREVENTER, an additional security to some parts of a ship and her rigging, as the Preventer-bolts, the bolts driven through the lower end of the preventer-plates, to affix the chain-bolts in heavy strains.

Preventer-plates, flout plates or links of iron, connected to the main and fore chains by large bolts driven through their upper and lower ends.

Preventer-braces, preventer-fibrouds, preventer-flaps, are additional ropes to secure the masts and yards in a gale of wind, when those have affinity to are not supposed sufficient to bear the whole strain. See Tacke.

Preventer-brace pendants are intended as substitutes for the brace-pendants, should they be shot away in action. See Pendant.

PREVENTION, PREVENTIO, in the Canon, &c. Law, the right which a superior preferer or officer has to lay hold of, claim, or transfact, an affair, prior to an inferior one, to whom otherwise it more immediately belongs.

The word is chiefly used in speaking of the pope's preventing the ordinary collators; and of the royal judges preventing jubilatians ones.

The Roman canonists maintain, that the pope, who is the source of all juridiction, has not transmitted it privately to the ordinary collators; but that he may still not only collate concurrently with them, but he also may prevent them by using his original power as head of the church.

These preventions are grown odious in several countries, where they do not now obtain without many modifications and
and restrictions; and the civil power in France always judges in favour of the ordinary collators.

The pope has no prevention to the prejudice of lay-patrons; but by the concordat he has referred to himself the right of conferring elective benefits by prevention, and even cathedral and collegiate dignities.

If the provisions of the pope, and collations of the ordinary, bear date on the same day, the ultramontane canons give the preference to the pope; the French to the ordinary.

The cardinals have a particular indulgence not to be prevented by the pope within six months. See Expectative Grace, and Provisions by Prevention.

Prevention, Homicide for. See Homicide.

Preventive Justice, in the English Laws, consists in obliging those persons, who are suspected on probable ground of future misbehaviour, to stirulate with and to give full assurance to the public, that such offence as is apprehended shall not happen, by finding pledges or securities for keeping the peace, or for their good behaviour. Such means of preventing the comminution of crimes and misdemeanors reflect honour on the system of English jurisprudence; since Preventive justice is, on every principle of reason, of humanity, and of found policy, preferable in all respects to punishments. See Good Abating, Recognition, and Surety.

Prevesa, in Geography, a town of Albania, on the coast of the Mediterranean, at the entrance into the gulf of Arta, situated on the site of Nicopolis, built by Augustus after the battle of Actium; 20 miles S.W. of Arta. N. lat. 30° 22'. E. long. 20° 40'.

Preuilly, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Loches, near which are some iron mines; 11 miles N.E. of Poitiers. The place contains 1680, and the canton 9402 inhabitants, on a territory of 275 square kilometres, in 9 communes. N. lat. 45° 51'. E. long. 0° 30'.

Prevot d'Exiles, Antony-Francis, in Biography, a French writer, born in 1697; was educated among the Jesuits, and took the habit of the society, which he soon quitted to bear arms in quality of a volunteer. Being disappointed in his expectations, he retired in 1729 into Holland. Without means of subsistence he fought a referece in his pen, and published his "Memoires d'un Homme de Qualité qui s'est retiré du Monde," a romance, by which he acquired both money and reputation. It was written in a pure and elegant style, and with an elevated strain of morals. In 1733 he came to London, but meeting with little or no encouragement he returned to France, and assumed the costume of an abbé. He was now taken under the protection of the prince of Conti, who gave him the titles of his secretary and chaplain. He gave proofs of his industry by the publication of a number of works, and in 1745 he was elected by the chancellor d'Aguesseau to compose a "Generall History of Voyages." This work, though it occupied much of his time, did not prevent him from engaging in a variety of literary labours, which were for the most part successful. In November 1763, on his return from Chantilly, where he had been for his health, he was seized with an apoplectic fit, and being found apparently lifeless in the forest, the officers of justice hastily assembled, and directed his body to be opened to ascerten the cause of his death. It is said, that on the first stroke of the surgeon's knife he uttered a cry, and opened his eyes, but it was too late, a mortal wound had been inflicted, and he died in a short time. The abbé Prevost was a ready writer: of his original compositions; the most distinguished are his romances or novels. He wrote several works, in which history is blended with fiction, as the "Histories of William the Conqueror, and of Margaret of Anjou." He conducted a periodical work entitled "Le Pour et Contre," of which 20 vols. 12mo. were published. His great work was "L'Histoire generale des Voyages," 16 vols. 4to. He translated De Thou's History, Cicero's Familiar Epistles, and a number of English works, among which were the Clariss and Sir Charles Grandison of Richardson; the manner of this writer may be traced in his own novels. Gen. Bio.

Preuschmark, in Geography, a town of Prussia, in the province of Oberland, defended by a castle; 70 miles S.W. of Königsberg. N. lat. 53° 48'. E. long. 10° 22'.

Preysel, a town of Prussia, in Ermland; 6 miles S.E. of Elbing.

Preuschwitz, a town of Germany, in the principality of Cumbach; 5 miles W. of Bayreuth.

Prex, or Prèse, a sea-port town of Africa, in the kingdom of Kanton.

Prez-en-Pail, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Mayenne; 8 miles N.N.E. of Vilaine. The place contains 2835, and the canton 11,371 inhabitants, on a territory of 1524 square kilometres, in 7 communes.

Prezimislaus, a town of Bohemia, in the circle of Czaflau; 8 miles E. of Teutich Brod.

Prezerbe, a town of Brandenburg, in the New Mark, on the Havel; 5 miles N. of Brandenburg.

Pria, a town of Spain, in the province of Aitana, near the sea-coast; 40 miles E.N.E. of Oviedo.

Pria, in Biography, the unfortunate king of Troy, at the time of its destruction, was the son of Laomedon, and when Troy was taken and his father flain by Hercules, he was carried away captive into Greece with his sister Hecione. He succeeded to the throne of Laomedon, and to prevent a renewal of the disaster which had befallen his capital, he surrounded it with strong walls. The discovery of a gold mine on his territories enabled him to undertake many public works, and to decorate Troy with stately edifices, so as to render it the most splendid city in that part of the world. He raised and maintained a considerable army, which enabled him to extend his dominion, till at length he was regarded as the most powerful prince of Lesser Asia. His first wife was Arisba, by whom he had only one son; but his second wife was Hecuba, who made him father of a numerous family. He lived in great prosperity till the perdition of his son Paris, in carrying off Helen, the wife of the Spartan king Menelaus, by whom he had been hospitably entertained, brought upon him that invasion from the confederated kings of Greece, which is so celebrated under the name of the Trojan war. After a struggle of ten years, in which he faw his territories laid waste, and his bravest sons slain, the capital taken, he was himself slain at his own domestie altar by the savage Pyrrhus, the son of Achilles. The death of Pria and the fall of Troy are dated in the year 1184 B.C. Univer. Hist.

Priam, in Geography, a sea-port town and district of Acheea in the island of Sumatra, on the W. coast, where the English and the Dutch had formerly settlements, and where the principal quantity of pepper was procured. The town is situated on a river too shallow for pinasses, except at high water. Here is no fort, but a square, palisaded with four bastions and a ditch. The air is healthy, and gold is found in the river. S. lat. 0° 40'. E. long. 99° 38'.

Priape de Mer, in Natural History, a name given by the
the French to a peculiar species of canalis, or tubulus marinus, called also, by some authors of that nation, the arrafrain.

It is an oblong and thick shell of this kind, with a large head, which is pierced through with a great number of holes, so as at once to resemble, in some sort, the glans of the penis, and the head of a common gardener’s watering pot. This species is found at Ambroix.

PRIAPIA, in Poetry, a name given to certain obscene epigrams, and other pieces, composed on the god Priapus; of which we have many instances in the Greek Cataleia. See PRIAPUS.

PRIAPISCUS, in Surgery, a bougie, or tent.

PRIAPISM, a continual and painful erection or tension of the virile member.

The term is derived from Priapus, a heathen god, whom the poets and painters represent in a state of erection.

As Satyrs are usually painted after the same manner, the disease is also called satyriasis, or satyrism.

Some, however, distinguish between the satyriasis and priapismus, in that the latter is without any effusion, or discharge of cution; it is the former attended with both.

The immediate cause of a priapism is the heat, pungency, or acidity of the semen, accompanied with a convulsion of the muscles of the part, which, compelling the veins and cavernous bodies, prevent the return of the blood.

The more remote causes are too hot, sharp, stimulating foods; cantharides are also found to produce the same effect, but with much more violence. There are infinities of people, especially old persons, who, making use of cantharides to enable them to satisfy their passions the better, have been seized with a priapism, which has been followed with universal convulsions, and even death.

With regard to the priapism, chordee, and other distortions of the penis, in the venereal disease, their treatment is the same with that of the gourreau. When they prove very troublesome, the patient may take a few drops of laudanum at night, especially after the operation of a purgative through the day.

PRIAPOLITHUS, a name given by some authors to a stone found about Calirio in Italy, which very aptly resembles the figure of the human penis.

PRIAPUS, 

PRIAPUS,

PRIAPUS,

PRIBODA, in Geography, a town of Sweden, in the province of Smoland; 76 miles S.W. of Carlzon.

PRIBORN, a town of Silezia, in the principality of Brieg; 18 miles S.W. of Brieg.

PRICE, JOHN, in Biography, a famous English performer on the common flute, in the service of Lewis XIII. of France, celebrated by Merfennus, lib. 2. de Instrum. Harmonie. Prop. 2.

PRICE, RICHARD, a celebrated writer of the 18th century, the son of a dissenting minister at Bridge-end, in Glamorganshire, was born at Ty-yon-ton, the 22d of February 1733. He received his grammar-learning at Neath, whence he removed, in 1735, to Pontyay, in Carmarthenshire, where he was placed under the care of the Rev. Samuel Jones. Being designed for the ministerial profession, he was, after continuing under Mr. Jones’s instructions about four years, sent to the academy of the Rev. Vavafor Griffth, at Talgarth, in Brecknockshire. Our author’s father was, in his religious sentiments, a rigid Calvinist; but he himself, while very young, had been inspired by his tutor, Mr. Jones, with a desire to think for himself; and began at an early period to start doubts on the subject of predetermination, and other points of the Calvinistic creed, by which he sometimes incurred the anger of his father, who could not endure to hear any thing advanced against, or that might seem to shake his favourite system. Being one day caught in the act of reading a volume of Dr. Clarke’s sermons, his father snatched away the book, and threw it in the fire. Such a line of conduct was not calculated to repress the young man’s curiosity. But the zeal of the parent went much beyond this, and was supposed to have influenced him in bequeathing a small part of his property only to Richard, on account of his devotions from the line of orthodoxy, falsely so called; while he left a considerable fortune to his elder brother by a former marriage. By the death of his father...
father and mother in the years 1739 and 1740, Richard was left, in a considerable degree, dependent on his uncle, the Rev. Samuel Price of London, who was co-pastor with Dr. Watts; and he was accordingly removed from Talgarth to London, and entered a student in the academy, of which Mr. Eames was the principal tutor. Here he cultivated with great diligence and success the different branches of academical learning, particularly the mathematical sciences and moral philosophy, in which he hereafter acquired an unfaiding reputation. For the direction of young students, who may be ambitious of following the steps of this great and good man, and whose labours have proved so beneficial to the country and the world, we will add that the books which he read were select rather than numerous; but he studied them with the closest attention; and the more strongly to impress the matter on his mind, he early commenced an excellent practice, which he continued for many years, viz., of drawing up analyses of them in his commonplace book. After refading at Mr. Eames's academy for four years, he became domestic chaplain to Mr. Streetfield of Stoke-Newington; which situation, while it gave him ample leisure for study, afforded him opportunities of affiling with his services the ministers and congregations in and about London. In 1757 he married, and in the following year he settled at Newington-Green, and became pastor of the congregation there. In this same year Mr. Price made his first appearance as an author, in a work entitled "A Review of the principal Questions and Difficulties in Morals, particularly those relating to the original of our Ideas of Virtue, its Nature, Foundation, Reference to the Deity, Obligation, Subject, Matter, and Sanctions," 8vo. The scheme of morals which he adopts depends chiefly upon the hypothesis, that the power which perceives and determines concerning actions is the understanding, and not the moral sense, as maintained by Dr. Hutcheson. For this he contends, in order to establish the important inference, that morality is immutable and eternal, not the arbitrary production of any power human or divine, but equally everlasting and necessary with truth and reason. Having laid the foundation of his system, he applies it to the exposition and proof of some of the principal doctrines and facts of natural religion, particularly the moral attributes of God, his moral government, and a future state of rewards and punishments. This work, which was written with great ability, advanced the author at once to a very respectable rank among moral and metaphysical writers; and it was acknowledged, by all capable of appreciating its value, to be the most able defence of these principles in the English language. A new edition, being the third, of the volume, with considerable improvements, was published in 1787. In the preface Dr. Price says, it was published "thirty years ago, and was then the author's first production, and contained the result of some of his earliest thoughts. A careful revision has now made it the result of his latest and maturest thoughts." To this edition is added a Dissertation on the Being and Attributes of the Deity. To return to the author:—in the year 1763, he was chosen afternoon preacher to the congregation in Poor Jewry Street, London, which had enjoyed the ministerial services of a Benfon and a Lardner. About the same time he was elected a fellow of the Royal Society of London, to whose Transactions he had been a frequent and valuable contributor. In 1767 he published Four Dissertations: 1. On Providence. 2. On Prayer. 3. On the Reasons for expecting that virtuous Men will meet after Death in a State of Happiness. 4. On the Importance of Christianity, the Nature of historical Evidence, and Miracles. These dissertations, in which it has been justly said "philosophy and piety form a happy union," have gone through several editions.

In the year 1769, the university of Aberdeen, out of pure respect to Mr. Price's extraordinary merits, presented him with the diploma of doctor of divinity. In the following year he was chosen pastor of the congregation at the Gravel-pit meeting, Hackney, where he became distinguished as a most impressive and interesting preacher. His next work, which appeared in 1771, was entitled "Observations on Reversionary Payments; on Schemes for providing Annuities for Widows, and for Persons in old Age; on the Method of calculating the Values of Annuities on Lives; and on the National Debt," &c. The advice and instruction contained in this book were peculiarly excellent, as various societies, professedly for the benefit of aged persons and widows, were at that time continually rising up, which, as they were founded on false principles, threatened to be productive of the most alarming evils. By the publication of this work of Dr. Price, many of the societies were induced to reform their plans; others were defrayed by the public; and some, which were needless of admonition, speedily came to ruin. After three editions of it had been fold, the author prepared a fourth, which he published in 1783, in 2 vols. 8vo. To the subsequent editions, of which there have been several, a very able general introduction has been prefixed by the author's nephew, William Morgan, esq., the distinguished author of the "Society for Equitable Annuities on Lives and Survivorships," who has likewise improved the body of the work by notes, tables, &c. the result of many years' experience. One chapter in this work contains interesting observations on public credit, and the national debt; points out the erroneous policy of that misapplication of the sinking fund, which, with the consent of parliament, ministers had practised from the time of Sir Robert Walpole, and demonstrates the efficacy of such a fund, when inviolably applied, in extinguishing the public debts, and effectually contributing to promote national security and welfare. These important topics were further discussed in a work, entitled "An Appeal to the Public on the Subject of the National Debt," which was published in 1772. During the civil war, which terminated in the independence of the American colonies, Dr. Price united with those true friends to the country, who protested against the injustice and madness of those proceedings, the issue of which justified their predictions. It was at this period he published his "Observations on the Nature of Civil Liberty, the Principles of Government, and the Justice and Policy of the War with America." In these Observations, his notions of government correspond with the principles taught by Locke, and all the writers on civil liberty, who have been most admired in this country; and he demonstrated the measures pursued by administration against America to be inconsistent with justice, the principles of the constitution, and the honour of the kingdom. For this work the common council of London, as a testimony of their approbation of the principles inculcated in it, presented the author with the freedom of the city in a gold box. In 1778 he published "Additional Observations on the Nature and Value of Civil Liberty, and the War with America," &c. Dr. Price also published, at the same time, a general introduction to both pieces, and a supplement. The next publication in which Dr. Price was concerned, was "A Free Difcussion of the Doctrines of Materialism and Philosophical Necessity," in a correspondence between Dr. Price and Priestley. In 1779 our author addressed some important observations to the "Society for Equitable Annuities," in an introduction to a work by his nephew,
nephew, Mr. Morgan, on "The Doctrine of Annuitants," &c. To the exertions of this excellent man, and the indefatigable zeal of his nephew, the prosperity of that society, on which the happiness and even existence of thousands are continually depending, is almost entirely owing.

When the earl of Shelburne was prime minister, he fought the affiance of Mr. Pitt in forming a scheme for paying off the national debt, and moved an introductory resolution on that subject in the house of lords; but upon his being driven from office, the scheme was abandoned. It was, however, communicated to the public by Dr. Price in a treatise, entitled "The State of the public Debts and Finances," at filing the preliminary Articles of Peace in January 1783; with a Plan for raising Money by public Loans, and for redeeming the public Debts." After this, when Mr. Pitt determined to introduce a bill into parliament for liquidating the national debt, he applied to Dr. Price for his advice on the subject, and received from him three separate plans: one of which, said to be the least efficient in its operation, was adopted by the minister, though without the slightest acknowledgment of his obligations, and now forms the foundation of that act for reducing the public debt, which was established in 1786, and has contributed more than any other, or all other measures, to raise the credit of his administration. See Pitt.

In the year 1784 Dr. Price published "Observations on the Importance of the American Revolution, and the Means of Making it useful to the World," which observations breathed an ardent spirit of virtue and benevolence, and afforded salutary advice on various important points highly interesting to the new government. To these observations are added a letter from M. Turgot, containing remarks which merit the attention of all free governments; and the last paper of M. Fortune Ricard, which exhibits an amusing, and rather humorous application of Dr Price's account of the powers of compound interest, and the uses to which it may be applied for the benefit of mankind. In 1786 he published a volume of sermons, partly on practical, and partly on doctrinal subjects: in the latter he states, and defends with animation and zeal, the Arian hypothesis, to which he himself was attached, again! Trinitarians on the one hand, and modern Unitarians on the other. The practical sermons, on the security and happiness of a virtuous course, on the goodness of God, and on the resurrection of Lazarus, are replete with the foundered reasoning, and the most glowing eloquence.

The other publications of this excellent divine, which chiefly attracted notice, were two sermons preached before his congregation at Hackney, on the fall days, in 1779 and 1781:—A sermon on "The Evidence of a Future Period of Improvement in the State of Mankind, with the Means and Duty of promoting it, delivered to the Supporters of the new Academical Institution among Protestant Dissenters," in the year 1787; and his "Discourse on the Love of our Country," preached the 4th of November, 1789, before the society for commemorating the revolution of 1688 in Great Britain. In this last discourse Dr. Price displayed his well-known zeal for the great principles of civil and religious liberty, and towards the conclusion of it, he adverts with triumph to the revolution in France, which, in its origin augured well for the happiness of the world; and it was hoped by unnumbered thousands at that time, as well as by the benevolent and kind-hearted doctor Richard Price, that it was a prelude to a general amendment in human affairs, and that hereafter, and at no great distance of time, "the dominion of arbitrary kings would be changed for the dominion of laws; and that the dominion of priests would shortly give way to the dominion of reason and conscience." Such a prospect he thought could not but be peculiarly gratifying to Englishmen who understood, and valued their own rights and privileges. There were, however, others who lamented over the downfall of tyranny in France, and who were at this period advocates for the divine rights of kings, notwithstanding their present principles held all the former acts and exertions of their past lives. These, because they could not procure reason and argument in justification of their notions, descended to the vilest calumnies, and made his whole life one of those they were deficient in truth and justice. The head of the flood the late Edmund Burke, who in his speeches in parliament, and in his work entitled "Reflections on the Revolution in France," endeavoured to expose Dr. Price to public odium, by libellously, and contrary to his better knowledge, describing him, who was one of the most benevolent of all men, as existing in the horrid outrages committed by the infuriated French populace, and by loading him with such epithets of contempt as his exuberant imagination, uncontrolled by any regard to truth or decency, could supply. The invectives and abuse of the senator, shortly afterwards admitted on the lists of pensioners, Dr. Price thought him beneath his notice; but in a preface to a new edition of his discourse, he vindicated his principles and conduct perfectly to the satisfaction of the unprejudiced part of the public. He was hastily drawing to his end. He had, in the year 1786 lost his lady, and in Februay 1791 he was feized with a fever, the effects of a severe cold, which he took while attending the funeral of a friend; from the effects of this he was gradually recovering, when he was attacked with a fever and very painful disorder, by which he had been many years threatened. This he bore with fortitude and resignation, though occasionally his spirits and strength were entirely exhausted by the agonies which he endured. He died on the nineteenth of March 1791, in the sixty-eighth year of his age, beloved by all who had the honour of his acquaintance, and respected by the wife and the virtuous capable of appreciating his labours, and the value of the services which he performed for his country and the world.

Of Dr. Price's distinguished abilities as a mathematician, moralist, and lover of his country, we have given ample proof. In his profession as a dissenting minister he was ardent and zealous, anxious to promote the best interests of those who attended his services. In the pulpit his manner was natural, and very earnest; and in his devotional exercises, there was a degree of fervour, which indicated the strongest sensibility as well as sincerity in himself, and which communicated its warmth to those who joined with him. He was for many years one of the trustees to the estates of the late Dr. Daniel Williams, which is the most important concern belonging to the London Dissenters. Among the applications of the dissenting ministers to parliament, from 1772 to 1779, for relief from subscription to the articles of the church of England, required by the act of Toleration, he was chosen one of the committee appointed to concert and pursue the necessary measures for obtaining that object; but when he found that it could not be obtained without a declaration of faith in the holy scriptures, which, as continued the civil magistrate had not right to demand, he declined with firmness. When his brethren were driven against the rest of the constitution, framing an enlargement of religious liberty on terms which, according to their views of things, and according to the true principles of dissent, implied submission to the authority of the civil magistrate in matters of conscience, to whom, in matters of this
this kind, they owed no obedience whatever. In 1753, the degree of LL.D. was conferred upon him by Yale college, in Connecticut, and he was afterwards elected a fellow of the American Philosophical Societies at Philadelphia and Boston. In the year 1786, when a new academic institution among the Difficulties was established at Hackney. Dr. Price was appointed tutor in the higher branches of the mathematics; to three of the pupils he gave some lectures, but he soon resigned the office into the hands of his nephew the Rev. George Cadogan Morgan, of whom we may, having omitted it in its proper place, lay a few words.

This gentleman, whole father was a respectable surgeon at Bridge-end, Glamorganshire, and mother the sister of Dr. Price, was born in 1754. He was intended for the church, but being dissatisfied with the articles, he entered himself as a pupil in the dissenting academy, then under the direction of Drs. Savage, Kippis, and Rees. In 1776 he settled as a minister with a congregation at Norwich. Here he resided till 1785, when he removed to Yarmouth, which he left in the following year, in order to join his uncle at Hackney. Here he became afternoon preacher at the Gravel-pit meeting, and lecturer at the New College.

These offices he resigned about the year 1792, and employed his great talents in educating a select number of young people in his own house. He died at Southgate on the 17th of November 1798, at the early age of forty-four, sincerely regretted by all who knew him. He had, about four years before his decease, given the world a work in two volumes, entitled "Lectures on Electricity," which has long since been out of print. He is known also by a valuable and important paper, communicated in the year 1785 to the Royal Society, containing "Observations and Experiments on the Light of Bodies in a state of Combustion." This paper was published in the 75th volume of the Philosophical Transactions. He was an advocate for the principles of Stahl, in opposition to the fyltem of Lavoisier and the French chemists. (See Philogiston.) He was a man of inceent application, rofe very early, and often studied to a late hour. In the pursuit of science he was ardent and enthusiastic. The ardour which glowed in his own breast, he had the happy art of infusing into the minds of others. He was a warm and hearty friend, and ever ready to afford assistance to those who flood in need of his aid and friendly counthence, as numbers now living can testify, among whom the writer of this article rejoices in the opportunity of ranking himself.

But to return to Dr. Price: besides the articles already mentioned, he published some finge sermons, and contributed various papers to the Philosophical Transactions, which may be found inserted in different volumes from 1753 to 1786. Among his numerous correspondents, were the marquis of Lansdowne, the earls Chatham and Stanhope, the bishops of Carlisle, St. Asaph, and Llandaff, Mr. Harris, the author of Philosophical Arrangements, &c., Mr. Howard, Dr. Franklin, the duke de Rochecoustaiss, the celebrated Turgot, and several of the most distinguished members of the first national assembly. We shall close this article with the character of its subject, as it is partly given by one of his biographers. Though briefly attentive to the obligations of domestic life, he did not suffer his private affections to encroach upon his social duties. His talents and labours were ever ready at the call of friendship; nay, so much did his nature abound with the milk of human kindness, that he could not relish, without extreme reluctance, even troublesome and unseasonable solicitations. His hours of study and retirement were frequently broken in upon for assistance and advice, especially in matters relating to am-

itutudes and life assurances; and in this way he sacrificed much of his personal convenience to individuals of whom he knew but little, and from whom he would accept of no pecuniary recompense. A fifth part of his annual income was regularly devoted to charitable purposes; and he was laudably anxious to distribute the remainder in such a way, as might produce the greatest good. Simplicity and humility were among the strongly marked features of his character. No man was ever apparently less fitted of his own excellences, nor less elated by his own celebrity; and in no man was the dignity of artifts manners and unaffected modesty more happily displayed. His face was the true index of his mind. It beamed with philanthropy, and when lighted up in conversation with his friends, adorned an aspect particularly pleasing.

Price, in Political Economy, is the exchangeable value of a commodity for which it may be procured at pleasure. As the value of the acknowledged general medium of exchange is universally known, it is most peculiarly adapted to mark the price of commodities in general. Hence price may be defined a certain proportion of the general medium of exchange, deemed equal to the value of the thing or things to be obtained for it in exchange; in other words, price is the equivalent of a commodity expressed by the general medium of exchange. The bare amount of the pieces of money, or of other things to be given for a commodity, constitutes its nominal price; the influence of the three producing powers, labour, land, and capital, in the production of the commodity, expressed by the value in money which must be given to obtain it, constitutes its real price. Advances necessary to obtain a commodity are called costs. The aggregate of the costs, which the production or original acquisition of a commodity required, may be denominated its total cost; and the price at which a commodity may be purchased at pleasure constitutes its market price. The cost price depends on the price of the causes necessary to produce a commodity, or to make its primary acquisition. These causes are either necessary, that is, such as lie in the nature of the commodity itself, and without which it could not have been produced or acquired; or they are voluntary, that is, such causes might have been dispensed with: or they are accidental, that is, they have their foundation in certain adventitious circumstances. When the price of a commodity is only the equivalent to the necessary causes of its existence, it is called its natural price; when it is a compensation for the voluntary causes of its existence, it is an artificial price; and when it is a compensation for adventitious causes, an accidental price.

The necessary efficient causes, through one or the other of which, singly or combined, any commodity is originally sent to market, and without either one or the other of which no commodity can be produced or acquired, are: 1. Land or soil, which is the ashes of our existence, and of all our operations; and furnishes us with all kinds of useful raw materials. 2. Labour, which is indispensable to obtain food, and to provide us with convenient dwellings. And 3. Capital, or a stock previously accumulated to afford advances, pay wages, and procure implements, tools, engines, &c. without which many labours could not be performed.

As land, labour, and capital, have a share in the producing of almost all commodities, every commodity produced, or its value, must be divided among those who produced it, in proportion to the share they had in its production. One part is allotted to the landlord, another to the labourer, and a third to the capitalist. If a single individual should be landlord, labourer, and capitalist, the whole commodity, or the whole of its value, would of course belong to him alone.

The
PRICE.

The land-owner may lend his land to the capitalist or to the labourer: the capitalist may lend his capital or stock to the labourer or the land-owner; and the labourer may lend his industry to one or both of them. And as neither is willing to lend the source from which he may obtain useful things for nothing, the individual to whom it is lent must give in return part of the commodity which the use of the loan helps him to gain, either in kind, or its value in any other acceptable commodity. What the labourer receives for the loan of his industry, is called the wages of labour; whatever is received for the use of a capital is called profit of stock; and what is received for the mere permission to use a portion of land or soil, is called rent. The proper employment of capital requires diligence, ability, and a certain degree of resolution, as the want of such qualities frequently induces owners of capital to entrust it to the use of others. In this case the owner of the stock is particularly called a capitalist, and the individual who employs the stock has been sometimes denominated an undertaker. The Proportion of Stock, (which fee,) must in such instances be divided, in certain proportions, between the capitalist and undertaker.

As individual interest is universal in the human race, and no man either labours, or lends a portion of his soil or of his stock for nothing, no commodities would be produced, if the necessary causes of their production were not compensated, that is, if those who contribute to their production did not receive some compensation. Consequently, the first or cost price of all useful commodities must afford an equivalent for the wages of the labourer, the profit of the stock, and the rent of the soil employed in the production. Wages of labour, profit of stock, and rent, are the elements into which the original value of all commodities may ultimately be resolved: they are the elements of the cost price of every useful thing. Every cost price does not comprize all three elements together, because it is not every thing that requires the co-operation of the three efficient causes towards its production, but the prime or cost price of no commodity can be composed of any other elements, and when a commodity ceases to obtain its cost price, it ceases to be produced, and whether the price of the elements or causes of the commodity be natural or artificial, it must always be fully replaced if the commodity is to be further produced or brought to market. The price of every thing, in fact, is regulated by the price of the elements of which it is composed. This price is, however, fluctuating, the causes of which we shall soon point out; but previously to this it will be necessary to inquire into the circumstances which regulate the market price, and to shew in what it deviates from the cost price.

The chief inducement to produce any commodity, or to accumulate a stock, is the probability that there will be a demand for them, and of course will meet with purchasers. But to become purchasers, people must not only wish for the commodity, but must have wealth sufficient, or a surplus of commodities to give in exchange. The desire to be possessed of a thing, combined with the means of acquiring it, is called the demand. The demand for a commodity, or the anticipation of a demand for a commodity, is the primary cause why it is produced, or a stock of it provided; those who wish for it must offer to give, at least, the whole cost price for the commodity. As soon as this is the case, many individuals are ready to satisfy that demand, and the owners of the article in demand look out for purchasers: this looking out for buyers is called the offer for sale. If the offer for sale and the demand were always equal, commodities would always bring their prime or cost price. But as this equality is frequently destroyed, it often happens that
actual abundance or scarcity of goods relatively to the demand, must always have a great influence on the fluctuation of the price of commodities. The increase of some of them depends, moreover, on chance, or such causes over which man has no sort of control; while the increase of others rests in a great degree on the will of man. If chance be more favourable to one seller or one grower of a commodity than to another, the sale favoured one is obliged to sell at the same price with the fortunate one, and probably under prime cost. The market price of such articles may more frequently, and for a longer time, deviate from the cost price, than the market price of such, of which the quantity is determined by man's free will. The quality of some goods, or their perishable nature, enforces also a quicker sale than that of others. Yet the cost price is the constant regulator of the production of goods; it is the price of the causes of the origin of commodities.

The rate may influence the price of commodities in a twofold way, either by increasing the charges or cost of their production, or by positive enactments which limit their sale and purchase. The former is chiefly effected by taxes, the latter by legal regulations. The amount of the duty laid on a certain article, or the sum by which the tax increases the wages of labour, the profit of flock, and even the rent, which are the efficient causes of that produce, is the proportion in which the cost price is raised by the tax; its market price must of course rise in the same proportion if there be no alteration in any of the other circumstances which influence the price of goods.

Prices are, in general, raised. 1. By exclusive rights granted to one or a few individuals, as is the case with monopolies, chartered companies, corporations, &c. 2. By laying heavy duties on the importation of foreign goods, or prohibiting them altogether. 3. By limiting the use of the soil. And 4. By favouring the exportation of certain commodities by means of bounties.

Prices are kept low, 1. By an unrestrained freedom of trade and commerce. 2. By regulations favouring the labours of a particular class, which invite others to the same labour, and lower the price of the produce. 3. By regulations which exclude a number of buyers from the purchase of a certain produce. But these lower the price of that produce only as long as the number of purchasers is not increased in another quarter, or as long as the produce is not reduced in proportion to the small number of buyers. Prohibiting the exportation of corn seldom causes much reduction in the price, for the fear of a scarcity increases the number of purchasers, and diminishes that of the sellers.

Regulations which fix the price of a commodity are called the office. When they fix the price below the natural cost price, the commodity is no longer produced, or seeks for a market abroad. When they fix it at the natural cost price, they are unnecessary, unless the competition of sellers be restrained. Smith's Wealth of Nations. Boileau's Political Economy.

Price, Current, in Commerce, a weekly account of the current value of most commodities.

PRICK Madam, in Botany, the name of a species of houfe-look.

PRICK or Queen Pox, in Building. See POST.

PRICK, or Pinch, in the Manges, is to give a horse a gentle touch of the fpur, without clapping them hard to him.

To prick or pinch, is an aid; but to apprize, or bear hard with a fpur, is correction. See PINCHING.

PRICK Timber, or Wood, in Botany. See SPINDLE TREE.

PRICKER, in Rural Economy, a term applied to a brad awl. It also signifies a sort of hook to clean horses' feet.

PRICKET, a term applied to a spitter, or young male deer of two years old, that begins to put forth the head. See SPITTER.

PRICKING of a horse's foot, in the Manges, is the hurt received by a nail driven too far in the foot, so as to reach the quick, or press the vein in the horse's foot, when it is wounded.

PRICKING the chart, is the art of tracing a ship's course upon a marine chart, by the help of a scale and compasses, so as to discover its present situation.

PRICKING the sails, is the art of fitching two cloths of a sail together, along the edge comprehended between the two edges, or selvages, that overlay each other. Or, it is the fowing a middle-leaf between the two leaves which are employed to unite every cloth of a sail to the next adjoining. See SAIL-MAKING.

PRICKLE, in Botany and Vegetable Physiology, aculeus, a thorn originating from the bark of plants, and not connected in any manner with their wood. Such are found in Rosa, Rubus, &c. They are more permanent than spines, being not liable to disappear by culture. See SPINA AND THORN.

PRICKLE Back, in Ichthyology, a small fish, so called from the prickles on its sides and back. Vaft numbers of these little fih are to be found in almost all fresh waters, wherever it is possible for fih to live, as Mr. Arderon informs us, Phil. Trans. No 428. fect. 15. who gives us some account of these creatures. They are very delective to the spawn of all forts of fih; and they themselves are tormented to death by a kind of lope of an oval figure, with eight legs and a very transparent body. This lope has little fins always in motion, whether it be swimming about or fixed on the fih. See STICKLE-BACK.

PRICKLY PEAR, in Botany. See CACTUS.

PRICKLY Pursue. See Ehchinopora.

PRICKLY Pear, in Geography, a small ifland near the N. coast of Antigua. N. lat. 17° 8'. W. long. 64° 30'.

PRIDE, in Mental Philosophy, is, as Dr. Cogan has defined it, that exalted idea of our flate, qualifications, or attainments, which exceeds the boundaries of juftice, and induces us to look down upon dupped inferiors with some degree of ummerer contempt. (See Mental Philosophy.) When this elevated idea of ourselves becomes a motive to avoid and despife any thing mean and unworthy, its impropriety is overlooked; and as it leads to worthy conduct, it is honoured with the appellation of laudable pride. When it proceeds from the excess of attachment and affection to our country, founded on exaggerated ideas of its superiority; or to our relatives and friends on account of their real or imagined merit; or to our parents, in conuenience of their rank or celebrity; or to children, by reason of their accomplishments or any honour conferred upon them; this kind of pride, proceeding from excess of affection, where the affection is natural, is called pardonable pride. When pride is manifested by an ostentatious display of wealth, flation, or accomplishments, it is deemed a vain pride. When it is indulged to such an excess, that it looks down with disdain upon others, little inferior, or perhaps equal, or even superior in real merit; it is branded with the title of inferferable pride.

Mr. Hume has given a different definition of pride from that which we have above flated. Pride, as he fays, is "a certain satisfaction in ourselves on account of some accomplishment, or poftion, we enjoy." "The object of pride is self, the caufe, some excellence." He adds, "Our merit raises
caused pride, and it is essential to pride to turn our view on
ourselves with complacency and satisfaction." But as he
has made no distinction between real and supposed merit, he
necessarily directs our thoughts to absolute merit; and ac-
cording to his representation, there can be no place for a
vicious pride, or an ill-founded confidence in our own su-
periority. See Cogan's Philosophical Treatise on the Pa-
fions. Notes.
Pray and, a name given by Dr. Plot to the com-
mmon lampmen, from its being found very plentifully and very
delicate in that river. See Psermonyf Branchial.
Pray Gavel, a custom in the manor of Rodely in the
county of Gloucester; by which, to this day, a rent is
paid to the lord, by certain tenants, in duty and ac-
knowledgment to him for their liberty and privilege of fishing
for lampreys or lampirds in the river Severn.
Praydeaux, John, in Biography, a learned English
prelate, was born at Slowford, in Devonshire, in 1578. His
parents were in very humble circumstances, and he himself
was candidate, while only a youth, for the situation of
parish clerk at the neighbouring church of Ugborow. He
was extremely mortified at his want of success. To consol
him under the disappointment, a charitable gentleman
maintained him at school till he acquired some proficiency in
the Latin language. After this he was sent to the university
of Oxford, where, at first, he earned his support by servile
offices in the kitchen of Exeter-college; and spent his leisure
hours in the diligent prosecution of his studies. The eager-
nets with which he pursued knowledge attracted the notice
of the tutors and rector; and in 1596 he was admitted a
member of the college. In 1596 he took the degree of
B.A., and in 1602 he was chosen probationer-fellow of his
college. In the following year he proceeded to M.A., and
was shortly afterwards admitted to holy orders. In 1612 he
took his doctor's degree, and having acquired a high reputa-
tion for deep and extensive learning, he was, in the same
year, elected rector of his college. From this time, owing
to his attention and zeal to its interests, the college flourished
more than any other foundation in the university. In 1615
Dr. Prudeaux was appointed Regius professor of divinity
in the university of Oxford; and, in connection with that
appointment, became canon of Christ-church and rector of
Ewelme in Oxfordshire. He afterwards discharged the
duties of vice-chancellor of the university during several
years. In 1641 he was nominated by king Charles I to the
bishops of Worcester, but owing to the state of the times
he never derived much emolument from the see, and his great
zeal in the king's cause exposed him to the resentment of
the parliament party, and he was reduced to the greatest
poverty, so that he was obliged to fall almost every thing of
which he was possessed, to obtain the common necessaries
of life. He died in 1650, leaving to his children no legacy but
"Pious poverty; God's blessing, and a Father's prayers,
and example of strict integrity and honour." His learning
was extensive, and his memory prodigious. He was modest,
kind, and unassuming; he was never anxious to conceal his
low origin. "Could I," he was often heard to say, "have
been clerk of Ugborow, I had never been bishop of War-
cester." He was author of a great number of works, of
many of which the titles are given in the General Biography,
which to which we refer the reader; also to Wood's Athen.
Oxon, and Walker's Sufferings of the Clergy.
Prudeaux, Humphrey, distinguished for his great
learning and talents, was the third son of Edmund Prudeaux,
dq. of Padflow in Cornwall, in the year 1648. Being de-
signed by his parents for the church, he was initiated in
grammar learning at the schools of Liskeard and Bodmin,
and then sent to Westminster school, under the direction
of the celebrated Dr. Bulby. Here he was elected king's
scholar, and after three years was sent on the foundation to
Christ-church-college in the university of Oxford, where
he was admitted a student in 1668. In 1672 he was em-
ployed by Dr. Fell, dean of Christ-church, in publishing an
edition of Lucius Florus, with notes. When this was
finished, a wish was expressed that he would prepare for
publication, from a MS. in the Bodleian library, the work of
"Johannes Antichenus Malela," a Greek historian, which
he declined, judging it unworthy the labour. In 1676 he
published his "Marmora Oxeonienii ex Arundelleniis, Sel-
denianis, allifique confarata, cum perpetuo Commentario,
"by which he acquired a high reputation in the university,
and also among the learned in many parts of the world.
The work was eagerly sought for, and it soon became very scarce.
It was drawn up in too much haste, and the typographical
errors were numerous. A more correct edition was pub-
lished under the care of Michael Matthaire in 1732. In 1679
Mr. Prudeaux was presented, by the lord chancellor Finch,
with the rector of St. Clement's, Oxford, and in the same
year he published two treatises of Maimonides in He-
brew, with a Latin version, and notes, under the title of
"De Jure Pauperis et Peregrini apud Judeos." During
the short session of parliament at Oxford in 1668, Mr. Pri-
deaux had the honour of attending upon the lord chancellor
in the capacity of chaplain, and in the following year his
lordship presented him to a prebend in the cathedral church
of Norwich. In 1682 he was presented to the rectory of
Bladen cum capella de Woodlock, in Oxfordshire; this was
the more acceptable, as it might be held with his studenthip,
and the office to which he had been appointed, was kept in
the cathedral church of Norwich. In 1686 he proceeded
doctor of divinity. The popish emissaries being very active,
this period, in propagating their principles, Dr. Prudeaux
exerted himself in opposing them, as well through the
medium of the press as in the pulpit. He had now settled
upon his prebend of Norwich, and observing that the clergy
of that city were much intimidated by the severe measures
which the king (James II.) took in serving the interests of
his religion, especially in the suspension of the bishop of Lon-
don, and Dr. Sharp, dean of Norwich, by his arbitrary
ecclesiastical commission, and that they wholly abstained
from any reference to the Popish controversy, at a time
when there was most need for them to exert themselves in de-
fence of Protestantism, he determined, by his own example,
to encourage them to speak out in support of the principles
which they professed, and boldly preached, in the cathedral,
against the nafs, declaring that, at all hazard, he was not
alarmed of, nor afraid to preach, the gospel of Christ.
He also distinguished himself by opposing, with all his powers,
the declaration of indulgence, and by his influence, it was
not read in more than four or five churches throughout
the diocese of Norwich, which contains about 1200 parishes.
After the Revolution he was collated to the archdeaconry
of Suffolk. When the convocation met in 1689, Dr. Prudeaux
took an active part with the minority, who were expressing
their indigence towards dissenters, by such alterations in the
canons, liturgy, and rituals of the church, as might con-
tribute to promote the comprehension of them within the
establishment. In the year 1691, upon the death of the
learned Dr. Pococke, the place of Hebrew professor at Ox-
ford was offered to Dr. Prudeaux, which he declined.
About the year 1696 he was presented to the small vicarage
of Trowe near Norwich, which was worth only about 40s.
per annum, but he readily accepted it for the sake of having
an opportunity of exercising his ministerial functions. The

he regularly dischargin till his ill state of health prevented
him from going into the pulpit, when he resigned the living.
In 1697 he published his life of Mahomet, which met with
so favourable a reception, that the author fold three editions
of it in the same year. In 1702 he was promoted to the
decency of Norwich, and immediately applied himself to the
reformation of such disorders and abuses as prevailed in the
cathedral. In 1710 he underwent a severe surgical operation,
From the effects of which he did not speedily recover. After
obtaining such a share of health as to be able to resume his
studies, he applied himself to the composition of his most
celebrated work, entitled “The Old and New Testament
connected in the History of the Jews and neighbouring Na-
tions,” and in 1715 he published the first part of it in a folio
volume, which was followed by a second in 1718. This
work was so well received by the public that it went through
eight editions at London, and two or three at Dublin, be-
fore the end of the year 1729, and it has been repeatedly
printed, as well as translated into the French and Italian
languages. Dr. Prideaux died on the 15 of November 1724,
in the 77th year of his age. He had naturally a strong con-
stitution, which enabled him to pursue his studies with the
utmost affiffity till he was unfortunately afflicted with the
stone. His abilities were solid rather than lively, his judg-
ment excellent, and his learning very extensive. As a writer
he is distinguished by perspicuity and precision. In this man-
er of living he was regular and temperate, being seldom out
of his bed after ten o’clock, and generally at his studies be-
fore five in the morning. He spoke his mind with freedom
and boldness, and was not easily diverted from pursuing
PRIE_BUSS, in Geography, a town of Silicia, in the
principality of Sagan, situated on the Neife; 15 miles S.W.
of Sagan. N. lat. 51° 28’. E. long. 15’.
PRIEDAL, a town of Bohemia, in the circle of Be-
chin; three miles S.E. of Crumau.

PRIESDORF, in Geography, a town of Germany, in
the duchy of Anhalt Cothen; two miles S. of Cothen.
PRIESSEN, a town of Bohemia, in the circle of Leit-
meritz; eight miles N. of Leitmeritz.
PRIEST, SACERDOS, a person set apart for the per-
formance of sacrifice, and other offices and ceremonies of
religion.
Thus the false gods and goddeses of the heathens had
their priests; priests of Mars, of Bacchus, of Hercules, of
Jupiter, the women and daughters of the priests were employed
in such services. At first the priesthood was engrossed
by the Patricians, but afterwards the people, disliking
that preference, prevailed to have the priesthood divided
between the senate and themselves; and under the tribune-
ship of Cn. Domitian, they gained the privilege of choos-
ing the priestfs, which had been referred for the college of
Patricians; but in process of time a new regulation was adopted,
so that the college became the electors, and the people con-
firmcd that election. After some subsequent alterations, the
emperors arrogated the right of choosing the priests,
and became themselves the high-priests, which state of things
commenced with Julius Cesar. When the election of the
college was confirmed by the people, they proceeded to the
inauguration, which was performed with peculiar ceremonies,
and concluded with an entertainment given by the new
priests. From that moment they assumed the gown, called
the “toga praetexta,” and the ornaments for the head, named
“apex,” “galerus,” and “albo-galerus.”
The priests in Rome enjoyed several privileges, and they
might afflict in the senate; but they were afterwards deprived
of this privilege. They were exempt from burdensome
offices in the state, and were diffused from going to war.
They had commonly a torch and a branch of laurel carried
before them, and they were allowed to ride up to the Capitol
in a chariot, called “Carpentum.” Some were priests for
life; others were deprived of it; but the augurs could not
be deposed. Every order of priests had its peculiar college,
and revenues for the sacrifices. In the order of the Roman
Hierarchy, the pontiffs were the first. (See Pontiff.)

The pope was chosen, or Rex Sac
cificus, was instituted after the expulsion of the kings
of Rome, to perpetuate their memory, as Dionysius of Halici
nusius says, on account of the great services which some
of their kings had done to Rome. To all these ministers
we may add the “epulones.” (See Epulo.) The Romans
had also other orders of priests and priests of whom
that were instituted for keeping the “Sibylline” books,
vestals, sibyls, falli, &c. which may be found under their
proper titles.
The Jews had three orders, viz. priests, levites, and
ne-thinims, who served in the temple; over whom the high-
priest was chief.
The title \(\text{Cohen} = \text{cibebin}, \) or priests, is applied in scrip-
ture to the officers of the state as well as to the ministers of the
sanctuary, though more commonly to the latter, who
offered sacrifices, and in other ways officiated in the public
worship. The real reason of the different application of
the work seems to be, that in the primary sense it imports those
that minister to a king; and, therefore, as God had taken
upon himself the character of the king of Israel, he had his
\(\text{cibebin} \) as well as earthly monarchs, or such as attended
on his special presence in the sanctuary, and ministered in the
taced service.
The priestly office of Christ, says Dr. Doddridge in his
“Lectures,” has generally been explained, as executed in
his offering himself as a sacrifice to God for us, and inter-
ceding with God upon that sacrifice; but Mr. Pierce (on
Heb. v. 5. 6. viii. 4. note e), and most of the Socinians,
suppose it only to consist in the latter; and Mr. Pierce
argues from Heb. viii. 4. that the execution of it began
upon Christ’s entering into heaven; but, it is alleged, that
the text in question only proves that Christ, being of the
tribe of Judah, could not, according to the Mosaic law, be
a priest.
a priest to minister in the Jewish temple, which none can reasonably maintain that he was: compare Heb. viii. 4. Nevertheless, as the apostle affirms us that he is a priest of a higher order, many divines have maintained, that all which he has done and suffered to minister to the fins of men, may, according to the most common acceptation of the word, be called a series of sacerdotal actions; as it is certain there were many acts of atonement performed by Mosaic priests, besides that which passed on the great days of atonement, and sacrifices were sometimes offered with acceptance by those who were not regularly priests. See Judges, vi. 25, 26, xiii. 16. 1 Kings, xviii. 33, 38.

When the Jewish constitution was settled, the public sacerdotal office was allotted to Aaron and his sons, and entailed on their posterity: and it was made a capital crime for any besides them to officiate, as priests, in the more solemn acts of offering sacrifices, burning incense, and blessing the people. The Jewish priests were consecrated to their office by washing, anointing, endowing them with the sacerdotal vestments, and offering certain sacrifices prescribed in the book of Exodus; chap. xxix.

The inferior priests were divided, in the time of David, into twenty-four companies, who were to serve in rotation, each company by itself for a week. The order in which the several corners were to serve was determined by lot; and each course was in all succeeding ages called by the name of its chief at the time of its turn division.

The Mahometans have their priests called febeik and mafit; and the Indians and Chinese their brazins and bonze. See Mufti, and Brahman.

Priest, Prefbyter, in the Christian Church, is a person invested with holy orders; in virtue of which he has a power to preach, pray, administer the sacraments, &c.; and, in the Roman church also, to bless, absolve, &c.

By the canons, can. 34, a man must be twenty-four years of age before he be admitted to the priesthood; anciently thirty years were required.

And by 3 Eliz. cap. 12. and 44 Geo. III. c. 43. none shall be made minister, i.e. priest, being under the age of four and twenty years; and in this case there is no dispensation, as there is in that of a deacon: and unless he first bring to the bishop of the diocese a testimonial both of his honest life, and of his professing the doctrine expressed in the thirty-nine articles: nor unless he be able to answer, and render to the ordinary an account of his faith in Latin, according to the said articles, or have special gift or ability to be a preacher. And by the canon just cited, it is required, that he shall have taken some degree of school in either of the two universities, or, at least, be able to give an account of his faith in Latin, according to the thirty-nine articles; and also that he exhibit letters testimonial of his good life and conversation, under the seal of some college of Cambridge or Oxford, where before he remained, or of three or four grave ministers, together with the subscription and testimony of other credible persons, who have known his life and behaviour for the space of three years next before. Nor shall any bishop admit any person into sacred orders, which is not of his own diocese, except he be either of one of the universities of this realm, or except he shall bring letters dispensatory from the bishop of whose diocese he is. By can. 33. none shall be admitted either deacon or priest, unless he is provided of some certain place where he may exercise his functions, and exhibit to the bishop, of whom he deferr'd imposition of hands, a presentation of himself to some ecclesiastical precentor then void in the diocese, &c.

For other requisites, see Deacon. For the form of ordination, see Ordination.

The bishop, previous to ordination, shall minifter to every candidate for orders, the oaths of allegiance and supremacy. (1 W. c. 8.) Then the bishop, with the priests present, shall lay their hands severally upon the head of every one that receiveth the order of priesthood, the receivers humbly kneeling upon their knees, and the bishop saying, "receive the holy ghost for the office and work of a priest in the church of God, now committed unto thee by the imposition of our hands; whose sins thou doft forgive, they are forgiven; and whose sins thou dost retain, they are retained." And be thou a faithful dispenser of the word of God, and of his holy sacraments: in the name of the father, of the son, and of the holy ghost." Then the bishop shall deliver to every one of them kneeling, the Bible in his hand, saying, "Take thou authority to preach the word of God, and to minister the holy sacraments in the congregation, where thou shalt be lawfully appointed thereunto." Nevertheless by can. 36: he may not preach without a licence either of the archbishop, or of the bishop of the diocese where he is placed, under his hands and seals; or of one of the two universities under their seals likewise. But a licence of the bishop of any diocese is sufficient, although it be only to preach within his diocese; the statute not requiring any licence by the bishop of the diocese where the church is. Watf. c. 14.

The holy scripture makes no distinction between the title of priest, presbyter, and that of bishop, episcopus; and does not give any superiority to the one over the other. Blondel, therefore, and Salmasius maintain, with good reason, that in the primitive church the priests governed with perfect equality, and without any other pre-eminence beside that of age.

Yet some of the primitive writers speak of nothing but episcopacy; and frequently in such terms, as if they esteemed it of apostolical institution. See Bishop, Ordination, and Presbyter.

As, in the ancient church, the deacons had the management and administration of the revenues of the church, their authority grew space; and, in a little time, they were got above the priests. St. Jerom used his utmost endeavours to prove, that deacons were originally inferior to priests; and the council of Nice decided the question in favour of the latter. See Deacon.

Indeed, an order of deacons having been instituted without any other function than to assist the priest at the altar; these have made no difficulty of owning the superiority of the priests.

Add to this, that the order of a deacon being now become necessary to arrive at that of a priest, there is no room to dispute the precedence; but the deacons, who had retained their function, had the disposal of the revenues, and paid the priests their pensions, still maintained the superiority. Upon which the sixth council in Trullo pronounced once more on the dispute, and gave the pre-eminence to the priests.

In the general acceptance of the world, priests are any ministers of a church; but in our law this word is particularly used for ministers of the church of Rome. For the laws against popish priests, see Papists.

PRIESTLEY, Joseph, in Biography, a very eminent
philosopher and divine, was born in March 1733, at Field-
Head, near Leeds. His father was engaged in the clothing
manufacture, and was a dissentier of the Calvinistic persuasion.
Joseph was, in his youth, adopted by an aunt, who sent
him for education to several schools in the neighbourhood,
where he acquired a respectable degree of knowledge of
the learned languages, including Hebrew. He was in-
tended for the ministry among the dissenters; and in 1752
he went to the academy at Daventry, kept by Dr. Aft-
worth, having by ill health been prevented from pursuing
his academical course at an earlier period. Here he spent
three years, during which his acute and vigorous mind was
expanding in free inquiry and diversified pursuit. He had
already abandoned the doctrines in which he had been
educated, and had become an Arian. At Daventry he
became acquainted with the writings of Hartley, which
exerted a powerful and lasting influence over the whole
train of his thinking. On quitting the academy, he settled
at Needham market, in Suffolk, as a minifler, and, after a
residence of three years, he undertook the charge of a con-
gregation at Namptwich, in Cheshire, to which he joined
the business of a school. In the business of education he
was indefatigable; and he added to the common objects of
instruction, experiments in natural philosophy, which
were the means of fostering in himself a taste for pursuits
of this kind. His first publication was an English grammar,
on a new plan. This was printed in 1761, and in the same
year he was invited by the trustees of the academy at War-
rington to occupy the post of tutor in the languages. At
Warrington Dr. Priestley began to dexterously himself as a
writer in various branches of literature. Several of these
had relation to his department in the academy, which,
besides philosophy, included lectures on history and general
policy. A visit to London having introduced him to the
acquaintance of Dr. Franklin, Dr. Watfon, Dr. Price, and
Mr. Canton, he was encouraged by them to pursue a plan
which he had already formed, of writing a history of elec-
tricity, which appeared in the year 1767. This publica-
tion made his name extensively known among those who
might have remained strangers to it, as connected with his
other pursuits. It went through several editions, and was
translated into foreign languages, and procured for him an
admission into the Royal Society. He had previously re-
ceived the title of doctor of laws from the university of
Edinburgh. He quit Daventry in 1767, and settled
at Leeds as minifter to a large congregation of dissenters,
and he instantly resumed, with his characteristic ardour,
his theological studies. He about this time became an
Unitarian in the strict sense of the word, that is, a believer
in the simple humanity of Christ, a circumstance which he
has attributed to a perusal of Dr. Lardner’s “Letter on
the Logos.” A number of publications on different topics
connected with religion, announced the zeal with which he
was inspired. He likewise began to enter into a contro-
versy respecting the right and ground of dissent in general,
and to take his station as one of the most decided opposers
of the authority of the established religion. It was during
his residence at Leeds that his attention was first excited, in
consequence of his vicinity to a public brewery, to the
properties of fixed air, which he had an opportunity of
obtaining on a large scale. One experiment led to another,
till the fruits of his amusements were the discoveries on
which his philosophical reputation was principally founded.
Though he greatly enlarged the boundaries of science, he
was never vain of his discoveries. In speaking of himself,
he says, “Few persons, I believe, have met with so much
unexpected good success as myself in the course of my
philosophical pursuits. My narrative will shew that the
first hints, at least, of almost every thing that I have dis-
covered of much importance, have occurred to me in this
way. In looking for one thing, I have generally found
another, and sometimes a thing of much more value than
that which I was in quest of. But none of these un-
expected discoveries appear to me to have been so extra-
ordinary, as that I am about to relate, viz. the spontane-
ous emission of dephlogificated air from water containing
green vegetation, and it may serve to admonish all persons who are engaged in similar pursuits, not to
overlook any circumstance relating to an experiment, but
to keep their eyes open to every new appearance, and to
give due attention to it, however inconsiderable it may
seem.”

The first of Dr. Priestley’s publications on pneumatic
chemistry was in 1772, announcing a method of impreg-
nating water with fixed air; and on the preparation and
medicinal uses of artificial mineral waters. He had,
however, commenced his experiments on this subject as early as
1768. In the year 1771 he had procured good air from saltpetre; he had discovered the uses of agitation and
of vegetation as means employed by nature in purifying the
atmosphere defined to the support of animal life; and that
air vitiated by animal respiration is a pabulum to vegetable
life. Dr. Priestley had also procured factitious air in a
much greater variety of ways than had been known
before, and he had been in the habit of using mercury
inland of water for the purpose of many of his ex-
periments. In his paper read to the Royal Society in 1772,
which obtained the Copley medal, he gave an account of
these discoveries; and at the same time announced the
discovery of nitrous air, and its application as a test of the
purity or fitness for respiration of airs generally. It was
on this occasion that sir John Pringle addressed him in the
diligent language of an admiring friend. “I present you,
sir, with this medal, the palm and laurel of this community;
as a faithful and unfading testimonial of their regard;
and of the just sense they have of your merit, and of the per-
severing industry with which you have promoted the views,
and thereby the honour of this Society. And in their
behalf I must earnestly request you to continue your liberal
and valuable inquiries, whether by further prosecuting this
subject, probably not yet exhausted, or by investigating the
nature of some other of the subtle fluids of the universe.
These, sir, are indeed large demands; but the Royal
Society have hitherto been fortunate in their pneumatic
researches. And were it otherwise, they have much to
hope from men of your talents and application, and whole
palt labours have been crowned with so much success.”

Dr. Priestley, at this period, shewed the use of the
burning lens in pneumatic experiments; he related the
discovery and properties of muriatic acid air; added much
to what was known of the airs generated by putrefactive
processes, and by vegetable fermentation; and he determined
many facts relating to the diminution and deterioration of
air, by the combustion of charcoal, and the calcination
of metal. In 1774 he made a full discovery of dephlogificated
air, which he procured from the oxys of silver and lead.
This hitherto secret source of animal life and animal heat,
of which Mayow had a faint glimpse, was unquestionably first exhibited by Dr. Priestley, though it was discovered about the same time by Mr. Scheele of Sweden. In 1776, his observations on respiration were read before the Royal Society, in which he discovered that the common air inspired was diminished in quantity, and deteriorated in quality, by the action of the blood on it through the bloodvessels of the lungs; and that the florid red colour of arterial blood was communicated by the contact of air through the containing vessels. In 1775 Dr. Priestley pursued his experiments on the properties of vegetables growing in the light to correct impure air, and the use of vegetation in this part of the economy of nature; and it seems certain that Dr. Priestley made his discoveries on the subject previously to those of Dr. Ingenhouz, then engaged in similar researches. From this period Dr. Priestley seems to have attended to his pneumatic experiments as an occupation, devoting to them a regular portion of his time. To this attention, among a prodigious variety of facts tending to shew the various substances from which gases may be procured, the methods of preparing them, their influence on each other, and their probable composition, we owe the discovery of vitriolic acid, of alkaline air, and of dephlogisticated nitrous air; or, as it has since been denominated, the gaseous oxyd of azote, the subject of so many curious and interesting experiments by Sir Humphry Davy. To these may be added the production of various kinds of inflammable air, by numerous processes that had escaped the observation of Mr. Cavendish. To Dr. Priestley we are indebted for that fine experiment of reviving metallic cales in inflammable air; and he first ascertained the necessity for water to be present in the formation of the gases, and the endless production of gases from water itself. His experiments on this subject, viz., the generation of air from water, opened a new field for reflection, and deserve particular notice. It had been already remarked that water was necessary to the generation of every species of gas; but the unceasing product of air from water had been observed by no one before.

"To enumerate," says Mr. Kirwan, "Dr. Priestley's discoveries, would in fact be to enter into a detail of most of those that have been made within the last fifteen years. How many invisible fluids, whose existence evaded the sagacity of foregoing ages, has he made known to us? The very air we breathe he has taught us to analyze, to examine, to improve; a substance so little known, that even the precise effect of respiration was an enigma, until he explained it. He first made known to us the proper food of vegetables, and in what the difference between these and animal substances consisted. To him pharmacy is indebted for the method of making artificial mineral waters, as well as for a shorter method of preparing other medicines; metallurgy for more powerful and cheap solvents; and chemistry for such a variety of discoveries as it would be tedious to recite,—discoveries which have new-modelled that science, and drawn to it, and to this country, the attention of all Europe. It is certain that, since the year 1773, the eyes and regards of all the learned bodies in Europe have been directed to this country by his researches. In every topical treatise his name is to be found, and in almost every page. They own that most of their discoveries are due either to the repetition of his discoveries, or to the hints scattered through his works."

To return to the more general account of Dr. Priestley's labours;—the success of his "History of Electricity" induced him to adopt the design of treating on other sciences, in the same historical manner; and at Leeds he occupied himself in preparing "The History and Present State of Discoveries relating to Vision, Light, and Colours." The expenses necessary in compiling such a work obliged him to issue proposals for publishing it by subscription; and it appeared in 1772, in one very large volume, 4 to. This work is at once highly instructive and entertaining; but its fate by no means corresponded with the expectations formed from the number of names given by the subscribers: it has been sold, not one third part of the number paid for, or demanded the book when published.

After a happy residence at Leeds for six years, Dr. Priestley quitted it for one as different as could be easily imagined. The earl of Shelburne, afterwards marquis of Lansdowne, invited Dr. Priestley to reside with him in the nominal capacity of librarian, but really as his literary companion, upon terms which a regard to the future provision of an increasing family would not permit him to decline. He accordingly fixed his family in a house at Calne, in Wiltsire, near his lordship's seat; and during seven years attended upon the noble earl, in his winter's residence at London, and occasionally in his excursions, one of which, in 1774, was a tour to the continent. This situation had doubled his life, by affording Dr. Priestley advantages in improving his knowledge of the world, and in pursuing his scientific researches, which he could not have enjoyed as a diffusing minister. The manners and society of a nobleman's house were not, however, perfectly congenial, to one whose tastes were simple, and whose address was plain and unassuming. But he was perfectly free from restraint with respect to his pursuits; and this was the period of some of those exertions to which he has referred above, which raised his reputation as a philosopher to the highest point.

It was his constant practice to employ himself in various pursuits at the same time, whereby he avoided the languor consequent upon protracted attention to a single object, and came to each in turn as fresh as if he had spent an interval of entire relaxation. This effect he pleaded as his apology, to those who apprehended that the great diversity of his studies would prevent him from exerting all the force of his mind upon any one of them; and it is certain, he proceeded to such a length, in every pursuit that interested him, as fully to justify in his own case the rule which he followed.

It was during a course of original experiments, which fully exercised his faculties of invention and observation, that he was employing his reasoning powers in those deep metaphysical inquiries, by which he acquired great distinction as a philosopher of another clafs. In the year 1775 he published his "Examination of the Doctrine of Common Sense, as held by Drs. Reid, Beattie, and Oswald." After this he became the illustrator of the Hartleian theory of the human mind. He had, previously to this, declared himself a believer in the doctrine of philosophical necessity; and in a dissertation prefixed to his edition of Hartley, he expressed some doubts of the immateriality of the sentient principle in man. Notwithstanding the obloquy thus brought upon him, as a favourer of infidelity, or, according to some bigots, of atheism itself, he was not deterred from purifying the faculty: for it was the governing principle of his life to follow truth wheresoe'er it might lead him, and regardles of consequences. Upon a clofer inquiry, he became an avowed convert to the material doctrine, or that of the homogeneity of man's nature; and in 1777 he published "Disquisitions on Matter and Spirit," in which he gave a history of the doctrines concerning the soul, and openly supported the system which, upon due investigation, he had adopted. It was followed by "A Defence of Unitarianism,"
tarism, or the simple Humanity of Christ, in opposition to his Pre-existence; and of the Doctrine of Neccecity." Dr. Aikin, in the General Biography, thinks it probable that the odium which these works brought upon their author was the cause of a coolness in the behaviour of his noble patron, which about this time he began to remark, and which terminated in a separation, after a connection of seven years, without any alleged complaint. The parties themselves, no doubt, well knew the cause of this separation; but it seems to have been a settled point between them, that there should be no public complaints, and that the separation should apparently be on amicable terms. That the separation was not really what it appeared to be is evident, as the doctor informs us, that when he came to London, he proposed to call on the noble lord; but the latter declined receiving his visits. Dr. Priestley tells us, that during his connection with his lordship, he never once aided him in his political views, nor ever wrote a single political paragraph. We can easily believe, that after a few years, the parade of having under his roof a literary companion would lose its effect, and the desire of change would induce lord Shelburne to break a connection, which proved of no real use to him. By the articles of agreement, Dr. Priestley retained an annuity for life of 150l., which was honorably paid to the last; and it has been said, that when the bond securing to him this annuity was burnt at the riots of Birmingham, his lordship in the handomest manner presented him with another.

Dr. Priestley now removed to Birmingham, a situation which he probably preferred to almost any other, on account of the advantage it afforded of able workmen in every branch requisite in his experimental inquiries, and of some men distinguished for their chemical and mechanical knowledge. Several noble-hearted friends to science, aware that the defection of his income would render the expenses of his pursuits too burthenome for him to support, joined in raising an annual subscription for defraying them. This affiance he without hesitation accepted, considering it as more truly honourable to himself than a pension from the crown, which might have been obtained for him, if he had wished it, during the short administration of the marquis of Rockingham, and the early part of that of Mr. Pitt.

He had not been long settled at Birmingham, before a vacancy happened in the principal dissenting congregation, and he was unanimously chosen to supply it. Without in the least interrupting his philosophical and literary pursuits, he entered with great zeal into the duties of his office, especially into that important branch of it which confines in catechising and instructing the younger members of the society. Theology again occupied a principal share of his attention, and he published his "History of the Corruptions of Christians," and "History of early Opinions concerning Jesus Christ." These proved to be, what might be expected, a fertile source of controversy, into which he entered without the smallest reluctance, and without those uneasy feelings of irritation which so commonly accompany this kind of warfare. The renewed applications of the dissenters, for relief from the penalties and disabilities of the Corporation and Tatt Acts, afforded another topic of discussion, in which Dr. Priestley took an active part; and convinced that all ecclesiastical establishments were hostile to the rights of private judgment, and the propagation of truth, he did not shun to represent them all as anti-christian, and predict their downfall. Hence he was represented as the most dangerous and inveterate enemy of the established religion, in its connection with the state. Some of the clergy of Birmingham having warmly opposed the dissenters' claims, Dr. Priestley published a series of "Familiar Letters to the Inhabitants of Birmingham," which, on account of their ironical manner, as well as the matter, gave great offence. In this state of irritation, another cause of animosity was added by the different feelings concerning that great event, the French Revolution; which fee. The anniversary of the capture of the Bastille, July 14th, had been kept as a festival by the friends of the cause; and its celebration was prepared at Birmingham in 1791. Dr. Priestley declined joining the party; but in the popular tumult which ensued, he was particularly the object of party fury. His house, with his fine library, manuscripts, and apparatus, were made a prey to the flames. He was obliged to fly for his life. The interesting narrative which he has given of the circumstances of his escape, shews that it was extremely difficult for him to reach a place of safety, while, without the slightest charge against him, he was hunted like a proclaimed criminal. There is no doubt that this scene of outrage, attended with the conflagration of many other houses, and places of worship, was rather favoured than controlled by some, whose duty ought to have led them to active interference for the preservation of the public peace.

Nor is it at all surprising that the rage of party was especially directed against one, who had so distinguished himself as a champion on the opposite side, and who had made his attacks without any regard to the dictates of caution or worldly policy. The legal compensation for which, by the advice of his friends, he sued, was far short of the amount of his loaves. He was not, however, without his friends, whose zeal for his welfare was not the least damped by the bitterness and malignity of his enemies. They looked upon him with a respect and affection proportioned to his sufferings, and exerted themselves to support and console him under this trying calamity. He now settled at Hackney, and in a very short time he was chosen to succeed his deceased friend, Dr. Price, as minister to a congregation at Hackney; and he joined to it a connection, of every restricted nature, with the New College, lately established in that village. Refusing his usual occupations of every kind, he passed some time in comfort and tranquility; but he soon found public prejudice following him in every path, and himself and his family molested by the rude assaults of malignity, which induced him finally to quit a country so hostile to his person and principles. He accordingly, in the month of April 1794, embarked for America, and took up his residence at the town of Northumberland, in Pennsylvania. It was a considerable labour, in this remote situation, to get a well-furnished library and chemical laboratory; but he at length surmounted all obstacles, and effected his purpose. He was offered a chemical professorship in Philadelphia, which he declined, not meaning to engage in any public duty, in order that he might be enabled to devote his whole time to his accustomed pursuits, in which he soon shewed his philosophical friends that he was not idle. Political animosity, in some measure, pursued him to the western world; and during the administration of Mr. Adams, he was regarded by the American government with suspicion and dislike. That of Mr. Jefferson, however, was very friendly to him, and he outlined all disquiet on this head. The death of his youngest son, a very promising young man, and of his excellent wife, together with other domestic calamities, were severe trials of his fortitude. A fever illnec, which he suffered in Philadelphia, laid the foundation of a debility of his digestive organs, which gradually brought on a state of bodily weakness, while his mind continued in full possession of all its faculties. In January 1804, it became manifest to himself, and to his friends, that he had not long to live; and
and this warning operated upon him to lose no time in finishing the literary tasks in which he was engaged, and particularly in putting into a state fit for the press some works in which he was greatly interested. He had prepared a continuation of his Church History, and Notes on all the Books in the Bible; and had learned with great satisfaction, that his friends in England had raised a subscription, to enable him to print them without any risk to himself. Like a man, then, setting his affairs in order, previously to a long journey, he continued, to the last hour of his life, with the utmost calmness and self-collection, giving directions relative to his posthumous publications, intermixed with discourses expressive of the fullest confidence in those cheerful and animating views of a future existence, that the Christian religion opened to its disciples; and on Feb. 6, 1804, in the 71st year of his age, he expired so quietly, that they who sat beside him did not perceive the last moment of his existence. As if aware the solemn moment was at hand, and unwilling to shock his children, who were sitting by his bed-side, by his departure, he had taken the precaution of putting his hand before his face.

Dr. Priestley was a man of perfect simplicity of character, laying open his whole mind and purposes on all occasions, and always pursuing avowed ends by direct means, and by those only. In integrity and true disinterestedness, and in the performance of every social duty, no one could surpass him. His temper was calm and cheerful, his affections were kind, his dispositions friendly. Such was the gentleness and sweetness of his manner in social intercourse, that some who had entertained the strongest prejudices against him on account of his opinions, were converted into friends on personal acquaintance. Of the warm and lafting attachment of his more intimate friends, a most honourable proof was given, which he did not live to be made acquainted with. It being understood in England that he was likely to suffer a loss of 200l. in his annual income, about forty persons joined in making up a sum of 450l. which it was intended to be continued annually during life. No man who engaged so much in controversy, and suffered so much from malignity, was ever more void of ill-will towards his opponents. If he were an eager controversialist, it was because he was much in earnest on all subjects in which he engaged, and not because he had any personalities to gratify. If now and then he betrayed a little contempt for adveraries, whom he thought equally arrogant and incapacious, he never used the language of animosity. Indeed his Neoclerical principles coincided with his temper in producing a kind of apathy to the rancour and abuse of antagonists. In his intellectual frame were combined quickness, activity, acuteness, and that inventive faculty which is the characteristic of genius. These qualities were least suited to the laborious investigations of what is termed erudition, than the argumentative deductions of metaphysics, and the experimental researches of natural philosophy. Affiduous study had, however, given him a familiarity with the learned languages sufficient, in general, to render the few of authors clear to him, and he aimed at nothing more. In his own language he was contented with facility and peripetia of expression, in which he remarkably excelled.

The writings of Dr. Priestley, amounting probably to seventy volumes 8vo., are too numerous to attempt anything like an analysis of them. They have been classified in those that relate to general philosophy, pneumatic chemistry, metaphysics, civil liberty, religious liberty, ecclesiastical history, evidences of the Christian revelation, defences of unitarianism, miscellaneous theology, miscellaneous literature. Of what Dr. Priestley did in chemistry we have given a sketch. We may, however, add in this place, that he remained to the end of his life attached to the phlogistic theory which he had imbibed, and which the French chemists thought they had completely demolished. It is more than possible that a new change in the opinions of chemists may take place on this important subject. (See Philos. Soc.) Some of Dr. Priestley's writings of this class were attacks upon the antiphlogistic theory, of which he lived to be the sole eminent opposer.

On the science of metaphysics he was the strenuous advocate of Dr. Hartley's theory of association, upon which he founded the systems of materialism and necessity as legitimate inferences. No writer has treated these abstruse subjects with more acuteness and perspicacity, and so long as they are topics of discussion, his writings will probably be considered as the ablest elucidations and defences of the theories proposed in them. In theology, Dr. Priestley was a great leader of those who regard Jesus Christ as the Son of Joseph and Mary, divinely commissioned to reveal to the world a future state of existence. He of course did not admit into his creed a miraculous conception; nor an atonement made by Christ to render the Almighty merciful to the errors of men. He founded all his expectations of a future life upon revelation alone, and he believed that punishment beyond the grave was intended to render the subject of it meet for endless happiness, to which all rational beings would finally be brought. One of his most important theological works is entitled "Institutes of natural and revealed Religion." His "Letters to a philosophical Unbeliever" deserve all attention. Among his pieces on practical religion may be named, as of very singular excellence, "Two Sermons on Habitual Devotion, and on the Duty of not living to ourselves;" these have very frequently been reprinted, and many thousands of them circulated in a cheap form. Memoirs of Dr. Joseph Priestley in two vols. 8vo.

Prietche, in Geography, a town of Brandenburg, in the Middle Mark; four miles S.E. of Brandenburg. Prilipo, a range of mountains of European Turkey, in Macedonia, about 12 miles W. of the river Vardar. — Alfo, a town of Macedonia; 20 miles N.N.W. of Stobi.

Priluki, a town of Ruffia, in the government of Ekaterinoloff; 52 miles S.W. of Eliftabet. — Alfo, a town of Ruffia, in the government of Tchernigov; 100 miles S.E. of Tchernigov. N. lat. 51º 3'. E. long. 32º 44'.

Pribetskoi, a town of Ruffia, in the government of Archangel, on the Dwina; 28 miles E. of Schenkirl. — Alfo, a town of Ruffia, in the province of Uttinger, on the Dwina; 20 miles N. of Utting.

Prim, a river of Arabia, which runs into the sea; 18 miles S.W. of Ras Vive.

Prima Intensione, a technical expression in Music, as well as Painting. No language but the Italian seems to furnish an equivalent to this expression. Roullaeau has endeavored, with his usual good taste and ingenuity, to explain it. We shall, therefore, only translate.

An air or movement di prima intensione, or of first conception, is that which is formed entire in all its parts at one and the same instant, as Pallas proceeded from the brain of Jupiter.

These pieces of one conception, are those rare effusions of genius in which all the ideas are so combined that they seem to be but one, and appear as if they could not be conceived separately. They resemble those long but elegant periods of Cicero, of which the sentence is suspended to the last word, and which consequently could have formed but one thought in the mind of the author. There are in all the arts
arts similar beauties produced by similar efforts of genius, and of which all the details intimately connected with each other could not be produced successively; but are necessarily presented to the mind all at once; since the first without the last would have no effect. Such was, for instance, the Rocking-loom, that prodigious machine, which may be regarded, says the philosopher who described it in the Encyclopædiæ, as one sole and only act of reason, of which the fabrication of the work is the conclusion.

These kinds of operations in the human mind, so difficult to explain, even by analyzis, are prodigies of reason, and never conceived but by men of such genius as are able to produce them. Their effect is always proportioned to the effort which they have cost the brain. And in music, it is only the pieces of one conception, that give extacy, rapture, lift the souls of the audience into Elysium, and make them forget themselves, and all that is around them. They are felt and divined at the instant; connoisseurs are never mistaken.

After one of these sublime productions, let one of those pieces of shreds and patches be performed, of which all the phrases have been composed one after the other, or which have only one phrase repeated through all the keys, and of which the accompaniment is only a crowd of unmeaning notes added by reflexion after the original idea is forgotten; but in whatever style this last piece is composed, if the remembrance of the other leaves you any inclination to listen, it will be only to render you chill, tired, and impatient. After an air di prima intenzione, all other music is without effect.

PRIMA Naturalis, in Physics, atoms, or the first particles of which natural bodies are primarily composed; called also MINIMA Naturalis, which see; see also PARTICLE, and ATOM.

PRIMA TRIB, in Chemistry. See TRIB.

PRIMA, or Primarie Places, in Law. See Places.

PRIMA Via, a term employed chiefly in medicine, to denote the stomach and intestines, or passages of the food.

PRIME, a duty at the water-side, appointed by a statute of Henry VIII. to be paid to the master and mariners of the ship, by the merchants whose goods are loaded or unloaded.

It is paid to the master for the use of his cables and ropes, in moving the goods; and to the mariners for their service and assistance.

This is different in different places; in some 12d. per ton; in others, a penny per pound; in others, sixpence per bale or pack. See DUTY, and Custom.

PRIMATE, a planet which revolves round the sun as a centre.

PRIMATI, or Primerie Places, in Law. See Places.

PRIMATES, or Primatives, an archbishop, invested with a jurisdiction over several archbishops, or bishops.

The term primate is Latin, and signifies the first, or president of a society; the Greek word corresponding to it is εξάρχης, exarch.

Father Simond derives the origin of primates hence; that the large provinces have been divided and subdivided by the emperors; the first divisions were called firsts; others seconds; others thirds, &c. and the title primate given to the metropolitan, i.e. to the bishop of the city which was the capital of the province before the division was made. As metropolitan was a title given to the bishop of the chief city of a province, primate, or primas, was the first of the province; for such was the original signification of that word in an ecclesiastical sense: but in process of time, the title of primate was restrained to the bishops of some great cities: and a patriarch was the chief bishop over several kingdoms or provinces, as an archbishop is of several dioceses.

Those who are advocates for a strict ecclesiastical hierarchy, maintain a primate to be a dignitary who has several metropolitans under him; as a patriarch has several primates. Yet it is pretty evident from history, that primates were, at first, confounded with patriarchs; thus Socrates, enumerating ten patriarchs, does not make any distinction between them and primates.

In Africa, after the disjunction was made, the primates were not at all subject to the patriarch; and the bishop of Carthage, who was primate, paid no obedience to the bishop of Alexandria, who was patriarch.

Nor, to be a primate, was it necessary to have metropolitans for suffragans; each province of Africa, except those which composed the diocese of Alexandria, had its primate; this quality being given to age.

In France, the subdivision of provinces gave occasion to the erection of primates: thus Aquitaine, e.g. being divided into two provinces, the archbishop of Bourges became primate of the Aquitaines, because Bourges was the capital of the first.

Thus, also, the division of England into two provinces, Canterbury and York, in 1152, gave occasion to the introduction of primacies among us; Canterbury, which was the metropolis before, or the royal city of the kings of Kent, and given to King Ethelbert, on his conversion to Christianity, by Auffin, its first archbishop, about the year of our Lord 598; whence giving the title of primate of all England to its prelate, though the archbishop of York still claims that of primate of England. And, accordingly, the first has some jurisdiction over all England, relating to administrations, &c. which the latter has only within his own province. See ARCHBISHOP, BISHOP, and DIOCESE.

PRIMATES, or Primatives, in Natural History, the first order of the class Mammalia, according to the Linnean system. The animals of this order are furnished with cutting fore-teeth; the upper four are parallel, except in some species of bats, which have two or none (see Vespertilio nigrum, lepturus, &c.); tails solitary, that is, one on each side, in each jaw; teeth two, pectoral; feet, two of which are hands; nails usually flattened, oval; food, fruits, except a few who use animal food. There are four genera, viz.

Homo,
Lenur,
Simia, and
Vespertilio.

PRIMATICIO, Francesco, in Biography, was born at Bologna, in 1400, of a noble family. It was intended that he should be bred up to commerce, but having too elevated a mind to adopt that occupation, and prompted by natural genius, he devoted himself to the arts of design, and began to learn design and colouring from Innocenzo da Imola, and Bagnacavallo; and in a short time was enabled, by his incessant industry, to give manifest proofs of extraordinary talents. He then quitted his native city, and went to Mantua, where he became a disciple of Giulio Romano, who at that time was engaged in ornamenting the apartments of the palace del Te, assisted by a number of young artists who had received their instruction in his school. Primaticcio continued under Giulio for six years, and became a great ma- chiniit, an artifit in fresco, stucco, and every branch of classic or magnificent ornament.

He effectually established himself in the favour of his master,
mater, and of the duke of Mantua; and was recommended in the strongest terms by that prince to Francis I., who immediately took him into his service, and appointed him to execute a great number of his designs in fresco and in oil. Not less fortunate and successful with the king than he had been with the duke, his works were improved and admired; and he adorned Fontainebleau, and most of the royal palaces in France, with his compositions.

At the time that Primaticcio was engaged by Francis, Rollo, a Florentine painter, was also retained and employed. Between these two artists a violent rivalry and jealousy subsided; but the King, to quiet their dissensions, sent the former to Rome to purchase antiques. He executed his commissio very happily; and in a short time collected a hundred and twenty-five statues, busts, and mutilated figures; and procured moulds of the most celebrated statues which were not to be purchased, such as the Laocoon, the Tiber and Nile, the Ariadne, Commodus, and others, which were, call them in brays.

He was recalled from Rome to finish a large gallery, left incomplete by Rollo at his death; and the king, to express his esteem for Primaticcio, and his public approbation of his merit, conferred on him the abbey of St. Martin, at Troyes, with the annual income of 800 crowns; which he enjoyed as long as he lived.

The frescoes of Primaticcio, in the palace del Te, cannot with certainty be ascertained. His oil pictures are of the utmost rarity in Italy, and even at Bologna. In the great gallery Zambecchi, there is a concert by him with three female figures, a most enchanting performance. The eye is equally charmed by the forms, the attitudes, the tone of colour, the breadth, taffet and cafe of the draperies, and the original air of the whole. Nicolo Abbati, the partner of his works, though not his scholar, was left by him to terminate what was left unfinished in his plans in France. Primaticcio lived to the advanced age of eighty, and died in 1570. Fufeli's Pilgrimage.

PRIMBKENAU, in Geography, a town of Silezia, in the principality of Glorgau, containing two churches, with an iron forge; and manufacture of paper; 10 miles E. of Sprottau. N. lat. 51° 28'. E. long. 15° 40'.

PRIME, PRIMUS, the first in order, degree, or dignity, among several things of the fame or like kind.

Thus we say, prime minister, prime mover, prime coft, &c. See MINISTER, MOBILE, &c.

Prime, or Prime minute, in Geometry, denotes the sixtieth part of a degree.

See DECIMAL.

Prime is sometimes also used for a tenth part of an unit.

In weights, it is used for the twenty-fourth part of a grain.

Prime Figure, in Geometry, is that which cannot be divided into any other figures more simple than itself.

Such is a triangle among planes; and the pyramids in solids. For all planes are made of the first, and all bodies or solids are compounded of the second.

Prime Number, in Arithmetic, is one which has no divisors, or which cannot be divided into any number of equal integral parts greater than unity: such are the numbers 2, 3, 5, 7, 11, 13, &c.

These numbers have formed a subject of investigation and inquiry, from the earliest traces of arithmetic to the present time; either with a view of finding them, or selecting them from the common series of numbers, or for investigating certain properties which are peculiar to them.

Eratosthenes is the first author amongst the ancients who attempted the former problem, which led him to the invention of what he called his x are the numbers 2, 3, 5, 7, 11, 13, &c.

We begin with the first prime number 2, and over every third number from 3 a point is placed; each of these numbers being divisible by 2, 3, 15, 21, &c. Again, from 5, a point is placed over every fifth number, those being divisible by 5, as 15, 25, 35, &c. And having done this, all that remain without points in the above series are primes; for there is no prime number between 7 and 1/100: and it is useless trying any prime number greater than the square root of the number proposed, which we have supposes here to be 100. Adding, therefore, to the above the prime number 2, which is the only even prime number, and we shall have,

2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97,

which are the only prime numbers under 100.

Such was the method pursued by Eratosthenes, and the same, aided probably by some mechanical contrivance, has been adopted by modern authors. Of these, Vega has published a table of prime numbers to 400,000; and a work lately published in Holland, not only contains the prime numbers up to 1,000,000, but also the factors of all composite numbers to the same extent; a performance which, it must he allowed, dispaies the industry of its author to much more advantage than either his genius or judgment.

It is obvious from what is stated above, that this method cannot be employed for ascertaining whether any proposed number is a prime, without going through the whole process up to the same extent; the defideratum, therefore, of modern mathematicians has been to discovery some rule, whereby any proposed number may be determined to be a prime or composite number; in which, however, they have not succeeded. Others, again, have endeavoured to find some formula, as \( x + x + 41, x + x + 17, 2x + 29, \) &c. which shall contain prime numbers only, whatever value may be given to \( x \); but neither in this have they been more successful. It is in fact demonstrable, that no such formula can be found; though some formula of this kind are remarkable for the number of primes included in them. Thus the first of these given above, by making successively

\( x = 0, 1, 2, 3, \) &c. will give a series, the first forty terms of which are prime numbers; the second, in the same way, gives seventeen of its first terms prime; and the latter,

twenty-
twenty-nine. These cafes shewed the great danger of inductive conclusions in mathematical investigations; for it will seldom happen that we have greater reason to draw a general conclusion, on those principles, than in the series above mentioned.

It was doubtless by not being sufficiently guarded on this point, that led Fermat, the father of the present theory of numbers, to asert that \( 2^n + 1 \) would always be a prime number, while \( x \) was taken any term in the series, 1, 2, 2', 2', &c.; but Euler found that it failed in the case \( x = 32 \), which gives \( 2^{32} + 1 = 641 \times 6700417 \).

It may not be amiss to observe, with respect to what is stated above, viz. that no rule has yet been found for ascertaining whether a given number be prime or not; that this is only meant with reference to a ready method: for, in fact, if we divide a number successively by all prime numbers less than the square root of itself, and no one of them will divide it without a remainder, that number is a prime, which, though long and tedious, may be called a rule for that purpose: there are also other rules depending upon the quadratic forms of prime numbers, but they are all extremely laborious for large numbers. Waring, in his “Meditations Algebraicae,” gives also a rule for this purpose, which he informs us is due to Sir John Wilton, and which, considered in algebra, is certainly as complete as can be defined. This is as follows:

If \( n \) be a prime number, then the continued product \((1 \times 2 \times 3 \times 4 \times 5 \&c. \times n - 1) + 1\), will be divisible by \( n \).

And as this property belongs exclusively to prime numbers, nothing can be more complete; but unfortunately the great magnitude of the product renders it totally useless as a practical rule.

The curiosity of the public has been lately much excited by the little American boy, Zerah Colburn, (already mentioned under our article MENTALISMI) who, without any previous instruction, performs many remarkable feats in arithmetical computations, no one of which is more singular, than the ready manner in which he discovers the factors of composite numbers, and ascertains those which have no factors or primes. The writer of this article has examined him very closely on these points, in order, if possible, to discover the process which he employs for this purpose, from the whole of which it appears, that he depends very much upon the terminating figures of the number proposed. As soon as a number is mentioned, he will tell you, that as it finishes with such and such figures, its divisor, if it has one, must finish with certain other figures, and it immediately attempts the division of it by prime numbers terminating in those digits; or, which is perhaps more probable, he endeavours to find a number which, multiplied by the former, will produce the number proposed, and if he does not readily succeed, he declares it to be a prime, and is frequently correct.

Not to mention a great many smaller numbers which were proposed to him, and which he answered with great facility, it will be more to the purpose to state a few particulars relative to the number 4294067297, which was proposed to him at a dinner, where he and his father were present. This is the number mentioned above, which Fermat had stated to be a prime, but which Euler had found to be composite, consisting of the factors 641 \( \times 6700417 \). It was not of course expected that he could readily detect the factors in a number of such magnitude; but his attempts threw considerable light upon the process which he employed. He found, by the terminating digits of the number proposed, that its factors must be terminated with certain other digits, and thus formed a sort of table, which his father noted down by his directions, and then again all such prime numbers as had those terminations, and by this means reduced the number of trials very considerably, and amongst the number of his divisors was found the real factor 641. In numbers of moderate extent, viz. such as consisting of four or five figures, this method of exclusion, which he employs, reduces the number of trials to a very few; and the rapidity with which he finds his supposed divisors, and applies them to the number proposed, is certainly one of the most extraordinary feats in the whole history of arithmetic. He undoubtedly possesses a remarkably retentive memory, but he owes still more to a very ready perception of the qualities and properties of numbers. And it is much to be regretted, that such rare talents are not duly cultivated, by placing him under the tuition of a master who is able to expand his infant ideas, and to direct his attention to subjects of greater interest than those in which he is now constantly engaged, in order to satisfy the curiosity of speculators, and the pecuniary views of his father.

We have been led into a longer digression than was at first intended respecting this remarkable boy: we shall now conclude this article by enumerating a few of the most remarkable properties of prime numbers, with a table of them as far as 216,000, which is double the extent to which they are carried in any other English work, and which it is presumed may be found useful in a great variety of cases connected with arithmetical and numerical problems.

1. Prime numbers are divided into different classes, according to the forms under which they are contained, each form having certain properties peculiar to it; and these are either linear or quadratic, according as the forms by which they are expressed are simple quantities or squares. Thus, the forms \( 4n + 1 \), \( 4n - 1 \), \( 6n + 1 \), &c. are linear forms; but when we lay prime numbers of the forms \( x^2 + y^2 \), \( x^2 + 2y^2 \), &c., there are called quadratic forms.

2. Every prime number is of one of the forms \( 4n + 1 \), or \( 4n - 1 \); that is, a prime number, when divided by 4, will either leave a remainder \( +1 \), or \( -1 \), which is one of the principal divisions or classifications of prime numbers; but these two forms, according as \( n \) is even or odd, are farther subdivided into the following: \( \text{viz. } 8n + 1, 8n + 3, 8n + 5, 8n + 7; \) and though a similar classification may be made to any modulus, yet those authors who have treated on this subject, seldom trace the properties of prime numbers to any other forms than those above given, and of these the most remarkable are as follow.

3. Every prime number of the form \( 4n + 1 \), is at the same time of the form \( x^2 + y^2 \); or, which is the same, every prime number of the form \( 4n + 1 \), is the sum of two integral squares, but it can be divided into two such squares only one way; thus \( 17 = 4^2 + 1^2 \), \( 29 = 5^2 + 2^2 \), \( 37 = 6^2 + 1^2 \), &c.

As the form \( 4n + 1 \) includes the two forms \( 8n + 1 \), \( 8n + 3 \), \( 8n + 5 \), \( 8n + 7 \); therefore every prime number contained in these two forms is the sum of two integral squares.

4. Every prime number \( 8n + 1 \), is of the three forms \( y^2 + z^2 \), \( y^2 + 2z^2 \), and \( y^2 - 2z^2 \).

Thus \( 41 = 5^2 + 4^2 = 3^2 + 2 \cdot 4^2 = 7^2 - 2 \cdot 2^2 \); and \( 73 = 8^2 + 3^2 = 1^2 + 2 \cdot 6^2 = 9^2 - 2 \cdot 2^2 \); and the same for all other prime numbers of this form.

5. Every prime number of the form \( 8n + 3 \), is of the form \( y^2 + 2z^2 \); that is, every prime number which, when divided by 8, leaves a remainder 3, is the sum of a square and double a square.

For example, 11, 19, 43, &c. are prime numbers of the form \( 3M_2 \).
form \(8n + 3\); and \(11 = 3^2 + 2 \cdot 1^2\), \(19 = 1^2 + 2 \cdot 3^2\), \(43 = 5^2 + 2 \cdot 3^2\), &c.

6. Every prime number \(8n + 5\), is of the form \(y^2 - 2z^2\); or every prime number which, when divided by 8, leaves a remainder 5, is equal to the difference between a square and double a square.

Thus, \(31 = 2^2 - 2 \cdot 3^2\), \(47 = 7^2 - 2 \cdot 1^2\), &c. and the same for all other prime numbers of this form.

7. From these four properties we may readily draw the following theorems.

All prime numbers of the forms \(8n + 1\), and \(8n + 5\), are, exclusively of all others, contained in the formula

\[y^2 + 2z^2\]

All prime numbers of the forms \(8n + 1\), and \(8n + 7\), are, exclusively of all others, contained in the formula

\[y^2 - 2z^2\]

All prime numbers of the form \(8n + 1\) are, at the same time, of the three forms \(y^2 + z^2\), \(y^2 + 2z^2\), \(y^2 - 2z^2\).

The general demonstration of these very remarkable properties of prime numbers was first given by La Grange, in the Memoirs of Berlin for 1776.

It may not be amiss to observe here, that, when it is said that every prime number is of a certain form or forms, it must not be understood that, also conversely, every number contained in those forms is a prime number; for the converse does not obtain, as will be evident from a moment's inspection of any of the forms above given, nor indeed can any form be found that has this property, as we have already observed in the preceding part of this article.

8. The number of prime numbers is infinite; but the number of them, under any given number \(N\), is very nearly expressed by the formula

\[N = \frac{\text{hyp. log.}}{1.08366} \cdot \frac{N}{100000}\]

as may be verified by means of the following table, which contains the number of the primes, under and between certain periods, from 1 to 400,000. But for the demonstration of it we must refer the reader to part iii. of Le Gendre's "Essai sur la Théorie des Nombres."

</table>

The above table represents the distribution of prime numbers up to certain values. Each cell shows whether a number is prime (true) or not (false). The table is organized in a grid format, with rows and columns indicating the range of numbers being evaluated. The columns represent increasing values, and the rows indicate the prime status of those values.

**Prime Numbers.**
The Romans had great variety of primicerii, both in the church and the emperor's court; a primicerius of the empress, primicerius Augyalis, primicerius of the hardier, primicerius of the legions, of the court, of the chamber, of the palace, &c.

The ecclesiastical primicerius, Du-Cange observes, was the same with the chantor among us.

In the church of Metz, the primicerius is the first dignitary of the diocese, and presides at assemblies of the clergy, in prejudice of the bishop.

At Venice the dean of the church of St. Mark is called primocirio, or primicerius: he is independent of the patriarch of Venice, and enjoys episcopal privileges.

PRIMIERO, in Geography, a small island in the gulf of Venice, near the coast of Friuli. N. lat. 45° 45'. E. long. 13° 30'.

PRIMING, or PRIME of a Gun. is the gunpowder put into the pan of small arms, and into the vent of cannon, near the opening of the touch-hole, in order to fire the piece. The priming is the last thing done in charging. See Charge.

For pieces of ordnance, they have a pointed iron rod to pierce the cartridge through the touch-hole, called the primer, or priming-iron: and it serves to discover whether the powder contained in it is thoroughly dry, and fit for immediate service.

PRIMING, among Painters, signifies the laying on of the first colour.

PRIMING, in Japan Work. See JAPANNING.

PRIMIPILARI, or PRIMOPILARI, or Primipilares; in Antiquity, were properly such as had formerly borne the office of primipilus, or first centurion of a legion, to whom was entrusted the care of the banner.

Some will also have primipilarii to have been a denomination given to the soldiers of the first cohort of a legion.

The primipilarii had considerable advantages; one of the chief was, that most of the soldiers who died in the campaign, left them their heirs.

PRIMIPILUS, or PRIMOPILUS, or Primipili centurio, the centurion of the first cohort of a legion, who had charge of the Roman eagle.

PRIMITIE, the first fruits gathered of the earth; of which the ancients made presents to the gods.

In Leviticus, the primitive of all fruits are enjoined to be offered to God.

In our law, the primitive are one year's profits, after avoidance, of every spiritual living, as rated in the king's books. See PRIMIPILUS, and First fruits.

PRIMITIVE, in Grammar, a root; or a word in a language, which is neither derived from any other language, nor compounded from any other words of the same. See Root, Word, &c.

Thus God is a primitive; Godly, a derivative; God-like, a compound.

PRIMITIVE, in Arithmetic. See PRIMI and NUMBER.

PRIMO, in the Italian Muses, is often abridged thus, P or P', and added to other words, as, primo canto, the first treble; alto primo, the first counter-treble; tenor primo, the first tenor; basso primo, the first bass; fagotto primo, the first bassoon; chord primo, the first chord, &c.

Primo beneficio ecclesiastico habendo, in Latin, a writ directed from the king to the lord chancellor, appointing him to yield the benefice that shall first fall in the king's gift, above or under such a value, upon this or that clerk. See Benefice.

Propositio de Primo adjuncta. See Proposition.

PRIMOCHÉ, Niz, in Geography, a town of Russia, in
the government of Saratov, on the Motchta; 104 miles E. of Chvalnik.

Primoeche, Sred, a town of Russia, in the government of Saratov, on the Motchta; 108 miles E. of Chvalnik.

Primoeche, Var, a town of Russia, in the government of Saratov; 116 miles E. of Chvalnik.

Primogeniture, Primogenitura, the right of first-born, or eldest son or child.

The right of primogeniture seems to be an unjust prerogative, and contrary to natural right; for since it is birth alone that gives children a title to the paternal succession, the chance of primogeniture should not throw an inequality among them.

The "infantile prerogative of primogeniture," as Mr. Gibbon denominates it, was unknown among the Romans; the two sexes were placed upon a just level; all the sons and daughters were entitled to an equal portion of the patrimonial estate; and if any of the sons had been intercepted by a premature death, his portion was represtented, and his share was divided by his surviving children. On the failure of the direct line, the right of succession must diverge to the collateral branches.

Accordingly, the right of primogeniture, which calls the elder born to the crown, preferably to the others, was not introduced into France till very late, it was unknown to the first race of kings; and even to the second.

The four sons of Clovis shared the kingdom equally among themselves; and Louise Le Debonnaire did the same: it was not till the race of Hugh Capet, that the prerogative of succession to the crown was appropriated to the first-born.

By the ancient custom of gavel-kind, still preferred in some parts of our island, primogeniture is of no account; the paternal estate being equally shared by all the sons. See Descent, and Right of Crown.

Primopilus. See Primipilus.

Primores, in Ornithology, denote the quill-feathers which spring from the first bones of the wings, and are ten in number.

Primorie, in Geography, a province of Dalmatia, on the coast of the Adriatic, between the Cetina and the Neretva. This was called by the ancients "Dalmatia," and by the later Greeks "Paralithallea."

Primrose, James, in Biography, an ingenious physician, was born of Scottish parents at St. Jean d'Angely, in the province of Guienne, in France, where his father was minister. He received the degree of master of arts at Bourdeaux, and then went to Paris, where he was enabled to pursue his medical studies by the liberal patronage of James I. king of England. He afterwards completed his education at Montpellier, where he was admitted to the doctorate in the year 1617; and then repaired to England, with a view to practise his profession. In 1629 he was admitted ad eundem at Oxford, and forthwith settled at Hull, where he acquired extensive reputation and practice. He was author of many works, some of which, however, remain the monuments of his illiberality and prejudice, being written in a captious style, in opposition to the discovery of the circulation, recently promulgated by the immortal Harvey, with all the demonstrative proofs that can even now be adduced, if we except that of the microscope. The following are the titles of his works: "Exercitationes et Animadversiones in Librum de Motu cordis et Circulatione sanguinis, adversus Gul. Harveum;" Lond. 1630. "Animadversiones de Joannis Waldi Difputatione quam pro circulatione sanguinis proponi, ibid. 1639. "De vulgi Erroribus in Medicina;" ibid. 1639. This work passed

Primrose, in Botany, &c. See Primaula.

Primrose, Evening or Night. See Enothera.

Primrose, Peersi. See Nargissus.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five angles, and five acute upright teeth, permanent. Cor. of one petal; tube cylindrical, about the length of the calyx, terminating in a small hemispherical neck; limb spreading, cut half way down into five inerally heart-shaped, emarginate, obtuse segments; throat pellucid. Stam. Filaments five, very short, in the neck of the corolla; anthers pointed, erect, converging, within the mouth. Petil. Germin superior, globose; style thread-shaped, the length of the calyx; stigma globose. Peric. Capsule roundish, full as long as the perianth which clothes it, of one cell, opening with ten teeth at the summit. Seeds numerous, roundish, on an ovate-oblong unconnected receptacle.

Eff. Ch. Capsule of one cell, with ten teeth. Tube of the corolla cylindrical; throat pellucid. Stigma globose.

Linnaeus reckoned up seven or eight species of Primula; Willdenow 18. They are all hardy, perennial, herbaceous plants, natives of cool, generally mountainous, countries, and blooming in the spring. Their leaves are simple and radical. Flower-stalks radical; for the most part umbellate. Flowers red, purple, or yellow, varying in some species from one hue to the other, and frequently sweet-scented. Four species, or more properly three, are natives of Britain; and of these, with a few of the most remarkable foreign ones, we shall give characters and synonyms.

—Leaves toothed, wrinkled. Stalks single-flowered. Limb of the corolla flat. —Native of groves, thickets and banks, on a fertile soil, throughout Europe, blooming with us in profusion in April and May. The root is oblong, toothed, rather fleshy. Leaves ovate-oblong, light green, rugged, somewhat pubescent, four or five inches in length, but much enlarged after the flowers are past. Flower-stalks numerous, about equal to the leaves, simple, though more or less distinctly united by a common base, and occasionally elevated all together on one general stalk, so as to compose an umbel, accompanied by lanceolate bracteas, termed by Linnaeus an involucrem. Flowers of a delicate sulphur-colour, with an orange eye, faintly but agreeably scented. A rose-coloured variety is found in the Levant, and sometimes occurs in England.
England. We have seen it originate, with either a simple or compound inflorescence, as above described, from seeds of the common Primrose, and hence perhaps came the Poleyanthus, so industriously cultivated. The gardeners keep a double lilac-coloured variety, Curt. Mag. t. 229, which is easily increased, and a leaf hardy one of a dark brown; but the double sulphur-coloured Primrose is peculiarly elegant. This leaf blooms regularly two or three weeks later than the rest.

P. eliator. Oxlip, or Great Cowslip. With. t. 234. Fl. Brit. n. 2. Engl. Bot. t. 513. Ait. n. 2. (P. eliator = Willd. n. 3. P. veris = Linn. Sp. Pl. 204.)—Leaves toothed, wrinkled. Stalk many-flowered. Limb of the corolla flat.—Found in groves, pastures and thickets, in England and elsewhere, but not frequently. It seems to be a variety of the former, with a greatly elevated common flower-flak, and much shorter partial ones. The flowers however are smaller, and more drooping. The leaves are occasionally contracted in the middle, but less regularly or distinctly than those of the following. We are more inclined to think this true P. eliator a mule between the Primrose and Cowslip, distinct from the casually umbellate varieties of the former that are described above.

P. veris. Common Cowslip, or Paigle. Linn. Sp. Pl. 204. Willd. n. 2. Ait. n. 3. Fl. Brit. n. 3. Engl. Bot. t. 5. Bulliard t. 171. (P. officinalis = Curt. Lond. fœc. 6. t. 15. P. veris major = Ger. Em. 780.)—Leaves toothed, wrinkled, contracted in the middle. Stalk many-flowered. Limb of the corolla concave. Plentiful in meadows and pastures of England and other parts of Europe, but only on a strong soil of clay or marle, flowering in April or May. This is unquestionably a most distinct species, though Linnaeus considered it as a variety of the Primrose. The blossoms communicate their aromatic fragrance, and narcotic quality, to made wines, which thence have a resemblance to the muscadnel wines of the south of France.

P. longiflora. Long-flowered Primula. Jacq. Austr. append. t. 46. Willd. n. 8.—Leaves serrated, smooth; powdery beneath. Umbel drooping. Tube of the corolla greatly elongated. Native of the Alps of Switzerland, Italy, Carinthia, &c. Wullen in Jacquin’s work well afferts this to be a distinct species from the last, from which it differs in the length, and paler purplish hue, of the corolla, as well as in having larger, less powdery, leaves. We have fine specimens from the late Mr. Davall’s herbarium.

P. marginata. Silver-edged Primula. Curt. Mag. t. 191. Willd. n. 10. Ait. n. 9.—Leaves ovate, with tooth-like powdery serrations. Stalk many-flowered. Brevitas shorter than the partial flaks. Said to be a native of the Swiss alps, from whence Meffrs. Lee and Kennedy obtained, in 1777, this very pretty plant, now common in gardens, where it blooms in March and April. It is best kept in pots, with little moiture; and will not bear forcing. The leaves have a musky scent, and are strikingly bordered with cream-coloured powder. The corolla is of an uniform deep lilac.

P. Auricula. Garden Auricula, or Bear’s-ear. Linn. Sp. Pl. 205. Willd. n. 11. Ait. n. 10. (Auricula urbi, flore luteo; Ger. Em. 784.)—Leaves ovate, slightly serrated, smooth, more or less powdery. Stalk many-flowered, about the length of the foliage.—Native of the Alps of Switzerland, Germany, Carniola, &c. We have gathered it on Mount Cenis. This, the origin of all the fine powdery garden auriculas, has, in a wild state, much less powdery leaves, whose edges are partially, but often coarsely, serrated; their form broadly and obtusely ovate, of a lax, leafy, twisted habit. The flowers are small and yellow, occasionally purple, or red, as usually seen in ordinary gardens. Their scent is grateful and peculiar.

Primula, in Gardening, contains plants of the low, fibrous-rooted, herbaceous, flowery, perennial kind, of which the species cultivated are, the common primrose (P. vulgaris); the great cowslip or oxlip (P. eliator); the common cowslip or paigle (P. officinalis); the birds’ eye primrose (P. farinosa); the long-leaved birds’ eye primrose (P. longifolia); the cortusa-leaved primrose (P. cortusoides); the silver-edged primrose (P. marginata); and the auricula, or bear’s ear (P. auricula).

The varieties of the first are numerous, being partly wild and partly produced by cultivation. The principal of which are; the common yellow-flowered; the white; the paper white; the red; the double yellow; the double white; the double red; the double pink; the double crimson primrose. It is a native of most parts of Europe, flowering in March and April with the wood anemone.

It is observed that a fine flower of this sort should possess a graceful elegance of form, a richness of colouring, and a perfect symmetry of parts. The properties are mostly similar to those which distinguish the auricula, in which relates to the stem or scape, the peduncles or flower-flaks, and the formation of the umbel, bunch or thyrse, vulgarly termed the truf; the tube of the corolla above the calyx should be short, well filled at the mouth with the anthers, and flushed termination rather above the eye; the eye should be round, of a bright clear yellow, and distinct from the ground-colour; the ground-colour is most admired when shaded with a light and dark rich crimson, resembling velvet, with one mark or stripe in the centre of each division of the border, bold and distinct from the edging down to the eye, where it should terminate in a fine point; the petals, technically termed the pips, should be large, quite flat, and perfectly circular, excepting the small indentures between each division, which separate it into five (sometimes six) heart-like segments; and the edging should resemble a bright gold lace, bold, clear and distinct, and so nearly of the same colour as the eye and stripes, as scarcely to be distinguished from it.

The second sort varies much in the colour of the flowers, but the chief are purple-flowered, red-flowered, gold-coloured, orange-coloured, with various shades of each.
The varieties in the third sort are the common single yellow cowslip; double yellow cowslip; scarlet cowslip; and hofe, and hofe cowslip.

The fourth sort varies in the size of the plant, having been found wild a foot and half in height; and in the cultivated plant, a tendency to become viviparous has been observed by Curtis, or to produce one or more tufts of leaves among the flowers of the umbel. In its wild state it feeds readily, and frequently when cultivated; the flowers also vary with different shades of purple, and have been found entirely white.

The eighth sort varies much in the leaves and flowers; as the oblong-leaved, roundish-leaved, broad-leaved, narrow-leaved, green-leaved, white or meal-leaved; the purple-flowered, of various shades and variegations; yellow-flowered, of different shades; double purple-flowered, double yellow-flowered, variegated purples, &c.

With regard to the properties of a fine auricula, they are thefe, according to Martyn; the item should be strong, upright, and of such a height that the umbel of flowers may be above the foliage of the plant; the peduncles or foot-flaks of the flowers should also be strong, and of a length proportional to the size and quantity of the flowers; which should not be less than seven in number, that the umbel may be regular and clofe; the tube, eye, and border should be well proportioned, which they will be, if the diameter of the first be one part, of the eye three, and the whole border fix parts or thereabouts; the circumference of the border should be round, or nearly so, or at leat not what is called flary; the anthers ought to be large, bold, and fill the tube well; and the tube should terminate rather above the eye, which should be very white, smooth, and round, without cracks, and distinct from the ground-colour; the ground-colour should be bold and rich, and regular, whether it be in one uniform circle, or in bright patches; it should be distinct at the eye, and only broken at the outer part into the edging; a fine black, purple, or bright coffee-colour, contrasted with the white eye; a rich blue, or bright pink, is pleasing; but a glowing scarlet or deep crimson would be most desirable, if well edged with a bright green; this, however, can seldom be expected; the green edge is the principal caufe of the variegated appearance in this flower; and it should be in proportion to the ground-colour, that is, about one-half of each; the darker grounds are generally covered with a white powder, which seems necessary, as well as the white eye, to guard the flower from the icorcing heat of the sun’s rays.

It is observed that all flowers that want any of the above properties are turned out into the borders of the garden, or rejected wholly by every good florist, for as there are varieties every year from feeds, the bad ones must make room for their betters; but in some the passion for new flowers so much prevails, that supposing the old flower to be greatly preferable to a new one, the latter must take place, because it is of their own raising.

Method of Culture.—These beautiful plants are raised without much difficulty, by proper care and attention in their management, with respect to the parting of the roots, and the planting them out in their due feafon; they succeed best in a strong foil, and some of them, as the primrose kind, in a shady situation.

Culture in the Polyanthus Kinds.—These are all capable of being increased by feed, and the parting of the roots, the former being the only method for obtaining new varieties, or a large supply of plants. The feed should be collected from such flowers as have large upright items, and which produce many flowers upon the falk, being large, beautifully striped, open, flat, and not pin-eyed, as from such feed a great variety of good sorts may be expected; care should however be taken that no bad or common flowers stand near them, as they will be apt to debase them, by the admixture of their familia.

The feeds should be fown in boxes or large pots filled with light rich mould. The proper feafon for this busines is in the autumn, or the early spring; but the former is the better, as by fowing then the plants come up well the fame year, and are strong and fit to plant out the following spring, and are fine plants for flowering the fectond fpring. In the firft feafon the fowing fhould be performed as foon as possible after the feed becomes well ripened; though fome advise December as a good time, or the fpring feafon, it may be done in February, March, or the following month. The feed fhould be fown over the furface tolerably thick, being covered in very lightly, and the boxes or pots placed where they may have a little of the morning sun, but not by any means the mid-day heats. The plants may be much forwarded by the pots or boxes being plunged in a mild hotbed; in the fpring, when dry, they fhould be frequently refrefhed with water, in very moderate proportions at a time, removing the plants more into the shade as the heat advances, as it foon deftruits them. The autumn-fown plants fhould have a warm fituation during the winter, or be protected from frofts or fevere weather by glaffes or other means.

In the fpring, or early fummer, the plants of the different fowings will be fufficiently strong to plant out, for which a bed or findy border fhould be prepared, and made rich by neat’s dung, on which the plants fhould be fet out about four or five inches ditant in every direction, care being taken to water them occasionally till well-rooted, after which they only require to be kept free from weeds; and when they flower in the following fpring the falt flowers fhould be marked, and the reft be removed into the borders or other places for affording variety; and the valuable plants may be removed, when they have finifhed flowering, into the borders or beds where they are designed to flower and remain, in the fame manner as above, watering them lightly till well rooted again. The roots afterwards require to be parted and removed annually, and the earth of the borders renewed, to prevent their degenerating.

It is neceffary, in order to keep up a proper stock of plants, to raife new feeding plants every two or three years, as the old plants moftly decline in beauty after the third year.

In the latter method, the roots fhould be parted in the beginning of the autumn, as foon as the flowering is over, and it may likewise be done early in the fpring; but the former is the bett time, as the plants get stronger and flower better in the fpring. In performing the work the plants fhould be taken up out of the ground, and each bunch divided into feveral fips, not too small, unlefs where a great increase is wanted, being careful to preserve some root to each fip; they are then to be planted in a frefh dug border, enriched with dung as above, letting them five or six inches alunder, giving them water directly, and repeating it occafionally, till they have taken good root. The approved forts may, in this way, be easily preferved.

These plants are obferved by the editor of Miller’s dic- tionary to be very liable to the deprecactions of snails and flugs, in the fpring of the year; the plants and pots there- fore fhould be carefully examined on all sides early in the morning. But their worst enemy is a small red fpeaker or acarus, which, in fummer, forms its web on the under-side of the leaves. These little infécts, scarcely visible without a magnifying-glass, caufe the leaves to become yellow and spotted,
PRIMUL A.

spotted, and eventually destroy the plant; they multiply with such rapidity as to take possession of a whole collection in a very short time. Such plants as appear infected should therefore be immediately selected from the rest, taken up, and soaked for two or three hours in a strong infusion of tobacco water, and then re-planted in a fresh foil or compost, and removed to a situation at a distance from the former. But if the whole bed or border be overrun with this insect, it is best to take up all the plants, and, having soaked them, to plant them elsewhere. The bed or border should then be trenched up, and remain fallow to the next season, or be planted with another crop not liable to this calamity.

In their after-management, they are said to blow at the same time, and require nearly the same treatment as auriculas, both with respect to foil and situation; they are, however, more impatient of heat and drought, and more partial to shade and moisture. They may be set in the same sized pots, and in the same compost as the auriculas, only with the addition of more loam; or they may be planted on cool shady beds or borders, being very hardy, and seldom perishing in the coldest and wettest winters, because their parent is a native of this country; but during the heats of summer they are frequently destroyed, unless proper precautions are taken. This dislike to heat seems to indicate, it is added, that the polyanthus is rather the offspring of the primrose, which requires shade, than of the cowslip, which grows in open pastures; though Mr. Miller seems to regard it as a variety of the latter.

The roots of the wild plants, when they can be procured, may be taken up, divided, and planted out in the autumn, when they will flower in the following spring.

The fourth fort readily feeds in its wild state, and also frequently when cultivated; but is scarcely worth the pains to raise it from seed, since a strong root may be divided so as to form many plants; the best time for doing this is in the spring, soon after the leaves are expanded. Each off-set should be placed in a separate pot, filled with two parts of flufilth loam, and one part of light sandy bog-earth, watering and setting them in the shade, under a north wall or paling, but not under trees, keeping them there during the summer in pans of water, but in the autumn, as the wet season comes on, taking them out of the pans, and either laying the pots on their sides, or placing them during winter under a common cucumber frame, to keep them from immediate wet, which this plant cannot bear, although it be a native of boggy meadows. In the following, if not the same year, these plants will blow strong; and they should be thus treated every year, as they require to have their roots frequently parted.

The fifth fort is increased by parting the roots, either in September, or at the beginning of March. It is hardy, of ready growth, and will succeed either in the pot or border, by guarding it from the sun in summer and from severe frost and too much wet in winter.

The fifth species, which is yet a rare plant, must be treated with care, as the fifth fort, and may be raised from seeds, or increased by parting the roots; but it is apt to be lost if not well attended to.

The seventh fort is delicate, and should be placed in a pot of flufilth loam, mixed with one-third rotten leaves, bog-earth, or dung, and plunged in a north border, taking care that it does not suffer for want of water in dry seasons; as when thus treated it increases by its roots nearly as readily as the auriculas.

Culture in the Auricula Kinds.—These plants may all be increased by seeds in order to procure new varieties, and by slipping the roots to increase the approved kinds.

In order to obtain good flowers from seeds, choice should be made of the best flowers, which should be exposed to the open air, that they may have the benefit of flowers, without which they seldom produce good seeds; the time of their ripening is in June, which is easily known, by their seed-vessels turning to a brown colour, and opening, being then careful to take the seeds and scatter them out of the vessel, or they will not be all fit to gather at the same time.

The proper soil for this fort of feed is good, fresh, light, sandy mould, mixed with very rotten neat's-dung, or very rotten dung from the bottom of an old hot-bed; with which the pots, boxes, or barks in which the seeds are to be sown should be filled; and having levelled the surface very smooth, the seeds should be sown, setting over them a little rotten willow mould; then covering them with a net or wire, to prevent cats or birds from scratching out, or burying the seeds so as to destroy them. Some persons never cover the seeds, but leave them on the surface for the rain to wash them into the ground, which is often the best method. The boxes, &c. should then be placed so as to receive half the day's fun during the winter season; but in the beginning of March be removed, where they may have only the morning fun till ten o'clock; for the young plants now soon begin to appear, which, if exposed to one whole day's sun only, are all destroyed. The proper season for sowing the seed is in the latter end of summer, or beginning of autumn, as about September, but they may be sown in the spring. During the summer season, the plants in dry weather should be often refreshed with water, never giving them too great a quantity at once. In the July following, the plants will be large enough to remove, at which time a bed must be prepared, or boxes filled with the above-mentioned soil, in which they may be planted about three inches apart, and shaded when in beds, every day, till they are thoroughly rooted, as also in very hot dry weather; but if they are in baskets or boxes, they may be removed to a shady situation.

When planted in beds, there should be some rotten neat's-dung laid about ten inches under the surface, and beaten down close and smooth; this will prevent the worms from drawing the young plants out of the earth, which they generally do where this is not practised. This dung should be laid about half a foot thick, which will entirely prevent the worms getting through it until the plants are well established in the beds; and the roots strike down into the dung by the spring, which makes their flowers stronger than usual: these beds should be exposed to the east, and screened from the north fun as much as is necessary.

In the spring following many of these flowers will flower; when such of them as have good properties should be selected, which should be removed, each of them into a pot of the same prepared earth, and preferred until the next season, at which time a judgment of the goodnes of the flower may be formed; but those that produce plain-coloured or small flowers should be taken out, and planted in borders in the out parts of the garden, to make a show, or gather for nosegays, &c.; the others, which do not produce their flowers the same year, may be taken up and set out in a fresh bed, to remain till their properties are known.

In the second method, the offsets or slips may be taken from the old roots in the spring or autumn, and be planted into small pots filled with the same fort of earth as was directed for the seedlings, and during the summer season be set.
let in a shady place, and must be often gently refreshed with water, and in the autumn and winter be sheltered from violent rains. In the spring following these plants produce flowers, though but weak; therefore, soon after they are past flowering, they should be put into larger pots, and the second year they will blow in perfection.

In order to obtain a fine bloom of these flowers, the plants should be preferred from too much water in winter, which often rots and spoils them, letting them have as much free open air as possible; but they should not be too much exposed to the sun, which is apt to forward their budding for flower too soon; and the frosty mornings, which often happen in March, thereby destroy their buds, if they are not protected; to prevent which, those who are curious in these flowers place their plants in autumn under a common hotbed frame, where, in good weather, the plants may enjoy the full air, by drawing off the glass; and in great rains, snow, or frost, be screened by covering them.

About the beginning of February, when the weather is mild, the upper part of the earth in the auriculas should be taken off as low as can be, without disturbing their roots, filling up the pots with fresh rich earth, which greatly strengthens them for bloom. As those plants which have strong single buds always produce the largest clusters of flowers, the curious florist should pull off the offsets as soon as it can be done with safety to their growing, to encourage the mother plants to flower the stronger; they should also pinch off the flowers in autumn, where they are produced, and not suffer them to open, that the plants may not be weakened by it. The pots should be covered with mats in frosty weather, during the time of their budding for flower, left the sharp mornings blight them, and prevent their blooming. When the flower items begin to advance, and the blooms buds grow turgid, they must be protected from hasty rains, which would wash off their white mealy farina, and greatly deface the beauty of their flowers, keeping them as much uncovered as possible, otherwise their items will be drawn up too weak to support their flowers, (which is often the case when their pots are placed near walls,) giving them gentle waterings to strengthen them, but none of the water should be let fall into the centre of the plant, or among the leaves.

When the flowers begin to open, their pots should be removed upon a stage (built with rows of shelves, one above another, and covered on the top, so preferve them from the wet; this should be open to the morning fun, but sheltered from the heat of the sun in the middle of the day); in this position they will appear to much greater advantage, than when they stand upon the ground; for their flowers being low, their beauty is hid; whereas, when they are advanced upon shelves, they are fully seen. In this situation they may remain until the beauty of their flowers is past, when they must be set abroad to receive the rains, and have open free air, in order to obtain feeds, which will fail if they are kept too long under shelter. When the feed is ripe, it should be gathered when it is perfectly dry, and exposed to the sun in a window upon papers to prevent its growing mouldy, letting it remain in the pots till the season for laying.

It is observed by the editor of Miller's Dictionary, that those who are very nice in raising auriculas, direct the compost to be made of one-half rotten cow-dung two years old; one-fifth fresh found earth of an open texture; one-eighth earth of rotten leaves; one-twelfth coarse earth or river sand; one twenty-fourth loft decayed willow wood; one twenty-fourth peaty or moary earth; one twenty-fourth ashes of burnt vegetables; to be spread upon the surface of the other ingredients. This compost is to be exposed to the sun and air, turned over once or twice, and palled as often through a coarse screen or sieve; then laid in a regular heap from fifteen to eighteen inches thick, and in this state remain a year, turning it over two or three times, and keeping it free from weeds. And it is added, that the pots for the auriculas should be hard baked; the inner diameter of the top to be six inches and a half, of the bottom four inches, and they should be about seven inches deep, for common-sized blooming plants; but smaller plants and offsets should have smaller shallower pots, and very large plants should have larger pots in proportion; the bottom should have a small degree of concavity, and the hole should be half an inch in diameter; the rims should project about half an inch, in order to take up and remove them with greater ease and safety. The pots should be buried in wet earth, or immersed in water three or four days, or a week before they are wanted, to take off their absorbent property.

In the after-management of the plants, they should be potted annually soon after bloom; curtailing their fibres, if grown very long, and cutting off the lower part of the main root if too long or decayed. The offsets at this season strike freely, and become well established before winter. The plants should be carefully examined, and where any unfoundness appears, be cut out entirely with a sharp penknife, exposing the wounded part to the sun, and when it is quite dry, applying a cement of bees' wax and pitch in equal quantities, softened in the sun or before a fire. If the lower leaves be yellow or dried up, they should be striped off in a direction downwards. Having put the hollow shell of an oyster over the hole of the pot, three parts of it should be filled with compost, highest in the middle, placing the plant there, with its fibres regularly distributed all round; then filling the pot with the compost, adding a little clean coarse sand beside round the item on the surface, and striking the bottom of the pot against the ground or table to settle the earth. The true depth of planting is within half an inch of the lowest leaves, as the most valuable fibres proceed from that part; and the offsets will be thereby encouraged to strike root sooner. When these have formed one or more fibres of an inch or two in length, they may, by means of a piece of hard wood, or by the fingers, be separated with safety, and planted round the sides of a small pot, filled with the same compost, till they are sufficiently grown to occupy each a separate pot; if a small hand-glass be placed over each pot it will cause the fibres to grow more rapidly; but if it be long continued, it will draw up and weaken the plants. And in the beginning of May, as soon as the operation of potting is finished, the plants should be placed in an airy shaded situation, but not under the trunk of trees. Here they may remain till September or October, when they should be removed into shelter.

The plants should, in the first favourable weather in February, be divested of their decayed leaves; and by the middle of that month earth them up; that is, taking away the superficial mould of the pots about an inch deep, and putting in fresh compost, with the addition of a little loam, to give it more tenacity. This contributes greatly to the strength of the plants, and the vigour of their bloom; at the same time it affords a favourable opportunity to separate such offsets as appear to have sufficient fibre to be taken off at this early season. The pots with these offsets should be placed in a frame, in a sheltered situation, till their roots are established. Though froit, unless it be very rigorous, will not destroy the plants, it will injure them.
and perhaps spoilt the bloom, especially early in the spring; they should therefore be covered with mats in a severe season. When any plant has more than one or two principal stems, it is advisable to pinch off the smallest and weakest, in order to render the blossoms of that which remains larger and more vigorous. And when the flowers (pips) become more turgid and begin to expand, the plants should be selected from the rest, removing them to a calm shady corner, suspending small hand-glaffes over them.

In this culture the plants for pots to stand on, when in bloom should have a northern aspect, and should consist of four or five rows of chaffes, rising one above another, the roof being covered with frames of glass; the taller long-stemmed plants being placed behind, and the shorter in front. The plants must be regularly watered two or three times every week during the blooming season.

All these plants are highly ornamental; the former in beds and borders, and the latter among curious potted flowering plants.

PRINCE, PRINCES, in Politic, a perfon invested with the supreme command of a state or country, independent of any superior.
PRINCE is also used for a perfon who is sovereign in his own territory; yet holds of some other, as his superior or lord, and pays homage or tribute to him.

Thus all the princes of Germany are feudalities of the emperor: they are as abfolute in their respective prinoples as the emperor himself; yet are all bound in certain services to him.

PRINCE, in Ancient Records, frequently signifies no more than lord. Du Cange gives a great number of instances of this uage.

In effect, the word prince in Latin, whence prince in English, originally signifies only the chief, or firft: it is compounded of the Latin primus, and caput; and is properly a word of dignity and office, not of property and sovereignty.

Thus in the charter of king Offa, after the bishops had subscribed their names, we read Brordonus patritius, Bissanuus princeps; and afterwards the dukes subscribed their names.

PRINCE of the Senate. There was one member of the Roman Senate distinguished always from the rest by the title of "prince of the Senate." This title was given of course to that person whose name was called over the first in the roll of the Senate, whenever it was renewed by the censors. He was always one of confular and censorial dignity.

After the institution of the censors, it became a custom to confer this title of "prince of the Senate" on the oldest senator then living of censorial dignity. Yet there were no peculiar rights annexed to this title, nor any other advantage, except an accedence of authority, from a notion which it would naturally impart of a superior merit in those who bore it. See Senate.

PRINCE of the Waters, an officer of flate in Peria. The number of wells and subterraneous pits, which were objects of peculiar attention in the reign of Nufhirvan, or Chosirues, so that fresh water was skillfully differted over the arid teritory of this country, is much diminished in later times, and of course the fertility of the foil. Four hundred wells, as we learn from Chardin and Tavernier, have been recently left near Tauris, and 42,000 were once reckoned in the province of Khorasan.

PRINCE of the Youth. Among the ancient Romans, it was the custom for the emperor in his life-time to nominate him whom he would have to succeed in the empire, under the title of princeps iuventutis, & Cesar.

In the ludius Trojanus, the youth who was chosen captain, was also called princeps iuventutis.

PRINCE is also a title given to the fife of princes, or thole of the royal family.

In which sense they are called, particularly in France, princes of the blood; as partaking of the blood to which the sovereignty is appropriated: and not by any hereditary right, but as a patrimony suffizint for the public welfare.

In England, the king's children are called sons and daughters of England: the eldest son is created prince of Wales. The cadets, or younger, are created dukes or earls, with what title the king pleases. They have no appendages, as in the former constitution of France; but only what the good pleasure of the king and parliament bestow on them.

The sons are all by birth counsellors of state: and the daughters are all styled prinses: to violate the eldest of which, unmarried, is at this day high treason. See Marriage and Premunire.

To all the king's children belongs the title of royal highnes; all subjects are to kneel, when admitted to kifs their hand; and at table, out of the king's presence, they are served on the knee. The younger sons and daughters of the king who are not in the line of succession, have precedence before all peers and public officers, as well ecclesiasticl as temporal. 31 Hen. VIII. cap. 10.

The first prince of the blood in France was, under the old government, called absolutely monsieur le prince. The quality of prince of the blood gave a rank and precedence, but it did not include any jurisdiction; they were princes by order, not by office.

Wicquefort observes, that it was not more than fifty years from his time that the princes of the blood of France gave place to all ambassadors, even those of republics; and it was at the king's request, that they were since allowed the precedence.

The moment a pope is elected, all his relations become princes.
Prince of Wales, the eldest son of England.

He is born duke of Cornwall; and immediately intituled to all the rights, revenues, &c. belonging thereto; as being deemed in law at full age on his birth-day.

He is afterwards created prince of Wales, and earl of Chester; the investiture of which is performed by imposition of a cap of state, and a coronet, a verge of gold, and a ring. He holds the principality by patent granted him and his heirs, by the kings of England.

The title and principality were first given by king Edw. I. to his eldest son; till that time the eldest son of England was called Earl prince. While Normandy remained to the king of England, the eldest son was always styled duke of Normandy: since the union, his title is Magnus Britanniae princeps.

He is reputed in law the same person with the king; to imagine his death, or to violate his wife, and also the prince's royal, or eldest daughter of the king, is high treason by Act Edw. III., as much as to confpire the death of the king, or violate the chastity of the queen. The reason of which is, that the prince of Wales is next in succession to the crown, and to violate his wife might stain the blood royal with baftardy; and the eldest daughter of the king is also alone inheritable to the crown, on failure of male issue, and therefore more respected by the laws than any of her younger sisters: insomuch that upon this, united with other (feudal) principles, while our military turaries were in force, the king might levy an aid for marrying his eldest daughter, and her only.

His revenues, as duke of Cornwall, have been computed at 14,000l. per annum. The revenues of the principality were estimated, three hundred and fifty years ago, at 4683l. per annum.

Prince of Pleasantry, prince de plaisance, in the Customs of Flanders. See Sports.

Prince of the Horse-comb. See Sports.

Prince's Feather, in Gardening, the common name of a beautiful flower plant. See Amaranthus.

Prince's Wood. See Cordia and Hamelia.

Prince's Bay, in Geography, a bay on the S. coast of Staten island, New York.—Allo, a bay called "Barawally," on the W. of the island of St. Vincent; two miles S. of Cumberland bay.

Prince's Island, an island in the Atlantic, near the coast of Africa, 90 miles in circumference, deriving its name from the aligning of its revenues to the prince of Portugal; discovered in the year 1471. The land is high and fertile, producing chiefly rice, tobacco, millet, oranges, bananas, cocoa, sugar-canes, manioc, and grapes; and the air is favorable. The town, which lies on the N. coast, contains about 200 houses, and has a good harbour. N. lat. 2° 50'. E. long. 7° 10'.—Allo, an island in the East Indian sea, visited by European ships for wood and water. It is subject to the king of Bantam. The Malays call it "Pulo Selan," but by the inhabitants it is denominated "Pulo Paneutan." It lies at the W. entrance of the straits of Sunda. Captain Cook, who visited it in 1771, gives the following account of it. It is woody and very small, part only has been cleared: there is no remarkable hill upon it, yet the English call the small eminence which is just over the landing-place, "The Pike." It was formerly much frequented by the Indian ships of many nations, but especially those of England, which of late have forsaken it, as it is fain, because the water is bad, and touch either at North Island, a small island that lies on the coast of Sumatra, without the east entrance of the strait, or at New Bay, which lies only a few leagues from Prince's Island; at neither of which places any considerable quantity of other refreshments can be procured. Prince's island is, upon the whole, certainly more eligible than either of them; and though the water is brackish, if it be filled at the lower part of the strick, yet higher up it may be found excellent. The first and second, and perhaps the third ship that comes in the season, may be tolerably supplied with turtle; but those coming afterwards must be content with small ones. Cocoa-nuts were bought at the rate of 100 for a dollar, if they were picked, and if taken promiscuously, 150. Plants he found in great plenty, also some pine apples, water melons, jaccas, and pumpkins, besides rice, the greater part of which was of the mountain kind, that grows in dry land. The inhabitants are Javanee, whose rajah is subject to the sultan of Bantam. Their customs are very similar to those of the Indians about Batavia; but they seem to be more jealous of their women. They profess the Mahometan religion. The houseth of their town are built upon piles or pillars, four or five feet above the ground; upon these is laid a floor of bamboo-canes, which are placed at some distance from each other, so as to leave a free passage for the air from below; the walls also are of bamboo, which are interwoven hurdleside, with small ficks that are fastened perpendicularly to the beams, which form the frame of the building. The disposition of the people, as far as they could discover it, is good. They dealt honestly, except that, like all other Indians, and the itinerant retailers of fish in London, they asked sometimes twice, and sometimes thrice as much for their commodities as they would take. They all speak the Malay language, though they have a language of their own, different both from the Malay and the Javanee. Their own language they call Catta Gunung, the language of the mountains; and they say that it is spoken upon the mountains of Java, whence their tribe originally migrated. E. long. 104°. S. lat. 6° 41'.

Prince's Islands. See Papas Aldeghi, and Prinkipois.

Prince Charles's Island, a small island in the North sea, near the W. coast of Spitzbergen.

Prince Edward's Islands, two islands in the Indian sea, discovered in the year 1772, by captains Marion du Frefne and Crozet, French navigators, on their passage from the Cape of Good Hope to the Philippine islands. Captain Cook failed between them in 1776, and gave them their present name, in honour of prince Edward, our sovereign's fourth son. Their distance from one another is about 15 miles. Captain Cook's account is as follows: we passed through this channel at equal distance from both islands; and could not discover, by the allusion of our belt glades, either tree or shrub on either of them; they seemed to have a rocky and bold shore; and excepting the south-east part, where the land is rather low and flat, a surface composed of barren mountains, which rise to a considerable height, and whose summits and sides were covered with snow, which in many places seemed to be of a considerable depth; the south-east parts had a much greater quantity on them than the rest; owing, probably, to the sun acting for a less space of time on thee, than on the north and north-west parts. The ground, where it was hid by the snow, from the various shades it exhibited, may be suppos'd to be covered with mofs or coarse grass. On the north side of each of the islands is a detached rock: that near the south island is shaped like a tower, and seemed to be at some distance from the shore. As we passed along, a quantity of sea-weed was seen, and the colour of the water indicated soundings; but there was no appearance of an inlet, unless near the rock just mentioned; and that, from its shallowness, did not promise a good anchoring-place. That which lies most to the south, and is also the largest,
we judged to be about 45 miles in circuit; and to be in S. lat. 46° 53'. E. long. 37° 40'. The most northerly one is about 27 miles in circuit, and lies in S. lat. 46° 40'. E. long. 38° 8'.

Prince Edward, a county of Virginia, between the Blue Ridge and the tide waters, containing 12,409 inhabitants. Hampden Sydney college is in this county, the building of which is large enough to accommodate 60 students. The principal rivers are the Buffalo, Bifcay, and Buft. On the N. fide, towards the middle, bordering on the Appamatox, the foil is of a good quality; the W. and S. parts are less fertile. This county contains three Episcopal, three Presbyterian, three Baptist, and one Methodift churches. The court-house is 50 miles from Lynchbury, and 358 from Philadelphia.

Prince Edward, a county of Canada, bounded S. by lake Ontario, W. by the carrying place or the lthimus of the Prefque Ile de Quinté, N. by the bay of Quinté, and E. from Point Pleasant to Point Traverle, by its several shores and bays. This county comprehends all the islands in lake Ontario, and the adjacent bay of Quinté.

Prince Edward's fjlet. See Washington's fjlet.

Prince Edward's Sound, an inlet which branches off from the Duke of Clarence's fjrait, and separates the S.E. coaft of the Duke of York's ifland from the continent of America. The S.W. entrance is between Point Onflow and Point Le Mefrinier.

Prince Frederick, the chief town of Calvert county, Maryland; 3 miles S. of Huntington.

Prince Frederick's Sound, an inlet on the North Pacific ocean, on the west coaft of North America; fo named by captain Vancouver, in honour of his royal Inhifees Frederick, duke of York. It extends eaftward from Chatham fjrait to the continent. About 42 miles to the north are Admiralty ifland, Stephens's paflage, and a part of the continent; and on the lhoufe are fome large iflands. N. lat. 56° 52' to 57° 12'. E. long. 225° 42' to 227° 20'.

Prince George, a county of Virginia, bounded north by James river, which waftes about 35 miles of it, in medial breadth 16 miles, containing 8050 inhabitants, five epifcopal churches, one meeting for Friends, and several meetings for Methodifts, and fome for Baptifts. This is a fertile county, and abounds with wheat, corn, flax, cotton, and tobacco. Its timber confifts of various kinds of wood, of good quality, and fit for ship-building. It has alfo abundance of wild grapes, fowering shrubs, farfaparilla, flnake-root, and ginfeng. Its peaches are finely flavoured; the almonds and h gardens grow in the open air. Large quantities of pork and bacon are cured here, and form the principal food of the inhabitants. It has a good, but unton indifferent; its poultry is good and abufant. The winters are short, and generally pleafant; and the country cannot be confidered unhealthy.

Prince George, a county also of Maryland, on the west fhorn of Chefpafke bay, between Patowmac and Patuxet rivers. The eaftern corner of the territory of Columbia borders on the west palf of this county. It contains 20,589 inhabitants.

Prince Rupert's Bay, a bay on the north-west coaft of the ifland of Dominica, which is deep, capacious, and fandy, and affords excellent shelter from the winds. On this bay is situated the town of Portsmouth, north of which is a cape called "Prince Rupert's Head." N. lat. 15° 42'. W. long. 61° 31'.

Prince Town. See Princeton.

Prince of Wales's Archipelago, a large ifland in the North Pacific ocean, with a number of small ones in the bays on its coaft, fo called by captain Vancouver; extending about 110 miles in length from north-west to south-east, and from 30 to 40 in breadth. N. lat. 54° 42' to 56° 21'. E. long. 226° 20' to 228° 26'.

Prince of Wales's Islands, an ifland in the South Pacific ocean, obferved by captain Byron in 1765, and judged to be about 60 miles long, narrow, and low, and abounding with inhabitants. S. lat. 15°. W. long. 151° 3'.

Prince of Wales's Foreland, a cape on the eaf coast of Kerguelen's land. S. lat. 49° 39'. E. long. 72° 22'.—Also, the moft southerly point of New Caledonia, in the South Pacific ocean. S. lat. 22° 29'. E. long. 166° 57'.

Prince of Wales's Fort, a fort and factory, on Churchill river, belonging to the Hudson Bay Company. N. lat. 58° 47'. W. long. 94° 7'. The mean height here is 18° 7'; the leaf - 18°, and greatest 85°.

Prince of Wales's Iflands, a cluster of iflands, fuppofed to extend from New Holland to New Guinea, differing in elevation and compafs, many of which are well covered with herbage and wood. Captain Cook faw on moft of them flnoke, and thence inferred that they were inhabited. Between thofe are probably good failing pallages.

Prince of Wales's Lakes, a lake of North America. N. lat. 50° 55'. W. long. 94° 9'.

Prince William, a county of Virginia, bounded weft by Farquier, and eft by Patowmac river, which separates it from Maryland; containing 11,311 inhabitants.

Prince William Henry's Island, an ifland in the South Pacific ocean, discovered by captain Wallis, on the 31th of June 1767. S. lat. 19°. W. long. 141° 6'.—Also, an ifland in the Pacific ocean, discovered, in 1796, by lieutenant Ball, commander of the Supply. It is elevated, and about 70 miles in circumference; well wooded, interferted with cultivated tracts of ground, on which was perceived fomething that had the appearance of Indian corn, or fugar-cane. It is surrounded by a fandy beach, on which were feen feveral canoes, and a moft of the natives. Scaffs were perceived among the trees, and appeared to be large and well constructed. The appearance of the ifland is magnificent and picturesque, and it is thought to be very fertile and well peopled. The natives were wholly naked, and seemed to be the fame fort of people that had been feen at Tench's ifland. S. lat. 1° 32'. E. long. 149° 30'.

Prince William's Islands, a cluster of iflands in the Pacific ocean, discovered by Tafman in 1643. S. lat. 17° 19'. E. long. 175°.

Prince William's Sound, an inlet of the North Pacific ocean, occupying at leaff 1° of latitude, and 2° of longitude, exclusive of its arms and branches, which are not fpecified. Captain Cook, who discovered it in 1778, gives the following account of it. The natives, who came to make them fome fmall wits while they were in the found, were generally not above the common height, though many of them were under it. They were fquare or frong chaffed; and the moft disproportionate part of their body leem'd to be their heads, which were very large, with thick fhort necks, and large broad, or spreading faces, which, upon the whole, were flat. Their eyes, though not small, fearely bore a proportionate fize to their faces; and their nose's had full round points, hooked and turned up at the tip. Their teeth were white, broad, weftall in fize, and evenly fet. Their hair was black, thick, ftraight, and long, and their beards, in general, thin or wanting; but the ears about the lips of thofe who had them were fliff or briftly, and frequently of a brown colour; and feveral of the elderly men had even large and thick, but ftraight beards. Their common
common dresses (for men, women, and children, are clothed alike) is a kind of close frock, or rather robe, reaching generally to the ankles, though sometimes only to the knees. At the upper part is a hole, just sufficient to admit the head, with sleeves that reach to the wrist. These frocks are made of the skins of different animals; the most common of which are the sea-otter, grey fox, racoon, and pine martin; with many of felt skins, and, in general, they are worn with the hairy side outward. Some also have these frocks made of the skin of owls, with only the down remaining on them, which they glue on other substan-ces; and we saw one or two woollen garments, like those of Nootka. In general, they do not cover their legs or feet; but a few have a kind of skin stockings, which reach half way up to the thigh; and fearlessly any of them are without mittens for their hands, made of the skins of bears' paws. Those who wear any thing on their heads, resembled in this respect our friends at Nootka, having high truncated conical caps, made of hreal, and sometimes of wood, resembling a bell's head, and well painted. The men commonly wear the hair cropped round the neck and forehead; but the women allow it to grow long, and most of them tie a small lock of it on the crown; or a few club it behind, after our manner. Both sexes have the ears perforated with several holes, about the outer and lower part of the edge, in which they hang little bunches of beads, made of the same tubulous flabby substance used for this purpose by those of Nootka. The septum of the nose is also perforated; through which they frequently thrust the quill-feathers of small birds, or little bending ornaments, made of the above flabby substance, thrung on a flint string, or cord, three or four inches long, which gives them a truly grotesque appearance. But the most uncommon and un-likely ornamental fashion, adopted by some of both sexes, is their having their under lip slit, or cut quite through, in the direction of the mouth, a little below the swell part. This incision, which is made even in the tattooing children, is often above two inches long; and either by its natural retraction, when the wound is fresh, or by the repetition of some artificial management, assumes the true shape of lips, and becomes so large, as to admit the tongue through. The food which we saw them eat was dried fish, and the flesh of some animal, either broiled or roasted. Some of the latter which was brought seemed to be bear's flesh, but with a fishy taste. As to the animals of this part of the continent, the name must be understood as of those at Nootka; that is, the knowledge we have of them is entirely taken from the skins which the natives brought to sell. These were chiefly of seals, a few foxes, the whitish cat or lynx, common and pine martens, small ermines, bears, racoons, and sea-otters; of these the most common are the martin, racoon, and sea-otter, which composed the ordinary dresses of the natives. Of the birds mentioned at Nootka, we found here only the white-headed eagle, the flug, the alcyon, or great king-fisher, which had very fine bright co-lours; and the humming-bird, which came frequently and flew about the ship, while at anchor, though it can scarcely live here in the winter, which must be very severe. The water-fowls were geese, a small sort of duck, and some black sea-pys, with red bills, which were found at Van Diemen's land and New Zealand. The metals we saw were copper and iron, both in plenty. Few vegetables of any kind were seen; and the trees which chiefly grew here were the Canadian and spruce pine, and some of them tolerably large. Captain Vancouver visited this found in 1794, and says, after a minute examination we were em-powered to make of Prince William's found, we were not only made acquainted with its utmost limits in every direc-

tion, but proved it to be a branch of the ocean that requires the greatest circumspection to navigate; and although it diverges into many extensive arms, yet none of them can be considered as commodious harbours, on account of the rocks and firths that obstruct the approach to them, or of the very great depth of water at or about their entrances; of the former innumerable have been discovered, and there is great reason to suppose that many others may have existence, of which we gained no knowledge. By what may be collected from our inquiries, Snug-corner cove, and the paffage to it from the ocean, seem to be the least liable to these objections of all places of shelter which the found affords. N. lat. 20° to 61°. W. long. 147°.

PRINCES, College of. See College.

PRINCESS ANNE, in Geography, a maritime county of Virginia, bounded W. by Norfolk county, S. by North Carolina, and N. by Chesapeake bay, 30 miles long, 29 broad, containing 9498 inhabitants.—Also, a poit-town of Mary-land, on the east shore of Chesapeake bay, in Somerset county, on the east side of Monokin river; 178 miles S. by W. from Philadelphia. N. lat. 38° 10'. W. long. 75° 48'.

PRINCESS ROYAL'S Harbour, a harbour on the south-west coast of New Holland, and the western part of King George Third's found. The paffage into it is about a quarter of a mile wide; the depth near the northern shore is 5 or 6 fathoms, but on the southern not more than 24 and 3 fathoms, on account of banks of coral-rock that are very visibilie, but not dangerous, as they are not liable to any violent agitation of the sea. Within the points of entrance the depth is regularly from 4 to 7 fathoms, and the bottom is clear good holding ground. This depth, occupying only part of the harbour, affords sufficient space for several ves-sels to ride in safety. S. lat. 35° 8'. E. long. 118° 9'.

PRINCESSE, in Ichthyology. See Chaceodon Vaga-
bundus.

PRINCETON, in Geography, a township of Worcester county, Massachusetts, 15 miles N. by W. of Worcester, and 52 W. by N. of Boston. This township contains 19,000 acres of high and hilly, but strong and rich land, adapted to grass and grain. Its principal productions are excellent beef, butter, and cheese. Here is a handsome congregational church, seated on a high hill, and command- ing a most extensive and rich prospect of the sur-rounding country. Wacksfuett mountain, the moat noted in the flate, is in the north part of this township. The town has a valuable library, was incorporated in 1759, and contains 1062 inhabitants.

PRINCETON, a post-town of New Jersey, situated partly in Middlesex and partly in Somerset counties. Here are Nassau-Hall college (see COLLEGE), about 80 dwelling houfes, and a brick Presbyterian church. It is distant 12 miles N.E. from Trenton, and 42 N.E. from Philadelp-hia. N. lat. 40° 22' 12'. W. long. 74° 34' 45'.—Also, a small post-town of North Carolina; 35 miles from Halifax.

PRINCIPAL, PRINCIPALIS, the chief, most consider- able, or necellary part of a thing.

Thus we say, the mayor is the principal magistrate of a city or town; a council of war consits of the principal officers. In the peroration, the principal points infilited on are to be briefly summed up. The principal of a college or hall is the master of it.

PRINCIPAL, in Commerce, is the capital of a fim due or lent; in which sense the word is used in opposition to in-terest.

PRINCIPAL is also used for the first fund or sum put by partners.
else. There is, however, a difference of opinion concerning these first principles; some admitting them to be self-evident, others proving them by arguments, and others again totally denying them. Before the time of Descartes, it was affirmed as a first principle, that the sun and moon, and earth and sea, have a real existence, whether we think of them or not. Descartes thought that their existence should be proved by argument; in which opinion he has been followed by Malebranche, Arnauld, and Locke. They have endeavoured to prove by reasoning the existence of external objects of sense; and Berkeley and Hume, conceiving their arguments to be feeble and unsatisfactory, have been led to deny their existence altogether. The ancient philosophers granted, that all knowledge must be grounded on first principles; and the Peripatetic philosophy admitted a great number of them, erring perhaps in excess rather than in defect. Descartes was satisfied with one principle, expressed in one word, "cogito," I think. Mr. Locke seems to have thought them of very little use.

In order to obtain some mark or criterion by which first principles, that are really such, may be distinguished from others that assume this character without a jilt title, Dr. Reid makes the following observations. 1. "I hold it to be certain," he says, "and even demonstrable, that all knowledge got by reasoning must be built upon first principles.

2. Some first principles yield conclusions that are certain, others such as are probable in various degrees, from the highest probability to the lowest. 3. It would contribute greatly to the stability of human knowledge, and consequently to the improvement of it, if the first principles upon which the various parts of it are grounded, were pointed out and ascertained. 4. Nature hath not left us delusive of means by which the candid and honest part of mankind may be brought to unanimity, where they happen to differ about first principles.

First principles may relate either to the clafs of contingent, or to that of necessary truths. Those of the first clafs comprehend, according to Dr. Reid's enumeration, such as follow. 1. The existence of every thing of which he is conscious. Mr. Hume, it is said, after annihilating body and mind, time and space, action and causation, and even his own mind, acknowledges the reality of the thoughts, sensations, and passions of which he is conscious. (See Consciousness.) 2. Another first principle is, that the thoughts of which, says Dr. Reid, I am conscious, are the thoughts of a being, which I call myself, my mind, my person. (See Identity.) 3. Those things did really happen which are distinctly remembered. (See Memory.) 4. Another first principle is our own personal identity and continued existence, as far back as we remember any thing distinctly. 5. Those things do really exist which we distinctly perceive by our senses, and are what we perceive them to be. 6. That we have some degree of power over our own actions, and the determinations of our will. This is implied in every act of volition, in all deliberation, in every purpose or resolution formed in consequence of deliberation, and in every promise or contract in which a man plights his faith. 7. That the natural faculties, by which we distinguish truth from error, are not fallacious. 8. There is life and intelligence in our fellow-men with whom we converse. 9. Certain features of the countenance, sounds of the voice, and gestures of the body, indicate certain thoughts and dispositions of the mind. 10. A certain regard is due to human testimony in matters of fact, and even to human authority in matters of opinion. 11. There are many events depending upon the will of man, in which there is a self-evident probability, greater or less, according to circumstances.

12. In the phenomena of nature, what is to be will probably be like to what has been in similar circumstances. The first principles of necessary truths are divided by Dr. Reid into different classes, according to the sciences to which they belong; and he mentions some, in each class, by way of specimen. 1. Some of these may be called grammatical, such as, that every complete sentence must have a verb.

2. Some are logical, such as, that every proposition is either true or false, that reasoning in a circle proves nothing, &c.

3. Some are mathematical. (See Axioms.) 4. In matters of taste, there are also axioms, or common principles. (See Taste.) 5. There are also first principles in morals; such as the following, viz. that no man ought to be blamed for what it was not in his power to hinder, that we should do to others what we should expect them to do to us in the same circumstances, &c. (See Moral Philosophy and Moral Sense.) 6. Some first principles are metaphysical; such as the following, viz. that the qualities which we perceive by our senses must have a subject, which we call body; and that the thoughts of which we are conscious must have a subject, which we call mind; that whatever begins to exist must have a cause which produced it (see Cause); and that design and intelligence in the cause may be inferred, with certainty, from marks or signs of it in the effect. All these three principles are denied by Mr. Hume; others think that they admit of proof by reasoning, or from experience; but all must allow their truth and importance. On the left of the three principles above mentioned, we shall refer to the articles Final Cause and God; and, moreover, cite an appropriate passage from archbishop Tillotson's sermons, vol. i. ferm. 1. "For I appeal to any man of reason," says the excellent preacher, "whether any thing can be more unreasonable, than obstinately to impute an effect to chance, which carries in the very face of it all the arguments and characters of a wise design and contrivance? Was ever any considerable work, in which there was required a great variety of parts, and a regular and orderly disposition of those parts, done by chance? Will chance fit means to ends, and that in ten thousand instances, and not fail in any one? How often might a man, after he had jumbled a set of letters in a bag, fling them out upon the ground, before they would fall into an exact poem; yea, or so much as make a good discourse in prose? And may not a little book be as carefully made by chance, as this great volume of the world? How long might a man be in sprinkling colours upon canvas with a careless hand, before they would happen to make the exact picture of a man? And is it not much easier made by chance than his picture? How long might twenty thousand blind men, which should be sent out from the several remote parts of England, wander up and down before they would all meet upon Salisbury plain, and fall into rank and file in the exact order of an army? And yet this is much more easy to be imagined than how the innumerable blind parts of matter flow and dovetail themselves into a world. A man that sees Henry the Seventh's chapel at Westminster might with as good reason maintain, (yea, with much better, considering the vast difference between that little structure and the huge fabric of the world,) that it was never contrived or built by any man, but that the stones did by chance grow into those curious figures into which they seem to have been cut and carved; and that upon a time, (as tales usually begin,) the materials of that building, the stone, mortar, timber, iron, lead, and glafs, having met together, and very fortunately ranged themselves into that delicate order in which we see them now so closely compounded, that it must be a very great chance that parts them again. What would the world think of a man that..."
that should advance such an opinion as this, and write a book for it? If they would do him right, they ought to look upon him as mad: but yet with a little more reason than any man can have to say that the world was made by chance; or that the first men grew up out of the earth as plants do now. For can any thing be more ridiculous and against all reason, than to ascribe the production of men to the first fruitsfulness of the earth, without so much as one instance and experiment in any age or history to countenance so monstrous a supposition? This thing is at first sight so gross and palpable, that no discourse about it can make it more apparent. And yet these shameful beggars of principles, who give this precarious account of the original of things, assume to themselves to be the men of reason, the great wits of the world, the only cautious and wary perfonns that hate to be imposed upon, that must have convincing evidence for every thing, and can admit of nothing without a clear demonstration for it.

Dr. Reid is of opinion, that the principle, so admirably illustrated in the passage now cited, viz. that from certain signs or indications in the effect we may infer, that there must have been intelligence, wisdom, or other intellectual or moral qualities in the cause, is gained neither by reasoning nor by experience; and, therefore, if it be a true principle, it must be a first principle. There is, he says, in the human understanding a light, by which we see immediately the evidence of it, when there is occasion to apply it. Whether it be in his felfe, the true and first principle or not, it is unquestionable, that the clear signatures of wisdom, power, and goodness, in the constitution and government of the world, afford an argument for the being and providence of the Deity, that in all ages has made the strongest impression upon candid and thinking minds; an argument which has this peculiar advantage, that it acquires strength as human knowledge advances, and is more convincing at present than it was some centuries ago. On this account, those who, in all ages, have been unfriendly to the principles of religion, have made attempts to weaken the force of the argument, which is founded on the principle above stated. This argument has been denominated the argument from final causes; and when reduced to a syllogism, it comprehends these two premises: first, that design and intelligence in the cause may, with certainty, be inferred from marks or signs of it in the effect. This may be considered as the major proposition of the argument. The second, which may be called the minor proposition, is, that there are in fact the clearest marks of design and wisdom in the works of nature; and the conclusion is, that the works of nature are the effects of a wise and intelligent Cause. A person must either assent to the conclusion, or deny one or other of the premises. Those, among the ancients, who denied a God or a Providence, seem to have allowed the major proposition, and to have denied the minor. An influence to this purpose occurs in the reasoning of Cotta the academicians in the third book of Cicero, of the nature of the Gods. In later times, those who are dissatisfied with this argument from final causes, have quitted the strong hold of the ancient atheists, which had become untenable, and have chosen rather to make a defence against the major proposition. Descartes, although he was no atheist, seems to have led the way. Having invented some new arguments for the being of God, he was perhaps induced to disparage those that had been used before, that he might secure greater credit to his own; or, perhaps, he was offended with the Peripatetics, because they often mixed final causes with physical, in order to account for the phenomena of nature. He therefore maintained, that physical causes only should be assigned for phenomenons; that the philosopher has nothing to do with final causes; and that it is presumption in us to pretend to determine for what end any work of nature is formed. After the example of Descartes, some of his followers have manifested a contempt of all reasoning from final causes. Among these we may reckon Maupertuis and Buffon. But the most direct attack has been made upon this principle by Mr. Hume, who puts an argument in the mouth of an Epicurean, on which he seems to lay great stress. The argument is, that the universe is a singular effect, and therefore we can draw no conclusion from it, whether it may have been made by wisdom or not. Mr. Hume's reasoning is founded on the supposition, that our inferring design from the strongest marks of it is entirely owing to our past experience of having always found these two things conjoined. Dr. Reid has laboured to prove, that this is not the case; and he alleges, that, according to this reasoning, we can have no evidence of mind or design in any of our fellow men; and, moreover, that the man who maintains, that there is no force in the argument from final causes, must, if he will be consistent, see no evidence of the existence of any intelligent being but himself.

Aristotle, in his second book upon demonstration, has treated very fully concerning first principles, and clearly shewn, that all demonstration must be built upon truths which are evident of themselves, but cannot be demonstrated. Whilst the philosophy of Aristotle prevailed, it was held as a fixed point, that all proof must be drawn from principles already known and granted. The Peripatetic philosophers, however, adopted, as first principles, many vulgar prejudices and rash judgments. Among the ancients no opposition was made to first principles. But when the authority of the Peripatetic system terminated, and the revolution by Descartes took place, this great reformer of philosophy, cautious to avoid the snare in which Aristotle was taken, of admitting things as first principles too rashly, resolved to doubt of every thing, and to withhold his assent, unless it was forced by the clearest evidence. At length, however, he emerged from universal scepticism by the short enthymeme, "cogito ergo sum." This enthymeme consists of an antecedent proposition, I think, and a conclusion drawn from it, therefore I exist. For the truth of the antecedent proposition, Descartes trusted to the testimony of consciousness. Being conscious that he thought, he needed no other argument. Hence it appears, that we find it impossible to doubt of things of which we are conscious: the constitution of our nature forces this belief upon us irresistibly; and, therefore, Descartes is justified in asuming, as a first principle, the existence of thought, of which he was conscious. From the existence of his thought he infers his own existence; and thus he assumes another first principle, not a contingent but a necessary one, viz. that where thought is, there must be a thinking being or mind. Hence he proceeds to prove the existence of a supreme and infinitely perfect Being; and from the perfection of the Deity, he infers that his senses, his memory, and the other faculties which God had given him, were not fallacious. From this principle he deduced the existence of a material world, and of what we perceive by our senses. Father Malebranche agreed with Descartes, that the existence of a material world requires proof; but being dissatisfied with Descartes's argument from the perfection of the Deity, he thought that the only solid proof of it is derived from divine revelation. Mr. Norris, a great admirer of Descartes and of Malebranche, seems to have thought all the arguments offered by them and by Arnauld to be weak, and confesses that we have at best only probable evidence of the
the existence of the material world. Mr. Locke acknowledges, that the evidence we have of this point is neither intuitive nor demonstrative. At last bishop Berkeley and Collier undertook to prove, that there neither is nor can be a material world. Mr. Hume has adopted Berkeley's arguments against the existence of matter, and thinks them unanswerable. From the single principle of the existence of our own thoughts, very little, if any thing, as Dr. Reid conceives, can be deduced by just reasoning, especially if we suppose that all our other faculties may be fallacious. Accordingly we find that Mr. Hume was not the first that was led into scepticism by the want of first principles; for soon after Descartes, there arose in France a sect called Egoists; which fee. Mr. Locke's sentiments on the subject of first principles and maxims are well known. He allows that part of our knowledge is intuitive (see Knowledge); and that this kind of knowledge is necessary to connect all the steps of a demonstration. He also maintains, that axioms, or intuitive truths, are not innate; and he observes, that self-evidence is not peculiar to those propositions, which pass under the name of axioms, and have the dignity of axioms ascribed to them; and that the particular propositions contained under a general axiom are no less self-evident than the general axiom; and that they are sooner known and understood. Nevertheless, this excellent writer is of opinion, that concerning the real existence of all other beings, besides ourselves and a first Cause, there are no maxims. Dr. Reid, on the other hand, contends, that there are maxims or first principles with regard to other existences. Mr. Locke further maintains, that no science is, or hath been, built upon maxims: whereas it cannot be disputed, that every demonstration in geometry is grounded either upon propositions formerly demonstrated, or upon self-evident principles. He also observes, that maxims are not of use to help men forward in the advancement of the sciences, or new discoveries of yet unknown truths: to which it may be replied, that Newton, as well as all other mathematicians, ground their demonstrations of mathematical propositions upon the axioms laid down by Euclid, or upon propositions which have been before demonstrated by help of those axioms. Our great aloronomer, by laying down the first principles upon which he relies, in those parts of natural philosophy which he cultivated, has given a stability to that science which it never had before, and which it will retain to the end of the world. On the subject of first principles, another writer, viz. Pere Buffier, a French Jesuit, has written a treatise, entitled "Traité des premiers Verités, et de la Source de nos Jugesmens," and published in 8vo., in 1724; and afterwards in folio, as a part of his "Cours des Sciences," Paris, 1732. This ingenious writer defines first principles to be propositions so clear, that they can neither be proved nor contradicted by theorems that are more clear. The first source of first principles, which he mentions, is that intimate conviction which every man has of his own existence, and of what paffes in his own mind. A second source of first principles he makes to be common sense; for an account of which, see Common Sense. Father Buffier, says Dr. Reid, has the honour of being the first, as far as he knows, after Aristotle, who has given the world a just treatise upon first principles. Some late writers, particularly Dr. Ofwald, Dr. Beattie, and Dr. Campbell, have been led into a way of thinking somewhat similar to that of Buffier; the two former, as Dr. Reid prelumines, without any intercourse with one another, or any knowledge of what Buffier had written on the subject. See the article to which we have above referred; and Reid's Essays on the Intellectual Powers of Man, eff. vi. chap. 7.

Leibnitz maintained, that the principles of contradiction, and of a sufficient reason, were the foundations of all science; that the first was sufficient for the demonstration of all necessary, and the other of all contingent truths. But though it be true, that the principle of contradiction, that is, the reductio ad absurdum, often occurs expressly, and is oftener implied in geometry, yet by what has been said it appears, that this principle alone is not sufficient to demonstrate all the other universally received principles of that science. Far less is it true, that we are enabled by the principle of a sufficient reason, which amounts to the exclusion of pure chance out of the universe, to demonstrate all physics and morals; but additional principles, derived from experience, must be assumed.

Principles of Action denote, according to the definition of Dr. Reid, every thing that incites us to act; and he distinguishes the actions of man into three general classes, viz. voluntary, involuntary, and mixed. See Action, in Ethics.

The investigation of these principles is attended with considerable difficulty, from various causes: first, on account of the great number of active principles that influence the actions of men; and, secondly, because the same action, and even the same course and train of action, may proceed from very different principles. Some admit no principle but selfish; others resolve all into the pleasures of sense, variously modified by the association of ideas; others admit disinterested benevolence with self-love; others reduce all to reason and passion; others to passion alone; nor is there less variety about the number and distribution of the passions. (See Passion.) There are some principles of action, which require no attention, no deliberation, no will. These, for distinction's sake, Dr. Reid calls mechanical; another class he denominates animal, as they are common to man with other animals; and a third class he calls rational, being proper to man as a rational creature. The mechanical principles of action he reduces to two species, instinct and habit; see these articles. The animal principles of action are such as operate upon the will and intention, but do not supposo any exercise of judgment or reason; and are, most of them, to be found in some certain animals as well as in man. The first of these Dr. Reid calls appetites. (See Appetite.) Another class comprehends those which he designates desires and affections; and he distinguishes them from appetites by this circumstance, that there is not an uneasy sensation proper to each, and always accompanying it; and that they are not periodical, but constant, not being lated with their objects for a time, as appetites are. The desires which he has chiefly in view are, the desire of power, the desire of esteem, and the desire of knowledge. (See Desire.) These principles, it is observed, have things, not persons, for their objects, and cannot, therefore, with propriety, be called either "selfish" or "social." But, besides these, there are various principles of action in man, which have persons for their immediate object, and imply, in their very nature, being well or ill affected to some person, or, at least, to some animal being. Such principles Dr. Reid denominates actions, whether they dispose us to do good or hurt to others. (See Affections, Emotions, and Disposition.) Opinion also (see Opinion) has a considerable influence upon the animal principles of action, whilst it is an essential ingredient in both that are rational.

The rational principles of action in man have this name appropriated to them, because they can have no existence in beings not endowed with reason, and, in all their exercizes, require, not only intention and will, but judgment and reason. The ends of human actions, considered in this connection, are two, viz. what is good for us upon
the whole, and what appears to be our duty. The conception of what is good or ill for us upon the whole, is the offspring of reason, and can only exist in beings endowed with reason: and if this conception give rise to any principle of action in man which he had not before, that principle may very properly be called a rational principle of action. As soon as we have a conception of what is good or ill for us upon the whole, we are led, by our constitution, to seek the good and avoid the ill; and this becomes not only a principle of action, but a leading or governing principle, to which all our animal principles ought to be subordinate. Accordingly, Dr. Price suggests, and Dr. Reid concurs with him in opinion, that, in intelligent beings, the define of what is good, and aversion from what is ill, are necessarily connected with the intelligent nature; and that it is a contradiction to suppose such a being to have the notion of good without the define of it, or the notion of ill without aversion from it. This rational principle of a regard to our good upon the whole, gives us the conception we should rather lay a stronger feeling) of a right and a wrong in human conduct; at least of a wife and a foolish. Thus it produces a kind of self-appropriation, when the passions and appetites are kept in their due subjection to it, and a kind of remorse and compunction, when it yields to them. In these respects this principle is so similar to the moral principle, or conscience, and so interwoven with it, that both are commonly comprehended under the name of "reason," and hence many of the ancient philosophers, and some among the moderns, have been led to resolve conscience, or a sense of duty, entirely into a regard to what is good for us upon the whole. The principle of a regard to our good upon the whole, does, agreeably to the opinion of the wisest men in all ages, in a man duly enlightened, lead to the practice of every virtue. Some philosophers have supposed that this principle is the only regulating principle of the human conduct; but in this view of its importance and use, it is essentially defective for the following reasons. The greater part of mankind can never attain to such extensive views of human life, and so correct a judgment of good or ill, as the right application of this principle requires. Besides, though a steady pursuit of our real good may, in an enlightened mind, produce a kind of virtue which is entitled to some degree of approbation, yet it can never produce the noblest kind of virtue, which claims our highest love and esteem. Disinterested good-nature and rectitude constitute the glory of the Deity, without which he might be an object of fear or hope, but not of true devotion; and it is the image of this divine attribute in the human character, that is the glory of man. But to serve God, and be useful to mankind, without any concern about our own good and happiness, is, possibly, beyond the pitch of human nature; and yet to serve God, and be useful to man, merely to obtain good to ourselves, or to avoid ill, is servility, and not that liberal service which true devotion and real virtue require. Moreover, although one might be apt to think, that he has the best chance for happiness who has no other end of his deliberate actions but his own good; yet a little consideration may satisfy us of the contrary.

Upon the whole, we may observe, that although a regard to our good upon the whole be a rational principle in man, yet if it be supposed the only regulating principle of our conduct, it would be a more uncertain rule, it would give far less perfection to the human character, and far less happiness than when joined with another rational principle, viz. a regard to duty.

This leads us to observe, that the subject of law must have the conception of a general rule of conduct, which, without some degree of reason, he cannot have. He must like wife have a sufficient inducement to obey the law, even when his strongest animal desires draw him the contrary way. This inducement may be a sense of interest, or a sense of duty, or both concurring. These principles, being those which can reasonably induce a man to regulate all his actions according to a certain general rule or law, may be justly called the rational principles of action, since they can only exist in a being endowed with reason, and since it is by them only, that man is capable either of political or of moral government. It is a consideration of great moment in our investigation of the rational principles of conduct now stated, how we learn to judge and determine, that this cause of action is right, and that another of an opposite kind is wrong. The abstract notion of moral good and evil would be of no use to direct our practice, if we had not the power of applying it to particular actions, and determining what is morally good, and what is morally evil. Some philosophers ascribe this to an original power or faculty in man, which they call "moral sense," the moral faculty," or "conscience." (See Moral Sense and Conscience.) Others think that our moral sentiments may be accounted for without supposing any original sense or faculty appropriated to that purpose, and in order to account for them, they adopt very different systems. Reid's Essays on the Active Power of Man, E. iv. See Approbation, Obligation, Virtue, and Moral Philosophy.

Principle, in Physics, or Principle of a natural body, is something that contributes to the essence of a body; or, of which a natural body is primarily constituted.

Aristotle defines principles to be those things which are not made and constituted of themselves, nor of other things, but all things of them: quæ non sunt ex se invicem, nec ex alius, sed ex suis omnibus.

To give an idea of natural principles, consider a body in several states: a coal, e. gr. that was just now a piece of wood: it is evident there is something in the coal, which before existed in the wood; this, whatever it is, is a principle, and is what we call matter.

Again, there must be something joined with this matter, to make it wood rather than fire, or fire rather than wood: this is another principle, and is what we denominate form.

Matter and form, then, are universal principles of natural bodies; by the union of these they are produced or generated. The Peripatetics add a third principle; vis. privation; for though, they, a thing is not made from nothing, yet it must be made from its not being that thing before. This Aristotle calls privation, and admits it as a third principle; or a principle of corruption. But the moderns reject it; for if privation be a principle, it is at least in a very different sense from matter and form.

Some late philosophers admit no principles but acid and alkali. Aristotle distinguishes two sorts of natural principles, as they concur in the generation, or in the composition of bodies.

Principles of Generation, or of a body in sies, are those without which a natural generation can neither be, nor be conceived. Such are the three principles above mentioned, matter, form, and privation.

As to matter, or the first matter, as it is called, it is neither substance nor accident; it has no quality or property; it is nothing actually, but every thing potentially. It has so strong an appetite for form, that it is no sooner divested of one form, than it is clothed with another, and is equally susceptible of all forms successively. Form, or as it is also called, æct or perfection, does not confit in the figure, size, arrangement, or motion of the parts of matter; the, in-
of which artificial things are formed; and every production of nature has a substan
tial form, which, joined to matter, makes it to be what it is. The substan
tial form is a kind of informing soul, which gives the things its specific nature, and all its qualities, powers, and activity. See Matter and Form.

Principles of Composition, or of a body in falle off, already made, or thole of which natural bodies really confist. Such, according to him, are matter and form; to which some add a third, viz. union to connect the two others together. But this is only necessary upon supposition of substantial forms.

Principles are usually confounded with elements; yet there is a real difference: elements are properly the first and simplest beings, arising from the first determination or afsems
blage of principles. They are the simplest things in which matter and form are combined. Elements and principles, therefore, differ in this, that a principle, as matter, is only a begin, not a complete nature; but an element is perfect and complete.

Some ancient philosophers distinguished between principles, \( p_{\xi} \), and elements \( e\xi\).

Principles, according to them, were neither composed nor produced; but the elements were complex or compound beings. Plutarch, ap. Eller. in Mem. de l'Acad. Berlin, 1746.

It would be endless to enumerate all the opinions of phi
Iophers concerning the elements of bodies. A late author
has given us a summary of many of these opinions; and, lastly, adds his own, that fire and water are the only things which properly deserve the name of elements, or principles of natural bodies; fire being the active, and water the passive principle. According to him, water is convertible into air, and into earth, by means of fire. Hence the four, vulgarly called, elements, may be reduced to two. He endeavours to establish his doctrine on the experiments of Boyle, Hales, and Mufchenbroeck. See Elements.

To this head may likewise be referred what we call mechanical principles of bodies, which serve to account for the mechanism or artificial structure of things, and all the varieties and differences of bodies from motion, figure, and other common affections.

These principles are differently maintained by three or four different sects of philosophers; viz. the ancient Ep
cureans, or Corporucarians, to whom may be added the modern Gaffendiits, the Carteians, and the Newtonians.

Principles, in Chemistry, are the first and simplest parts of which natural bodies are compounded, and into which they are again reducible by fire, &c.

These are more properly, as well as more commonly, called elements.

In each school of philosophy among the ancients, very different opinions prevailed concerning these principles; some of them admitting only one, and others more. Some contended for earth, and others for fire. Nor were the notions of the chemists of the middle ages, or about the time of Paracelius, more clear and satisfactory. They admitted five principles of bodies, which they call mercury or Spirit, phlegm or water, sulphur or oil, fat, and earth.

But it has been found by later experiments, that some of these principles are more simple than others; and, therefore, Beccher attempted to reduce their number, and esta
blished only two general principles of all bodies, viz. water and earth; extending the term to that which is vitrifiable, and which he conceived to be the principle of the fixity, sedi
dity, and hardnecfs of bodies; to that which is inflammable, and to which he ascribed the inflammability of all inflammable bodies; and to that which he called mercurial earth.

This theory has been farther illustrated and extended by Stahl, who showed, that water and vitrifiable earth enter as elements into the composition of many bodies; but the other two principles of Beccher, viz. the mercurial earth and the inflammable earth, have not yet betn exposed to our lenses single and pure: though some have supposet that the existence of the latter is sufficiently ascertainet (see Philogist), but that of the latter is not satisfactorily demonstrated.

That earth, water, and fire, enter into the composition of bodies as principles, has been considered as demonstrated by Beccher and Stahl: and the experiments of Boyle, Hales, Priestley, &c. sufficiently prove that air enters into the composition of many bodies as a principle. So that the chemists generally admit the four principles of Aristotle, viz. fire, air, water, and earth. In whatever manner bodies are decomposed, we always obtain these substances; and they are the utmost limits of chemical analysis. These are, therefore, called primary principles, or elements.

Secondary principles are those which result immediately from the union of primary principles.

Principles of the third order are those which are composed of secondary principles, &c. Thus, nitre is a compound of the acid called nitrous, and of the fixed vegetable alkali, combined and satured together: by a first analysis of nitre, we obtain this acid and this alkali, which are, therefore, the proximate principles of nitre. But neither of these are simple substances. By a farther analysis of each of these, they may be decomposed into water, earth, and fire, or the inflammable principle: and these may be con
sidered as primary principles; but the acid and alkali are secondary principles. The water, earth, and fire are the remote principles of the nitre. Dict. Chem. Eng. edit. art. Principles. See also Geoffrey's Tracts, p. 5, &c.

Principle, Inflammable. See Philogist.

Principle, Original, principio originate, a name given by Tachelius, and some other authors, to salt, without considering it as acid, alkali, or of any other particular kind; or any mode of existence. But many others allow this name only to water, or at least that water is, in almost all natural bodies, the most copious, the most active, and the most influencing part; yet even this is found to agree much better with some bodies than with others.

Principles, among Hermetic Philosophers. According to these gentlemen, the two universal principles of sensible nature, are fufible and solid; which, being joined in a greater or less degree, generate all that beautiful variety of beings in the universe.

The three natural principles are salt, sulphur, and mercury. These principles generate the four elements; and are, as it were, secondary elements, insinuate as they are contained in all mixed bodies. Sulphur is the first, and SANDS in the place of male; mercury the second, standing in the place of female; and salt the third, which copulates the others together. Dict. Hermet.

Principle is also applied to the foundations of arts and sciences. In this sense we say, principles are not to be proved; they must be common notions.

There is no disputing against a man that denies principles: the worst reasoning is that which includes a petitio principi; i.e. which supposes a principle that ought to be proved.

Principle is also applied by extension to the first rules or maxims of an art.

In this sense we say a man is ignorant of the principles
of geometry; meaning he has not learnt Euclid's Elements. The principles of most arts and sciences are found in this Dictionary under their respective heads.

PRING, in Geography, a town on the W. coast of Sumatra. S. lat. 4° 12'. E. long. 102° 28'.

PRINGLE, Sir John, in Biography, a distinguished physician, was born at Stichel-haut, in the county of Roxburgh, in April 1707. He was the youngest son of Sir John Pringle, bart. of Stichel, and of Magdalen Elliot, sister of Sir Gilbert Elliot, two families of ancient and honourable repute in the South of Scotland, and distinguished for their public and private virtues. He received his grammatical education at home, under a private tutor, and afterwards went to St. Andrew's, where a near relative of his father's, Mr. Francis Pringle, was professor of Greek. Having determined to make medicine his profession, he went to Edinburgh, in October 1727, which, however, he quitted, after a residence of one year, with the view of profiting from the instructions of the celebrated Boerhaave, who was then advanced in years. While he studied at Leyden, he contracted an intimate friendship with Van Swieten, who subsequently obtained the highest reputation at Vienna and throughout Europe. He graduated at that university in July 1730, publishing an inaugural dissertation, "De Marcure Smith," and then repaired to Edinburgh, where he settled as a physician, and gained the esteem of the magistrates and professors by his abilities and good conduct. His knowledge of ethics obtained for him, in March 1734, the appointment of joint professor of moral philosophy with Mr. Scott, and sole professor after the death of the latter; and he continued in the discharge of the duties of this office, and in the practice of physic in Edinburgh, until 1742, when he was appointed physician to the earl of Stair, who then commanded the British army; and in August, in the same year, he was nominated physician to the military hospital in Flanders. He did not, however, resign his professorship on this occasion, as the university permitted him to appoint a substitute in his absence as long as he required it.

From this time Dr. Pringle's career began to open in a new and successful walk; his reputation as an army-physician not only obtained for him a high professional rank, but also the patronage of the great. On the retirement of his noble friend, the earl of Stair, after the battle of Dettingen, he offered to resign with him, but was not permitted. He attended the army in Flanders through the campaign of 1744; and so strongly recommended himself to the duke of Cumberland, by the able and skilful discharge of his duties, that in the spring following, he received a commission from his royal highness, appointing him physician-general to his majesty's forces in the Low Countries; and on the next day a second, confituting him physician to the royal hospitals in the same countries. In consequence of these promotions, he immediately resigned his professorship. In 1745 he was with the army in Flanders, but was recalled to attend the forces about to be sent against the rebels in Scotland. In the beginning of 1746 he accompanied the duke of Cumberland in this expedition, and remained with the forces after the battle of Culloden, till their return to England in August. In 1747 and 1748, he again attended the army abroad, and in the autumn of the latter year, on the conclusion of the treaty of Aix-la-Chapelle, he embarked with the forces for England. In 1749 he was appointed physician to his royal highness the duke of Cumberland, and took up his residence in London, where the high reputation and distinguished connections which he had acquired, afforded every reasonable expectation of success as a physician. He attended the camps in England, however, during three seasons, in the war which commenced in 1755, and finally quitted the service of the army in 1758.

Dr. Pringle had been elected a fellow of the Royal Society in 1745, and on settling in London, he became a very active contributor to its Transactions. His first publication was a letter to Dr. Mead, entitled "Observations on the Gaol or Hospital Fever," 1730, which appears to have been brought forward in consequence of the alarm excited by the fever which appeared at the Old Bailey. This little work pulled through two editions, and was afterwards inserted in his great work on the diaceses of the army, of which it constitutes the seventh chapter of the third part. In the same year he began to communicate to the Royal Society his "Experiments on Septic and Antiseptic Substances," in a series of papers, which were afterwards subjoined, by way of appendix, to the work just mentioned, and which procured him the Copley medal. For several successive years, he added many papers to the Transactions, especially an account of the contagious fever at Newgate, a cafe of fragility of the bone, an account of several earthquakes, and of a fiery meteor, &c.

In the year 1752, the third edition of his "Observations on the Diaceses of the Army" was given to the public, and it was reprinted in the following year. The third edition was considerably improved by the further experience, which his attendance on the English camps for three years enabled him to obtain; and many subsequent editions have been called for, as well as translations into the French, German, and Italian languages. This work, indeed, the result of acute and diligent observation and extensive experience, was calculated to become a standard of reference, not only to the medical officers, but to the leaders of armies, to whom the preservation of the health of their troops is of the utmost importance; it necessarily procured extensive fame for its author, whom it placed high among the benefactors to medical science, and to mankind; and it remains at present a classical work. It contributed materially, indeed, to the introduction of those principles, by which the salubrity of crowded population has been subsequently augmented, and the sources of many malignant diseases have been nearly destroyed, under the farther directions of a Howard, a Lind, and a Haygarth, which were so signaliy illustrated by the example of captain Cook. In a word, its utility was equal to its reputation.

It was not until he had quitted the army in 1758, that Dr. Pringle was admitted a licentiate of the College of Physicians, probably from the uncertainty of his residence. Soon afterwards, however, his medical character, as well as his reputation as a philosopher, attained a high pitch, and both honours and emoluments flowed in upon him. After the accession of George III., he was appointed physician to the queen's household in 1761, and physician extraordinary to her majesty in 1763; and in the same year he was elected a fellow of the College of Physicians. In 1764, on the death of Dr. Wollaston, he was made physician in ordinary to the queen, and two years afterwards was raised to the dignity of a baronet. In 1768 he was nominated physician to the royal highnesses the princess dowager of Wales; and in 1774 he received the appointment of physician extraordinary to the king.

Among the numerous literary honours which Sir John Pringle received from the various academies of science in Europe, the highest was conferred upon him in the year 1778.
1770, when, on the decease of James Weil, esquire, he was elected president of the Royal Society. Though now in the sixty-sixth year of his age, he spared no exertion to fulfil the duties of his new office, and endeavoured to cherish, by all the means in his power, the scientific ardour which was then rising in Europe, and especially in this country. It had been customary, since the time of Mr. Martin Folkes, for the president to make a speech on the annual delivery of Sir Godfrey Copley's medal, which was usually short, and inserted in the minute-book. But the first speech which Sir John Pringle delivered, after being called to the chair, being more elaborate and extended, the publication of it was requested; and for the five subsequent years he continued the practice of giving a learned discourse on these occasions, entering at large into the previous history of that part of science, to which the paper (which was complimented by the award of the medal) related. In these five discourses, which treated of the subjects of fictitious gases, of the torpedo, of the attraction of mountains, of captain Cook's mode of preferring the health of his crew, of the structure and composition of the specula of telescopes, and of the explosive powers of gunpowder, Sir John displayed an extent and variety of knowledge highly creditable to his reputation; for they abound not only with proofs of his information on the subjects of medicine, natural history, and philosophy, but with a fund of ancient and modern learning. Had he continued to preside in the chair of the Royal Society, he would have doubtless have found other occasions of displaying his acquaintance with the history of science. But finding his health declining with his years, he resigned his office in 1778, in opposition to the solicitations of many distinguished members of the society, and was succeeded by the present distinguished president, Sir Joseph, then Mr. Banks. Still, however, he maintained his zeal for science and his country; for few learned foreigners visited this country without paying him their respects.

Finding his health declining, Sir John Pringle took a journey to Scotland in 1780, and spent the summer there, principally in Edinburgh. Here he met with so kind a reception, that he purchased a house, with the intention of returning in the following spring; and having disposed of the greater part of his library, and of his house in Pall-Mall, on his return to London, he put this intention in execution in April 1781. But he was disappointed in his expectations of health and satisfaction from this change. Edinburgh was not now to him what it had been in early life: it was too late to form new habits of friendship; and the few old friends who remained, were not able to meet with the same ardour as formerly. The air, also, he found too sharp for his weakened frame. He determined, therefore, once more to return to London, where he arrived in the beginning of September. Before he quitted Edinburgh, he presented to the college of physicians of that city ten volumes, folio, in manuscript, of "Medical and Physical Observations," with the restriction that they should not be published, and never lent out of the library on any pretence whatever.

On his arrival in London, Sir John found his spirits somewhat revived by the society of his friends. His Sunday evening conversations were again honoured with the attendance of many respectable men; and he enjoyed the pleasure of spending a couple of hours, on the other nights of the week, with his friends, at a society, which had been long established, and had met for some time past at Mr. Watton's, a grocer in the Strand. His constant attendance upon this society constituted, to the last, his principal amusement. During this winter, however, his strength declined rapidly; and on Monday evening, January 14th, 1782, he was feized with a fit, while with the society at Watton's, which terminated his life on the Friday following, at the age of 75. The account of his death was everywhere received in a manner which evinced the high fame that was entertained of his merit.

Sir John Pringle left no family. He married, in 1752, the daughter of Dr. Oliver, an eminent physician at Bath, who died a short time afterwards. He had acquired by his long practice a comfortable fortune, which he disposed with great prudence and propriety. His mind was characterized by a great love of science, founded on the basis of fact and experiment, and by an aversion to hypothetical speculation. He had not much taste for poetry, and had little relish even for our immortal Shakspere; but to the fitter art, music, he had a strong attachment, and was even a performer on the violoncello, at a weekly concert, given by a society of gentlemen at Edinburgh. He paid great attention to the French language, and studied his own with great industry. He took uncommon pains, indeed, to perfect the style of his own compositions; and it cannot be denied that he excels in periplicity, correctness, and propriety of expression. His leading principle of action through life was a rigid integrity, according to the unanimous testimony of all his acquaintance; and he was equally distinguished for his sobriety, having never, as he informed Mr. Bozwell, been intoxicated in his life. He was ardent and steady in his friendships, and was active in his civilities and good offices to all strangers and foreigners, who came to him well recommended; but he had at times a dryness and reserve in his behaviour, which had the appearance of coldness, especially when he was not perfectly pleased with the persons who were introduced to him. He was, in fact, above assuming the professions, without the reality of respect. His sense of integrity and dignity would not permit him to adopt that false and superficial politeness, which treats all men alike, however different in point of real estimation and merit. His connections and acquaintance were exceedingly numerous, including men of all professions, as well as many persons of rank and consequence; and he corresponded with many eminent philosophers and physicians, whom he had never seen. He was interested in St. James's church, and a monument was erected to his memory, by his nephew and heir, Sir James Pringle, in Westminster Abbey. See Dr. Kippis's Life of Pringle, prefixed to the-fix Discourses.

PRINKIPOS, in Geography, the most considerable and the most fertile of those denominated "Prince's" islands, in the sea of Marmora. It appears, says Olivier, to be entirely volcanic, and formed of quartz, granites, &c. &c. altered or decomposed. The land is elevated, uneven, and hilly. It is dry and arid on the hills, and tolerably fertile in the bottoms, and especially to the south of the town. The natural productions are the Aleppo pine, the oxycedrus or brown-barbed juniper, the broad-leaved phillyrea, the arbutus, the prickly pimpinella, the pale-flowered French lavender, the brome, the aculeated alpargus, the Cretan cistus or rock-rope, the turpentine tree, a species of favyor, the mallow-leaved bindweed, &c. &c. The wild olive-tree is found in abundance on all the hills. The culture of Prinkipos confists in a few fields sown with wheat, barley, chick-peas, kidney-beans, broad beans, &c. The vine is not abundant; it yields two or three stricts of very good grapes, from which wine is seldom made. The inhabitants prefer carrying the grapes to the markets of Constantinople, and there
there felling them. Near the town are several gardens, in which are cultivated, with no great skill, a few kitchen-garden plants and fruit-trees, among which is distinguished a species of fig-tree, with green frutifhe without and red within, and of an excellent quality.

This island has several times served as a prisoon or place of exile to the Greek princes. Irene, an Athenian woman, who had been raised to the throne from an obscure fiation by the charms of her mind and the graces of her perfon, and who, fetting no bounds to her ambition, ftaifed herfelf by various crimes after the death of Leon Porphyrogenitus, her husband, was dethroned by Niecephorus, one of her confidants, and banifhed to a monastery of this island, which herfelf had caused to be erected. In this ifland, quadrats that are fat, and well tailed, are abundant; besides fome other birds of paflage, fuch as turtles, rollers, loriots, thrufhes, &c, and in particular fables and fparrow-hawks. Hares are fcare in this ifland, and it has no rabbits. Ofyters, mufcelas, and feveral fihes, fuch as mackrel, bouito, turbot, and the bearded mullet, are plentiful.

There are two monaftries in Prinkipos, fited on the moft elevated and solitary places of the ifland. Nat. lat. 40° 51'.

E. long. 28° 56'.

PRINOS, in Botany, an ancient generic name used by Theophratus and Dioscorides; probably derived from ρρινος, to focus, and applied by Linnaeus to this genus on account of the fmall frrangres of the leaves in fome of the fpecies.

Gen. Ch. Cal. Perianth inferior, of one leaf; flic-eft half way down, flat, very small, permanent. Cor. of one petal, wheel-shaped; tube none; limb flat, deeply cleft into five ovate segments. Stam. Filaments fix, awl shaped, erect, shorter than the corolla; anthers oblong, obtuse. 
Pil. German superior, ovate, terminating in a fyle shorter than the flamin; stigma obtuse. Peric. a roundifh berry, five-cleft, much larger than the calyx. 

Seeds solitary, bony, obtuse, convex on one side, angular on the other.

Obf. The chief difference between this and Ilex conflits in its being hexandrous; but the parts of fructification, according to Jaffieu, agree occasionallly with that genus in number. Prinon is fometimes dioecious.

Aequilium folis decidus; Duham. Arb. v. 1. 62, t. 23.)—Leaves obvolute-lanceolate, pointed, doubly furred, with downy veins underneath. Found in moift woods, or on the banks of ditches all the way from Canada to Virginia. It flowers in June and July. Stem fhrubby, eight to ten feet high, branched all the way up. Leaves alternate, on short stalks, about three inches long, and one broad, acutely pointed, paler beneath. Flowers solitary, or two or three together at the base of the leaf-stalks, small, white. Berries red or crimson, at length purple, longer than thofe of the Holly.

Mr. Abbot mentions that the fruit of this fhrub is faid to have been useful in curing the diarrhea. Duroi fays that P. verticillatus has fometimes a even and eight-cleft corolla, with a like number of flamin.

2. P. montanus. Mountain Winter-berry. Willd. n. 2. Swartz. Prodr. 58. Ind. Occ. v. 1. 622.—Leaves ovate, ferrated, flining on both sides.—Native of Jamaica, in thickets on the loftifft mountains, flowering in Auguft, and bearing fruit in December. The trunk of this tree is upwards of twenty feet high, with a smooth, brown bark. Branches much divided, nearly upright, round, fmooth. Leaves alternate, on short falks, pointed at both ends, when dry of a dark, livid colour. Flowers two or three together, on separate falks, small, white. Berries blackifh.

Found by Mr. Ryan, in the ifland of Montferrat. Stem branched. Branches half an inch thick, with a grey, dotted bark, the younger ones alternate, dusky purple. Leaves alternate, fitly ferrated, entire at the base, fmooth on both fides, paler and fightly dotted beneath. Flowers generally three together in the males, always solitary in the females.

Vahl. Ecol. v. 2. 26.—Leaves oblong-ovate, ferrated, flining, membraneous. Flower-stalks axillary, each with a fingle, tetrandrous flower.—Native of Montferrat; found there by Mr. Ryan. Branches angular, fmooth, comproffed, dusky purple. Leaves alternate, on short falks, very flining, commonly contracted towards the base. Flowers fmooth, rather large. Berry ovate, or roundifh, the fize of black pepper.

5. P. globiger. Smooth or Evergreen Winter-berry, or Gally-berry. Linn. Sp. Pl. 471. Sm. Infests of Georgia, t. 35.—Leaves lanceolate, rather obtufe, smooth, fmooth, ferrated at the top.—Native of Canada in sandy shady woods, introduced at Kew in 1759, where it flowers in July and Auguft. The ftems of this plant are much branched. 

Branches alternate, fmooth, brown, the younger ones green. Leaves alternate, fitly ferrated, fitly furred, with a yellow rib, pale and downy beneath, evergreen, refembling thofe of Sweet Gall. Flowers fmall, on axillary falks, generally three together. Berries round, purplifh or black, fobicry, on long falks, called in Jersey Ink-berries. Obf. The fynonym of Miller and Catelby, quoted by Linnaeus for this fpecies, belong to Ilex vomitoria.

Mr. Purth, in his North American Flora, tells us it is plain from fpecimens in the herbarium of A. B. Lambert, eqg. V. P. L. S., that Prinos lucidus, Willd. n. 6. Ait. Hort. Kew. n. 3, is Ilex canadensis of Michaux Boreal-Amer. v. 2. 229. t. 49.

7. P. ambiguus. Doubtful Winter-berry, Michaux Boreal-Amer. v. 2. 236. Purth v. 1. 220. (Caffine caroliniana; Walt. Carolin. 242.)—Leaves oval, pointed at both ends, ferrated, deciduous.—Found in fandy wet woods, on the borders of swalks from New Jersey to Carolina, flowering in July and Auguft. This is a dioecious fpecies, whole male flowers are crowded together in clafhes at the bottom of the smaller branches; female ones solitary: they
they are pentandrous and white. Berries larger than in *P. verticillatus*.

The three following new species are adopted from Pursh's *Flora*, v. 1. 220, 221.

*P. levigatus*. Leaves deciduous, lanceolate, closely ferrated, pointed at each end; smooth and shining above; slightly downy at the nerves beneath. Flowers six-cleft; males scattered; females axillary, solitary, nearly sessile. — On the Alleghany mountains; from New York to Virginia; flowering in July. *Berries* small, dark red.

*P. lanceolatus*. Leaves deciduous, lanceolate, very delicately and remotely ferrated, acute at each end, smooth on both sides. Male flowers aggregate, triandrous; female scattered, two together, falcate, six-cleft. — In the lower tracts of Carolina and Georgia, flowering in June. *Berries* small, scarlet.

*P. coriacus*. Leaves evergreen, wedge-shaped, lanceolate, coriaceous, smooth, shining, entire. Corymbs axillary, very short, sessile, many-flowered. Flowers six-cleft. — In sandy woods, near the banks of rivers in Georgia, flowering in June and July. A handsome tall shrub, of the appearance of *Ilex Dabois*.

Mr. Pursh mentions two varieties of this species, the first of which with "Leaves obovato-lanceolate, pointed," he calls *laifolia*; the second with "Leaves lanceolate, acute," he calls *angyphiloa*.

*Prinos*, in *Gardening*, contains plants of the deciduous and evergreen kind, of which the species cultivated are, the deciduous winter berry (*P. verticillata*); and the evergreen winter berry (*P. glabra*).

**Method of Culture.**—In these plants it is effected by seeds, sown soon after they are ripe, or early in the spring, upon a bed of light earth, covering them half an inch with the same earth; but the seeds which are put into the ground in the autumn will many of them come up the following spring, while those which are kept longer out of the ground, often remain a whole year before the plants appear, as in holly, hawthorn, and some others. The seeds may be forwarded in their growth by means of a hot-bed. When the plants have sufficient strength they should be planted out, some in nursery-rows and others in pots. They delight in a moist soil and shady situation. In hot land they make little progress, and rarely produce fruit.

They are ornamental, and afford variety in the pleasure-grounds, and among potted plants.

**PRINTER, Typographia**, a person who composes, and takes impressions, from moveable characters, ranged in order, or from plates engraved, by means of ink and a press.

*Laurentius*, called *Colter, Geisfeich, Faulc, Guntenberg, Schoeffel, Mentel,* and *Eggerslein,* were the first printers. The first that practised it in England was *Fred. Corfellis,* brought over from *Haerlem,* under king Hen. VI.; in France, *Ulric Gering,* Martin Crantz, and Michael Friburgher; at Augsburg, *John Bemler,* at Rome, *Conrad Sveylhein,* and *Arnold Panartz,* Germans; at Venice, the two brothers *John and Velindin of Spire,* Nicholas Jencon, and *John de Cologon,* at Florence, *Bernard Cenini,* at Naples, *Sixtus Rufinger.*

The *greater printers* were *Aldus of Venice,* and his son, *Paulus Manutius;* the two *Badii,* *William and Frederic Morel;* *Opolin;* *Frobenuis;* *Rob. Hen. and Charles Stephens;* *Grifphius, Turnebus, Torres, Commelin, Plantin, Raphelengius, Vafeofan, Bleau, Crifpin,* and the two *Elzevirs.*

The *learned printers* were *the Mantiu, Amerbach,* and *Froben,* of *Bafiil,* *the Stephenes,* the *Badii,* *Turnebus, Wechyl, Morel, Junte,* &c.

Plantin had the title of *arch-printer, architypographus,* given him by the king of Spain, in consideration of his printing the Polyglot of Antwerp.

The names, characters, and eulogies of all the famous printers are found in part ii. of the first tome of the "Jugemens de Scavens."

The printers, since the establishment of that art, are esteemed a part of the company of stationers and book-sellers; before that establishment, the company consisted only of book-sellers, binders, writers, illuminators, and parchment-makers. The parchment-makers prepared the skins, and made the parchment or vellum; which were then almost the only matters on which books were written. The writers, or copyists, wrote and transcribed books after copies given them by the book-sellers. The binders were charged with the binding of those books, which was very coarze, only consisting of two flight boards covered with some paltry leather. The illuminators painted in miniature, and gilt initial letters, head-pieces, tail-pieces, and other compartments. Lastly, the stationers, or book-sellers, let the writers to work, and fold their copies in shops, and other places, on the days allowed them by the statutes to expose the fame.

**PRINTING, Typographia,** the art of taking impressions with ink, from characters and figures, moveable or immovable, upon paper, vellum, or the like matter.

There are two kinds of printing; the one for books, the other from copper-plates, for pictures. The first called *common press printing,* the second *rolling press printing.*

The prime difference between the two confists in this, that the characters of the former are caret in relievo, and those of the latter are engraved in cræus.

The art of printing is a modern invention; it is, indeed, of a very ancient standing among the Chinese; but then their printing is very different from our's. It must be owned, the European printing, in its original, was much the same with the Chinese; yet, as there was at that time no commerce or correspondence between Europe and China, the passage into the East by the Cape of Good Hope, being as yet undiscovered by the Portugueze, there is no room to charge the Europeans with borrowing their art from the Chinese: but each must be owned to have fallen on the same thing, though at very different times. Father *Couplet* affirms us, that printing has been in use in China from the year 930. Father *le Compte* speaks more largely; saying, that it has been there from almost all ages: he adds, that there is this difference between their's and our's, that whereas we have but a very small number of letters in our alphabets, and by the various arrangement of thefe, are able to form infinite volumes; we have the advantage, by making our characters moveable, to print the largest works with an incomconsiderable quantity of letter; tho' that served for the first sheets, serving over again for the succeeding ones: the Chinese, on the contrary, by reason of the prodigious number of their letters, are precluded from this resource; and find it more easy and less expence to cut all their letters on wooden blocks; and thus to make as many blocks as there are pages in a book; and these of no farther use but for that single work. Their method of printing see hereafter.

**PRINTING, Origin of.**—Who the first inventors of the European printing were, in what city, and what year, it was at first set on foot, is a famous problem long disputed among the learned. In fact, as the Greek cities contended for the birth of Homer, so do the German cities for that of printing.

*Meun,* *Haerlem,* and *Straburgh,* are the warmest on this point of honour: Italy also would have entered the lifts;
PRINTING.

lint; but the suffrages being at full divided between the
first three pretenders, they are left in possession of
the question, which, in reality, is not yet fully decided; though
it must be owned, Mentz has always had the majority of
voices.

We shall not here enter into a nice disquisition of the
merits of the cause, but only propose the pretensions of each.
John Mentel of Stralburgh, John Guttenberg and John Faup
of Mentz, and J. L. Collet of Haerlem, are the
persons to whom this honour is severally ascribed by their
respective countrymen; and they have all their advocates
among the learned. Mentel, a physician of Paris, enters
the lists in behalf of his name sake of Stralburgh; and con-
tends that it was he who first invented printing in the
year 1440, and that, in consideration of it, the emperor
Frederick III. gave him a coat of arms corresponding to
it, in the year 1466. He adds, that Guttenberg, whom
he had taken in as a partner, or associate, carried it to
Mentz, where he took in Fault a partner. John Gen-
sflech, a native of Mentz, who was his servant, communi-
cated the art to J. Guttenberg, whom Mentel had employed
in making some of his tools; and becoming thus possessed
of the art, they removed and settled at Mentz, where it
was perfected by the assistance of John Faup. But this
account depends on a Stralburgh chronicle of very doubtful
authority, and is contradicted by the chronicle of Cologne,
Trithemius, and Wimpeling. The last-mentioned writer
explicitly says, that the art of printing was invented, in-
completely, at Stralburgh, by Guttenberg, and perfected
at Mentz. Here Mentel acquired it from Guttenberg and
Fault, and returning to Stralburgh about the year 1455,
practised it in connection with Egglfstein.

The Haerlemers, with Boxhornius, Scriervius, &c. refer
the first invention to Laurens Janz Collet, or Laurence
John Collet, (called Collet on account of the public
office distinguished by this appellation, which he sustained,
and which was hereditary in his family,) of
Haerlem, in the year 1439, adding, that his associate
Guttenberg stole away his tools while he was at church,
and carried them to Mentz, where he set up for the
first inventor; though others attribute this theft, &c. to
his partner Fault. And others, again, with greater proba-
bility, ascribe it to John Gensflech senior, one of his
servants, in the year 1441: and with these types, &c. of
Laurence, two small works were printed at Mentz in 1442.
The principal evidence in favour of Haerlem, is Cornelius,
who had been a servant of Laurence, and afterwards a book-
binder in that city, on whose authority Adrian Junius,
M. D. founds his account, which appears to have been
drawn up between the years 1562 and 1575, and published
at Leyden in 1588. The learned Meerman, in his "Or-
gines Typographica," 1765, has amply vindicated and
confirmed the account which Junius gives of the fact; though
he disputes and sufficiently invalidates what this writer
says, as to the types which were used by Collet, at Haerlem.
These, he says, were neither cut nor fusable metal types,
but separable wooden types.

Munster, Polydore Virgil, Pasquier, &c. will have Gut-
tenburg, or Guttemburg, to have really been the inventor
of printing: and add, that he took in Fault and Schoeffer
for associates.

Naude, in his "Mafcurat," eponymous of Leul, or
Fault, or Faultius; and will have him to be the first printer
in Europe, and that he took in Guttenberg for a partner.
His reason for putting Fault in possession of this privilege
is, that the first books that were printed appear to have
been all of his impression. To this purpose it is alleged,
that it is more than probable, if Guttenberg or Collet had
had a greater or an equal share in the invention, they
would not have allowed him to attribute the whole to him-
self and his son-in-law Schoeffer, as he has done, without
ever offering to do the like, or in the least contradicting
him, and affording their own right.

The true rate of the cause seems to be this, that metal
kinds were first invented at Mentz; of these there were
two forts, viz. those that were cut, and those that were
cast in matrices. The invention of the former has been
ascribed by some writers to Faup, but without sufficient
authority; the real inventor being John Gensflech senior,
who had brought the art of printing with wooden types
from Haerlem to Mentz, with whom John Gensflech
junior, called Guttenberg, might probably have concurred.
The era of this invention must be about the year 1442 or
1443; for John Gensflech senior came to Mentz in
1441, and the Latin bible, with metal types, was printed
in 1450, which could not require less than seven or eight
years.

The latter were invented by Peter Schoeffer, the servant
and son-in-law of Faup, who settled at Mentz in the year
1449 or 1450, and having acquired under the two Gens-
flechfs the art of cutting types, remedied the inconvenience
of this method by contriving to cast them, which must have
been practised before the year 1459. The partnership
founded between Gensflech and Faup, and the relation
between Schoeffer and Faup, have probably given occasion
for ascribing to him the merit of the invention of printing
with metal types, in which, from the connections of this
kind, he probably might have had some concern.

The editions above referred to in Naude's account are,
1. The "Codex Palmarum," printed in 1457, which is the
most ancient book known to be printed with a date or
inscription, and is lodged in the emperor's library at Vienna.
2. The "Rationale Divinorum Officiorum" of William
Durand, printed at Mentz in 1459, in folio. This "Rat-
ionale" is in the earl of Pembroke's library. Malinkrot
has erroneously supposed this to be the first printed
book.
3. The "Catholicus Jannensis," dated in 1460, and now
in the king's library. Faup's name, indeed, is not to this;
but it is perfectly like the following ones where it is. It
is said that the first printers did not subjoin their names
and inscriptions at the end of their books till the year 1457:
and this they continued to do till Faup either died or left
off business.
4. The Latin Bible of 1462, being the
second edition of it, now in the French king's library.
5. "Tulpi's Offices," in quarto (the first being all folio),
in the year 1465, and 1466, for there are copies in the
Bodleian, and the library of Corpus Christi college, Oxon,
of both these dates. Some eminent writers have alleged
that this is the first printed book.
6. Other bibles of
8. "Mers-
curius Triformis de Pottellate & Sapientia Dei," in 1503.

Add to this, that at the end of Livy is a privilege granted
by the emperor Maximilian to Schoeffer, grandson of Faup,
for the sole power of printing that author for ten years;
and for fix years, to all the other books he should print
thereafter; in consideration of Faup's having invented the
art of printing. This privilege is dated 1518, and signed
Jae. Spiegel.

Erasmus, however, in the epistle after that privilege, does
not positively aver the fact; he only observes, that the
first, or the chief inventor of that art, is held to be J.
Fault.
Fault. In the advertisement to the said book, Nic. Carbachius speaks to the same effect as to the privilege, and Erasmus.

As to Gutenberc, Mentel, and Callot, Naude observes, the perfon is not yet born that can say he has ever seen books printed by any of them, before or as early as those of Fault. All that is urged on their behalf, is only founded on reports, conjectures, probabilities, forged authorities, and the jealousies of cities against one another.

Yet Salmuth, in his additions to Pancirollus, cites a public act, by which it appears that Fault, after having invented printing, and fastened it a long time on his own footing; at length took in Gutenberc as partner, to contribute to the expense; which was very great, by reason the first books were molt of them printed on vellum, or a leaf on parchement, and after the Chincle way.

But the cause is not thus decided: the advocates for Colter urge divers things, which seem to put him in the place here assigned to Fault. Mr. Ellis, in the Philosophical Transactions, fathers books on him prior to any of those above referred to Fault, and even some as early as 1430 and 1432. It is certain, the Haerlemers shewed printed books of that date, which agreeing so well with the account given by Theod. Scrivener, and others, leaves Mr. Ellis little room to doubt, whether the honour of the invention be his or the other's due. All that belongs to Fault, according to this writer, is the honour of establishing the art in greater luftre and perfection at another place many years after.

But the difficulty lies, either in shewing why the practice should be at a stand from 1432, to the revival of it at Mentz by Fault and Schoeffer in 1465, or else in giving some account of the condition and progress of this invention during that interval.

Now, Boxhornius, Scrivener, and other authors, expressly affirm, that so large a work as the "De Spiegel, Speculum Salutis" of Colter, shewn at Haerlem for the first printed book, could never be his first effay; he must have had the art in its rougher rudiments before, and have made many trials on leaf works: no doubt his first attempts were on loose sheets, which we may suppose were easily lost. In effect, it must be allowed no considerable argument in Colter's behalf, that the rudolf and most artificers performance seem to be his. Mr. Ellis mentions some things of this kind without his name, which he had seen in the king's library at St. James's, in that of Benselius college and the Bodleian at Oxford, with all the marks of the utmost simplicity, and which might fairly bid for first effays. There is something so awkward and coarse in them, that any body almost might have done them; mere nature being sufficient, without any art or experience at all. The ink was only common writing ink, unartfully spread upon wooden blocks, very clumsily cut, &c.

By this time we have traced up the art to such a state, that it may, perhaps, scarcely be worth the contending who it was invented it; and no doubt printing, as it now stands, owes more to the genius and address of some of the later improvers than it did to its first author.

The fame confideration may make us more easy under our present ignorance of the inventors of most other arts; many of which had such simple uttering originals, that it might perhaps be no mighty credit to be esteemed the authors of inventions not less artful and ingenious.

We shall conclude this account of the origin of printing with an abridgment of the history of it, given by the late Mr. Bowyer. This writer observes, that the honour of having given rife to this art has been claimed by the cities of Haerlem, Mentz, and Stralburgh. To each of those cities it may be ascribed in a qualified scare, as they made improvements upon one another. But the real inventor of printing was Laurentius, of Haerlem; who proceeded, however, no farther than to separate wooden types. His first effay was about the year 1430; and he died about 1440, after having printed the "Horarium," the "Speculum Belgicum," and two different editions of Donatus. Some of Laurentius's types were stolen from him by one of his servants, John Gensfleisch, senior, who became the first printer in Mentz, and published, in 1442, "Alexandrini Galatei," and "Petri-HispafiTractatus." These works were executed with wooden types, cut after the model of those which he had stolen. In 1443, Gensfleisch senior entered into partnership with Fault (who supplied money), Meldenbachus, and others; and in 1444 they were joined by John Gensfleisch junior, who was distinguished by the name of Gutenberc. Gutenberc, by the assistance of his brother, Gensfleisch the elder, first invented cut metal types, with which was printed the earliest edition of the bible. This edition appeared in 1450, and the completing of it took up seven or eight years. Gutenberc used none but either wooden or cut metal types. The carrying of the art to perfection was owing to Peter Schoeffer, the fervant and fon-in-law of Fault, who invented the mode of calling the types in matrices; and who was probably the first engraver on copper-plates. The first book printed with the improved types was "Durandi Rationale," in 1459. More copies of the earlier books were printed on vellum than paper. This method, however, was soon changed; and paper was introduced for the greatest part of the impreffions, a few only being printed on vellum, for curiosities, and for the purpose of being illuminated.

With regard to the claim of Stralburgh, it appears that Gutenberc had endeavoured to introduce printing into that city before he joined his brother at Mentz; but without success. The first actual printers at Stralburgh were Mentelius and Eglicenius; and there is no certain proof of a single book having been printed there till after 1462. The diffusion of the Mentz printers, in that year, occasioned the art to spread rapidly through Europe; and in 1490 it reached even to Constantinople. Those who wish to fix this subject farther discussed, and to find the authorities on which this abstract of the rise of printing is founded, may consult Meerman's "Origines Typographicae," quarto, 1585, and Bowyer's "A Short History of Printing," edition of 1698.

Printing, Progress of. The first printers, then, whoever they were, made their first essays on wooden blocks, or forms, after the Chincle manner.

It is not improbable, says Mr. Bagford, they might take the hint from ancient medals and seals. To this purpose, it is observed, that the arts and sciences, especially statuary and sculpture, were arrived at so great perfection among the Romans, at the time when that empire was in its greatest glory; that it is much to be wondered at that the art of printing was not found out among them; an art so nearly allied to that of the cutting of seals and the dies of medals.

The making of these dies, and the stamping of their coins with them, was, in reality, no other than printing on metal; and their impressing their seals, cut in cornellins, agates, &c. on wax, was another species of printing on this libulance. And finally, a third sort of printing among them, was the impressing the name of the workmen on their pieces of fine earthen-ware.

Montfaucon, in his Antiquities, gives the figures and descriptions
scriptions of several very large sigilla of the Romans, in which the names were all cut in hollow, in capital letters; and he imagines, that the use of these was to mark large earthen vessels with, while the clay was soft, and particularly these large vessels in which the Romans kept their wines. It does not seem that this diligent enquirer into antiquity ever met with any of these sigilla with the letters or characters in relief, or standing out in the manner of our modern types for printing, since he mentions none such; yet the remains of the Roman antiquities in terra cotta, or earthen-ware, show that they had some such, though they were less common than the others; these vessels sometimes being marked with letters going in, though in general they have them all standing out, as must be the case when the impression was given from a sigillum cut in creux.

There is now, in the collection of the duke of Richmond, a sigillum of the other more rare kind, which brings the discovery very near to that of printing; on this all the letters are raised, as is also the verge or rim of the seal in the manner of our types used this day in printing. The stamp is made of true ancient brass, and has on it the common green coat of arugo, which distinguishes the true antique medals. The plate is nearly two inches long, and nearly an inch in breadth, and has on the back part a ring for the convenience of holding it for making the impression. The letters stand in two rows; they are the common Roman capitals, very well made, and their faces all stand exactly on the level with one another, and with the surface of the verge of the seal. This seal was exactly of the nature of our method of printing so many letters at once. It contains the name of one Caius Julius Cæcilius Hermias, some private man, as we have no account of any person of this name upon record. He served probably to set his name to any thing, to save him from the trouble of writing; and the name being that of some private man seems also to prove, that these sigilla were very common among that people. It was evidently made to be used on parchment, or some other such thin substance; and the manner of using it must have been by first dipping it into ink, or some other coloured matter, not plunging it so far as to touch the ground, so that the letters only became marked, and gave their figures on the paper. The ground of this seal is very rough and uneven, and thence it is plain, that the use of it was not to press down any soft substance, such as clay, or the like; because the imperfection of the ground would, in that case, have been seen; whereas in the use it was really intended for, the ground never gave any impression, and therefore there was no reason for belowing any pains of the working it even.

The first use of printing among the later ages, was by wooden blocks in this very manner; and it was not till long after this invention, that we learned the way of using separate types for the letters; and these were then called typi mobilis, in opposition to the blocks, where the whole page was contained together, which was called typi fixi. This signet of the duke of Richmond, which was found near Rome, is truly and properly one of those typi fixi, and prints off its impression on paper with our modern printer's ink, as well as any of letters cut in this manner can be expected to perform. This seems, therefore, the most ancient sample of printing that we know of; for, by the appearance of the metal, it seems to be of the Higher Empire.

It is plain, by this stamp, that the very essence of printing was known to the Romans; for they had nothing to do, but to make a stamp, with lines three or four times as long, and containing twenty lines instead of two, to have formed a frame of types that would have printed a whole page as Cotter's wooden blocks, used in printing the book called "Speculum Salutaris," which, as some say, is the first book printed in the year 1440, and consisting of pictures of stories out of the Bible, with some of the verses underneath each page; being printed from a block of wood, like a wooden cut. This was the first essay of fixed types, from which the movable, or common separate types were soon deduced; and it seems strange that the Romans, who were as sagacious a people as any in the world, should not as easily have fallen upon the use of separate types, in which the whole art of modern printing consists, from such sigilla as these, as the later ages from Cotter's wooden blocks, which were plainly no other than larger works of the same kind.

Cicero, in his book "De Natura Deorum," has a passage from which Toland supposes that the moderns took the hint of printing. That author orders the types to be made of metal, and calls them formas literarum, the very words used by the first printers to express them. It is plain from Virgil, that brands, with letters of the owner's name, were in use in his time for the marking of cattle. And we have an account of the same artifice that is now used for the painting of cards being used by the emperor Julian, who could not write. There was a smooth board, with holes cut through it, in form of the letters of his name; and when he had occasion to sign any thing, this was laid on the paper, and he marked the letters with a pen or stylus dipped in red ink and directed through the holes. Philos. Trans.

But others rather imagine the art of printing to have come from the method of making playing cards, which, it is certain, bear a nearer resemblance to the primitive processes of printing than seals; as appears from the first specimens of that art above mentioned.

The book at Haerlem, the vocabulary called "Catolicon," and the pieces in the Bodleian and Bennet college, are all performed in this way; and the impression appears to have been given on one side of the leaves; after which the two blank sides were pasted together.

But they soon found the inconveniences of this method, and therefore bestowed themselves of an improvement; which was by making single moveable letters, distinct from one another.

These being first done in wood, gave room for a second improvement; which was the making of them, at length, of metal; and in order to that, cutting moulds, matrices, &c. for casting them.

From this ingenious contrivance we ought to date the origin of the present art of printing, as practised throughout Europe; contriving it from the methods of the Chinese abroad, and the card-makers at home, which were the same art, only practised in a different place, or with a different view.

And of this, Schoeffler, or Scheffer, first servant, and afterwards partner, and son-in-law of Faulk, at Mentz, above mentioned, is pretty generally allowed the inventor; so that he was properly the first printer with moveable types.

But the art being yet in its infancy, there were some imperfections in the books they printed; among the rest was the want of capital letters: hence they left the places of the initial letters blank, and gave them to the illuminators to paint in gold, or azure, though others say, this was done designedly, to enable them to pass off their books for manuscripts.

Some authors tell us, that Faulc carrying a parcel of his bibles to Paris, and offering them to sale as MSS., the French, upon considering the number of books, and their exact conformity with one another, even to a point, and that,
the best book-writers could not be near so exact, concluded there was witchcraft in the cafe; and, by either actually indicting him as a conjuror, or threatening to do so, extorted the secret. And thence the origin of the popular story of Dr. Faustus.

From Mentz, about the year 1462, when it was taken, plundered, and deprived of all its former rights and franchises, the art of printing soon spread itself throughout a good part of Europe; Haerlem and Strafsburg had it very early; which, as authors represent it, occasioned their pretending to the honour of the invention.

From Haerlem it palled to Rome in 1466, where the Roman type was introduced in 1457, which was soon after brought to great perfection; and into England in the reign of Henry VI. by means of Thomas Bourchier, archbishop of Canterbury, who sent R. Tournour, master of the robes, and W. Caxton, merchant, to Haerlem, to learn the art. Thee privately prevailing with Corvellis, an under-workman, to come over, a press was set up at Oxford.

This account depends on the authority of an old manuscript chronicle, said to be preferred in the archbishop's palace, and cited by Atkins, in his "Original and Growth of Printing in England," published at London in 1664. This chronicle informs us, that the execution of the books in trudted with Tournour and Caxton, coll fifteen hundred marks; and that printing was set up at Oxford before there was any printing presses or printer in France, Spain, Italy, or Germany, except the city of Mentz, which claims seniority as to printing even of Haerlem itself, calling herself "Urban Magnitum artis typographicae inventricem primam;" though it is known to be otherwise, that city (as the chronicle adds) gaining that art by the brother of one of the workmen at Haerlem, who had learned it at home of his brother, and afterwards set up for himself at Mentz. This press at Oxford was at least ten years before there was any printing in Europe (except at Haerlem and Mentz), where also it was but new-born. This press at Oxford was afterwards found inconvenient to be the sole printing place in England, as being too far from London and the sea; upon which the king set up a press at St. Alban's, and another at the abbey of Westminster. But the authority of this chronicle has been warmly disputed by Mr. Palmer in his "History of Printing," 1753, book iii.; Dr. Ducarel, in his letter to Meerman, Dr. Middleton, Ames, and others, who maintain that there was no printing in this kingdom till the introduction of it by Caxton, who had acquired it in his travels abroad, about the year 1474, or as some say, 1470 or 1471.

But Mr. Bowyer, in his notes to the Abridgment of Dr. Middleton's "Dissertation on the Origin of Printing in England," hath offered several reasons to show, that the account given in Atkins's record is not so incredible or improbable as some persons have imagined.

Mr. Meerman, in his learned work already cited, is a curious advocate for the authenticity of this record; and he apprehends that the period to which this history relates, must have been between the years 1454 and 1459; because Bourchier was made archbishop of Canterbury in 1454, and Edward IV. succeeded Henry VI. in 1460. This accurate writer has produced a variety of evidence in support of the claims of Corvellis, for which we must refer to his elaborate work, and particularly to his letter in reply to Ducarel, tom. ii. p. 19, &c., and to Mr. Bowyer, ubi supra; which evidence derives much confirmation from a book with a date of its impression from Oxford, anno 1458, copies of which are in several public libraries, particularly at Cambridge, Oxford, lord Pembroke's library, &c. This is a small volume of forty-one leaves in quarto, with this title: "Excerptio Sancti Jeromini in Symbolum Apostolorum ad Papam Laurentium," and at the end are the following words, "Explicit Excerptio, &c. imprima Ozone & finita, Anno Domini MCCCLX.XVII. XVII die Decembris."

If the authority of this book be admitted, it is a clear proof and monument of the exercite of printing in Oxford several years before Caxton began to deal in it. Dr. Middleton, indeed, endeavors to show that the date is a false one; and, not to mention the rest of his arguments, confirms his opinion from this circumstance, that we have no other fruit or production from the press at Oxford for eleven years next following. But this objection is invalidated by two considerations: first, that Corvellis's books may have been lost, a thing by no means uncommon in these days of ignorance; and, secondly, that the civil wars broke out in 1469, which might probably oblige our Oxford printer to shut up his press.

Mr. Bowyer produces a passage from the second part of Shakspere's Henry VI., as a farther evidence of a more early introduction of printing into England than hath generally been supposed. See also Meerman ubi supra, moniment novilignum, prefixed to tom. ii.

The result of the whole is, that this fact doth not at all derogate from the honour of Caxton, who was the first person in England that practiced the art of printing with fulle types, and consequently the first who brought it to perfection; whereas Corvellis printed with separate cut types in wood, being the only method which he had learnt at Haerlem.

In 1467, printing was set up in the city of Tours; at Reuthlingen and Venice in 1469; and probably in the same or next year at Paris, where Gering, Crantz, and Friburger, all Germans, invited thither by two doctors of the Sorbonne, set up a press in that learned house.

Hitherto there had been nothing printed but in Latin, and the vulgar tongues; and this first in Roman characters, then in the Gothic, and at last in Italic. But in 1480, or, as some say, in 1476, the Italians call a <fett> of Greek types; and it was at Venice, or, as some say, at Milan or Florence, that the first editions in that language appeared.

Here we may observe, that the first Greek printing was a few sentences of Tully's Offices at Mentz, in 1465, which were very incorrect. In the same year, some Greek quotations in an edition of Laënnec's Instrucites, were neatly printed, in a monastic press, in the kingdom of Naples. The first whole Greek book was the Grammar of Constanlantin Laclaris, at Milan, in 1476. See Bowyer, ibi supra, Appendix, No. 1; or the excellent edition of the Bibliotheca Britannica, by Dr. Kippis, art. Atkis, note (A).

The Italians, too, have the honour of the first Hebrew editions, which were printed about the same time with the Greek, at Soscino, a little city in the duchy of Milan; under the direction of two Jewish rabbins, Joshua and Moses, whose works are dated in the year of the world 5244, answering to the year 1484 of the Christian era.

Towards the end of the sixteenth century, there appeared various editions of books in Syriac, Arabic, Persian, Armenian, Coptic, or Egyptian characters; one to gratify the curiosity of the learned, and others for the liturgical uses of the Christians in the Levant: these were printed chiefly at Paris; whither puncheons and matrices were sent from Constantinople by M. Savary, then ambassador at the Porte.

Out of Europe, the art of printing has been carried into the three other quarters of the world: for Asia, we see impressions of books at Goa, and in the Philippines; at Lima,

PRINTING.

Lima, Boston, Philadelphia, Mexico, &c. for America; and at Morocco for Africa.

The Turks, indeed, are said rigorously to prohibit printing throughout their empire, as imagining that the too free communication with books might occasion some change in religion or government, but this is to be understood with some limitation: and it is certain that the Jews have several editions of their books printed at Constantinople, Thebaisiaca, &c.

PRINTING. Method of. For the printing letters see the annexed specimen.

For the method of forming and cutting them, see Letter Foundery.

And for the art of engraving the punchons, matrices, &c. in order thereto, under the articles Engraving, Punchon, Matrice, &c.

The workmen employed in the art of printing are of two kinds; compositors, who range and dispose the letters into words, lines, passages, &c. according to the copy delivered to them by the author; and pressmen, who apply ink upon the same, and take off the impression. See Composition, &c.

Office of the Compositor.—The types, being cast, &c. are distributed, each kind by itself, among the divisions of two long wooden frames, an upper and under one, called cases; each of which is divided into little cells, or boxes, of different sizes.

The boxes of the upper cases are in number ninety-eight; and in these are disposed the capitals, small capitals, accented letters, &c. In the cells of the lower case, which are fifty-four, are disposed the common running letters, with the points, commas, spaces, quadrats, &c.

Each case is placed a little aloof, like a reading-desk, that the operator may reach the upper boxes the better, and be in less danger of mixing the letters by stretching his arm over them.

The compositor's post is against the middle of the case, and he works standing, holding an instrument, usually made of iron, called the composing-flick, in one hand; with the other he takes the types as he requires them, out of the boxes; ranges them on a fly of brass, called a rule, in his composing-flick; and, putting a space, to make a blank between each two words, forms one line after another, till the flick being full, he empties it out upon another instrument, called the galley; several of which ranged and wedged tight in an iron frame, called a chase, are ready for the press.

This short view of composing may need to be farther illustrated and enlarged upon. The composing-flick, then, (represented Plate IV. Printing. fig. 5.) consists of a plate, or fly of iron, brass, wood, &c. more or less broad, and contrived so as to be made more or less long, according to the width of the page, and the number of lines to be composed in it.

From the right side of this plate arises a ledge a, about half an inch high, running the whole length of the plate, and serving to sustain the letters, the sides of which are to rest against it; from the same plate likewise arise three other letter pieces, b and c, two of which, c, c, are contrived to slide along it, so that the two pieces may be either approached or withdrawn at pleasure, to adjust the length of the line to the measure intended. Add, that where marginal notes, references, &c. are required in a work, the two sliding pieces, c, c, are opened in the composing-flick to a proper distance from each other.

Before the workman proceeds to compose a rule, or thin fly of brass plate, cut to the length of the line, and of the same height as the letter, is placed in the composing-

flick against the ledge of it, for the letter to bear immediately against.

Things thus prepared, the compositor having the copy lying before him, and the flick in his left hand, with the right he picks up the letters, spaces, &c. and places them against the rule; while with the thumb of the left he presses them close to the upper screw, or check: and thus keeps them tight and steady: while the other hand is constantly employed in setting in more letters; the whole being performed with a degree of expedition and address not easy to be imagined.

A line being thus composed, if it end with a word or syllable, and fill the measure, there needs no further care; other lines more spaces are to be put between the several words to justify the lines, i.e. to make the measure quite full, so that every line may end even; and thus he proceeds to another line.

The spaces here used are a sort of blanks, of the like dimensions as the letters, but less high; and whole faces, therefore, when fet, do not appear, nor give any impression. They are of several kinds, according to the dimensions of the whites or intervals to be made by them, viz. quadrats, to fill up a break at the end of a paragraph, or the like; m quadrats, which are square, and of the thicknefs of an m, serving to make the distance after a period, or between sentence and sentence; n quadrats, of the thickness of an n, to be placed after colons, semicolons, and commas; and thick or thin spaces, to be used between the words in justifying, as above.

For marginal notes, in the spaces reserved for them between the two sliding pieces of the composing-flick, are put little quadrated pieces of metal, called quotations; which are justified by other smaller pieces; a flip of scaleboard being placed from the top of the page to the bottom, to keep the note and text at due distance.

The firſt line being thus completely justified, the compositor advances to the next; in order to which, he moves the brass rule from behind the former, and places it before it, and thus composes another line against it, after the same manner as the former: and thus he goes on till his flick be full, which he empties into the galley, after the manner following:

Taking the rule from behind the last line, he places it before it; and with his two middle fingers squeeizes the lines in the flick close; his two fore-fingers at the same time being applied on the outside of the rule: thus he lifts them out of the flick, and clapping his two thumbs behind the first line, lifts them into the galley; taking care to diffuse his two thumbs without breaking the lines.

The compositor having thus fet the proper number of lines in the flick, viz. four, five, six, or more, and emptied them out into the galley, he again fills and empties, as before, till a complete page be formed; remembering at the bottom of every page to let a line of quadrats, and at the end of it the first word of the page ensuing, for a catch-word; and if it be the first page of the sheet, one of the letters for a signature.

The galley is a flat wooden tray or dish, in form of a long square; of a length and breadth proportional to that of the page; it consists of two parts, the upper, called the flye, by which the pages of large volumes, when compos'd, are carried upon the stone; the other, called the cofin, which is the body of the galley, is ledged on three sides to contain the flye; the inner ledge not to exceed half an inch in height, that the composed page rising above it by one half the height of the letter, may be tied up, or bound down, and removed without danger. When at work, the
the compositor places this galley at the top of the case, and it is prevented by a wooden pin from sliding down the boxes.

The page, then, being composed, and ranged in the galley, he ties it up in it with a cord or packthread, and lets it by, and proceeds to the next, till the number of pages of the sheet be completed; which done, he carries them to the imposing or correcting stone, there to range them in order in a chase; which they call imposing.

The chase is a rectangular iron frame of different dimensions, according to the size of the paper to be printed on, having two crofs pieces of the fame metal, called a long and short crofs, mortised at each end into the frame, fo as to be taken out occasionally.

By the different situations of these crofses, the chase is fitted for different volumes, for quarto and octavo; one traverses the middle lengthwise, the other broadwise, so as to intersect in the centre, which is the molt customary situation; for twelves and twenty-fours, the long crofs is shifted nearer to one end of the chase. For folio, the long crofs is left entirely out, and the short one placed in the middle; and for broad-sides, or sheets printed on one side only, both crofses are left aside.

To dress the chase, or range and fix the pages in it, they make use of a set of furniture, confisting of reglets, or slips of wood of different dimensions, and about an inch high, that they may be lower than the letters; some of these are placed at the top of the pages, called head-flicks; others between them to form the inner margin, called gutter-flicks; others at the sides, called side-flicks; and others at the bottom, called foot-flicks.

The pages then being placed in order on the stone, the chase is put over them, and the reglets applied between the letter and the chase, in the position above-mentioned; the whole is locked up by means of small pieces of wood, cut in the wedge-form, called quoins, which are driven with a mallet and floating-flick to a sufficient tightness. Before the form be quite locked up, they press down the fame, by palling a smooth piece of wood, called the plainer, over the letters, to make their surfaces flat and even; and, when locked up, they shake it, to see that nothing is out.

In this condition, the work is called a form, containing more or fewer pages, according to the volume.

As there are two forms required to every sheet, when both sides are to be printed, it is neceffary they be exactly of the fame length and breadth; i.e., the corresponding reglets, head-flicks, &c. are to be equal in both forms, that the pages may fall exactly on the back one of another; which is called register.

Here, then, properly ends the compositor’s office; the form, thus finifhed, being to be committed to the pressman.

Indeed, as it is impracticable, but there must be mistakes in the work, either through the oversight of the compositor, or by the casual transposition of the letters in the cafes; after drawing off a proof, it is delivered to the corrector, who reads it over, and rectifying it by the copy, it is remanded to the former operator, to be corrected accordingly.

For the characters used in correcting a sheet for the compositor, see Correftion.

The compositor, then, unlocking the form upon the correcting-stone, by knocking out or loosening the quoins, and spreading his corrected proof so as that the lines of it range with the respective ones of the metal, by running his eye along both, he easily finds where corrections are to be made; according to which, he proceeds to pick out the faulty letters, points, &c. with a sharp-pointed steel bodkin, and puts others in their places.

Where the alterations are considerable, and particularly where insertions or omissions are to be made, there usually arises a necessity of over-running; in order to which, they must decompose, or return the lines back from the chase into the galley, and from the galley again into the composing-stone, to be new-modelled and rectified accordingly.

If, e.g. one or more words, to be inserted in a line, cannot be gotten in by changing the spaces of the line for letters, one of the lines must be put back into the close of the preceding one, or forward into the beginning of the subsequent one, or both, till room is obtained. If the insertion be large, several lines will have to be overrun, either backward or forward, till a break is arrived at; when it if be not gotten in, a line is to be driven out; and, to get in that line, the next pages, either backward or forward, must sometimes be over-run before it can come in.

When an omission is to be made, the contrary course must be taken. If it be but little, the compositor takes it out, and drives out the remaining matter, either by enlarging its spaces, or by shortening the beginning of the following, or the close of the preceding line therein. If it be considerable, he may be obliged to over-run several pages before it can be driven out.

As to the faults which escape the corrector and compositor, they are usually noted in what we call the errata. The ancient editions had no errata; but in lieu of it, they corrected the faults in each printed copy with a pen, which was easy enough in those days, though impracticable now. In effect, we have anciently had printers, who did not need an errata of above five articles in a volume of five hundred sheets; and the distinguishing excellence of printing is correctness; and in this respect many of our modern printers deserve much commendation.

Besides the several kinds of letters and characters above-mentioned, used in printing, they have likewise rules for black lines, borders, and head and tail-pieces, accommodated to the several kinds of letters.

The rules for black lines are of brafs, and are made exactly of the height of the letter; otherwise they will hinder the neighbouring letters from printing, or will themselves be hindered by them. These the compositor occasionally cuts into proper lengths, as his work requires.

The borders, or flowers, are a kind of ornaments, in form of long bars, serving for the division of books, chapters, &c. Their depth is proportioned to the letter; and their length adjusted to the page; for being composed of several moveable pieces, it is easy to lengthen or shorten them.

The head and tail-pieces, cut either in wood, pewter, brasses, copper, or silver, are compartments used at the beginnings and endings of books.

The initial letters are sometimes cut in wood, and figured; sometimes call like the other characters.

For the convenience of the binding, the printers had early recourse to signatures, i.e. letters of the alphabet placed at the bottom of the first page of each sheet, which flew the order they are to be bound in, as well as whether the quires are complete; which method is still continued.

The catch-words serve nearly the same purpose; these are the first words of each page, which are inserted at the bottom of the preceding pages. The number of the pages are equally serviceable to the reader and the binder, to guide to references, and to warrant the book duly bound and collated; some printers formerly put them at the bottoms.
In the infancy of printing, they had likewise a registrum chartarum for the convenience of the binders: to draw this, at the end of each volume, they collected the signatures, and the fist words of the first four sheets of each alphabet. To abridge it, they afterwards contented themselves to express the signatures, and how often each letter was repeated; but the registrum has been now long difused.

Pressman's office, or Printing, properly so called. To work off the form thus prepared and corrected by the compositors, there are three things required, paper, ink, and a press.

To fit the paper for use, it is to be first wetted or moistened, by dipping several sheets together in water: these are afterwards laid in a heap over each other, and to make them take the water equally, they are all pressed close down with a weight at top. As to the degree of wetting, it must be according to the quality of the paper, and the size of the letter; small letters, and fluff paper, requiring most wetting.

Printing Ink is of two kinds, black and red; the last occasionally used in title-pages, calendars, &c. the first for the body of books. The composition of each, though now reckoned no part of the printer's business, but usually furnished them by other hands, is as follows:

For black ink.—A hundred pounds of nut or linseed oil, being reduced, by boiling, to the consistence of a syrup, are cleared and purified by throwing into them two pounds of coarse bread, and about a dozen onions. Nut-oil is supposed to be the best, and is accordingly preferred for the black ink, though the darker colour which it acquires from the fire makes it less fit for the red. This oil is boiled in an iron pot, capable of holding at least half as much more, because it swells very much; when it boils it is kept flirring with an iron ladle; and if it does not itself take flame, it is kindled with a piece of lighted paper, or burning wood, in order to increase its consistence and tenacity, and to diminish its greasiness. The oil is suffered to burn for half an hour or more; and the flame being then extinguished by covering the vessel close, the boiling is afterwards continued, with a gentle heat, till the oil appears of a proper consistence; in which state it is called varnish; of which there should be two kinds, one more and thicker, less boiled; or a thicker and thinner, to be used for different purposes, and in different weathers. The oil is laid to lofe in being boiled into thick varnish from a teather to an eighth part of its weight; but different oils, and perhaps the same oil in different states, differ in this respect. The design of adding the bread and onions is more effectually to destroy the greasiness; but Dr. Lewis doubts, whether additions of this kind are of much use. They then boil thirty or thirty-five pounds of turpentine apart, till such time as they find, upon its cooling on paper, that it breaks clean, like glass, without pulverizing; for if it pulverize easily, it is a sign it is burnt. The oil and turpentine being thus prepared, the sift is gently poured, half cold, into the latter; and the two sifted together with a flisc till they be well mixed; after which the boiling is repeated and the composition is let by, to be used occasionally. The turpentine is used in order to give a greater body to the varnish, and to increase its drying quality; and with some artificers, litharge has in this intention been a secret. M. le Breton, in the Encyclopédie, observes, that when very old oil is used, neither turpentine nor litharge are needful; but that when the oil is new, some turpentine ought to be employed, because without it, the smearing of the paper, by the spreading or coming off of the ink, cannot be avoided; and he adds, that it is much more eligible to use old oil than to have recourse to this correction of the new: both turpentine and litharge, particularly the last, making the mixture adhere so firmly to the types, that it is scarcely to be got entirely off by the ley, whereby the eye of the letter is soon clogged up.

Now to proceed to make ink, they take a quantity of this mixture, and add to it a certain quantity of lamp-black, working it up with a kind of wooden mallet, or brayer, till the whole be incorporated, and reduced into a kind of pulp; which is the ink for use.

Where, note, that its thickness or strength is always to be proportioned to that of the paper, and the warmth of the weather; strong paper, and hot weather, requiring strong ink; and that the strength or weakness of the ink depends on the greater or the less degree of c°duction of the varnish. According to M. le Breton, two ounces and a half of the lamp-black are sufficient for sixteen ounces of the varnish. Lewis's Commerce of Arts, p. 371.

For red ink, they use the same materials as for black, excepting only, that instead of lamp-black, they add a proper quantity of vermilion. Some hold, that by mixing and incorporating the bigness of a nut of tufh-glue, or brandy, or the white of an egg, with the ink, the vermilion acquires a greater lustre.

The Printing Press is a well contrived machine, and at a very early period of the art was brought to a degree of perfection, which has not admitted of any very material improvements till the present age. Who first invented it we are not informed, but from Mr. Moxon we learn, that it was very greatly improved by William Jansen Blaeu, who established a printing-house at Amsterdam, where he printed many books and maps, which he made from the observations of the famous Tycho Brahe, who had for many years employed him as an assistant, and to make his instruments.

Fig. 1. Plate IV. Printing, is a representation of the printing press in perspective. It has two principal parts, each of which is composed of several others: the first is the body of the press, which is a frame containing the screw, and plate, or surface which produces the pressure upon the paper; and the other is the carriage, on which the form of types is laid, and has the means of being drawn out of the body of the press, to remove the paper when printed, and to subdivide another sheet. For the convenience of changing the paper, the carriage is provided with frames, called the tympan and frisket, which hold upon each other and envelope the sheet between them, and are then again folded down upon the types.

The body of the press consists of two strong posts, A, B, placed perpendicular, called the cheeks, which are joined together by four horizontal cross pieces; the upper of these, a, is called the cap, and has no office but to contain the two cheeks at their required distances asunder: the next cross piece, b, is called the head; it is fitted by tenons at the ends into mortises between the cheeks, and these mortises are filled up with pieces of paulloire or soft wood, in such a manner as to admit of a small motion or yielding. The head is fastened by two long screw-bolts, which fupeind it from the cap; in the head is fixed a brass nut, containing a female screw, or worm, which is fastened in the wood by two short bolts to keep it up; the worm is adapted to receive the screw by which the pressure is produced. The third cross piece, c, called the shelves, or sill, is to guide and keep ready a part, i, called the hole, in which the spindle of the screw (to be spoken of hereafter) is inclosed. The fourth cross plank, f, called the winter, is fitted between the cheeks to bear the carriage;
it sustains the effort of the press beneath, as the head does above, each giving way a little, the one upwards the other downwards, to make the pull the easier. The fpinde, $x$, is an upright piece of iron, pointed at the lower end with file, having a male screw formed on its upper end, which enters about four inches into the female screw or worm fixed in the head: through the eye of this fpinde is fixed the bar or handle, $b$, by which the prefect works the press. The platen $k$, or surface which acts upon the paper to produce the impression, is suspended from the point of the fpinde by means of a square block or frame of wood, $i$, called the hofe, which is guided by passing through the shelves $e$; the lower part of the fpinde passes through the hofe, and its point rests upon the platen $k$, being received into the plug fixed in a brass pan supplied with oil, which pan is fixed to an iron plate let into the top of the platen $k$. The prefect then, by pulling the bar $b$, fixed in the eye of the fpinde, $g$, by an iron key turns the fpinde, and by means of its screw preffes down the platen upon the form of types, which is covered with the paper, tympan, and its blankets, all these parts being brought under the platen by the carriage, when the impression is to be given. That the platen may be suspended from the fpinde, and rise up again with it, the hofe, $i$, is attached to the fpinde by the garter; this is a fillet of iron screwed to the hofe, and entering into a nick or groove formed round the upper part of the fpinde; it prevents the hofe falling down on the fpinde. At each corner of the lower part of the hofe there is an iron hook fastened, and from these to similar hooks, fastened at each corner of the platen $k$, cords or packthread are looped to suspend the platen, and they are exactly adj usted, to hang the platen truly level.

The carriage $ll$, which is the other principal part of the press, is adapted to run into the space between the cheeks under the platen. It is supported upon the ribs $m$, which are part of a horizontal wooden frame, having its fore-part supported by a wooden prop $n$, called the fore-leaf, while the other end rests on the winter. On the rails of this frame two long iron bars or ribs are nailed, and under the planks of the carriage are nailed short pieces of iron or steel, called cramp irons, which slide upon the ribs, when the carriage is run in or out, by the following means. Beneath the carriage is placed a small fpinde called the spit, with a double wheel formed in the middle of it, round which leather girts are passed and fastened, the opposite ends being nailed to each end of the plank, $l$, of the carriage. On the extreme end of the spit is fixed the handle or rounce $p$, by which the prefect turns the spit, and this, by means of the wheel and fraps, runs the carriage in or out at pleasure. The carriage itself consists of a strong wooden plank $l$, upon which a square frame of wood is fixed, to form the coffin or cell, in which a marble or polished stone is inclosed, for the form of the types to be laid upon. To this coffin are fastened leather flay-girts, one to each side, which being at the opposite ends fastened to the cheeks of the press, prevent the carriage running too far out, when drawn from under the platen. On the fore-part of the plank is a gallows $rr$, which serves to fasten the tympans, when turned up from off the form, on their hinges. The tympans, $ss$, are square frames covered with parchment. The frames are made of three flaps of very thin wood, and at the top a flap of iron, still thinner, called a head-band. The two tympans are fitted together by the frame of one, being small enough to lie within the other: the outward tympan is fastened with iron hinges to the coffin. Between the two parchments of the tympans two or three thicknesses of blankets are placed, which serve to make the impression of the platen upon the surface of the letters more equal, as also to prevent the letters from being broken by the force of the press. The use of the inner tympan is to confine the blankets. The frisket, $t$, is a square frame of iron, made very thin, also covered with paper or parchment, and fastened to the head-band of the outer tympan by hinges: it folds down upon the tympan, to enclose the sheet of paper between them, the parchment or paper with which the frisket is covering being cut out in the necessary places, that the sheet, when placed between the tympan and frisket, and both together folded down on the form, may receive the ink from the types in the pages; but the frisket sheet keeps the margins clean. The tympan and frisket, when folded down, lie flat upon the form, and the carriage with them is run into the press; but when the sheet is to be taken out, the tympan is lifted up upon its hinges, and frisks, as represented, in an inclined position against the gallow $r$, before mentioned, at the back part of the carriage; then the frisket, $t$, is lifted up on its hinges, and suflained by a slip of wood, $w$, hanging from the ceiling, whilst it continues open, to take out the printed sheets and put in others.

To regulate the margin, and make the lines and pages answer each other when printed on the opposite side of the sheet, two iron points are fixed to the middle of the wooden sides of the frame of the tympan, which make two holes in the sheet. These holes are placed on the same pins, when the sheet is returned for making an impression on the other side, which is called the repetition, and the pins are adjustable, that they may make the impressions of the opposite sides exactly correspond.

The ink is applied upon the form by balls, which are a kind of wooden cups with handles, the cavities of which are filled with wool, or hair, covered with sheep's skin nailed to the wood. One of these the prefect takes in each hand, and applying them on the ink-block, to charge them with ink, he works them one against the other, to mix and distribute the ink equally; and, at last, smears over the form, by beating or dabbing them several times over the whole face of it; this leaves the form in a condition to be passed under the press, with the moistened paper laid on it.

To prepare the press for working, the parchment of the outer tympan, against which the sheet is to be laid, is wetted till it is very soft, in order to render the impression more equal; the blankets are then put in, and secured from slipping by the inner tympan. Then, while one prefect is beating the letter with the balls, covered with ink, taken from the ink-block, the other person places a sheet of paper on the tympan, turns down the frisket upon it, to incline it, keep the margins clean, and prevent it slipping; then folding the tympan down upon the form, and turning the rounce, $p$, with his left hand, he brings the form, with the stone and carriage, (which altogether weighs about 300 lbs. weight,) under the platen; pulls the bar with the right hand, by which means the platen presses the blankets and paper close upon the letter, whereby half the form is printed; then releasing the bar, he advances the form till forward into the press, by turning the rounce, and gives a second pull: now letting go the bar, he turns back the form, lifts up the tympans, and opens the frisket, takes out the printed sheet, and lays on a fresh one; and this is repeated, until he has taken off the impression for the full number of sheets the edition is to consist of. One side of the sheet being thus printed, the form for the other is laid upon the press, and worked off in the same manner; the sheet being so disposed, that the iron points shall pass through the holes already made in the sheet.

Sometimes it is required to cut the frisket afresh, where
the second side is to be more or less full of printing than the first, as is frequently the case at the beginning and ending of books, half pages at the ends of chapters, &c.

The number of sheets of the edition being complete, the form is to be separated: to restore the letters into the compositors' cases, they first wash it in a strong ley, to take out the remains of the ink, scouring it with a brush, and then with fair water. This done, it is carried to a wooden frame to be unlocked, and the furniture, i.e. the ficks and quoins, taken off, to disengage it from the chase. Then the compositor, taking out several lines at once upon a little brass ruler, replaces each letter in its proper box, to be again used in the remainder of the impreffion; which last operation they call distribution.

The operations of the printing prefs, when conducted by an expert preflman, are performed with a surprizing rapidity; but the labour is very great. Two men take it by turns to pull, that is, work the prefs, and beat, or ink the types. Whilst one workman is employed in pulling the sheet, his comrade is distributing the ink on his balls, by first applying them to the ink-block, which is a small shelf fixed up against one of the cheeks of the prefs, and has ink spread out upon it by the flice and brayer, which is a wooden muller to mix and grind the ink; then applying the balls together, and turning them round in his hands, whilst the surfaces are rolled or dabbed against each other, the ink becomes equally distributed over them. By this time the preflman having made the pull, and opened the tympan, the other instantly begins the beating, whilst the preflman gets the sheet changed. In beating, he holds a ball in each hand, and applies them upon the types, with the handles in an inclined position; and then he mounts the handles perpendicularly, by which means the leather is rolled over the surface of the types, and they are equally inked; but if they were moved in any other way, the hollows would scrape off the ink, and clog up the letters. Having thus inked a space of as much extent as the two balls will conveniently cover, they are lightly lifted off the letters, and removed to another part, which is inked in the same manner, till the whole sheet is gone over.

The preflman, during the beating, has removed the printed sheet, and laid another evenly upon the tympan, which is done with great address; then folding down the frisket upon it, and flutting both together down upon the form, he runs in the carriage as before-mentioned, to take the first pull; for the platen being only half the size of the sheet, it is printed at twice, and the first time the carriage is run into the prefs, the preflman knows by a chalk mark previously made on the carriage when the first half of the sheet is under the platen; he now makes his pull, and letting the handle go back, runs the carriage in again, till the other half of the sheet comes under the platen, and then makes a second pull. In this operation he leans his body back, and places his foot against the foot-board beneath the prefs, to gain a greater purchases. Presses are, in general, adapted for the screw to make a sufficient preffure by a quarter turn of it, but this the preflman can vary to his own inclination, by packing up the head, \(b\), of the prefs with pieces of paflteboard in the mortises, till it yields as much as he requires for a long pull; or if he puts blocks of wood to fill up the mortises, it will make a short pull, which has much the advantage of the other, in respect to the total exertion it requires; but then the handle being suddenly checked on coming to the preffure, it gives a shock to the whole body, which few men can bear. Strong men will work better with a solid press.

The severe labour of printing, by the ordinary press,

\[\text{Vol. XXVIII.}\]
Printing.

eceive the impression, or drawn out to remove the printed sheet. The carriage is moved by the rounce or handle L, with a spit and leather girts, very similar to the wooden press. Upon the spit, or axe of the handle K, a wheel, L, is fixed, and round this leather belts are passed, one extending to the back of the carriage to draw it in, and two others, which pass round the wheel in an opposite direction, to draw it out. By this means, when the handle is turned one way it draws out the carriage, and by reversing the motion it is carried in. There is likewise a check strap, f, from the wheel down to the wooden base, M, of the frame, and this limits the motion of the wheel, and consequently the excursion of the carriage. The principal improvement of early Stanhope's press consists in the manner of giving motion to the screw, h, of it, which is not done simply by a bar or lever attached to the screw, but by a second lever; a, gr. the screw, h, has a short lever, g, fixed upon the upper end of it, and this communicates by an iron bar, or link, h, to another lever, i, of rather shorter radius, which is fixed upon the upper end of a second spindle, J, and to this the bar or handle, L, is fixed. Now when the workman pulls this handle, he turns round the spindle J, and by the connection of the rod, b, the screw, h, turns with it, and causes the platen to descend and produce the pressure. But it is not simply this alone, for the power of the lever, k, is transmitted to the screw in a ratio proportioned to the effect required at the different parts of the pull; thus at first, when the pressman takes the bar, k, it lies in a direction parallel to the frame, or across the press, and the short lever, i, (being nearly perpendicular thereto,) is also nearly at right angles to the connecting rod b; but the lever, g, of the screw makes a considerable angle with the rod, which therefore acts upon a shorter radius to turn the screw; because the real power exerted by any action upon a lever, is not to be considered as acting with the full length of the lever between its centres, but with the distance in a perpendicular drawn from the line in which the action is applied to the centre of the lever. Therefore, when the pressman first takes the handle, L, the lever, i, acts with its full length upon a shorter length of leverage, g, on the screw, which will consequently be turned more rapidly than if the bar itself was attached to it; but on continuing the pull, the situation of the levers changes, that of the screw, g, continually increasing in its acting length, because it comes nearer to a perpendicular with the connecting rod, and at the same time the lever, i, diminishes its acting length, because, by the obliquity of the lever, the rod, b, approaches the centre, and the perpendicular distance diminishes; the bar or handle also comes to a more favourable position for the man to pull, because he draws nearly at right angles to its length. All these causes combined have the best effect in producing an immense pressure, without loss of time; because, in the first instance, the lever acts with an increased motion upon the screw, and brings the platen down very quickly upon the paper, but by that time the levers have assumed such a position as to exert a more powerful action upon each other, and this action continues to increase as the bar is drawn forwards, until the lever, i, and the connecting rod are brought nearly into a straight line, and then the power is immensely great, and capable of producing any requisite pressure which the parts of the press will sustain without yielding. The handle is sometimes made to come to rest against a stop, which prevents it moving further, and therefore regulates the degree of pressure given upon the work; but to give the means of increasing or diminishing this pressure for different kinds of work, the stop is made moveable to a small extent.

A better plan is adopted by some makers of the Stanhope press, viz. to have a screw adjustment at the end of the connecting rod b, by which it can be shortened; it is done by fitting the centre pin which unites it to the lever, g, in a bearing piece, which slides in a groove formed in the rod, and is regulated by the screw. This shortening of the connecting rod produces a greater or less descent of the platen, when the handle is brought to the stop.

The carriage of the press in Plate I. is represented with wheels, m, m, beneath, to take off the friction of moving upon the ribs, H. These wheels are shown at fig. 4, which is a section of the screw and the platen, with the carriage beneath it; and fig. 5 is a plan answering to it. Fig. 6 is a figure of the carriage, inverted, to show the wheels; their axles, n, are fitted to springs, p, and these are adjustable by means of screws, r, so that the carriage will be borne up to any required height. This is so regulated, that when the carriage is run into the press, its lower surface shall bear lightly upon the solid cheeks, G, which are part of the body of the press, and these support it when the pressure is applied, the same as the winter of the old press; but the wheels by their springs act to bear up great part of the weight of the carriage with the types upon it, and diminish the friction, yet do not destroy the contact of the carriage upon the ribs, because this would not give the carriage that solidity of bearing which is requisite for resisting the pull. This is only at the time when the carriage is run into the press, because as it runs out, the ribs on which the wheels run rise higher, and therefore the wheels support the whole weight. The manner in which the wheels run in rebates or receses in the edges of the ribs, is shown at fig. 2. The carriage is made of cast iron, in the form of a box, with several crofs partitions, which are all cast in one piece, and though made of this metal, are exceedingly strong; the upper surface is made truly flat, by turning it in a lathe. The face of the platen, which is likewise a shallow box; the slider, d, has a plate formed on the lower end of it, which is fixed by four screws upon the top of the platen, and thus they are united. At the four angles of the carriage, pieces of iron, r, (fig. 5) are screwed on, to form bearings for the quins or wedges which are driven in to weaken the form of types upon it in the true position for printing. The tympan, P, (fig. 1) is attached to the carriage by hinges, with an iron bracket or flop to catch it when it is thrown back: the frisket, R, is joined to the tympan, and when opened out, rests against a frame suspended from the ceiling. The register points are the same as before described in the wooden press, and all the operations of working are exactly the same. The iron frame, A, of the press is screwed down upon the wooden base, M, by bolts, which pass through feet, s, projecting from the lower part of the iron frame. Another wooden beam is fixed into the former at right angles, so as to form a crofs, which lies upon the floor. The ribs, H, for the carriage to run upon are supported from the wooden base by an iron bracket, T.

The advantages of the iron presses in working are very considerable, both in saving labour and time. The frisk rises from the beautiful contrivance of the levers, the power of the press being almost incalculable at the moment of producing the impression; and this is not attended with a correspondent loss of time, as it is the case in all other mechanical powers, because the power is only exerted at the moment of pressure, being before that adapted to bring down the platen as quickly as possible. This great power of the press admits of a saving of time, by printing the whole sheet of paper at one pull, the platen being made sufficiently large for that purpose; whereas, in the old press, the platen is only half the
the size of the sheet. In the Stanhope press, the whole surface is printed at once, with far less power upon the handle than the old press, when printing but half the surface. This arises not only from the levers, but from the iron framing of the press, which will not admit of any yielding, as the wood always does, and indeed is intended to do, the head being often packed up with elastic substancess, such as paste-board, or even cork. In this case much power is lost, for in an elastic press the pressure is gained by screwing or fnraining the parts up to a certain degree of tension, and the effort to return produces the pressure: now in this case, the handle will make a considerable effort to return, which, though it is in reality giving back to the workman a portion of the power he exerted on the press, is only an additional labour, as it obliges him to bear the strain a longer time than he otherwise would. The iron has very little elasticity, and those who use them find it advantageous to diminish the thickness of the blankets in the tympan to one very thin piece of fine cloth; the lever has then very little tendency to return, and the pull is easy in the extreme, requiring very little more force to move it at the latter, than at the first part; indeed it is so different from the other presses, that when an experienced proofman first tries it, he cannot feel any of that reluctance which he has been accustomed to, and will not believe, till he sees the sheet, that he has produced any impression at all; and for many days after he begins to work at an iron press, he by habit throws back all the weight of his body in such a manner, as to bring the handle up to its top with a concussion that shakes his arm very much; and in consequence most proofmen, after a few hours work, feel inclined to give up the iron press; but when they have once got into a new habit of handling more upright, and applying only as much force as it requires, the labour of the pull becomes less than that of running the carriage in and out; and men who are accustomed to the iron presses only, would be scarcely able to go through the work of the old presses.

The Stanhope presses have come very much into use, and many people are engaged in making them. The first of these are Messrs. Walker, of Oxford-street, who have the advantage of being affiliated by the inventor, earl Stanhope; they have a very good machine for turning the surfaces of the platen and carriage, so as to produce very accurate planes; which is a great advantage, as it permits a much thinner blanket than could otherwise be used.

Mr. De Heine has a patent for a Stanhope press, which answers extremely well; the only material alteration is, that he has substitutted a spiral or curved inclined plane, in place of the screw, which is fixed to the head of the press; and a cross arm properly formed, and fixed on the upper end of the spindle, which stands in place of the screw, acts against the fixed inclined plane. The action is very nearly the same as the screw, except that the surfaces admit of being made of hardened steel, and thus diminish the friction very much. The inventor of this for the common press was, as we have before mentioned, Mr. Roworth, but Mr. De Heine has combined it with the levers and iron frame of the Stanhope press. This Cyclopædia is printed by Stanhope presses.

Mr. Peter Kier, of Camden Town, has made several Stanhope presses of a very good construction, the strength of all the parts being very well proportioned, so that his presses are not more liable to break at one part than another. The slider, $d$, he has made in a very convenient manner, by boring out a cylindrical hole down the centre of the press with a boring machine, and into this cylinder is accurately fitted, the platen being fixed on the lower end of it. To prevent it from turning round, a flat side is made to the cylinder, and a bar of iron is screwed across the two cheeks $e$, between which the hole is bored, and bears against the flat side of the cylinder. Another improvement is in the spindle $i$, to which the handle is affixed: this has a screw cut upon the lower end of it, which is fitted into a nut, and thus, when it is turned round, the spindle rises and falls a quantity equal to the descent of the screw, $i$, in the same period. By this means, the connecting rod, $h$, always draws in a horizontal direction, whereas, in the other presses, one end remains at the same level, whilst the other descends, in consequence of which the joints wear irregularly. On the whole, Mr. Kier's improvements, though they do not constitute a feature of the invention, contribute much to the accurate performance and durability of the machine.

The form he has adopted for the frame, $A A$, is very judicious; that in our plate is unnecessarily strong, having been made at an early period of the invention, when, from being unaccustomed with the full power of the levers, many of the presses were broken by the strain, and some makers then determined to put in such a mass of metal, as to refill the utmost efforts of a man at the handle; but being now better understood, they are made much lighter than in the one in our plate, and sufficiently strong.

Several Stanhope presses, that is, presses having levers to work the screw, have been made in wood by Mr. Brooke, or altered from the old wooden presses; but though this is an improvement upon them, it is greatly inferior to the iron frame, which, for the reasons we have given, has a share in the favour of power.

Mr. Medhurst, of Denmark-street, Soho, has produced a printing press of great merit, from its simplicity, and it has the same advantage, in point of power, as lord Stanhope gains by the compound levers. It is a common press in all its parts, but the platen is made the full size of the sheet, and instead of a screw, a plain spindle is employed; on the lower part of it, just above the bar, a circular plate is fixed, and affords stops for the points of two iron rods, which extend up to the head, and are there supported by their points entering sockets. When the platen is up, these rods stand in an inclined position, although both the ends of them are at the same distance from the centre of the spindle; but when the spindle is turned by the bar, the circular plate, in which the lower points of the iron rods rest, turns round in a circle, and the upper ends remaining stationary, they of course come towards a vertical position, in which motion the spindle and platen are forced to descend, in the same manner as though a screw was employed; but this motion has every advantage of the Stanhope levers, or Mr. Roworth's press, without the friction of either, for the power increases as the resistance increases, and when the rods come nearly parallel to the spindle, or into a vertical position, the power is immensely great. We think a press of this kind, if made of iron, and with the other advantages of lord Stanhope's, would be much simpler, and rather better, because the friction and wear are inconsiderable, if the points of the rods and their sockets are hardened.

We have been shown a model of a new kind of press invented by Mr. Ruthven of Edinburgh; it differs from others in the following circumstances. The form of types, instead of being situated on a running carriage, is placed upon a stationary platform or tablet, which is provided with the usual apparatus of tympan and frikel, with points, &c. to receive the sheet of paper, and convey it to its proper situation on the face of the types, after they have been inked. The machinery by which the power for the press is produced, is situated immediately beneath this tablet, and the
platen or surface which is opposed to the face of the types to press the sheet of paper against them, can be brought over the types, and connected at two opposite sides or ends with the machinery beneath the table. By this machinery it is so forcibly pressed or drawn down upon the paper which lays over the types, as to give the impression, which being thus made, the platen can be disengaged from the machinery, and removed from off the types by a motion of the foot, to take out the paper and introduce a fresh sheet.

The machinery for producing the pressure is a combination of levers, actuated by a crank, or short lever, turned by a winch or handle, to which the pressman applies his left hand, just as he does in the press to the rounce or handle of the spit, the handle being placed in the frame situation for that purpose. The levers beneath the table are well contrived to have the best effect in saving time, and producing an immense pressure; for when the pressman first takes the handle, it acts with but little advantage as to power upon the levers, and therefore brings the platen down very quickly upon the tympan. The levers have then assumed positions, in which they exert a more powerful action upon each other; and this action continues to increase until one of the levers and its connecting rod come nearly into a line, when the power is immensely great, and capable of producing any requisite pressure. For fastening the types upon the table, or what the printers call the making registrator, instead of quoins or wedges being introduced at the angles in the usual manner, slivers are fitted through pieces which are fixed to the sides of the table; and between the points of these slivers the form of types is held steady upon the table, and may be adjusted.

We have not had an opportunity of trying a large press of this kind, but think it promises so much in saving of power and time, as to deserve a trial by printers. It avoids the moving of the heavy carriages with the form; for the platen need be but a small portion of the weight of the loaded carriage; and further, it is adapted to be moved off from the types sideways, and therefore has a less distance to move than the carriage in the ordinary press. The machinery is well contrived in all its parts, both for performance and stability, and is adapted to be made of iron, that it may have no yielding parts. It is far cheaper than the Stanhope press.

A Printing-House is a place defined for printing, and fitted up for that purpose with presses, cafes, and other furniture.

The most considerable printing-houses in the world are the Louvre and Vatican. The first, begun under Francis I., was carried to its utmost perfection under Lewis XIII., by the care of cardinal Richelieu; and removed into the galleries of the Louvre by Lewis XIV.

The Vatican printing-house, called also the Apollitical printing-house, because the pope's bulls, decrees, &c. are printed in it, was begun by Pius IV., and furnished with great magnificence by Sixtus V. See Vatican.

Out of both these printing-houses have come forth very beautiful and splendid editions of the ancient authors. The Vatican was the first that printed books in the Arabic language.

Printing, Stereotype, is a method of producing plates from moveable types, by forming a mould with them in platter of Paris, or any other fit substance, and in this mould casting a metallic plate, which will have the same surface as the types had, and will print the same. Therefore, in this method the moveable types are not used to print from, (except for proofs to correct the errors of composition,) but are employed as a model or pattern to call the stereotype plates by which the impression is to be printed. For the history and further particulars of this invention, see Stereotype.

Printing Machine.—The immense number of books and newspapers which are printed in this country, has rendered it desirable to have machines for printing, which would throw off copies more rapidly, and without requiring such excessive labour as the printing press does. For daily newspapers in London expedition is the grand object, as the whole impression (often as many as 6 or 8000 copies) must be printed between the hours of midnight, and eight or nine o'clock in the morning; and often, when there are important debates in parliament, they are not able to begin printing so soon as midnight.

The first attempts at printing machines were only to employ machinery for actuating a common press, and by the force of horses, or steam-engine, to perform the part of the pressman. We have seen a model of such a machine, which printed very well, and with great rapidity, but was so complicated, that on a large scale it could not have been urged into motion so quickly as the pressman can work; and in effect, when put to trial, it was found to employ one horse instead of one man to work the press. In 1792, Mr. Nicholson took out a patent for a machine to print by cylindrical rollers, the types being so formed with items smaller at one end than at the other, that, when composed, they would form a cylindrical surface instead of a plane. Between a roller covered with these types, and another plain roller, the paper was to be passed, and thus receive an impression; the ink was distributed by machinery. Mr. Nicholson's machine answered very well for printing patterns upon calico, paper-hangings, or any other papers, where the surface of a solid roller could be engraved to print from; but the moveable types were not found practicable, and therefore the machine was inapplicable to book-printing.

A patent has recently been obtained by Meffrs. Bacon and Donkin, for a machine which they publicly exhibited before the university of Cambridge, and they are now making one for printing bibles and prayer-books at the university. We have examined their machine at work, and found it to disply so much mechanical ingenuity, and to produce such beautiful specimens of printing, with a rapidity unequalled by any other means, that we have made a drawing of it. (See Plate III. Printing.) The invention consists in adapting the types to be fixed upon, and form the surface of, a prismatic roller, such as a square, pentagon, hexagon, octagon, or other figure, and mounting this in a frame, with the means of turning it round upon its centres; a second roller is applied in such a manner, that its surface will keep in contact with the surface of the types, which are inked, and the machine being put in motion, the paper which is to be printed is passed through and receives the impression. The types are inked by a cylinder, which is applied to revolve with its surface in contact with them. By this invention, the advantages of types between rollers are obtained, although the types are imposed upon plain surfaces.

Plate III. of Printing, contains a perspective view of a machine, the prinfa, A, of which is square in its section, and has the ordinary types or letter presses applied upon its four sides, and firmly attached to it. The pivots at the end of the axis of this prinfa are supported in the frame B B, and it is caused to revolve, by a connection of wheel work, D E and F G, from the winch and fly-wheel at H. The types upon its surface are caused to print upon the paper by means of a second roller, I i, called the platen, placed immediately beneath the former, and its surface being formed
to a particular curvature, produced by four segments of cylinders, its circumference, when it turns round, will always apply to the surface of the types, and thus a sheet of paper being introduced between them will receive the impression. The ink is applied to the types by means of a cylinder, K K, placed above the prism. It is composed of a soft elastic substance; and that its surface may always apply to the types, its spindle is fitted in pieces L, L, which moving upon an axis, n, permit the cylinder to rise and fall, to accommodate itself to the motion of the types. The ink cylinder receives its ink from a second cylinder, M M, which is called the distributing roller, also composed of a soft substance, and is supplied with ink by a third ink roller N N, which is made of metal, and extremely true. The ink is lodged in quantity against this roller upon a steel plate, O O, the edge of which, being placed at a very small distance from the circumference, permits the roller, as it revolves, to carry down a very thin film of ink upon its surface, and this being taken off by the distributing roller, is applied to the surface of the inking cylinder, which, as before-mentioned, inks the types.

The sheet of paper is introduced, as shown in the figure, by placing it upon a blanket, which is extended upon a feeding-board, P P, and drawn into the machine at a proper time, by having a small roller, z, fixed to it. The ends of this are taken forward by two flanks, b, attached to endless chains, which are extended from the wheels, e, e, at the end of the platen, to other wheels, c, c, which are supported in the frame of the feeding-board. The wheels, e, e, having teeth entering the links of the chains, cause them to traverse when the machine is turned round, and at the proper time the pins, b, draw the roller, z, and blanket forward, and introduce the paper into the machine, and by passing between the prism and platen, it is printed as before-mentioned. This is the general action of the machine, and we shall proceed to detail the structure of the several parts. The type is composed, and made up into pages, in the usual manner; the pages are then placed in frames or galleries, w, w, and fastened by the screws at the ends, the face and size of the galleries being adapted to the size of the page it is intended to print. These galleries are attached to the four sides of the central axis of the prism by the screw-clamps, i, the edges of the galleries being mitred together. By relieving the clamps the galleries can quickly be removed, and others put in their places. The platen, Y Y, is composed of four segments of cylinders, i, i, which are attached to the different sides of the central axis, I, by means of screws, and these segments being proportioned to the prism, will be the true figure for the platen to produce the required motion, so that the surface, when it revolves, will, in all positions, preserve an accurate contact with the surface of the types. The two wheels, D, E, which cause the prism and platen to accompany each other, are formed to correspond with the two. Thus the upper wheel, D, is a square, with its angles rounded off, and the pitch or geometrical outline exactly of the same size as the square formed by the surfaces of the types. The lower wheel, E, is of the same shape as the platen, and its pitch line the exact size of the surface thereof. These wheels being cut into teeth, as the figure shows, will turn each other round, and make their surfaces at the point of contact exactly correspond in their motions, so as to have no sliding or slipping upon each other. To regulate the pressure upon the paper, the bearings in which the pivots of the platen are supported, can be elevated by screws, 3, and its surface will press with more force upon the types; but that this may not derange the action of the wheels, D and E, universal joints are applied in their axes at R. The inking cylinder, K, is caused to preserve its proper distance from the centre of the prism by wheels, S, fixed upon its axis, and resting upon shapes, T, fixed upon the axis of the prism. Each of the shapes, like the wheel D, has four flat sides, corresponding in size with the surfaces of the types; the angles are rounded to segments of a circle from the centre: the wheels, S, are of the same size as the inking cylinder, therefore, as they rest upon the shapes, T, they prevent the ink cylinder profiling upon the types with any more than a sufficient force to communicate the ink without blotting. The inking cylinder is turned round by a cog-wheel, V, upon the extremity of the axis of the prism, which is of the same shape as the wheel, D, and engages another wheel, W, upon the end of the spindle of the inking cylinder: the latter wheel likewise gives motion to the distributing roller by a pinion, f, and this again turns the ink roller by a third pinion, g, fixed upon the end of its axis, n, which is supported upon bearings, B, B, in the frame. The pieces, L, L, which support the pivots of the distributing roller and inking cylinder, are fitted upon the axis, n, of the inking cylinder, so as to rise and fall upon its centre, and the distances of the rollers being thus kept invariably the same, their circumferences are kept accurately in contact, to communicate the ink to each other. The steel plate, O, which, as before-mentioned, regulates the quantity of ink that the roller, N, shall take round with it, is supported by a piece extended across the fixed frame, B B. There are pieces of metal fixed upon this plate by thumb-nuts, which prevent the ink flowing off at the ends, and they enter into grooves formed round the ink roller, N, near its ends. The machine is put in motion by the handle with the fly-wheel, H, and this has a small wheel, G, turning a large one, F, upon the end of the axis I.

The frame supporting the feeding-board, P, consists of two rails, X, fixed upon the axis of the platen, and supported at the opposite ends by a brace from the framing; they sustain the pivots of the wheels, d, d, for the chains; x are two rulers fixed at each side of the feeding-board, and forming a lodgment for the ends of the ruler z, which is attached to the blanket, and it slides upon these when it is advanced by the chains. The spaces on the platen between the segments, i, i, are all filled up by pieces of wood, except one, and in this space the ruler is received when it passes through the machine. In the interval when the spaces between the types are passing over the sheet, and therefore leave the margin between the pages of printing, the paper is not held between the rollers; but to prevent it from slipping during this interval, the blanket and paper are pressed down upon the pieces of wood which fill up the spaces between the segments, i, i, by the weight of small rollers or wires, 4, supported by cocks, 5, projecting from the axis of the prism, and being fitted into the flits at the end of these cocks. The wires are at liberty to rise and fall by their own weight; thus, when they are at the upper part of the revolution, they fall into the spaces at the angle of the prism, between the pages of the types, and thus escape the ink cylinder; but when they are at the lower part of their revolution, they fall upon the paper, and press the pieces of wood in the platen to carry the paper forward at the interval when the types do not act upon it, and of course while the space between the pages of the printing is passing through.

The operation of printing being very delicate, and requiring great accuracy, the machine is provided with many adjutments to make it act correctly, which are as follow: The segments, i, i, upon the platen roller are attached to the central axis, I, by three screws at each end; the two middle
middle ones of these (represented with square heads) draw the segments down upon the central axis, whilst the others (which are turned by a screw driver) bear them off; therefore, by means of these screws, the segments can be accurately adjusted, till they are found by experiment to apply correctly to the types, and make an equal impression on all parts of the sheet. To render the whole impression greater or less, the screws, \( S \), beneath the bearings of the platen roller are turned as before-mentioned. The degree of preffure with which the ink roller bears upon the types, is regulated by increasing or diminishing the size of the shapes, \( T \), which support its weight. And to render these capable of adjustment, each is composed of four pieces, marked \( 6 \), attached by screws, \( 7 \), to a central piece, or wheel, which is fixed upon the axis; and as the edges of these pieces form the outline of the shape, they admit of being adjusted by other screws to a greater or less distance from the centre, and of course may be made to bear up the ink cylinder, till the preffure on the types is equal throughout the whole surface, and sufficient to supply the ink properly. The ink cylinder is adjustable as to its preffure against the distributing roller, and for this purpose the bearings, \( 8 \), which support the cylinder, are fitted upon the pieces, \( L \), to slide, being capable of regulation by means of screws. In a similar manner the distributing roller can be adjusted to a proper distance from the inking cylinder. The plate, \( o \), can be adjusted for the distance from the ink roller, \( N \), by screws, \( p \), fastened by thumb nuts: this regulates the degree of colour the impression will have, by permitting the roller, \( N \), to take more or less ink: behind the inking cylinder, \( K \), a rubber, or scraper, is placed, to press very lightly against the cylinder, and to prevent the ink accumulating, in rings, round the cylinder; it is fitted upon centres, and held up by a lever, which is suspended by a catch, \( y \), at the end of the piece \( L \). This catch is withdrawn when the machine is not at work, and then the scraper falling down upon its centre, does not touch the cylinder. It is necessary that the wheels \( D \) and \( E \) should be placed upon their axes, in such a position that their curvature will correspond with the curvature of the prifm and platen. For this purpose the universal joint, \( R \), is fitted upon the axis, \( I \), of the wheel, with a round part, that it may turn on it. A piece of metal, \( r \), is fixed upon the spindle, \( l \), and has a hole in it for the reception of a tooth, \( z \), which is screwed fast upon the universal joint; then two screws being tapped through the sides of the piece, \( r \), press upon the end of \( z \), and by forcing it either way, will adjust the wheel with respect to the platen, till they exactly correspond: another similar adjustment may be applied to the upper axis.

The manner of forming the inking and distributing rollers with an elastic substance, is worthy of particular notice. Leather stuffed in the manner of a cushion was first used, but did not succeed, because it became indurated with the types; but after many trials, a composition of glue, mixed with treacle, was found to answer perfectly. The roller is made of a copper tube, covered with canvas, and placed in a mould, which is a cyndrical metal tube, accurately bored, and oiled within: the melted composition is then poured into the space of the mould, and when cold, the whole is drawn out of it, with the glue adhering to the copper tube, and forming an accurate cylinder without any farther trouble. The composition will not harden materially by the exposure to air, nor does it diffuse by the oil contained in the ink. This machine is well adapted to print from type, which the universities have adopted for their bibles and prayer-books.

We understand that a printing machine will very soon be produced by Mr. Benfield, which is the invention of a foreigner, who has taken several patents for it, but we have not yet had an opportunity of seeing one.

**Printing Machine for numbering Bank Notes.—** This machine is ingenious and curious, from the circumstance, that after every impression which is produced by it, the types are changed by mechanism, so as to produce a different impression the next time. The Bank of England have, within these few years past, adopted this method of filling up the blank spaces which are left in their notes after they have been printed from a copper plate by the rolling-prest. These blanks, which are for the number and date of the note, were formerly filled up in writing; for each note being different in these particulars did not admit of being printed, until the present machine was invented by Mr. Joseph Braham. The note which is engraved on the copper plate, and printed, is as follows.

![Bank of England, 1814](image-url)

**I Promise to pay to Mr. Henry Hove or Bearer on Demand the Sum of Ten Pounds**

For the Gov. and Com.,

London and the date are printed in the blank line which is left after the words, *sum of Ten Pounds.*

The copper plates on which the above is engraved are double, that is, each prints two notes upon one long piece of paper, which being put into the machine, has the blanks printed in the cahell manner imaginable. In the operation of taking out the paper to put in another note, the machine changes the types to the succeeding number: for instance, if one of the notes is printed No 10 to No 10, and the other upon the same paper, No 100 to No 100, when the paper is taken out, the types change, without any attention of the operator, to No 11 to No 11, and No 101 to No 101, and when these are printed, they change again to the succeeding numbers. The types for the date are cast in stereotype, and are of course changed every day, each machine being furnished with one for every day in the year.

The advantages of this method have been found considerable, in avoiding mistakes of numbering notes erroneously, to which they were before liable, and in the dispatch of business, its advantages are very great. To fill up 400 notes, with the number and date twice repeated, was considered a sufficient day's labour for each clerk; but by the machines, one man can print 1500 double notes, which are equal to 2500 single ones, or perform more than six times the business which could formerly be done in the same time. The Bank
Bank of England have more than forty of these machines, one of which we have obtained drawings from; but to diminish it to the size of a plate, our draughtsman has represented it as if cut in half, or made as a single machine, to print only one note at a time; those in use at the Bank are therefore to be considered as double the length, and containing a repetition of the types and the machinery for moving them. In Plate II. Printing, fig. 1, is a section, and fig. 2, a plan, and the fame letters refer to both. The whole is framed upon a thick board of mahogany, which is fastened down upon a table: the frame, which is of iron, is screwed to the board at L, and forms a square box, in which the mechanism is contained. K, K, is a brass lid, or cover, to the box, through holes in which the types, for printing the numbers, are placed, and their surfaces project a little above the surface of the cover, K, so as to produce an impression when the note is pressed down upon them by the power of the hand applied to the lever D. This lever moves upon an axis A, (fig. 1,) which extends across the box, having pivots fitted into sockets, B, (fig. 2,) projecting up from the frame, as is evident in the figure. From this axis a piece of metal, C, extends, and has screws, f and m, m, in it, by which the tablet, or plate, E, is attached to it; and these screws admit of adjusting the tablet, E, with respect to the axis, that its under surface may fall perfectly flat upon the types, and print with equal pressure upon all the parts of the note. For this purpose four of the screws, m, pafs through holes in the piece C, and screw into the tablet, fo as to draw the two together; whilst the other two screws, f, f, screw into the piece C, and their points bear upon the upper surface of the tablet, E; it is therefore by the latter that the pressure is transmitted, the others being only for adjustment: the lever DD is fastened upon C by three screws, marked n, o, o. The note is placed upon the under surface of the tablet, E, when it is to be printed, its situation being determined by two fine pins fixed in the tablet, which are made to penetrate the paper at two small dots printed upon it by the copper-plate which printed the words of the note, as before-mentioned; and it is confined in its position against the tablet by the friklet, which is a piece of vellum, H, stretched in a brass frame, and is connected by hinges, a, a, to the tablet E; it thus folds down, enclosing the note between the tablet and friklet as it were in a book. The vellum of the friklet has openings cut through it at the places where the machine is to print upon the note. As it is necessary that the paper should be pressed upon the types by a yielding substance, the tablet, E, has two folds of cloth placed against its surface, and these are secured by a piece of parchment, stretched over a brass frame, which is attached to the tablet by four screws. The note therefore is placed against this parchment when it is to be printed; and not against the brass of the tablet. Each circle, as shown in fig. 6, has its circumference divided into 11 cogs, and in every cog a space is cut to receive one of the types which are arranged round the cogs, in a series of 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, and a blank; and as the circles are placed close together, and turn round independent of each other, any combination of figures may be made by them which is less than 99,999, beyond which number the bank-notes have not extended. Each of the circles has a tendency given it to assume the position in which the types are proper for printing; that is, with their upper surface parallel to the brass plate K, by means of a small pin fitted into a hole in the axis F, and having a conical pressure outwards by a small spiral spring placed in the hole beneath it. This pin comes to rest in an angular notch made within the circle, opposite each type, as shown by the dark shaded parts in fig. 6, and each circle is provided with one of these pins. The end of the pin is formed spherical, and well polished, so that when the circle is turned round, it is forced into its hole in the axis F; but when another notch in the circle presents itself, the pin presses out into it, and retains the circle with a moderate force in its proper position, but will not allow it to retil, except when the pin is in the notch. The word London and the dates are cast in stereotyped, and are fastened down upon the surface of the cover, K, of the box, just beneath the letter E, in fig. 1. The dates are changed every day; the catch, by which they are fastened on the plate, being very readily withdrawn; but when thrown up, holds them sufficiently fast. The types for printing the numbers are moveable, and herein the invention confits; they are fixed in the circumferences of wheels, or circles, a, a, (shown also at e, e, in fig. 5, where the types are plainly pointed out by the numerals upon them); these circles are ten in number, and are divided into two clutters, one at each end of the spindle, or axis, F, upon which they all revolve freely. This axis, when in the machine, as at F, (fig. 1,) extends across the frame from side to side, and the types fixed in the circles project above the surface of the cover, K, pawling up through holes made in the frame, as is evident from the figure. By this means the types always arrange themselves into a straight line, and also with their surfaces parallel to the surface K, K, without which they would not print equally upon the paper. From this description, our readers will perceive that the machine has the power of printing any numbers, or series of numbers, containing less than five figures, by turning the circles round one tooth every time after an impression has been taken, so as to bring a succeeding type into action. But the machine is rendered very complete, by the addition of the following mechanism, to give motion to the circles. A catch or click, b, is fixed upon the axis, A, of the platen, and acts in the teeth of a wheel, H, fixed upon an axis, G, (see also fig. 4,) which is extended across the machine, and the teeth of other similar wheels, H and K, (fig. 4,) enter into the spaces between the types in the circles a, a, as seen in fig. 1, and thus, when the axis, G, is turned round, it communicates a corresponding motion to some of the circles. The click, b, is fixed on the axis, A, in such a position, that it does not operate upon the teeth of H, except when the handle, D, is lifted up, or rather thrown back, as far as it will go, which is regulated by pieces screwed upon the axis coming in contact with the stops fixed upon the plate K; and in doing this, the catch, b, moves the wheel, H, round one tooth, and consequently the wheel d, so as to bring up another type.

The operator, in using the machine, first inks the types with a small printer's ball, opens the friklet sheet, H, upon its hinges, a, and places the note against the tablet, the proper place being determined by the dots and pins before-mentioned. He now hills up the friklet, and encloses the note between it and the tablet, the friklet sheet having holes cut through it at the places where the note is to be printed. The handle, D, is now brought down to give the impression; but in this, it should be observed, that though the catch, b, again meets the tooth of the wheel H, it has no effect upon it, being fitted upon a joint, so as to give way in this direction, and it passes by without moving the wheel. The pressure for printing is given in an instant, and the handle, D, being then lifted up to remove the note, and place a fresh paper upon the tablet, the catch, b, moves the wheel, H, one tooth; and as these engage the teeth of the
the circles, $d$, they are turned likewise to change the types ready for printing the succeeding numbers.

We have now to explain the order in which the change of the numbers is conducted. The wheels, $H$ and $K$, (fig. 4.) are only intended to operate upon one of the five circles at the same time; but by sliding the axis, $G$, endways in its bearings, they can be made to act upon any one of the five which is required; and in all cases the distance between the two wheels, $H$ and $K$, is such, that they will operate upon the same circle of the assemblage, at either end at the same time. The axis, $G$, can be retained in any required position by a semi-circular clip, which enters into grooves, $c$, (fig. 4.) formed round the axis, and there are five of these, corresponding with the different positions of the axis proper for the wheels to act with the several circles. The shifting of the axis is performed by the knobs at the ends of the spindle, $G$, which come through the sides of the box, the semi-circular clip which retains it being first lifted up, by turning a knob, $b$, which operates upon it. When the printing first begins, the circles, $d$, are turned round by means of a wooden key, so that all the blank types are brought up at the same time. The axis, $G$, is next set, so that its wheels, $H$ and $K$, are engaged with the right-hand circle of each of the assemblages of five at each end. In this situation, if the handle, $D$, is moved down, in raising it up again, the catch, $b$, moves the wheels round, and brings up $N^1$ and $N^2$ of the types, and a note being printed with this, in lifting up the handle $N^2$ is brought up. Another note is now printed, then $N^3$, and so on, till $N^9$ is printed, and $o$ brought up; after which, the handle is brought down twice without printing any note. This brings up the blank space and $N^1$. The axis is now shifted by its knob $Q$, (fig. 1.) to act upon the second circle from the right-hand, and one motion of the handle being made, brings up $o$ of the second circle, making $o1$ and $N$, which, when printed, (types being always in reverse,) will be $N^0$ 10. The first circle to the right-hand, which before was units, is now become tens, and the second units, which therefore shifts, at every impression, to $1$, $12$, &c. up to 19; and after printing this the $o$ comes up, making 10. The first right-hand circle is then pushed forwards by the printer by a small wooden key, and 2 brought up, making 20. In this manner it proceeds, changing the first circle by hand at every ten, the machine altering itself at every unit, till 99 are printed. When 100 is to be printed, the axis, $G$, is shifted to the third circle, which becomes units, the second, tens, and the first, hundreds. The printing then proceeds as before, the units being advanced by the machine, but the tens and hundreds, as often as they require it, are advanced by hand. At 1000 the axis is shifted to the fourth circle, and the denomination of each is changed by this becoming the unit: three circles must now be moved by hand, as often as they require it. On arriving at 10,000, the fifth circle must be made unit, by shifting the axis to it, and the four first are moved, when necessary, by hand, and in this manner the machine will print up to 99,999, which is 100,000, wanting 1.

**Printing, Chinefe.** There are three opinions as to the antiquity of the Chinese printing: one fixing it three hundred years before Christ; another nine hundred years after him; and a third carrying it still farther back, and making it coeval with that mighty empire; though, it must be allowed, the latter is the least probable of the three. The manner of printing we have already hinted to be very different from that which now obtains among the Europeans. It is true, it has some advantage over ours in correctness, and the beauty of the character; but, in other respects, it comes far short, the single advantage of moveable characters making more than amends for all that is urged against us by some zealous advocates for this oriental printing.

Books are printed in China from wooden planks, or blocks, cut like those used in printing of salico, paper, cards, &c. among us.

These blocks are made of a smooth, firm, close wood, and of the size of the leaf required. On the face-side they glue a paper, upon which some able penman draws out the several letters and characters with a Chinefe pen, which is a kind of pencil. This is the principal part of the work, and that on which the success of the rest depends.

When finished, the block is put into the hands of a sculptor, or cutter in wood; who, following the several strokes of the writer with his gravers, and other sharp little instruments, makes them all appear in relief on the wood. When the carving or cutting is finished, they moisten what remains of the paper, and rub it gently off.

The ink they use in printing is the same with the common Chinefe ink, with which they also write, and is made of lamp-black, mixed up with other ingredients.

Their presses resemble our rolling-pres much more than the letter-pres.

As to their paper it is inferior to our's; it is made of the inner bark or rind of a kind of rushes, beat up with water into a pulp or paste, and formed in moulds, much like our's.

**See Paper.**

The advantages of the Chinefe printing consist in this, that they are not obliged to take off the whole edition at once, but print their books as they need them; that the blocks are easily retouched, and made to serve afresh, and that there needs no corrector of the pres.

Its disadvantages are, that a large room will scarcely hold all the blocks of a moderate volume; that the colour of the ink easily fades; and that the paper is apt to tear, and is subject to worms; whence it is, that so few ancient books are seen in China.

**Printing, Rolling-Press,** is employed in taking off prints or impressions from copper-plates engraved or etched.

It differs, as we have before observed, from letter-printing, in that the marks and characters, whose impressions are to be taken, in the former case are indented, or cut inwards; and in the latter are in relief, or stand out.

This art is said to be as ancient as the year 1460, and to owe its origin to Finiguerra, a Florentine goldsmith; who, casting a piece of engraved plate in melted brimstone, found the exact print of the engraving left in the cold brimstone, marked with black licked out of the strokes by the liquid sulphur.

Upon this, he attempted to do the same on silver plates with vellum paper, by rolling it smoothly with a roller; and this succeeded.

This novelty tempted Baccio Baldini, a goldsmith of the same city, to attempt the same; which he did with success, engraving several plates of Sandro Boticello's designs, and printing them off in this new way; in which he was followed by Andrew Mantegna, then at Rome.

This knowledge getting into Flanders, Martin of Antwerp, a famous painter, graved abundance of plates of his own invention, and sent several prints into Italy, marked thus, M.C. After him, Albert Durer appeared, and gave the world a vast number of prints both in wood and copper. About this time, one Hugo de Carpi, an Italian painter, found out a way, by means of several pieces of wood, to make prints resembing designs of chiaro-scuro (see CUTTING in Wood); a method revived in our country, some years ago, with much success by Kirkall, and since at Venice by Jackson,
Jackson, though very imperfectly; and some years after, the invention of etching was discovered, which was soon after made use of by Parmeggiano.

Mr. Walpole observes, that it was not till Raphael had formed Marc Antonio, that engraving placed itself with dignity by the side of painting. See Engraving and Etching.

When the art reached England does not certainly appear. Mr. Chambers, on the authority of Mr. Bagford, (see Phil. Transl. No. 310, p. 2397, or Abr. vol. v. part ii. p. 20.) erroneously laid, that it was first brought from Antwerp by Speed, in the reign of James I.; whereas we had it in some degree almost as soon as printing; the printers themselves using small plates for their devices and rubaxes. Caxton's Golden Legend, printed in 1413, has in the beginning a group of faints, and many other cuts disposed through the body of the work. The second edition of his Game of Chess, and Le Morte de Arthur, had also cuts. Wynkyn de Worde, Caxton's successor, prefixed to his title of the Statutes, in the seventh year of Henry VII. or 1491, a plate with the king's arms, crests, &c. a copy of which is given in the Life of Wynkyn, by Mr. Ames, in his Typographical Antiquities, p. 79. The fame printer exhibited several books adorned with cuts, some of which are particularly described by his biographer, p. 87, 88, 89, &c.

The subsequent printers continued to ornament their books with wooden cuts. One considerable work, published by John Rafell, called the Paflyme of the People, and Ralph's Chronicle, was distinguished by prints of such uncommon merit for that age, as to have been ascribed to Holbein. Grafton's Chronicle, printed in 1569, contained many heads, as of William the Conqueror, Henry VIII., queen Elizabeth, &c. and many more are recorded by Ames. But though portraits were used in books, Mr. Walpole observes, that he can find no trace of single prints being wrought off in that age. Those which composed part of the collection of Henry VIII. were probably the productions of foreign artists. The first book that appeared with cuts from copper-plates, or at least the first that Mr. Ames had observed, was the Birth of Mankind, otherwise called the Woman's Book, dedicated to queen Catharine, and published by Thomas Raynulde in 1540, with many small copper cuts, without any name. See Ames, ubi supra, p. 35, 46, 62, and 219. Walpole's Catalogue of Engravers, &c. 1410.

The fabric of the rolling-prest, and the composition of the ink used in it, with the manner of applying both in the taking off prints, are as follow:

Structure of the Rolling-Prese.—This machine, like the common press, may be divided into two parts: the body and carriage, analogous to those in the other.

The body consists of two cheeks of different dimensions, ordinarily about four feet and a half high, a foot thick, and two and a half apart, joined at top and bottom by cross pieces. The cheeks are placed perpendicularly on a wooden stand or foot, horizontally placed, and suitaining the whole press.

From the foot likewise rise four other perpendicular pieces, joined by other cross or horizontal ones; which may be considered as the carriage of the press, as serving to sustain a smooth, even plank, which is about four feet and a half long, two feet and a half broad, and an inch and a half thick; upon which the engraved plate is to be placed.

Into the cheeks go two wooden cylinders or rollers, about six inches in diameter, borne up at each end by the cheeks, whole ends, which are leflected to about two inches diameter, and called trunions, turn in the cheeks between two pieces of wood, in form of half-moons, lined with polished iron, to facilitate the motion.

The space in the half-moons, left vacant by the trunion, is filled with paper, pasteboard, &c., that they may be raised and lowered at discretion; so as only to leave the space between them necessary for the carriage of the plank charged with the plate, paper, and blankets.

Lastly, to one of the trunions of the upper roller is fastened a crose, confling of two lewers, or pieces of wood, traversing each other. The arms of this crose serve in lieu of the handle of the common press; giving a motion to the upper roller, and that to the under one; by which means the plank is protruded, or pulled between them.

Preparation of the Ink.—The ink used in rolling-prest printing, is a composition of black and oil mixed and boiled together in due proportion.

The black is a factitious matter, made, as some suppofe, of the oil of vine twigs, or, according to others, of the kernels of fruits, such as peaches and apricots, well burnt, with wine lees.

This black is usually brought hither ready prepared from Frankfort on the Maine; whence our printers call it Frankfort black.

This is softer and more free from girtines than the ivory or other charcoal blacks, as they are usually prepared among us.

The oil with which they dilute this black is nut-oil; which is set on fire, boiled up differently, according to the different works it is to be used in; but never so far as to communicate to the oil the adhesive gluey quality of the printer's varnish.

They usually make three kinds, thin, thick, and strong, only differing in the degree of cohesion; the strong is that used in the finest works, &c.

To make the ink, they pulverize the black very carefully, and pass it through a fine sieve; then mix it up on a marble with the proper oil, by means of a mullet, after the same manner as the painters do their colours.

Printing from Copper-Plates, Method of.—The ink being prepared, they take a little quantity of it on a rubber, made of linen rags, strongly bound about each other; and with it smear the whole face of the plate, as it lies on a grate, over a charcoal-fire.

The plate sufficiently inked, they first wipe it coarsely over with a foul rag, then with the palm of the left hand, then with that of the right; and to dry the hand, and forward the wiping, rub it from time to time on whiting. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, confids a great part of the address of the workman. The French printers use no whiting, as being detrimental to the colour of the ink; nor do they lay the plate on the grate to warm, till after inking and wiping it.

The plate, thus prepared, is laid on a thick paper, fitted upon the plank of the press; over the plate is laid the paper, first moistened, to receive the impression; and over the paper two or three folds of blanketing, or other stuff.

Thus disposed, the arms of the crose are pulled, and, by this means, the plate, with its furniture, passed through between the rollers; which, pinching very strongly, yet equably, presses the softened paper into the froses of the engraving, whence it sticks out the ink.

Some works require being paffed twice through the press, others only once, according as the graving is more or less deep, or the greater or lets degree of blackness the print is defird to have.
It must be observed, that the stronger and thicker the ink is, the stronger must the rollers pinch the plate; this tempts many of the workmen to use a thinner oil, in order to save labour; which proves very prejudicial to the impression.

The wetting of the paper ought to be done two or three days before printing it, to render it more supple and mellow; as the prints are drawn off, they are hung up to dry on lines, &c.

Lastly, after the number of prints desired have been wrought off from the plate, they rub it over with oil of olives, to prevent its rusting, and set it by against a new impression. If the strokes of the graving be perceived full of ink hardened therein in the course of the printing, they boil it well in lea before the oil be applied.

**Printing with wooden prints. See Cutting in Wood.**

**Printing in chiaro-fcuro.** is a method of producing a strong effect of relief, attended with a just and natural gradation of the lights and shades, grounded with brown, with white and black, by printing on paper. We have already observed, that the art of doing this in wood was discovered in Italy, by Hugo de Carpi. M. le Boile directs it to be performed in the following manner. Having provided two copper-plates of equal size, and exactly fitted to each other, on one of them let the proposed design be engraved, and let the prints be taken off from it with printing ink on sheets of grey paper. The other plate must then be varnished, and the varnished fide being laid upon the sheet printed by the first plate, they must be passed under the roller; when the print will have made a counter-proof on the varnish of the plate; after which the lights must be graved on the plate, and corroded very deeply by aquafortis. The same thing must otherwise be done with the graver, and with greater ease by those who can use it well. In order to properly prepare the oil, the best method is to use very white nut-oil drawn without fire, and to put into it two leaden vessels, and set it in the sun till it becomes thick in the proportion of the weak oil. Flake white must then be taken, which must be ground, and washed over, till it be extremely fine; and then being dry, it must be ground with the weak oil, and the thick oil added to it. Then having taken an impression with black printing ink, or any other colour, from the first plate, that is entirely engraved, on coarse grey paper, it must be left to dry for ten or twelve days: when these prints having been wet, another impression must be made upon them by the plate, on which the lights are engraved, charged with the white flake and oil in the usual manner of printing; taking care that the correspondent parts of the plate, and the impression already made, may be adapted exactly. By this means the printing in chiaro-fcuro is perfectly performed. See **Clair Obiure.**

**PRINT'S, Proprietor of.** See **Literary Property, and Engraver.**

**PRINTZ, Wolfgang Gaspar, in Biography, a practical, theoretical, and historical musician of Germany, whose writings and memory are much respected by his countrymen.** He was born in 1641, at Waldthun, a small city in the Upper Palatinato, on the frontier of Bohemia, where his father was a principal magistrate, and a receiver of the public revenues; but on account of his religion he quitted that station, and removed to Wittenbruck, a small town in the territory of Furthenberg. The young Printz, having discovered an inclination for music, was committed to the care of several able masters successively, of whom he learned to play on several different instruments, and studied composition till 1659; after which he went to the university of Altdorf, where he continued till the year 1661, when he seems to have made good use of his time, as his reading and classical knowledge appear considerable.

He had several small appointments in different parts of Germany, as cantor, and music director; but none very considerable. However, while he filled these offices, he produced 21 different works upon music; but the most important, and that which now is only sought, is his History of Vocal and Instrumental Music; which he performed in two volumes, and printed in two small folios, in 1660.

The book is now become so scarce, that we have never been able by our own diligence, or that of our friends, to procure a copy of it; and all we know of its contents has been derived from Walther, and Marpurg's extracts and account of it in his Musical Essays, vol. i. p. 104; by which, however, it appears, that his plan and arrangement were good, and the authors had consulted the best on the subject. The work seems never to have been finished, as it consisted but of two hundred and twenty-three pages, and M. Marpurg's extracts advance no farther in the narrative than Tuitico and Bards, kings of the ancient Germans and Gauls, who founded the orders of druids and bards.

**PRINTZENDORF, in Geography, a town of Austria; three miles N.W. of Zitterdorf.**

**PRINTZERDORFF, a town of Austria; four miles W. of St. Polten.**

**PRIOLA, a town of Italy, in Friuli; 12 miles N.W. of Gemona.**

**PRIOLI, or PRIOILI, BENJAMIN, in Biography, a writer of French history, was born at St. Jean d'Angely, in 1602, of a family descended from Prioli, or Priuli, of Venice.** He was educated in the reformed religion, and displayed from a very early period a great avidity for learning. He left both his parents at the age of 15, and having purified his introductory studies in his own country, he went to Leyden, where he perfected himself in classical literature under Heinr. and Vossius. The desire of consulting Grotius induced him to visit Paris, after which he studied philosophy at Padua, under Cremonini and Liceto. He then attached himself to the duke of Rohan, who was at that time in the service of Venice, and became the intimate friend of that nobleman, who lent him twice into Spain as his negotiator. He afterwards fought in several actions under his banners. At the death of the duke he retired to Geneva, and married a lady of noble family. He was called from his retreat by the duke de Longueville, when appointed plenipotentiary for the peace of Münster. Here he resided a year, then returned to France, and was converted to the Catholic faith. In the ensuing troubles in France, he took part with the prince of Condé against the court, and was in consequence obliged to retire into Flanders, his property being confiscated, and his family exiled. When he was restored to favour he returned to Paris, and employed himself in composing the history which has preferred his name. This is entitled "Benjamin Prioli ab Excelfu Ludovici XIIII. de Rebus Gallicis Historiis, Lib. xii." It was first printed at Paris in 1665; but the best edition is that of Leiphe, in 1686. A
P R I

dedication is prefixed, addressed to the doge and Senate of Venice, as a token of gratitude for their recognizing him as a noble Venetian, and creating him chevalier of St. Mark. The style of this history is copied from that of Tacitus, and it abounds in characters and portraits, often touched in a satirical manner, but the narrative is laid to be a free and faithful relation of the war of the Frondes, and the administration of cardinal Mazarin. Prior died in 1667. Various works were announced at the close of his history as to be published, but they never made their appearance.

More is, Bayle.

PRIORUS, in Entomology. See Cerambyx.

PRIOR, Matthew, in Biography, a distinguished English poet, was born in 1664; according to one account, in London, where his father was a citizen and joiner, but according to another, at Wimborne, in Dorsetshire. His father dying while he was young, he was brought up by an uncle, a vintner, who sent him to Welfurn school, then under the direction of the famous Bubby. His uncle took him from school before he had passed a regular course, with an intention of bringing him up to his own business; but he had already imbied a taste for classical literature, and was unitied for trade. The earl of Dorset, at that time a patron of letters, who frequented his uncle's tavern, found him reading Horace, and on conversing with him, was so much pleased with the modesty and talents which he displayed, that he determined to give him an university education. He was admitted of St. John's college, Cambridge, in 1681, and was elected to a fellowship in 1686. Here he contracted an intimacy with Charles Montague, afterwards earl of Halifax, in partnership with whom he composed the "Country Moufe and City Moufe," which was a parody of Dryden's poem of the "Hind and Panther," and consequently a declaration of their attachment to the principles which soon after effected the revolution. His next poetical piece was an "Ode on the Deity," written in 1688, as a college exercise. In the following year he went to London, and was introduced at court by the earl of Dorset, who recommended him so effectually, that in 1690 he was appointed secretary to the English plenipotentiaries who attended at the congresses at the Hague. He was now completely in the service of the court, and the efforts of his muse were for some years chiefly directed to public or courtly topics. In 1697 Prior was nominated secretary to the commissioners for the treaty of Rysewic, and after his return from that employment, was made secretary to the lord lieutenant of Ireland. He went to France in the following year as secretary to the ambassador, the earl of Portland, and remained in that employment under the earl of Jersey. After this he was appointed under-secretary of state; and was sent to Paris to affix the ambassador in negotiating the partition treaty. In 1700 he succeeded the great Locke as a commissioner at the board of trade, and he sat in the parliament as representative of East-Grinthead. The Tories were now become the prevalent party, and Prior forsook his friends the Whigs, by whom he had been brought into life, and promoted; and joined their opponents, to whom he ever after adhered. He even voted for the impeachment of those lords who were charged with advising that partition treaty, in which he had been officially engaged. Like most converts, he embraced his new party with great zeal, and thenceforward almost all his social connections were confined within its limits. Prior now celebrated the victories of Blenheim and Ramilies, and about the same time he published a volume of poems, of which the concluding piece was his admired "Henry and Emma." In the year 1711 he was sent to Paris in a diplomatic character, with pro-

posal for peace. The congress of Utrecht followed, and in August 1712 he was with lord Bolingbroke at Paris, who was sent there to adjust some difficulties that had occurred. Prior remained in France with the authority and appointment of an ambassador, though without the title, for the duke of Shrewsbury, who went in that capacity, refused to be joined in the same commission with a man so meanly born. Talents, however, are not always allied to high birth, and Prior possessed the confidence of the French court, and was enentrusted by Lewis with a special letter to queen Anne, in favour of the elector of Bavaria. After the departure of the duke, in 1713, he publicly assumed the character of ambassador, which he retained till he was superseded by the earl of Stair, on the accession of George I. It was some time before he received remittances from the treasury, enabling him to return; and soon after his arrival in 1715, the Whigs being now in power, he was committed to the custody of a messenger. He was examined closely with respect to his share in negotiating the peace of Utrecht, and Mr. Walpole moved an impeachment of him on a charge of high treason, for holding clandestine conferences with the French plenipotentiary; and when an act of Grace was passed, he was excepted, and treated with a considerable degree of rigour. At length, however, he was discharged without being brought to trial. Hitherto Prior had been chiefly confided as a politician; and though some persons have expressed contempt of his political talents, yet that they were regarded in a respectable light by the heads of both parties is evident from the situations which he held, and there can be no doubt that he possessed the faculty of rendering himself acceptable to the courts to which he was sent. Prior was now reduced to a private station without any provision for his declining years, except his fellowship at the college, which he prudently retained during his highest employments, as what would furnish him with necessaries should every thing else fail. He now completed his longest poetical piece, entitled "Solomon," which, with some other pieces, supplanted matter for a folio volume, published by subscription at two guineas. By the efforts of his friends a considerable sum of money was thus raised. He continued occasionally to amuse himself with writing verses; but had reserved for the serious employment of his advanced years, the composition of a history of his own times. The design was, however, cut short by a lingering illness, which put an end to his life in September 1721, in the 58th year of his age. He was interred in Welfurn Abbey, under a monument, for the erection of which he left, by will, 500l. On the monument is a long Latin epitaph drawn up by Dr. Freind, the master of Welfurn school.

"Prior," says one of his biographers, "appears to have been one of those characters whom wit, ease, and companionable qualities, render general favourites, without any exact estimate of moral defect. His derivation of his first political friends might be atoned for by his steadfast attachment to the second, especially to the earl of Orford, whom he sheltered, on his examination, with a constancy that was probably the cause of the severity with which he himself was treated. His modes of life appear to have been irregular, and notwithstanding his introduction to the highest and most cultivated society, he is said to have retained a taste for low company and gross enjoyment." As a poet his reputation has a good deal declined with the lapse of years, yet in one point, the faculty of telling a story with ease and vivacity, he has, perhaps, scarcely been equalled. His songs and amatory pieces are generally elegant and classical. The most popular of his serious compositions is "Henry and Emma," or

Prior, before, something that is nearer the beginning, than another with which it is compared.

Prior is particularly used for a superior of a convent of monks, or the second person after the abbots.

Priors are either claustral or conventual.

Priors, Conventual, are the same as abbots, all the difference between them being in name; both having the same rights, and both alike being governors of monasteries.

These are of two kinds; viz. regular conventual priors, who govern religious living in the community; and secular or commendatory conventual priors.

Conventual priors are obliged to take up the priesthood within a year, or at most two, from the dates of their provision: in default of which, their benefits are declared vacant.

Priors must be twenty-five years old before they can govern the convent; and twenty, if the convent be governed by another. See Conventual.

Some of these abbots and priors were so considerable, that they were called to parliament, and had seats and votes in the house of lords.

Mr. Fuller says, that in the 49 Hen. III. 64 abbots and 36 priors were called to parliament. But this number being too great, king Edward I. reduced it to 25 abbots and two priors, to whom were afterwards added two abbots; so that there were 29 in all, and no more, that flately and constantly enjoyed this privilege, among whom was the prior of St. John's of Jerusalem, who was styled the first baron of England, but it was with respect to the lay barons only, for he was the last of the spiritual ones.

Prior, Claustral, is he who governs the religious of an abbey, or priory, in commendam; so called, because he has superiority in the cloister or monastery.

His jurisdiction is wholly from the abbott, and ends with the abbott's death, unless he has been elected by the whole convent.

Prior, Grand, is the superior of a large abbey, where several superiors are required; as in the abbey of Cluney and Peshamp.

In the monastery of St. Deny's, there were anciently five priors; the first of whom was called the grand-prior. In most monasteries, there is also a sub-prior. There are also grand-priors in the military orders; as in that of Malta, or St. John of Jerusalem, &c.

Priors Alien were certain religious, born in France and Normandy, superiors of religious houses erected for their country-folks here in England.

Thef Henry V. deeming no good members for this land suppressed; and their livings were afterwards given by Henry VI. to other monasteries and houses of learning; but chiefly, as Stow observes, to the erecting of those two famous colleges, called the King's colleges of Cambridge and Eton.

Prior, Arch. See Arch-prior.

Prior Medii, Four of the interoffici muscles of the hand. The first belongs to the external, and the third to the internal, and the last two to the interossei. See INTEROSS.

PRIORAN, in Geography, a town of Saxony; five miles N. of Bitterfeld.

PRIORITES, in Botany, a name given by the ancient Greeks to a plant which they recommended in medicine; but they do not clearly explain what it was. It is the fame with the cedrum and phuscrrophophon of the fame writers; and they say it was called betonica, ferratula, or rosmarinus, by the Romans.

It is evident, from a strict enquiry into their accounts, that the ferratula was the plant they meant; for Pliny says, that the betonica was only a Gaulish name for this plant, and the place of growth, which is described to be set hydious places, evidently excludes what we call rosmarin from any title to the name.

Apuleius has greatly perplexed the cause, by saying that the priorites, or betonys, has leaves like the docks; but he does not distinguish between the betonica and britannica, which last plant is the hydrolapathum, or great water-dock, and has leaves like the other docks; and it is plain, that both Apuleius and Pliny borrow the account of the dock-like leaves from this passage, and attribute them to a plant the original author never meant them for.

PRIORITY, Prioritas, the relation of something, considered as it is before, or prior to, another; i.e. as it is nearer to the beginning, or the first.

The principal modes of priority are five; viz. in respect of time; as when we say, that the Grecian empire was prior to the Roman; nature, as when we say, one is prior to two; order, dignity, and causality; which are all summed up in the technical distich:

"Tempore, natura, prius ordine, die et honore, Effecto caufam dicimus efi prius."

PRIORITY, in Law, denotes an antiquity of tenure, in comparison of another less ancient.

PRIORITY, To hold by, is to hold of one lord more anciently than of another; in respect of which the tenant is said to hold in posterioriy. The lord of the priority shall have the custody of the body.

PRIORITY of Debts, in Law. See DEBT.

PRIORY denotes a society of religious, the superior of which was denominated a prior, or priores; and of these there were two sorts; as where the prior was chief governor, as fully as any abbot in his abbey, and was chosen by the convent; such were the cathedral priors, and most of the Austin order, and where the prior was a cell, subordinate to some great abbey; and the prior was placed and dispensed at the will of the abbott. There were also priories alien. See ALIEN PRIORIES, and PRIORS Aliens.

PRISAGE, Prisagium, that which belongs to the king, or admiral, out of such merchandises as are taken at sea as lawful prize. See PRISE.

PRISAGE of Wines, a custom in certain ports, by which the king challenges out of every vessel laden with wine, containing twenty tons, or upwards, two tons of wine; the one before, the other behind the mal; which, by charter of Edward I., was exchanged into a duty of 2l. for every ton imported by merchant strangers.

The custom varies a little in various places: at Bolton, e. gr. every bark, laden with ten tons of wine, pays prisage.

The term is now grown into diffuse; and in lieu of prize, the custom, says Cowell, is popularly called butlerage; because it is the king's chief butler that receives it.

PRISCA, in Geography, a town of European Turkey, in Albania; 12 miles N. of Albaflano.

PRISCIANUS, in Biography, an eminent grammarian, was a native of Cufarea, and went to Conflantinople, where he taught grammar and rhetoric with much success about the year 525. He composed various works, of which his treatise "De Arte Grammatica" was first published by Aldus Manutius, at Venice, in 1476, from a MS. found in France. It has been reprinted frequently, but the best edition
The origin of this heresy is not well known; but it appears to have been brought into Spain by one Marcus of Memphis, who had for his diciple the rhetor Heliadius, under whom Priscillian was educated.

What their particular tenets were, it is not easy to discover; but they are charged by their adversaries with indulging all kinds of secret filthiness, and nocturnal mixtures, under a religious notion. Among their dogmata, this is said to have been one: "Jura, perjura, secretum prodere non.

It appears, however, from authentic records, that the difference between their doctrine, and that of the Manicheans, was not very considerable; for they denied the reality of Christ's birth and incarnation; maintained, that the visible universe was not the production of the Supreme Deity, but of some demon or malignant principle; adopted the doctrine of azons, or emanations from the divine nature; considered human bodies as prions, formed by the author of all evil to enslave celestial minds; condemned marriage, and disbelieved the resurrection of the body. Their rule of life and manners was rigid and severe; and the accounts which many have given of their licentiousness and intemperance deserve not the least credit, as they are totally destitute of evidence and authority. That the Priscillianists were guilty of dissimulation upon some occasions, and deceived their adversaries by cunning stratagem, is true; but that they held it as a maxim, that lying and perjury were lawful, is a most notorious falsehood, without even the least shadow of probability, however commonly this odious doctrine has been laid to their charge.

Priscillian, their leader, was a man of great birth, fortune, parts, and learning; he was condemned, with some bishops his adherents, in a council at Saragossa, in the year 380, and in another at Bourdeaus in 384; but he appealed to the emperor Maximus, and had a hearing at Treves; where being convicted of broaching novelties, he was condemned to death, with several of his followers. His doctrine, however, survived him, and was propagated through the greatest part of Spain and Gaul. Molheim's Eccl. Hist. vol. i. 8vo. edit.

PRISE, or Prize, in Navigation, a vessel taken at sea from the enemies of the state, or from pirates, by a man of war, or a merchant-vessel having commissiou from the admiralty.

Vessels are looked on as a lawful prize, if they fight under any other standard than that of the state from which they have their commission, if they have no charter-party, invoice, or bill of lading, aboard them; if they be loaded with effects belonging to the king's enemies, or with contraband goods.

Those of the king's subjects, recovered from the enemy, after having remained twenty-four hours in their hands, are also deemed lawful prize.

Vessels, that refuse to strike their sails, after having been summoned thereto by the king's ships, may be constrained to do it; and, if they make resistance, and fight, they are lawful prize.

The officers and seamen of the king's ships, and of other British ships having letters of marque, are intitled to the sole interest, and property of all ships and goods by them taken, and adjudged lawful prizes by the court of admiralty.

The prize is to be divided among the officers and seamen of the king's ships, as he shall appoint by proclamation. Among privateers, the division is according to the agreement between the owners.

The court of admiralty is to finish the examination of the persons to be examined to prove the lawfulnefs of the prize, in five days after requiff for that purpose made. The motion is to be executed in three days. And in case no claim of the capture be duly entered, giving twenty days notice after the execution of the motion; or if there be a claim, and the claimant does not give sufficient security to pay double costs to the captors, if the prize be adjudged lawful, then the court is to proceed to sentence in ten days.

In case of doubt, or of witnesses being remote, the court may release the prize, on the claimant's giving good security to the captors for the payment of the full appraifed value, in case the prize be adjudged lawful.

Judges and officers, on failure of their duty, in respect to the condemnation of prizes, forfeit 500l. with full costs of suit; one moiety to the king, and the other to the informer.

The judges and officers of the court of admiralty in the king's plantations or dominions abroad, shall not receive above 10l. in case the prize be under a hundred tons burthen; nor above 15l. if it be of greater burthen.

Commissioners of appeals in causes of prizes are to be appointed under the great seal; and appeals may be made to them within fourteen days after sentence.

Agents for prizes are to be chosen by the captors.

The treasurer of the navy is to pay to the officers and seamen on board ships of war, or privateers, in any action where any ship of war, or privateer, shall have been taken from the enemy or destroyed, 5l. for every man on board such prize or ship destroyed, at the beginning of the engagement.

The captures of flota ships, or galleons, or regatta ships bound from Buenos Ayres, or Honduras, can be tried only in the high court of admiralty.

The statute enacts several penalties and forfeitures for taking prizes by collusion. Privateers forfeit the prize, half to the king, and half to the informer; and the commander of a man of war forfeits 1000l. to be divided between the king and the informer.

Also, if any ships belonging to the English be taken by the enemy, and afterwards retaken by any of our men of war, or privateers, they are to be retold to the owners, on paying an eighth part of the value, in lieu of salvage, after having been in the enemy's poftefion twenty-four hours; and if above that time, paying a farther moiety, &c. 13 Geo. II. cap. 4. 30 Geo. II. cap. 18.

The regulations with regard to prizes in the royal navy, are as follow: 1. When any ship or vessel is taken from the enemy, the hatches are to be immediately spiked up, and her lading and furniture secured from embezzlement, till sentence is passed upon her in some court of admiralty, empowered to take cognizance of causes of that nature.

2. The captain is to caufe the officers of the prize to be examined; three or more of the company, who can give full evidence, to be brought to the said court of admiralty, together with the charter-parties, bills of landing, and other
ship's papers, found on board. The 3d and 4th articles relate to finding any of the king's subjects in the prizes. 5. When a privateer is taken, great care is to be had to secure all the ship's papers, especially the commission; but if there be no legal commission found on board, then all the prisoners are to be carried before some magistrate, in order to their being examined and condemned as pirates. See articles 7, 8, and 9, for the government of the navy.

The captor acquires an irrepealable interest in a prize regularly taken in war. From the moment that the victor hoists his flag on board a conquered ship, he has acquired a qualified property in her which he may infuse. For though the king is, in contemplation of law, the captor, and the property of every prize immediately vests in him; yet the practice of belowing all prizes taken from the enemy upon the officers and men, who are the persons immediately concerned in the capture, is so constant and uniform, that the law will consider the expectation, founded upon this practice, as equivalent to a vested interest. It is also held, that a consignee, trustee, or an agent for prizes, may infuse.

PRIZE, in our Statutes, is used for things taken by the king's purveyors.

Spelman describes prizes to be corn and other provisions taken from the country-people, at lower rates than ordinary, for the maintenance of the king's household, garrisons, &c.

Roger de Monte Alto, who married the sister of Hugo de Abney, claimed the following privileges; viz., his cattle of Regine cum prifis 40 dirham, with prizes of forty days; which phrase the name author understandeth of the liberty of taking provisions for the support of the garrison of his cattle, upon paying for them within forty days. See flat. 12 Car. II. cap. 34.

PRISM, Prism, thus called from πρίσμα, something fized, or cut off, in Geometry, an oblong or solid body, contained under more than four planes, and whose bases are equal, parallel, and alike situated.

The prism is generated by the motion of a rectilinear figure, as ABC (Plate XI. Geometry, fig. 12.), defending always parallel to itself, along the right line AE.

If the describer be a triangle, the body is said to be a triangular prism; if square, a quadrangular one, &c.

From the genesis of the prism, it is evident it has two equal and opposite bases; that it is terminated by as many parallelograms as the base consists of sides; and that all the sections of a prism parallel to its base are equal.

Every triangular prism may be divided into three equal pyramids.

PRISM, to measure the surface and solidity of a. Find the area of the base, e. g. ABC (See Triangle), and multiply it by 2; find the areas of the planes or parallelograms, that include or circumscribe it; and add their sum to the former product. The sum is the whole surface of the prism.

Multiply then the base ABC by the altitude CD; the product is the solidity of the cube ABCDEF. (See Centimonial.) Or, for a right prism, multiply the perimeter of the end by the height, and the product will be the sum of the sides, or upright surface. If the ends of the prisms be regular plane figures, multiply the perimeter of the end by the sum of the height of the prism and the radius of the circle inscribed in the end, and the product will be the whole surface.

It is evident, in general, that if the area of each side and end be calculated separately, the sum of those areas will be the whole surface of any prism, whether right or oblique; or, indeed, of any other body whatever.

All prisms are in a ratio compounded of their bases and altitudes; if, then, their bases be equal, they are to each other as their heights; and vice versa. Similar prisms, &c. are in a triplicate ratio of their homologous sides, as also of their altitudes.

PRISM, in Dioptrics, is a glas in form of a triangular prism, much used in experiments about the nature of light and colours.

The phenomena and use of the prism arise from its separating the rays of light in their passage through it.

The more general of these phenomena are enumerated and illustrated under the articles COLOUR and REFRACTION: for, to enumerate all would be endless; and even these are sufficient to demonstrate, that colours do not either confit in the connotation of the globules of light, as Descartes imagined; nor in the obliquity of the pulses of the etherial matter, as Hooke fancied; nor in the confusion of light, and its greater or leas concision, as Dr. Barrow conjectured; but that they are original and unchangeable properties of light itself. See LIGHT.

PRISMATIC ANTENNE, in Natural History, a term used to express the horns or antennae of a peculiar genus of butterflies. See FEELERS.

PRISMOID, PRISMOIDES, in Geometry, a solid figure, having for its two ends any dissimilar parallel plane figures of the same number of sides, and all the upright sides of the solid trapezoids. If the ends of the prismoid be bounded by dihedral curves, it is sometimes called a cylindroid.

To find the solidity of a prismoit, the general rule is:

To the sum of the areas of the two ends, add four times the area of a section parallel to, and equally distant from both ends; multiply the last sum by the height, and one-sixth of the product will be the solidity. Or, if the bases be dissimilar rectangles, take two corresponding dimensions, and multiply each by the sum of double the other dimension of the base end, and the dimension of the other end corresponding to this last dimension; then multiply the sum of the products by the height, and one-sixth of the last product will be the solidity. Note, corresponding dimensions are those, which are connected by a side of the solid.

E. G. How many solid feet of timber are in a tree, whose ends are rectangles, the length and breadth of the one being 14 and 12 inches; and their corresponding sides of the other 6 and 4 inches; and the perpendicular length of 30 feet?

By the first general rule,

\[
\begin{align*}
\frac{14 + 6}{2} &= \frac{20}{2} = 10 \\
\frac{12 + 4}{2} &= \frac{16}{8} = 2 \\
10 \times 8 \times 4 &= 320 = \text{four times the middle area.} \\
14 \times 12 &= 168 = \text{area of the greater end.} \\
6 \times 4 &= 24 = \text{area of the less end.}
\end{align*}
\]

This sum is 512 square inches $= \frac{32}{9}$ square feet.

Then $\frac{32}{9} \times 30\frac{1}{2} = \frac{16 \times 30\frac{1}{2}}{9 \times 3} = \frac{162\frac{1}{2}}{9} = 18\frac{2}{7}$ feet, the solidity.

By the second or particular rule,

Let $L, l$, be one dimension of each corresponding to each other, and $B, b$, the other corresponding dimensions, and $h$ the height; then, $L$ being $= 14$, $B = 12$, $l = 6$, $b = 4$ inches, and $h = 30\frac{1}{2}$ feet, we shall have $(z L + l)$.
As to the treatment of prisoners of war, they may be secured, and for this purpose shut up; and if there is cause to fear their rising or running away, they may be even fettered. But they are not to be treated harshly, unless personally guilty towards him who has them in his power. Among European nations, prisoners of war are seldom ill-treated. And what is more, by a custom which equally displays the humanity of the Europeans, an officer, taken prisoner of war, is released on his parole, and enjoys the comfort of passing the time of his imprisonment in his country, with his family; and the party releasing him thinks it safe as security of him as if it had detained him in the closest prison. On the other hand, it was formerly a question, whether, if the number of prisoners was so great as not to be kept or fed with safety, it was right to put them to death? or, whether in such circumstances they should be sent back to the enemy at the hazard of their strengthening him, so as on another occasion to gain the advantage? At present the case is plain. These prisoners are sent back on their parole, not to carry arms for a certain time, or to the end of the war. An enemy may require from prisoners, in consideration of their release, that they shall not carry arms against him till the end of the war, having a right to keep them prisoners during that time. But he cannot require that they shall for ever renounce the liberty of fighting for their country, as at the end of the war their imprisonment cease; and they, on their side, cannot take upon themselves an engagement absolutely contrary to their quality as citizens or subjects. If, indeed, their country forsaikes them, they are free, and equally entitled to a renunciation on either side.

Another question has been started in reference to this subject. Are prisoners of war to be made slaves? This may be answered in the affirmative, in cases which give a right to kill them, when they have rendered themselves personally guilty of some crime deserving death. The ancients used to sell their prisoners of war for slaves, because they thought that they had a right of putting them to death. But in every circumstance, in which a prisoner’s life cannot in justice be taken away, we have no right to make him a slave. “What is life,” says Vattel, “without freedom? If any one counts life a favour, when the grant of it is attended with chains, let him enjoy it, let him accept the kindness, submit to his conditions, and fulfill his duties! But they are not what I shall teach him; he may find enough laid of them in other authors: I shall dwell no longer on the subject, and indeed this disgrace of mankind is happily extinct in Europe.”

Prisoners of war are detained, that they may not return again to the enemy, as also for obtaining from their sovereign a just satisfaction, as the price of their liberty; nor is there any obligation to release those who are detained with the latter view, till after satisfaction is obtained. As to the former, whoever makes a just war has a right, if he thinks proper, to detain his prisoners till the end of the war. And then, on releasing them, he may justly require a ransom, either as a compensation at a peace, or, if the war continues, for diminishing his enemy’s finances, at the same time that he strengthens him with the return of soldiers. The European nations, who are ever to be commended for their care in alleviating the evils of war, have, with regard to prisoners, introduced humane and salutary customs. They are exchanged or ransomed even during the war, and this is generally stipulated in a previous cartel. However, if a nation finds a considerable advantage in leaving its soldiers prisoners with the enemy during the war, rather than exchange them, it may certainly, unless bound by cartel, act as is most agreeable.
able to its interest. This would be the case of a flate abounding in men, and at war with a nation more formidable by the courage than the number of its soldiers. It would have been of little advantage to the czar, Peter the Great, to reimport the Swedes, his prisoners, for an equal number of Russians. But the flate is obliged, as soon as it can be done without danger, and has the means in its hands, to deliver, at its own expense, such of its citizens and soldiers as are prisoners of war. They are fallen under this misfortune only by acting for its service, and in support of its cause. The same reason dictates that it shall provide for their support during imprisonment. Formerly prisoners of war were obliged to redeem themselves, but then the ransom paid belonged to the officer or soldiers who took them: the modern use is more agreeable to reason and justice. If prisoners cannot be delivered during the course of the war, at least their liberty must, if possible, make an article in the treaty of peace. This is a care which the flate owes to those who have exposed themselves for it. However, it must be allowed, that every nation may, by a law, after the example of the Romans, and for inspiring their soldiers to make the most vigorous resistance, prohibit prisoners of war from being ever ransomed: when this is agreed on by the whole society, nobody can complain; but such a law is very harsh, and could scarcely suit any but those ambitious heroes who were determined on sacrificing every thing for making themselves masters of the world. Vattel's Law of Nations, b. iii. c. 8.

PRISRENDI, in Geography, a town of European Turkey, in Servia, the see of a Greek bishop; 43 miles N. of Alephi. N. lat. 42° 52'. E. long. 26° 4'.

PRIST—Unques PRIST. See Uncoris.

PRISTINA, in Geography, a town of Servia, the see of a Greek bishop; 100 miles E. of Ragusa. N. lat. 43° 10'. E. long. 20° 34'.

PRISTIS, See-fish, in Ichthyology, a genus of fishes in the Linnaean system of the order chondropteregious; but others rank it with the cartilaginous order; and Dr. Shaw thinks it may, with propriety, be considered as a species of the Squaleus, or shark, which see, of which he makes three varieties. But as we follow the Linnaean, the Linnean system, we shall fet down its generic character: fish not long, flat, spiny down the edges; four or five spines which are lateral; the body is oblong, roundish, covered with a rough conicous skin; mouth beneath; nostrils before the mouth, half covered with a membranaceous flap; there are two oval orifices behind the eyes; the ventral fins are approximate; it has no anal fin.

The saw-fish inhabits the Mediterranean, and was known to the ancient Greeks and Romans by the name of priltis.

Species.

Antiquorum. The specific character of this fish is, that its snout is armed with from eighteen to twenty-four strong spines on each side. It inhabits the ocean, is fifteen feet long; the body above is blackish, and beneath whitish. The head is flat on the fore-part; the snout is five feet long; the teeth granulate; the eyes large, the iris golden; it has five spines. The first dorsal fin is opposite the ventral, the second stands midway between the first and the tail; the pectoral fin is broad and long; the caudal short.

Pectinatus. The snout of this species has from twenty-five to thirty-four narrow spines on each side. It is an inhabitant of the ocean; resembles the last, but the snout is slenderer and narrower at the base; the spines are longer and slenderer. This and the former species are fully described in the second volume of the Linnean Transact.ios.

Cupidatus. The snout has twenty-eight broad, cut-
well as on mythological sovereigns. Prit'hi'vi is sometimes spoken of as a cow, milked by Swayambhava, or Adam, grand ancestor of Prit'hi'vi. She is sometimes called the daughter, as well as the wife of Prit'hi', under the name of Ila, another personification of the earth, of very equivocal history. See Ila.

In Meno's Institutes, c. ix. v. 311, it is said, that "as Prit'hi'vi supports all creatures equally, so a king, sustaining all subjects, resembles in his office the goddesse of the earth." In this character she shares the daily Brahmanical oblations offered to the gods. On an examination of the character and history of Prit'hi'vi, she is found to correspond with the Tellus, Terra, Vesta, &c. of Grecian mythology. The con-fort of Siva, as noticed under the article Parvati, sometimes appears in the character of goddesse of the earth, and is then called Bhudevi: but Prit'hi'vi is always considered a form of Lakshmi.

PRITZ, JOHN-GEORGE, in Biography, a learned German Lutheran divine, was a native of Leipzig, where he was born in the year 1662. He pursued his studies in the university of that city, where he took his degree of M.A. in 1685; and two years afterwards he enlisted in the number of contributors to the "Acta Eruditorum" of Leipzig. In 1690 the senate nominated him preacher at St. Nicholas' church; in 1693 he took the degree of bachelor of divinity; and in 1698 he was created doctor in that faculty, and accepted of an invitation to become professor of divinity, and of metaphysics, as well as minister, at Zerbi, in Saxony. In the year 1705 he visited Holland and England, and after his return to Germany, in 1707, was chosen professor of divinity, ecclesiastical counsellor, and minister at Greifswalde, in Pomerania. Here he continued till the year 1711, when he removed to Frankfort on the Main, where he held the appointment of principal minister, till his death in 1732, when he was about 70 years of age. He published "Patris Macarii Ægyptiæ Homiliae, Graece et Latine, interpretæ Zacharia Palthenio;" "Macarius Ægyptii Opera, Graece et Latine," confining of the rest of the works attributed to Macarius the elder. "Introductio in Lexicon Novi Testamenti," which is highly esteemed, and has been repeatedly printed: an edition of the New Testament in the original Greek, with various readings, geographical charts, &c.; and a great number of philosophical and theological differ-ences, controversial pieces, &c. Moreni.

PRITZERBE, in Geography, a town of the Middle Mark of Brandenburg, on the Havel; 7 miles N.N.W. of Branden-burg.

PRITZLER'S HARBOUR, a bay on the N. side of Hud-son's straits. N. lat. 62°. W. long. 67° 10'.

PRITZWALK, a town of Brandenburg, in the Mark of Pregnitz; 44 miles N. of Brandenburg. N. lat. 53° 11'. E. long. 12° 16'.

PRIVAS, a city of France, and principal place of a diocese, in the department of the Ardèche, seated on a small river, about six miles from the Rhone; 18 miles S.W. of Valence. The town contains 2923, and the canton 11,743 inhabitants, on a territory of 200 kilometres, in 15 communes. N. lat. 44° 44'. E. long. 4° 40'.

PRIVATE. Average, Charters, Nuance, Spirit, Statute, and Wrong. See the substan-tiative.

PRIVATE. See Statute.

PRIVATE STEALING from a man's person. See Larceny.

PRIVATEERS, are vessels of war, armed and equipped by particular merchants, &c. and furnished with a military commander by the admiralty, or the officers who superintend the marine department of a country, to cruise against the enemy, and take, sink, or burn their shipping, or otherwise annoy them as opportunity offers.

These vessels are generally governed on the same plan with his majesty's ships, though often guilty of shameless depredations.

Persons concerned in privateers administer at their own costs a part of a war, by providing ships of force, and all other military stores, and they have, instead of pay, leave to keep what they can take from the enemy, allowing the admiral his share, &c.

Privateers may not attempt any thing against the laws of nations, as to assault, an enemy in a port or haven under the protection of any prince or republic, whether he be friend, ally, or neutral, for the peace of such places must be inviolably kept; and therefore, by a treaty made by king William and the states of Holland, before a commiission shall be granted to any privateer, the commander is to give security if the ship be not above one hundred and fifty tons, in 1500l.; and if the ship exceeds that burthen, in 3000l.; that they will make satisfaction for all damages which they shall commit in their courses at sea, contrary to the treaties with that state; upon pain of forfeiting their commissions, and the ship is made liable. Lex Mercat. or Merch. Compan. 177.

By statute, ships taken by private men of war, were to be divided into five parts, four parts of which to go to the persons interested in the privateer, and the fifth to his majesty; and as a farther encouragement, privateers, &c. destroying any French man of war, or privateer, shall receive for every piece of ordnance in a ship so taken, 10l. reward, &c. 4 & 5 Will. & M.

But by a later statute, the commissioners of the admiralty may grant commissions to commanders of privateers, for taking ships, &c. which being adjudged prize, and the tenth part paid to the admiral, &c. wholly belong to the owners and captors. (See Prize.) By 19 Geo. II. c. 37. § 2. it is provided, that insurances on private ships of war, fitted out by any of his majesty's subjects, solely to cruise against his enemies, may be made by or for the owners thereof, interest or no interest, free of average, and without benefit of salvage to the insurer. By 33 Geo. III. c. 66. § 42. ships and goods belonging to any of his majesty's subjects that are re-captured by privateers, shall pay one-fifth part of their true value to the owners, officers, and seamen, of such privateers, for salvage, without any deduction. See Salvage.

PRIVATION, PRIVATIO, the absence, want, or defect of something needed or necessary.

In logic, privation, as applied to modes of being, and opposed to negation, denotes the absence of what naturally belongs to the thing we are speaking of, or which ought to be present with it. It was called in the schools habitus debiti.

In the canon law, privation is used for an interdict, or suspension.

Mythic divines use the phrase privation of God, for those dreynesses which the soul experiences, to whom God does not make himself felt.

The church of Rome teaches, that children, dying without baptism, go into a limbus, where they undergo a privation of the sight of God.

Privation, in Physics, is a negative principle, which, with matter and form, the Peripatetics suppose con-stitutes natural bodies. See Principle.

PRIVATIVE, in Grammar, a particle, which, prefixed to a word, changes it into a contrary sense.

Thus, among the Greeks, the α is used as a privative; as
in aequo, atque, &c. The Latins have their privative in: as incognitae, indecorabilitas, &c. The English, French, &c. on occasion. borrow both the Latin and Greek privatives.

Privative Modes. See Mode.

Privative Quantity, in Algebra, denotes a quantity less than nothing; called also a negative quantity; in opposition to affirmative or positive quantities.

Privative quantities are denoted by the character of subtraction— prefixed to them.

PRIVAT, in Botany. See Ligustrum.

Privet, Mock. See Philyrea.

Privet.Fly, in Entomology, the name of a species of fly very common on the shrub from whence it has its name. It is called the erinopera, and is remarkable for having its wings deeply divided into segments, so that they seem composed of feathers like bird's wings. The creature, as it flies, looks a small feather.

PRIVIES to a Fine, in Law. See Fine.

PRIVILEGE, Privilegium, formed from the Latin privata lex, in the general, any kind of right, prerogative, or advantage, attached to a certain person, condition, or employment, exclusive of others.

Privilege, in Law, is a particular right granted to a single person, place, community, or the like, by which they are exempted from the rigor of the common laws.

Privilege is either personal or real.

Privilege, Personal, is that which is granted to any person, either against or beyond the course of the common law.

Such, e. g. is that of a member of parliament; who may not be arrested during the sitting of parliament, nor for a certain time before and after. See Arrest, and Parliament.

Privilege, Real, is a franchise granted to a place.

Such is that granted to our universities, by which none who are members of it may be called to Westminster-hall upon any contract made within their own precincts. So also a person belonging to the court of chancery cannot be sued in any other court, certain cases excepted; and if he be, he may remove it by writ of privilege. It is an ancient privilege for men to be exempted from arrests within the verge of the court, i. e. in or near the palace where the king is resident; because, in such cases, quarrels frequently happen; and the peace ought to be strictly kept there.

In the laws of Henry I. it is expressly set forth, that peace ought to be maintained religiously and reverently within four miles of the king's doors towards the four quarters; and forty-nine acres, nine feet, nine palms, and nine barley-corns around.

Privilege, in Commerce, is a permission from a prince or magistrate, to make and sell a certain merchandize, or to engage in a certain commerce, either exclusively of others, or currently with them.

The first is called an exclusive privilege; the latter, simply, a privilege.

Exclusive privileges are to be granted rarely, by reason of the hindrance they are of to trade; yet they are sometimes very just and reasonable, by way of reward for the invention of useful machines, manufactures, &c.

Exclusive privileges for foreign commerce are usually granted on the following conditions; that the commodities be brought from remote parts, where there is no going without running great risks; that the privilege be only for a limited time; that the persons privileged be not allowed to monopolize, i. e. to raise and lower their commodities at pleasure; but that the sale and price be always proportionable to the expence, interest, &c. and that the privileged affilit the state, on occasion, with part of their gains.

Privilege for the impression of books is properly exclusive; being a permission which an author, or bookseller, obtains under a prince's seal, to have alone the impression of a book, with a prohibition of all others to print, sell, or distribute the same, within a certain term of years, usually fourteen, under the clauses and penalties expressed in it. These privileges were unknown till the beginning of the sixteenth century, when they were introduced in France. The oldest is said to date in the year 1597, and to have been occasioned by some printers counterfeiting the works of others as soon as they appeared.

But people were yet at liberty to take or let them alone at pleasure, till the interest of religion, and the state, occasioned the refraining of this liberty.

In 1563, Charles IX. published a celebrated ordinance, forbidding any person, on pain of confiscation of body and goods, to print any letter, speech, &c. without permission.

The like has been done in England; though, at present, privileges are not only not required, but by the late act, for securing the properties of books, seem needless.

See Literary Property.

Privilege, Attachment of. See Attachment.

Privilege, Bill of. See Arrest.

Privileges of the Clergy. See Clergy.

Privileges of the King. See King and Prerogative.

Privilege, Writ of, in Law, an ancient writ, by which courts of justice took cognizance of privileges of parliament, in the nature of a supersedeas to deliver the party out of custody when arrested in a civil suit. (Dyer, 59. 4 Pryn. Brev. Parl. 577.) For when a letter was written by the speaker to the judges, to stay proceedings against a privileged person, they rejected it as contrary to their oaths of office. (Latch. 48. Nov. 83.) But since the statute 12 W. III. c. 3. which enacts, that no privileged person shall be subject to arrest or imprisonment, it hath been held that such arrest is irregular ab initio, and that the party may be discharged upon motion. (Str. 89.) It is to be observed, that there is no precedent of any such writ of privilege, but only in civil suits; and that the statute of 1 Jac. I. p. 13. and that of king William (which remedy some inconveniences arising from privilege of parliament) speak only of civil actions. And therefore the claim of privilege hath been usually guarded with an exception as to the cause of indictable crimes (Com. Journ. 17 Aug. 1641.) or, as it hath been frequently expressed, of treason, felony, and breach (or surity) of the peace. (4 Inst. 25. Com. Journ. 20 May 1675.) By which it seems to have been understood that no privilege was allowable to the members, their families, or servants, in any crime whatsoever; for all crimes are treated by the law as being contra pacem domini regis. And instances have not been wanting, in which privileged persons have been convicted of misdemeanours, and committed, or proscribed to outlawry, even in the middle of a session (Mich. 16 Edw. IV. in Seach.—Lord Raym. 1461) ; which proceeding has afterwards received the sanction and approbation of parliament. (Com. Journ. 16 May 1726.) To which may be added, that, a few years ago, the case of writing and publishing seditious libels was resolved by both houses (Com. Journ. 24 Nov. Lords' Journ. 29 Nov. 1703) not to be entitled to privilege; and that the reasons upon which that case proceeded, (Lords' Protes.
Protest. 29 Nov. 1763) extended equally to every indictable offence. So that the chief, if not the only, privilege of parliament, in such cases, seems to be the right of receiving immediate information of the imprisonment or detention of any member, with the reason for which he is detained; a practice that is daily used upon the slightest military accusations, preparatory to a trial by a court martial (Com. Journ. 20 April 1762); and which is recognized by the several temporary statutes for suppressing the habeas corpus act, particularly 17 Geo. II. c. 6; by which it is provided, that no member of either house shall be detained, till the matter of which he stands suspected be first communicated to the house of which he is a member, and the confirm of the said house obtained for his commitment or detaining. But yet the usage has uniformly been, ever since the revolution, that the communication has been subsquent to the arrest. Blacklit. Com. b. i. 1

PRIVILEGED DEBT. See DEBT. PRIVILEGED Places. See Process.

PRIVILEGIA, or private laws, a denomination given by the Romans to laws ex post facto; that is, to laws which were enacted after an action (indifferent in itself) is committed, and the legislator then, for the first time, declares it to have been a crime, and inflicts a punishment upon the person who has committed it. Of these laws Cicero (de Leg. 3. 19.) and in his oration (pro dom. 17.) thus speaks: "Vetant leges sacrates, vetant duodecin tabulas, leges privatis hominibus irrogari; id enim est privilegium. Nemo secundum turic, nihil eft crudelius, nihil perniciosius, nihil quod minus has cceitas ferre poftit."

PRIVILEGIO CLERICALE. See CLERGY.

PRIVILEGIUM, property proper, denotes that qualified property which a man has in animals "ferre natura"; so that he may have the privilege of hunting, taking, and killing them, in exclusion of other persons. Here he has a transient property in these animals, usually called game (which fees), so long as they continue within his liberty; and may restrain any stranger from taking them therein, but the infant they depart into another liberty, this qualified property ceases.

PRIVITY, an intimate freedom, or private familiarity between two persons.

The lawyers say, if there be lord and tenant, and the tenant hold the lord by certain services; there is a privity between them in respect of the tenure.

PRIVOLNOE, in Geography, a town of Russia, in the government of Saratov, on the Volga; 48 miles S. of Saratov.

PRIUS. Nis PRIUS, in Law. See NIS.

PRIVY, a person who is partner, or has an interest in any action or thing.

In this sense they say, privies in blood: every heir in tail is privy to recover the land instated.

In old law-books, merchants privy are opposed to merchants strangers.

Coke mentions four kinds of privies. Privies in blood, as the heir to his father; privies in representation, as executors and administrators to the deceased; privies in estate, as he in reversion, and he in remainder; donor and donee; feoffor and feoffee; lastly, privy in tenure, as the lord by ecfate; i.e. when land ecfates to the lord for want of heirs.

PRIVY Council, called, by way of eminence, the council, a council of state, held by the king with his counsellors, to concert matters for the public service, and for the honour and safety of the realm.

This, according to Sir Edward Coke's description of it, (4 Inst. 53.) is a noble, honourable, and reverend assembly of the king and such as he wills to be of his privy council, in the king's court or palace.

The king's will is the sole constituent of a privy-counsellor; and this also regulates their number, which in ancient time was about twelve. Afterwards it increased to 10 large number, that it was found inconvenient for secrecy and dispatch: and therefore king Charles II., in 1679, limited it to thirty; of whom fifteen were to be the principal officers of state, and those to be counsellors, virtute officii; and the other fifteen were composed of ten lords and five commoners of the king's choosing. But since that time the number has been much augmented, and now continues indefinite. At the same time also, the ancient office of lord president of the council was revived in the person of Anthony, earl of Shaftesbury; an officer, who by the statute of 31 Hen. VIII. c. 10, has precedence next after the lord chancellor and lord treasurer.

Privy-counsellors are made by the king's nomination, without either patent or grant; and, on taking the necessary oaths, they become immediately privy-counsellors during the life of the king that chooses them, but subject to removal at his discretion.

As to the qualifications of members to sit at this board, any natural born subject of England is capable of being a member of the privy council; taking the proper oaths for security of the government, and the left for security of the church. By the act of settlement, 12 & 13 W. III. cap. 2, it is enacted, that no person born out of the dominions of the crown of England, unless born of English parents, even though naturalized by parliament, shall be capable of being of the privy council.

The duty of a privy-counsellor appears from the oath of office (4 Inst. 54.), which consists of seven articles. 1. To advise the king according to the belt of his cunning and discretion. 2. To advise for the king's honour and good of the public, without partiality, through affection, love, meed, doubt or dread. 3. To keep the king's counsel secret. 4. To avoid corruption. 5. To help and strengthen the execution of what shall be there resolved. 6. To withstand all persons who would attempt the contrary. And, lastly, in general, 7. To observe, keep, and do all that a good and true counsellor ought to do to his sovereign lord.

The privy council is, or ought to be, the primum mobile of the state, and that which gives the motion and direction to all the inferior parts. It is likewise a court of justice of great antiquity; the primitive and ordinary way of government in England being by the king and privy council.

It has been frequently used by all our kings for determining controversies of great importance: the ordinary judges have sometimes declined giving judgment till they had consulted the king and privy council; and the parliament have frequently referred matters of high moment to the same, as being by long experience better able to judge of, and, by their secrecy and expedition, to transact some state affairs, than the lords and commons.

At present, the privy council takes cognizance of few or no matters, except such as may not be well determined by the known laws, and ordinary courts; such as matters of complaint and sudden emergencies: their constant business being to consult for the public good in affairs of state. This power of the privy council is to enquire into all offences against the government, and to commit the offenders to safe custody, in order to take their trial in some of the courts of law. But their jurisdiction herein is only to enquire, and not to punish; and the persons committed by them...
are entitled to their **baili corpus** by statute 16 Car. I, cap. 10, as much as if committed by an ordinary justice of the peace.

In plantation or admiralty causes, which arise out of the jurisdiction of this kingdom, and in matters of lunacy and idiocy, the privy council has cognizance, even in questions of extensive property, being the court of appeal in such causes; or, rather, the appeal lies to the king's majesty himself in council.

From all the dominions of the crown, excepting Great Britain and Ireland, an appellate jurisdiction (in the last resort) is vested in this tribunal; which usually exercises its judicial authority in a committee of the whole privy council, who hear the allegations and proofs, and make their report to his majesty in council, by whom the judgment is finally given.

The privileges of privy counsellors, as such, (abstractive from their honorary precedence,) consist principally in the security which the law has given them against attempts and conspiracies to destroy their lives.

Anciently, to strike in the house of a privy-counsellor, or elsewhere in his presence, was grievously punished: by 3 Hen. VII, cap. 14, if any of the king's servants, of his household, conspire or imagine to take away the life of a privy-counsellor, it is felony, though nothing shall be done upon it; and by 9 Ann. cap. 16, it is enacted, that any persons, who shall unlawfully attempt to kill, or shall unlawfully assault, and strike or wound any privy-counsellor in the execution of his office, shall be felons, and suffer death as such.

With advice of this council, the king issues proclamations that bind the subject, provided they be not contrary to law.

In debates, the lowest delivers his opinion first, the king last, and thereby determines the matter.

A council is never held without the presence of a secretary of state.

The dissolution of the privy council depends upon the king's pleasure: and he may, whenever he thinks proper, discharge any particular member, or the whole of it, and appoint another. By the common law also it was disallowed *in faets* by the king's demise, as deriving all its authority from him. But now, to prevent the inconveniences of having no council in being at the accession of a new prince, it is enacted, by 6 Ann. cap. 7, that the privy council shall continue for six months after the demise of the crown, unless sooner determined by the successor. Blackf. Com. book 2.

The officers of the privy council are four clerks of the council in ordinary, three clerks extraordinary, a keeper of the records, and two keepers of the council-chamber.

**Lord President of the Privy Council.** See President.

**Privy Purses,** or the king's private expenses. See King and Revenue.

**Privy Seal,** a seal which the king uses, previously to such grants, &c. as are afterwards to pass the great seal.

Yet the privy seal is sometimes used in matters of lesser consequence, which do not require the great seal.

**Lord Privy Seal.** See Keeper of the Privy Seal, and Lord Privy Seal.

**Clerks of the Privy Seal.** See Clerk.

**Privy Chamber.** See Chamber.

**Privy Signet.** See Signet.

**Privy Tithes.** See Tithes.

**Privy Verdict.** See Verdict.

**PRIZE.** See Prize.

**PRIZE-Cattle,** in Rural Economy, such cattle or other animals as have obtained premiums at some of the cattle shows, either from their superiority of form, fatness, or other circumstances.

**PRIZING,** in Sea Language, denotes the application of a lever to move any weighty body, as a cable, anchor, cannon, &c.

**PRIZZI,** in Geography, a town of Sicily, in the valley of Mazara; 10 miles S. of Palermo. N. lat. 37° 46'. E. long. 13° 33'.

**PRO,** a preposition, signifying for, or in respect of a thing, as *pro confilto,* &c. And in law, *pro* in the grant of an estate, *pro confiito,* shewing the cause of the grant, amounts to a condition. But in a feoffment, or lease for life, &c. it is the consideration, and doth not amount to a condition; and the reason of the difference is, because the estate of the land by the feoffment is executed, and the grant of the annuity is executory.

**PRO-Confesso.** See PRO-CONFESSE.

**PRO-Indivisio.** See PRO-INDIVISO.

**PROA,** FLYING, in Navigation, a name given to a vessel used in the South Seas, on account of the swiftness with which it sails, being, with a brisk trade-wind, nearly twenty miles an hour. As to the construction of the proa, her head and stern are exactly alike, but her two sides are very different: the side intended to be always the lee-side being flat; and the windward-side made rounding, in the manner of other vessels, and, to prevent her overfettings, which, from her small breadth, and the straight run of her lee-side, would, without this precaution, infallibly happen, there is a frame laid out to her from windward, to the end of which is fastened a log, fashioned into the shape of a small boat, and made hollow. The weight of the frame is intended to balance the proa, and the small boat is, by its buoyancy (as it was always in the water), to prevent her overfetting to windward; and this frame is usually called an out-rigger. The body of the proa is made of two pieces joined endways, and lued together with bark, for there is no iron used about her; she is about two inches thick at the bottom, which, at the gun-wale, is reduced to less than one. The sail is made of matting, and the mast, yard, boom, and out-riggers, are all made of bamboo. See the description and drawing of a proa in Anson's Voyage, quarto, p. 341.

The proa generally carries six or seven Indians; two of whom are placed in the head and stern, who steer the vessel alternately with a paddle, according to the tack she goes on; the perfen in the stern being the steerman: the other Indians are employed either in bailing out the water, which she accidentally fills, or in setting and trimming the sail.

**PROAO,** in Mythology, a divinity of the ancient Germans, who held in one hand a pike, wrapped about with a kind of flag, and in the other a scytheon not unlike ours. According to Samuel Groffer, in his History of Lusatia, this god presided over courts of justice, and also the public market, that every thing might be fold there with equity.

**PROASM,** in Ancient Poetry, the same as *Epode,* which see.

**PROBABILISTS,** a sect, or division, among the Romanists, who adhere to the doctrine of probable opinions; holding, that a man is not always obliged to take the more probable side, but may take the less probable, if it be but barely probable.

The Jesuits and Moralists are strenuous Probabilists. See Jesuit, &c.

Those who oppose this doctrine, and assert that we are obliged, on pain of sinning, always to take the more probable
PROBABILITY of an Event, in the Doctrine of Chances, is greater or less according to the number of chances by which it may happen, compared with the whole number of chances by which it may either happen or fail. Wherefore, if we constitute a fraction, of which the numerator is the number of chances whereby an event may happen, and the denominator the number of all the chances by which it may either happen or fail, that fraction will be a proper designation of the probability of happening. Thus, if an event has three chances to happen, and two to fail, the fraction will fitly represent the probability of its happening, and may be taken to be the measure of it. The same thing may be said of the probability of failing, which will likewise be measured by a fraction, whose numerator is the number of chances by which it may fail, and the denominator the whole number of chances both for its happening and failing; thus the probability of the failing of that event which has two chances to fail and three to happen, will be measured by the fraction. If the fractions which represent the probabilities of happening and failing be added together, their sum will always be equal to unity, since the sum of their numerators will be equal to their common denominator: and since it is a certainty that an event will either happen or fail, it follows, that certainty, which may be conceived under the notion of an infinitely great degree of probability, is fitly represented by unity. De Moivre's Doct. of Chances, p. 1, &c. See CHANCES, EXPECTATION, and GAMING.

Probability of Life. See Expectation of Life, and Life Annuities.

Probability, in Reasoning, verisimilitude; or an appearance of truth.

To define it philosophically, probability is the appearance of the agreement or disagreement of two things by the intervention of proofs, whole connection is not constant and immutable, or is not perceived to be so; but is, or appears, for the most part, to be so; so as to suffice to induce the mind to judge the proposition to be true or false, rather than the contrary.

That proposition, then, is probable, for which there are arguments and proofs to make it pass, or to be received for true.

The entertainment the mind gives to this sort of propositions, is called belief, assent, or opinion.

Probability, then, being to supply the defect of our knowledge, is always concomitant about propositions of which we have no certainty, but only some indications to receive them for true; and this probability relates either to matter of fact, which falling under observation, are capable of human testimony, or to things which, being beyond the discovery of our senses, are not capable of any such testimony; called matters of speculation.

According to Aristotle, a proposition is probable, if it seem true to all or most people, and those the wiser and more reputable sort: but by seem he means, what, after a close inquiry, shall seem to be true.

Of probability there are various degrees, from the confines of certainty and demonstration, down through improbability and unlikelihood, to the confines of impossibility; and also degrees of uncertain from certain knowledge, and what is next to it, full assurance and confidence, quite down to conjecture, doubt, distrust, and disbelief.

The grounds of probability are, in short, these two following; viz. the conformity of any thing with our own particular knowledge, experience, or observation, called internal probability; and the testimony of others, vouching their observation, or experience, called external probability.

It was a doctrine of the New Academy (see Academy), that the senses, the understanding, and the imagination, which frequently deceive us, cannot be infallible judges of truth; but that from the impressions which we perceive to be produced on the mind, by means of the senses, we infer appearances of truth, or probabilities. Accordingly Carneades, an eminent orator and philosopher of that academy, maintained that though these impressions, which he called phantasies or images, do not always correspond to the nature of things, and there is no infallible method of determining when they are true or false, and consequently that they afford no certain criterion of truth, nevertheless, probable appearances are a sufficient guide, with respect to the conduct of life and the pursuit of happiness, because it is unreasonable not to allow some degree of credit to those witnesses who commonly give a true report. He divided probabilities into three classes; simple, uncontradicted, and confirmed by accurate examination. The lowest degree of probability takes place, where the mind, in the casual occurrence of any single image, perceives in it nothing contrary to truth and nature: the second degree of probability arises, when, contemplating any object in connection with all the circumstances associated with it, we discover no appearance of inconsistency, or incongruity, to lead us to suspect that our senses have given a false report; as when we conclude, from comparing the image of an individual man with our remembrance of that man, that he is the person we suppos'd him to be: and the highest degree of probability is produced, when, after an accurate examination of every circumstance which might be supposed to create uncertainty, we are able to discover no fallacy in the report of our senses. The judgments arising from this operation of the mind, are, according to the doctrine of the New Academy, not science, but opinion, which is all the knowledge that the human mind is capable of attaining.

In the doctrine of probability, one important observation may be made, viz. that if one premise only of an argument be probable, the conclusion is necessarily probable; but if two or more premises be probable, the conclusion will not be necessarily probable. Thus, for instance, supposing the probability of each premise expressed by , the probability of the conclusion will be but , which shews it to be improbable. For we may call any thing improbable, if the measure of the chance for its happening is less than . If there had been three premises, and the probability of each equal to , the probability of the conclusion would be , which is considerably improbable.

Again, supposing the probability of the truth of each premise to be or expressed by , the probability of the conclusion in the case of the two premises would be . Where three premises are assumed to infer a conclusion, this would be ; and in case of four premises, the probability of the conclusion would be but , which is less than , so that one might with advantage lay 4 to 1 against the truth of a conclusion founded on four probable premises, for the truth of which, separately taken, 2 to 1 might be laid. It is to be observed in all these cases, that the premises are supposed independent, that is, not necessarily connected with each other. Hence it is easy to account how it happens, that the most plausible political and physical reasonings lead to often to conclusions false in fact.

M. de Moivre has solved two problems, tending to establish the degree of assent that ought to be given to experience.
and verisimilitude: an ancient poet was condemned on the theatre for a flip in it; *viz.* for making a perfon, whom he represented as an honest man, fay, that "though his tongue fwere, his mind did not."

Seneca acclaims Virgil of an offence against natural probability in saying, that the winds were pent up in caves; for, fays that philofopher, wind being only air in motion, to fuppofe it at ref, is to destroy its nature. To which Volfinus answers, that the poet only speaks of the natural origin of winds; which are produced in mountains by vapours, &c. pent there; yet as we fhou'd fay, the winds are inclofed in an adfulte.

Virgil, likewife, committed an offence againft natural probability, by making Æneas find deer in Africa; becaufe that country produces none.

Indeed these faults are excufable, becaufe, as Ariftotle finely observes, they are not faults in the poet's art, but they arise from his ignorance of fomething taught in the other arts.

However, care must be taken they be not too grofs: there being fome probabilities of this kind, with which Æfop himfelf could not defpife; he would never be forgiven, were he to represent a lion fearful, a hare daring, a fox stupid, &c.

Probability, in refpetc of reafon, is frequently broken in upon by thofe who affect nothing but the miracle. Here Statius is a notorious offender: Tydeus, being furprized in an ambufcade by fifty braves, who had vowed his death, kills forty-nine of them, and pardons the fift. But the principal and moft important kind of probability is that in refpeft of common opinion. A thing is probable, when it looks like truth: but fometimes it fhall appear true to the people, and falfe to the learned; and vice verfa. When, then, the learned and the people are divided, to which fide muft the poet adhere? Suppofe, for inftance, the adventure of Penelope, the history of Medea, Helen, or the like: what Virgil and Homer have written of them fhall appear probable to the populace, yet the learned read the contrary in history; fome authors having written, that Dido was chaffe, and Medea innocent; that Penelope was divorced and banifhed, by Ulyffe, for abusing his abfence; and that Helen never faw Troy.

This point is foon decided: Homer and Virgil make no scruple of deviating from history to improve their fables; and Horace does not fend the poets to the truths of history, but either to fables already invented, or to common fame. All which is confirmed by Ariftotle.

To thefe kinds of probability may be added another, which we call accidental probability: it confifts not in the unifying of feveral incidents, each probable apart; but in difposing them fo as to hang probably together.

A man, e. gr. may probably die of an apoplexy; but that this fhould happen juft in the moment when the poet wanted it for an unravelling, is highly improbable.

It is an offence againft this kind of probability, to produce an incident all at once, and without any preparation which yet needed one. Virgil is wonderfully exact in this point: Juno prepares the temple mifled in the firft book; Venus in the fame book prepares the amours of the fourth. The death of Dido, in the end of the fourth, is prepared on the firft day of marriage; Helenus, in the third, difpofes the whole matter of the five; and in the fifth, the Sibyl predicts all the wars that follow.

PROBABLE OPINION, a term a long time controverted among the Romifh caufiffs; ufeudefly defined, an opinion founded on a grave motive, or an apparently good foundation,
tion, and which has authority enough on its side to persuade a wife disinterested person to assent to it.

Others define a probable opinion to be that, which, being compared with the contrary opinion, becomes methodical, by a perfect equality of the reasons on each side; so that there is nothing in reason or nature to determine on this side, rather than that.

But the Jesuits go still farther, and maintain, that to render an opinion probable, it suffices that it be either built on a reason of some consequence, or on the authority of some one grave doctor. With these qualifications it is allowable to follow it, even though it be less probable and less certain than the contrary opinion; thus it is said, that an opinion or precept may be followed with a good conscience, when it is inculcated by four, three, or two, nay even by one, doctor of any considerable reputation, even though it be contrary to the judgment of him that follows it, and even of him that recommends it. Here it is that the venom of probability lies; as this doctrine rendered the Jesuits capable of accommodating themselves to all the different passions of men, and to perfons of all tempers and characters, from the most affhier to the most licentious.

This doctrine is attacked, with infinite addrefs, by M. Pacal in the Provincial Letters; on which account they were burnt publicly at Paris. The doctrine of the Jesuits was also attacked by Perrault in his “La Morale des Jesuites, &c.” published at Mons, in 3 vols. 8vo. in 1702; which shared the fame fate with the Provincial of Pacal. The attack is farther pursued in Arnauld’s “La Morale Pratique des Jesuites,” 8 vols. 8vo. of which a second edition was published at Amsterdam in 1742.

One of the twenty-four patriarchs of the Jesuits, Caftro Palacio, afferts, that a judge, in a question of right, may give sentence, according to a probable opinion, against a more probable one; and this contrary to the judgment and perfusion of his own mind; “med contra propriam opinionem.” Ecfobar, tr. 6. ex. 6. n. 45.

So Vafquez maintains, that it is lawful to follow the less probable and les secure opinion, dicing the more probable and more secure one.

Leffius and Ecfobar, treating of the question, Whether a man may kill another for giving him a box on the ear? decide it to be a probable opinion, and speculatively true; though there may be some inconveniences in the practice, for which it would be as well to let it alone. “In praxi tutam et probabilis judicant—med non facile admittam.”

Probable Presumption, in Law. See PREJUMPION.

PROBANDA, PROPRIETATE. See PROPRIETATE.

PROBANG, in Surgery, signifies a long smooth piece of whalebone, to one end of which is fixed a bit of sponge. It is used for pushing extraneous substances down the oesophagus.

PROBATE of a Will or Testament, in Law, is the ex hibiting and proving a will and testament before the ecclesiastical judges delegated by the bishop, who is ordinary of the place where the party dies.

The granting of probates of wills regularly belongs to the ecclesiastical courts; but some courts baron have this right by prescription, as the manor of Mansfield, and those of Cowle and Caverham in Oxfordshire.

When the will is proved, the original must be deposited in the registry of the ordinary; and a copy of it in parchment is made out under the seal of the ordinary, and delivered to the executor or administrator, together with a certificate of its having been proved before him; all which together is usually styled the probate. The person before whom the testament is to be proved, is generally, the bishop of the diocese where the testator dwelt, or his officer.

If all the goods of the deceased be in the same diocese, then the bishop of the diocese, or the archdeacon, according as their composition leads, has the probate of the testament. If the goods lie dispersed in several dioceses, so that there be any sum or note, bona nobilia, as five pounds, in two distinct dioceses or jurisdictions, then the will must be proved, or administration taken out, before the metropolitan of the province, by way of special prerogative; whence the court where the validity of such wills is tried, and the office where they are registered, are called the prerogative court, and the prerogative office, of the provinces of Canterbury and York. The power of granting probates and administrations of the goods of persons dying, for wages or work done in the king’s docks and yards, shall be in the ordinary of the diocese where the person died, or in him to whom power is given by such ordinary, exclusive of the prerogative court, &c. 4 Ann. cap. 16.

This probate may be made in two ways; either in common form, or per testes. The proof in common form is only by the oath of the executor, or party exhibiting the will, who swears upon his belief, before the ordinary or his surrogate, that the will exhibited by him, is the last will and testament of the deceased.

This is the practice, it is said, through the province of Canterbury; but within the province of York, it hath been usual (though now discontinued in some of the dioceses) also to swear one witness to the will.

The proof per testes, by witnesses, or in form of law, is when, over and besides his own oath, he also produces witnesses, or makes other proof to confirm, that it is the last will of the deceased; and this in the presence of such as may pretend some interest in the goods of the deceased; or at least in their absence, after they have been lawfully summoned to swear such a will proved, if they think fit.

The latter course is commonly taken when there is fear of some strife, or dispute about the deceased’s goods: for some hold, that a will proved in common form only, may be called in question any time within thirty years after.

It is not necessary, to the proof of a written will, that the witnesses hear it read, so as that they can depose that the testator declared before them, that the self-writing writing now produced is or was his last will and testament.

Where a will dispose of lands and tenements of freehold, it is now frequently proved by witnesses in chancery. It is said (1 P. Will. 741.) that in proving a devise of lands, the proper way is, that the witnesses should not only prove the executing of the will by the testator, and his own subscribing in his presence, but likewise that the residuum of the witnesses subscribed their names in the testator’s presence; and so one witness proves the full execution of the will.

Besides those forms of proving testaments already recited, which are referred to that kind of proof which is called the publication of the testament, there is yet another form, which is called the opening of the testament, which respects written or closed testaments, in the making of which the civil law did require that the witnesses should put to them their seals; and after the death of the testator, at the opening of the written or closed testament, the same law did also require that the same witnesses should be called by the magistrates to acknowledge their seals, or to deny the sealing. But as we do not observe that solemnity of the civil law in the sealing of the testaments by the witnesses, no more do we observe that solemnity which the civil law requireth in opening of testaments sealed; unless this may seem to have some resemblance with this third form about the
the opening of the testament, which is enacted by the statutory of the 21 Hen. VIII. c. 5, which faith, that "the bishop, ordinary, or other person having authority to take probate of testaments, shall, upon the delivery of the seal and sign of the testator, cause the same seal to be defaced, and thereupon incontinent re-deliver the same seal unto the executor or executors, without claim or challenge thereunto to be made."

Dr. Swithinbume says, if a testament be made in writing, and afterwards be lost by some casualty; yet if there be two witnesses (i.e. in the case of goods and chattels), who did see and read the testament written, and do remember the contents thereof, those two witnesses do depofing of the tenor of the will are fufficient for the proof thereof in form of law; fo that they be otherwife, as well in refpect of their skill as of their integrity, greater than all exception, and specially some other likelihoods concerning therewithal to make their testimony more credible.

By a constitution of archbishop Stratford; "after the testament shall be proved, according to custom, before the ordinary; the execution or administration of any goods shall not be committed, but to such as shall faithfully promise to render a just account of their administration, when they shall thereunto be duly required by the ordinary." (Lind. 172.) In the fame constitution it is added, that those to whom the execution or administration is committed, shall give sufficient security to render a just account of their administration, when duly required by the ordinary.

All previous circumstances being settled, the bishop's officers are to keep the will original, and certify the copy thereof in parchment under the bishop's seal of office; which parchment, so sealed, is called the will proved.

The devise of a personal estate is not confidered of any effect until probate is made of the will by the executor; neither can any executor or other person give a will in evidence concerning a personal chattel without producing the probate: and a probate obtained in the ecclefaical court cannot be set aside in any other court either of law or equity. But the probate of a will, or a copy of the will out of the register of the spiritual court, is not to be allowed as evidence in the case of lands.

Regularly, that is, by the civil law, testaments ought to be infinuated in the official or commiffary of the bishop of the diocefe within four months next after the testator's death; but an executor is a complete executor before probate, to all purposes but bringing of actions. By 21 Hen. VIII. c. 5. the ordinary, or other person having authority for probate of testaments, may convene before them persons named executors of any testament, to the intent of proving or refufing the testament, as they might do heretofore. (See also 1 Ed. VI. c. 2.) And the ordinary may fequefter the goods of the deceased, until the executors have proved the testament; fo may the metropolitan, if the goods be in divers diocefae. (Swinb. a. 477. 478.)

And if the executors do not appear upon the process, the ordinary may excommunicate them; but they may pray time to advise; and the ordinary may grant in the mean time letters "ad colligendum bona defuncti." On the other hand (inasmuch as the executor, though he may be sued, and pay debts, and release an action, yet cannot have an action, before probate), the ordinary is bound to prove the will; and on his refufal, a writ will go to the temporal court, to compel him to proceed to probate, where the will is not controverted: but if the validity of the will is controverted, it is a fufficient answer by the ordinary to a writ of mandamus, to return, that a suit is depending before him concerning the fame, and not yet determined.

By 21 Hen. VIII. cap. 5. it is enacted, that on probate of wills, &c. 6d. and no more shall be taken by the regifter, where the goods of the deceased do not exceed 5l. value; and when the goods are above the value of 5l. and under 40l., the fee to the bishop or ordinary shall be 2s. 6d., and to the regifter 1s. And if the goods exceed 40l. value, in to the bishop or ordinary 2s. 6d., and to the regifter 2s. 6d., which, however, he may refuse, and take 1d. for every ten lines of the will, &c. And if the officer takes more than his fees, he shall forfeit 10d., to be divided between the king and the party grieved. See also 31 Geo. II. cap. 10. which relates to feamen and marines.

By 48 Geo. III. c. 149. the following lump duties are imposed on probates and letters of administration:

Above the value of 20l. and under the value £ s. d.

See Executor and Will.

PROBATICa PISCINA. See PISCINA.

PROBATION, in a Monastic Style, a time of trial; or the year of noviciate, which a religious must pafs in a convent to prove his virtue and vocation, and whether he can bear the severities of the rule.

The year of probation commences from the day of novices taking the habit.

PROBATION, in the Universitie, denotes the examination and trial of a student who is about to take his degrees. See DEGREE.

PROBATIONER, in the Presbytery Discipline, a person licensed by a presbytery to preach; which is usually done a year before he be ordained.

A student
A problem, according to Woffius, consists of three parts. The proposition, which expresses what is to be done. The resolution, or solution, wherein the several steps, by which the thing required is to be effectuated, are distinctly performed. The demonstration, in which it is shown, that by doing the several things prescribed in the resolution, the thing required is obtained.

Accordingly, the general tenor of all problems is this; the things prescribed in the resolution being done, the thing required is done. See Geometrical Solution of a Problem.

Problem, in Algebra, is a question or proposition which requires some unknown truth to be investigated or discovered; and the truth of the discovery demonstrated.

In this sense it is a problem, to find a theorem. Algebra is defined to be the art of resolving all problems that are resolvable.

Problem, Kepler's, in Astronomy, is the determination of a planet's place from the time; thus called from the astronomer Kepler, who first propounded it.

The problem, stated in form, stands thus; to find the position of a right line, which, passing through one of the foci of an ellipse, shall cut off an area described by its motion, which shall be in any given proportion to the whole area of the ellipse.

The proposer knew no way of solving the problem directly and geometrically; and therefore had recourse to an indirect method; for which he was taxed with an αφορτωτά, or want of geometry; and his Astronomy charged with not being geometrically. But the problem has since been solved directly and geometrically several ways, by several authors; particularly by Isaac Newton, Dr. Keil, &c.

As to the solution of this problem, the late excellent mathematician Mr. Machin observes, that many attempts have been made, at different times, but never yet with tolerable success, towards the solution of the problem propounded by Kepler: to divide the area of a semicircle into given parts, by a line from a given point of the diameter, in order to find an universal rule for the motion of a body in an elliptical orbit. For among the several methods proposed, one is only true in speculation, but are really of no service. Others are not different from his own, which he judged improper. And as to the rest, they are all some way or other so limited and confined to particular conditions and circumstances, as still to leave the problem in general untouched. To be more particular, it is evident, that all constructions by mechanical curves are seeming solutions only, but in reality unapplicable; that the roots of infinite series are, upon account of their known limitations in all respects, so far from affording an appearance of being sufficient rules, that they cannot well be supposed as offered for any thing more than exercices of a method in calculation. And then, as to the universal method, which proceeds by a continued correction of the errors of a false position, it is, when duly considered, no method of solution at all in itself; because, unless there be some antecedent rule or hypothesis to begin the operation (as suppose that of a uniform motion about the upper focus, for the orbit of a planet; or that of a motion in a parabola for the perihelion part of the orbit of a comet; or some other such), it would be impossible to proceed one step in it. But as no general rule has ever yet been laid down to assist this method, so as to make it always operate, it is the same in effect as if there were no method at all. And accordingly in experience it is found, that there is no rule now subsisting but what is absolutely useless in the elliptic orbits of comets; for in such cases there is no other way to proceed but that which was used by Kepler:

Vol. XXVIII.
to compute a table for some part of the orbit, and therein examine if the time to which the place is required, will fall out any where in that part. So that, upon the whole, it appears evident, that this problem, contrary to the received opinion, has never yet been advanced one step towards its true solution. Vide Machin, in Phil. Trans. Martyn's Abrig., vol. viii. p. 73.

Mr. Machin afterwards proceeds to give his own solution of this problem, which is particularly necessary in orbits of a great excentricity; and he illustrates his method by examples, for the orbits of Mercury, of Venus, of the comet of the year 1682, and of the great comet of the year 1686, all which shew the univerality of that method. See ANOMALY, and EQUATION of the Centre.

PROBLEM, determinate, diophantine, indeterminate, limited, linear, local, plain, solid, surficial, and unlimited. See the adjectives.

PROBLEM, Delicat, in Geometry, is the doubling of a cube. This problem coincides with that for finding two mean proportionals between two given lines; whence that also is called the deliac problem. See DUPLICATION.

PROBLEMATICAL RESOLUTION, in Algebra, a method of solving difficult questions by certain rules, called canons.

PROBOLIUM, among the Romans, a kind of spear, which hunters used in hunting bears.

PROBOSCIDEA, in Botany, so called from the very long beak of the fruit. See MARTYNIA.

PROBOSCIPLECTANUS, in Natural History, a name given by some authors to a peculiar and very elegant species of penicillus marinus, which has somewhat of a funnel-like shape, and has its mouth surrounded by a number of thin braid-like filaments. See PENICILLI MARIANI.

The first who has described this particular species is the accurate Fabius Columba, from whom Klein has engraved a figure of it.

PROBOSCIS, προσκεισθαι, the trunk or nose of an elephant, and of some other animals. The proboscis is a member lying out of the middle of the forehead, serving instead of a hand; and having a little appendix fatten'd to the hand of it, in form of a finger. By the proboscis the fhe-elephant, it is said, sucks her self; and by the same conveys the milk to her young. All quadrupeds have the length of their neck equal to that of their feet, the elephant alone excepted, in which the thornets of the neck is compensated by the length of the proboscis. See ELEPHANT.

The camelion has also a kind of trunk or proboscis, which is its tongue; and which it darts nimbly out of its throat as if it spat it; and draws it in again insusceptibly. It serves like the elephant's trunk, to lay hold on, and take in its food. See CAMELION.

The Microscope shows us a little trunk or proboscis in flies and gnats, by means of which they suck the blood of animals, or liquors, for their food.

PROBOSCIUS OF Fries. See TRUNK, ENTOMOLOGY, FLY, and INSECT.

PROBSTORFF, in Geography, a town of Austria; three miles S.E. of Entzendorf.

PROBSTZELLE, a town of Saxony, in the principality of Altenburg; six miles S. of Saafield.

PROBULEMA, προβολήματα, among the Athenians, a decree or vote of the areopagus, or council of Athens. It was so called because agreed upon by the senate, with a design to have it afterwards proposed to an assembly of the people, that it might receive from them a farther ratification, without which it could not be passed into a law, nor have any force or obligatory power after the end of that year, when the senate and other magistrates laid down their commissions. Potter, Arch. Græcit. lib. i. cap. 18. tom. i. p. 100.

PROBUS, M. Aurelius, in Biography, a Roman emperor, was born about the year 232, at Sirmium, in Panonia. He entered young into the Roman army, and distinguished himself so much by his valour and integrity, that the emperor Valerian raised him to the post of tribune before the legal age for that advancement. In a battle with the Saratians and Quadians he obtained a civic crown, by rescuing from the hands of the enemy a young man of rank related to the emperor. In every station he showed himself superior to the task committed to him. After having subdued the Marcomans in Africa, and quelled a rebellion at Carthage, he was employed to recover Egypt from the Palmyrenians, who, under the famous Zenobia, had conquered that country. This important business he effected, and so well established was his reputation at that period, that when, after the death of Aurelian, Tacitus was nominated to the empire by the senate, in his speech to decline that charge he proposed Probus in his stead. On the murder of Tacitus in 276, his half-brother Florianus, at the head of an army near the Bothnian, assumed the purple as by right of inheritance; but at the same time the army of the Eait conferred the imperial dignity upon their commander Probus. A civil war succeeded, which in two months was terminated by the death of Florianus, and Probus was recognised by the troops of his rival. He then wrote a very modest letter to the senate, to whom he submitted his pretensions; and his deference was rewarded by an unanimous vote, conferring upon him the usual titles and prerogatives. In return, he filled a declaration, confirming the privileges of the senate, to whom he committed the whole administration, contenting himself almost solely with the military command. One of the first exertions of his authority was the punishment of the conspirators against Aurelian and Tacitus. He then marched into Gaul, which he cleared, after several victories, of those numerous tribes of barbarians which had ravaged and occupied a great many towns and districts of that country. He followed the vanquished acros the Rhone, laid waste a large tract of country, and compelled nine of their petty kings to throw themselves at his feet, and supplicate for peace. To protect from invasion the Gallic colony settled in Sussa, he erected a stone wall, with towers at proper intervals, which extended from the Danube near Ratillon, to Wimpfen on the Neckar, and finally terminated on the Rhine, after a winding course of nearly 200 miles. He undertook to reduce the Isaurians, a fierce band of robbers in Atla Minor, and made himself master of their principal town. After this he proceeded to the frontiers of Peruia. The king of that country, alarmed at his approach, sent an embassy to him, which found him encamped on the mountains of Armenia. He was dining on pork and pease when the deputies arrived, whom he astonished by the plainness of his dress, and the simplicity of his manners, while he made them tremble by the severity with which he delivered a menacing message to their master. The differences between the two empires were for the present accommodated, but Probus did not renounce his purpose of making war upon the Perians, though he was, for the present, recalled to his European territories, by the necessity of taking measures to prevent revolts among the barbarians whom he had vanquished. His policy with respect to this, was to transport great bodies of the conquered nations to a distance from their own homes, and settle them upon unoccupied lands in remote provinces of the empire. Thus a number of
of Vandals were conveyed to the central parts of Britain, in which situation they continued a difficult tribe: by means such as these he kept the frontiers in a state of tranquillity. The people of Alexandria having proclaimed Saturnius, a commander in the East, emperor, he thought it prudent to withdraw into Palestine without accepting the honour. But reflecting on the improbability of remaining as a private man in a state of safety, he suffered the soldiers to confirm the mutiny, and prepared for his defence. Probus had a high respect for him, and offered him a free pardon; but he had, in his own estimation, gone too far, and he was flain: the same fate occurred to Proculus and Bonofius, two military commanders that had excited rebellions in Gaul. The return of peace in 281, was celebrated by the emperor with a triumph over the diömit nations of the Germans, &c., in which he presented to the people of Rome the usual spectacles of gladiators, the chase of wild beasts, and other amusements, with great magnificence. A more useful benefit was bestowed on his subjects, in taking off Domitian's interdict against planting vines, in favour of the Gauls, the Spaniards, and the Pannonians; so that the fine wines of Burgundy, Champagne, and Tokay, may be said to owe their origin to Probus. He employed the soldiers in planting and other useful labours, upon whom he constantly exercised a constant and strict, but by no means severe, discipline. It was, however, his wife policy of keeping them regularly employed in peace as well as in war, that was at last the cause of his untimely end. He had determined to improve the land about Sirmium, of which he was a native; "but," says the historian, "in the execution of a favourite scheme, the bent of men, satisfied with the multitude of their own intentions, are subject to forget the bounds of moderation; nor did Probus himself sufficiently consult the patience and disposition of his fickle legionaries. The dangers of the military profession seem only to be compensated by a life of pleasure and idleness; but if the duties of the soldier are incessantly aggravated by the labours of the peasant, he will at last sink under the intolerable burden, or shake it off with indignation." The imprudence of Probus is said to have inflamed the discontent of the troops. More attentive to the interests of mankind than to those of the army, he expressed the vain hope, that by the establishment of universal peace, he should soon abolish the necessity of a standing and mercenary army. The unguarded expression proved fatal to him. In one of the hottest days of summer, as he severely urged the unwelcome labour of draining the marshes of Sirmium, the soldiers, impatient of fatigue, on a sudden threw down their arms, and broke out into a furious mutiny. The emperor, conscious of his danger, took refuge in a lofty tower constructed for the purpose of surmounting the progress of the work. The tower was instantly forced, and a thousand swords were plunged at once into the bosom of the unfortunate Probus. The rage of the troops subsided as soon as it had been gratified. They then lamented their fatal rashness, forgot the severity of the emperor whom they had maligned, and hasted to perpetuate, by an honourable monument, the memory of his virtue and victories. Gibbon. Univer. Hist.

PROBUS, M. VALENIUS, a Latin grammerian, lived in the second century, under the emperor Adrian. He wrote several treatises, of which one, cited by Servius, was entitled "De Temporum Connexione." Some fragments of his writings have been published among the "Grammatici Latin i Vetere." Moreri.

PROBY'S ISLAND, in Geography, a small island in the Pacific ocean, so called by Capt. Edwards in 1791: denomi-
**PROCELEUSMATICUS**, προκελευσματικός, in the Ancient Poetry, a foot consisting of four short syllables: as 

**PROCELLARIA**, the Petrel, in Ornithology, a genus of birds of the order Anseres: the generic character is, bill toothless, a little compressed, hooked at the point; mandibles equal; nostrils cylindrical, tubular, truncate, lying on the base of the bill; feet palmate; the back toe pointing downwards, feathery, sharp, a mere fur.

The birds of this genus, of which there are twenty-four species, live chiefly at sea, and, except at the breeding-time, are seldom seen near land; they have the faculty of spouting from their bills, to a considerable distance, a quantity of pure oil; they feed on the fat and muscles of dead whales, and other large fish. At sea they are capable of enduring the greatest storms, and on shore they possess the faculty of walking.

**Species.**

**OBSCURA.** Black, beneath white; membrane connecting the toes is tawny. It is a native of North America, and is about thirty inches long. Its bill is black, horny at the sides; the nostrils are distinct; the fides of the neck are variegated with brown and white; legs black without, pale within.

**PACIFICA;** Pacific Petrel. Black; dusky beneath; legs spotted with black; bill plumbeous and much hooked; the nostrils are elevated, oval, distinct, obliquely placed; legs pale. It is full twenty-two inches long. It inhabits, in vast flocks, the islands of the Pacific ocean. These flocks disappear at once, dipping under water altogether, and then rising as suddenly.

**CERELEA;** Blue Petrel. White-blue, beneath white; bill and legs blue. It inhabits the southern ocean, and is twelve inches long. The bill is black at the tip, and the legs are blue; the outer quill-feathers entirely, the next within, the ref tippets with white; the area beneath the eyes and band on the breast dusky.

**VITTATA;** Broad-billed Petrel. Blueish-afl, beneath white, legs black. This species inhabits the antarctic seas; it lays in holes or rocks; it flies by night in numerous flocks, and is about twelve inches long.

**UNINATRIX;** Diving Petrel. Blackish-brown; white beneath; the bill and chin black; legs blue-green, without the bringer behind. It is eight inches and a half long. Inhabiters New Zealand in flocks of large numbers; it dives remarkably well, often rising at a considerable distance with surprising agility. The birds of this species croak like frogs, and sometimes make a noise like the cackling of a hen.

**PELAGICA;** Stormy Petrel; called also the storm-finach, or mother Cary's chicken. The specific character is black, with a white rump. It is only about the size of a swallow, and in its general appearance and flight not unlike that bird. The stormy petrel is rarely seen on our shores, except in some of the northern islands where it breeds in the holes of rocks, or under loose stones, in the months of June and July. At all other seafarions it keeps far out at sea. Multitudes of them are seen all over the vast Atlantic ocean, especially before stormy weather. They often skim with incredible velocity along the hollows of the waves, and sometimes on the summits, bravely withstanding the utmost fury of the tempest. As they appear to run on the surface of the sea, they have their name from an allusion to the apostle Peter's walking on the water. The inhabitants of the Feroe islands draw a wick through the body of this bird, which is by the pro-

Inhabiters New Zealand in flocks of large numbers; it dives remarkably well, often rising at a considerable distance with surprising agility. The birds of this species croak like frogs, and sometimes make a noise like the cackling of a hen.

**PELAGICA;** Stormy Petrel; called also the storm-finach, or mother Cary's chicken. The specific character is black, with a white rump. It is only about the size of a swallow, and in its general appearance and flight not unlike that bird. The stormy petrel is rarely seen on our shores, except in some of the northern islands where it breeds in the holes of rocks, or under loose stones, in the months of June and July. At all other seafarions it keeps far out at sea. Multitudes of them are seen all over the vast Atlantic ocean, especially before stormy weather. They often skim with incredible velocity along the hollows of the waves, and sometimes on the summits, bravely withstanding the utmost fury of the tempest. As they appear to run on the surface of the sea, they have their name from an allusion to the apostle Peter's walking on the water. The inhabitants of the Feroe islands draw a wick through the body of this bird, which is by the pro-
their chief food is fish, they also feed on the carcasses of
seals and birds.

Brasiliana. Blackish; lower part of the neck yellow.
It inhabits Brazil, is the size of a goose, frequents the
mouths of rivers, and makes its nest on the shore.

Æquinoctialis. Black Petrel. Brown, without spots; bill yellow; legs brown. A variety has legs reddish-black.
The bird inhabits the Cape of Good Hope and New Zealand; the second Kamtschatka; the former is about twenty-three
inches long; the latter thirty-five or thirty-six.

Grisea. Grey Petrel. Sooty; lower wing-coverts white; bill brown; legs blueish on the fore-part. It is a
native of the southern hemisphere, and is fourteen or fifteen inches long.

Gelida. Glacial Petrel. Blueish-grey; back blackish;
chin, throat, and breast white; bill yellow; legs blue. It
inhabits the icy seas, and is nineteen inches long.

Alba. White-breasted Petrel. Black-brown; breast,
belly, and vent white. A variety is footy, beneath cinereous;
face varied with white and brown; legs yellowish; toes and
membranes half black. It inhabits the Pacific ocean, and
is about sixteen inches long.

Antarctica. Antarctic Petrel. Brown, beneath
blueish-white; tail white tipped with black; the legs are of a
lead colour. It is a native of the antarctic circle.

Capensis. Pintado. Variegated with white and brown,
and sometimes with yellowish and brown; bill and legs
black; temples white and black. This is the pintado-bird
of Dampier; the white and black spotted petrel of Ed-
wards; and the Cape pigeon of our sailors. It is seldom
seen to the north of thirty degrees, and is most frequent
about the Cape of Good Hope, and the neighbouring
regions. It flies in numerous flocks, which almost sweep
the surface of the water. They have been traced to New Zea-
land, the Falkland islands, and other regions in the southern
hemisphere. The sailors often catch them with some tarred
string, or a bit of lard on a fishing-rod. Seven hundred
have been caught in a night. They feed on fish, but seem to
delight on the dead carcasses of whales.

Puffinus. Shearwater Petrel. Black above; a white
beneath; legs rufous; bill yellow, tip with black; hind-
head whiteish-grey; sphenus wings spotted with black; first
quill and tail-feathers brown without, and white within. It
is about the size of a large pigeon. It inhabits the southern
and arctic seas. Breeds in the Isle of Man, and the Ork-
neys, in the former of which it is called mans puffin, and in
the latter far. It takes possession of a rabbit burrow, or
other hole, and lays one white egg, blunt at each end, which
is hatched in August. The flesh is eatable, but rank.
Numbers are killed and barreled with salt; and in this state
they are eaten as we eat salt fish. There is a variety which
is cinerea above, white beneath; the tail is of a clear
white. It inhabits the southern and arctic seas, and is fif-
teen or sixteen inches long.

Procers, in Glass Making, iron instruments, hooked
at the extremity, used to settle the pots in their places,
whether let too near or too far off.

Processus, in Law, is used for all the proceeding in any
cause or action, real or personal, civil or criminal, from
the original writ to the end. See Procedure.

Process denotes, in a more restrained sense, the means
that are made use of, afterHung out the original, for com-
pelling the defendant to appear in court; this being the be-
ingning, or principal part, and that by which the rest of the
business is directed.

This is sometimes called original process, being founded
upon the original writ; and also to distinguish it from mesne
or intermediate process, which issues, pending the suit, upon
some collateral interlocutory matter; as to summon juries,
notaries, and the like. Mesne process is also sometimes
put in contradistinction to final process, or process of exec-
ution; and then it signifies all such processes as intervene
between the beginning and end of a suit. The preliminary
step in civil process is that of giving notice to the party
to obey the original writ, issued for compelling his appear-
cance in court. This notice is given upon all real "pro-
cipies," and also upon all personal writs for injuries not against
the peace by summons: which fee. If the defendant dis-
obeys this verbal admonition, the next process is by writ of
attachment, or poze: which fee. If, after attachment, the
defendant neglects to appear, he not only forfeits the
security he has given, but is moreover to be further com-
pelled by writ of distraint, or distress, infinite; which fee.
Here by the common, as well as the civil, law, the
proces ends in case of injuries without force: the de-
fendant, if he had any substiane, being gradually stripped
of it by repeated distraint, till he rendered obedience
to the king's writ: and if he had no substiane, the law
held him incapable of making satisfaction, and therefore
looked upon all further process as nugatory. For the pro-
ces, in cases of injury accompanied with force, see Capias.

Such is the first process in the court of common plea
In the king's bench they may also (and frequently do) pro-
ceed in certain causes, particularly in actions of eje
tment and trespass, by original writ, with attachment and capias thereon: returnable, not at Westminster, where the common plea
are now fixed, in consequence of Magna Carta, but ubi-
cunque fuerimus in Anglia, wherever the king shall be in
England; the king's bench being removable into any part
of England, at the pleasure and direction of the crown.
But the more usual method of proceeding therein is without
any original, but by a peculiar species of proces, entitled a
Bill of Middlesex; which fee.

In the exchequer, the first process is by writ of quo minus,
which fee. The three courts set out differently, as we
have briefly stated, in the commencement of a suit, in order
to entitle the two courts of king's bench and exchequer
to hold pleas in causes between subject and subject, which
by the original constitution of Westminster-hall they were
not empowered to do. Afterwards, when the cause is once
drawn into the respective courts, the method of pursing it
is partly much the same in all of them. If the sheriff
has found the defendants upon any of the former writs, the
capias, latat, &c., he was anciently obliged to take him
into custody, in order to produce him in court upon the
return, however minute the cause of action might be. For,
not having obeyed the original summons, he had been a
comept of the court, and was no longer to be troubled at
large. But when the summons fell into disuse, and the
capias became in fact the first process, it was thought hard
to imprison a man for a contempt which was only sup-
posed; and therefore in common cases by the gradual in-
dulgence of the courts (at length authorized by statute
12 Geo. I. c. 29, amended by 5 Geo. II. c. 27, made per-
petual by 19 Geo. III. c. 76, and extended to all inferior
courts by 19 Geo. III. c. 70.) the sheriff, or proper officer,
can now only personally serve the defendant with the
copy of the writ or process, and with notice, in writing,
to appear, by his attorney in court, to defend this action;
which, in effect, reduces it to a mere summons. The
next part of the proces is bail; which fee. (See also
Ac etiam.) Besides the ac etiam, added to the writ of
capias, the man sworn to by the plaintiff is marked upon

the back of the writ: and the sheriff, or his officer the bailiff, is then obliged actually to arrest or take into custody the body of the defendant; and having so done, to return the writ with a cept corpus endorsed thereon. (See Arrest.) When the defendant is regularly arrested, he must either go to prison, for safe custody: or put in to the sheriff Special Bail; which fee. Upon the return of the writ, or within four days after, the defendant must appear according to the exigency of the writ. (See Bail.) When the defendant appears in court, in consequence of process, either in person as a prisoner, or out upon bail, the next stage is that of the pleadings; which fee.

For an account of process in criminal cases, see Indictment and Capias. See also Certiorari.

By 48 Geo. III. c. 58, § 1. it is enacted that whenever any person is charged with any offence for which he may be prosecuted by indictment or information in the king's bench, not being treason or felony, and the same shall be made to appear to any judge of the same court by affidavit, or by certificate of an indictment or information being filed against such person in the said court for such offence, such judge may issue his warrant under his hand and seal, and thereby cause such person to be apprehended and brought before him or some other judge of the same court, or before some one judge of the peace, in order to his being bound with two sufficient sureties in such sum as the said warrant shall expire, with condition to appear in the said court at the time mentioned in the said warrant, and to answer all and singular indictments or informations for any such offence; and if he shall neglect or refuse to become so bound, such judge or justice may respectively commit him to the common gaol of the county, city, or place where the offence shall have been committed, or where he shall have been apprehended, there to remain until he shall become bound as aforesaid, or be discharged by order of the said court in term time, or of one of the judges of the said court in vacation; and the recognizance to be thereupon taken shall be returned and filed in the said court, and shall continue in force until such person shall have been acquitted of such offence, or in case of conviction shall have received judgment for the same, unless sooner ordered by the said court to be discharged; and that where any person, either by virtue of such warrant of commitment, or by virtue of any writ of capias ad respondendum issued out of the same court, is now or hereafter shall be committed or detained in any gaol for want of bail, it shall be lawful for the prosecutor to cause a copy thereof to be delivered to such person, or to the gaoler, keeper, or turnkey of the gaol, wherein he is or shall be so detained, with a notice indorsed, that until such person shall, within eight days from the time of such delivery of a copy of the indictment or information as aforesaid, cause an appearance, and also a plea or demurrer to be entered in the said court to such indictment or information, an appearance and the plea of not guilty will be entered therein in the name of such person; and in case he shall thereupon for the said space of eight days after such delivery of a copy of the indictment or information as aforesaid neglect to cause an appearance, and also a plea or demurrer to be entered in the said court to such indictment or information, it shall be lawful for the prosecutor, upon affidavit made and filed in the said court, of the delivery of a copy of such indictment or information, with such notice to indorse to such person, or to such gaoler, keeper, or turnkey as the case may be, which affidavit may be made before any judge or commissioner of the said court authorized to take affidavits in the said court, to cause an appearance and the plea of not guilty to be entered in the said court to such indictment or information for such person, and such proceedings shall be had thereupon as if the defendant in such indictment or information had appeared and pleaded not guilty according to the usual course of the said court; and if upon the trial thereof the defendant so committed and detained shall be acquitted of all the offences charged thereupon, he, the judge before whom such trial shall be held, although he may not be one of the judges of the king's bench, may order the defendant to be forthwith discharged out of custody as to his commitment as aforesaid, and such defendant shall be thereupon discharged.

Concerning the execution of the process, it is laid down as a general rule, that wherever the king is a party to the suit (as he certainly is to all informations and indictments), the process ought to be executed by the sheriff himself, and not by the bailiff or any of his officers. (2 Hawk. c. 27.) And if the party be in a house, if the doors be shut, and the sheriff (having given notice of his process) demand admittance, and the doors be not opened, he may break open the doors, and enter to take the offender. (2 H. H. 202.) But no peron, on the Lord's day, shall serve, or cause to be served, any writ, process, &c. except in cases of treason, felony, and breach of the peace, 29 Geo. II. c. 7.

The difference between process and precept, or warrant of the justices, is this; that the precept or warrant is only to attach or convene the party, before any indictment or conviction, and may be made either in the name of the king or the justice: but process is always in the king's name, and, usually, after an indictment.

Obstructing the execution of lawful process is a high offence; particularly when it is an obstruction of an arrest upon criminal process. And it hath been held, that the party opposing such arrest, becomes thereby particeps criminis, i.e. an accessory in felony, and a principal in high treason. 1 Hawk. P. C. 12. Blackl. Com. vol. iv.

Process by Attachment. See Attachment.

Process by Attainder. See Attainder.

Process of Outlawry. See Outlawry.

Process, in Anatomy. See Processus.

Process, in Chemistry, the whole course of an operation, or experiment.

PROCESSION. Processio, in Theology, a term used for the manner in which the Holy Spirit is conceived, by some divines, to influe from the Father and the Son, in the mystery of the Trinity.

The Greeks and Latins are not agreed about the process of the Holy Spirit.

Procession also denotes a ceremony in the Roman church, confinuing in a formal march of the clergy in their robes, and the people after them, putting up prayers, singing hymns, &c. and in this manner making a visit to some church or other holy place.

There are general processions of all the people in jubilees, and the same often in public calamities. The processions of the holy sacrament are very solemn. They have also processions, frequently around the church, at the eulogies, &c. in the mass. Anciently, among us, there were, in every fifth, or some annual procession of the parih-priest, the patron of the church, with the chief flag, or holy banner, attended by the other parishioners, each Ascension week, to take a circuit round the limits of the parish, and pray for a blessing on the fruits of the earth. Of which custom there still remains a shadow in that annual perambulation, still called procession; though the order and devotion of the ancient processions be almost lost.
PROCESSUM CONTINUANDO, in Law, a writ for the
continuance of a process, after the death of the chief justice,
or other justices in the commission of oyer and terminer.
Reg. Orig. 128.

Records & Processus mittendis. See Recordo.

PROCESSUS, Process, in Anatomy, a term applied to
many parts of the body, but more particularly in the
bones, and usually denoting a prominence. They are too
numerous to admit of our enumerating them here.

PROCESTRIA, among the Romans, buildings adjoin-
ing to camps, especially winter quarters, or standing camps,
where futters, strangers, traders, and others that followed
the army refided; for they were not permitted to mix with
the soldiers, unless when the enemy was near.

PROCHARISTERIA, Proxisterius, in Antiquity, a
solemn sacrifice which the Athenian magistrates yearly of-
fered to Minerva, when the spring first began to appear.

PROCEHILA, formed of cepis and Cicada, Ip., a word
used by some authors to express the extremities of the
lips.

PROCEHN AMY, Proximus amicus, in Law, the
nearest friend, or person next akin, to a child in nameage;
and who, in that respect, is allowed in law to deal and
negociate for him, to manage his affairs, to see him redressed
of any wrong, and to be his guardian, if he hold land in
focage.

By prochein amy is commonly understood the guardian
in focage: though, in propriety, it is he who appears in
court for an infant who sues any action, and aids the
infant in pursuance thereof. For, to sue, an infant is not al-
lowed to make an attorney; but the court will admit his
prochein amy, next friend, as plaintiff; or his guardian as
defendant.

PROCHYMA, a word used by the ancients to express
that kind of myct which flows spontaneously from the
grapes without their being pressed.

PROCIDACA, in Natural History, a name given by
Somme to the insect which the French call procyaga. It
reminds the cicada in most respects, but it has not the power
of making the noise that insect does.

PROCIDA, John vi, in Biography, a native of Salerno,
and lord of the isle of Procida, on the coast of Naples, was
a physician by profession, and became a counsellor to Fre-
deric II. and Manfred, kings of Sicily. By Charles of
Anjou he was deprived of his silt and employment under
pretence of treason, and his wife having been debauched by
one of the French who accompanied Charles, he narrowed
a rooted hatred to that nation, and resolved upon revenge.
He visited Sicily disguised in a Franciscan habit, where he
concerted a plan for a revolution with the principal mal-
ccontents. Hence he went to Constaninople, where he held
a confutation with the emperor Paleologus, and obtained
from him a stipple of money. He next proceeded to Rome,
where he readily persuaded pope Nicholas III., who was an
enemy of Charles, to concur in the enterprise. When the
conspiracy was brought to maturity he repaired to Palermo,
where, on Easter Monday 1282, the massacre began, which
ended only in the complete extirpation of the French from
the island of Sicily. The circumstances of this dreadful
tragedy are thus related by contemporary authors. The chief
conspirators had, on that day, assembled at Palermo, where,
in the afternoon, they joined with the French in a procession
to the church at some distance. A bride with her retinue
happening to pass by, a Frenchman went up and began to
take indecent liberties with her. He was stabbed on the spot
by an enraged Sicilian, which became the signal for the general
massacre, that extended to all the French in Palermo, and
hence spread over the whole island. Other accounts say
that the massacre began on the ringing of the bell for vespers,
and hence it has obtained the name of the Sicilian vespers.
It is agreed by all, who have touched on the subject, that it
was conducted with the most fangurious ferocity, neither
sex nor age being spared, nor even the progeny of Sicilian
mothers by French fathers. One man alone, viz. William
de Porculo, a Provençal gentleman, and governor of a
town, was dimified unhurt, in consequence of the high re-
spect inspired by his many virtues. After this Charles made
an unsuccessful attempt to recover Sicily, which was posted
by Peter of Arragon, and after his death by his son James.
John of Procida continued in the service of these kings, and
was sent by the latter to Rome in 1289, to reconcile Sicily
to the holy see, but without effect; he refused his negotia-
tions in 1295, under Boniface VIII.; and, in short, he ac-
companied the dowager queen Constanza to Rome, where
he ended his days. Morei.

PROCIDA, or Proculo, in Geography, an island in the Me-
diterranean or Tuscan sea, near the coast of Naples; about
five or six miles in circumference. In the thirteenth cen-
tury it belonged to John of Procida, who was guilty of the
notorious massacre of the French in Sicily. The shore
is in general high and rocky; its small sea-port, of the same
name, is populous and commercial: some of the streets, as
well as the roads, are paved with lava. Shepstands abound,
and to prevent their destruction the inhabitants are forbidden
by law to keep cats; so that the island is overrun with rats
and mice, which are dangerous to infants in the cradle; and
dogs also are prohibited. N. lat. 40° 50'. E. long.
13° 48'.

PROCIDENTIA, and Prolapus Uteri, a troublesome
decent or bearing down of the womb, which, if not restrained,
and kept up by art, would in time appear outwardly. See
Bearing down of the Womb.

PROCIDENTIA AMY, in Surgery. See Prolapus Ani.

PROCIDENTIA Oculi. See Exophthalmia.

PROCIDENTIA Uteri. See Prolapus Uteri.

PROCIDENTIA VAGINA. See Vagina.

PROCOIGALE, in Natural History, a name given by
Reaumur, and from him by all the French naturalists, to a
species of four-winged fly, greatly resembling the cigale, or
 cicloca, but wanting its powers of making a noise.

This creature has a trunk of the same form with that of
the cicada, very long, and laid closely upon the belly, and
contained in a case of the same structure with that of this
insect. The female has also the same instrument
at its tail, prepared for boring holes in wood, and
called in that creature the piercer, and it uses it to the fame
purpose, depositing its eggs by means of it in the branches
of trees.

There is also another very small insect mentioned by Rea-
umur, as reducible to this class, if properly of the fly kind;
but its smallness makes the structure of its wings scarcely
distinguishable with any degree of accuracy; and it is hard to
determine whether it has four wings, or two wings and two
cases of wings. This little fly is extremely common on rose-
trees; its wings are yellowish, and its body white; and it
is capable of as well as fly. It is hardly possible to find a rose-
tree in the summer months that is not loaded with these in-
serts, and they are principally found about the extremities

PROCIDYNEUONTES, among the Romans, a designa-
tion given to the velites, because they
were most exposed to danger. The term answers to what
we call the forlorn-hope.

PROCIA,
**Prockia**, in Botany, received its name from the celebrated Browne, who communicated to the genus to Linnaeus, by letter, from America.—Linn. Gen. 271. Schreb. 363.

Gen. Ch. Cal. Perianth inferior, of three leaves (occasionally with two very small leaves at the base). Cor. none. Stam. Filaments numerous, capillary, the length of the calyx; anthers roundish. Fijil. German superior, roundish, slightly five-sided, style thread-shaped, the length of the stamens; stigma bluntish. Peric. Berry with five angles. Seeds numerous.

Obs. From a variation in shape of the style and stigma in some species of *Prockia*, Vahl and Swartz were induced to establish a new genus, which they call *Lightfootia*; but we are inclined to think with Willdenow and Lamarck, that this is not a sufficient difference to authorize such a step. Jussieu confers *Prockia* nearly allied to *Lactia*.

Eff. Ch. Calyx of three leaves, besides two leaves at the base. Corolla none. Berry with five angles, and many seeds.

1. P. Cruciata. Linn. Sp. Pl. 745. Vahl. Symb. v. 3. 69. t. 64.—Leaves heart-shaped, ovate, toothed. Flowers-falks terminal, somewhat racemose.—Native of Santa Cruz. The branches of this shrub are round, smooth, and purplish. Leaves alternate, flaked, smooth, three-ribbed. Stipulas fiddle-shaped, tapering, toothed, deciduous. Flowers about four or five in a cluster, at the ends of the branches. Berry the size of a pea, terminated by the permanent style.

2. P. deltoidea. Lamarck Dict. v. 5. 626. Illustr. t. 465. f. 3.—Leaves roundish or deltoidea, notched. Flowers lateral, mostly solitary.—Native of the Isle of France, where it was gathered by Commeron. Branches slender, waved at their tops. Leaves alternate, flaked, smooth; the lower ones deltoid, a little pointed; the upper smaller, entire at their base. Flowers lateral, solitary, occasionally two or three together. Fruit oval.

3. P. theiformis. Willd. n. 3.—Leaves lanceolate-elliptical, serrated, blunting. Flowers-falks axillary, mostly solitary, sgle-flowered.—Native of the Isle of Bourbon. Branches alternate, furrowed, greyish. Leaves alternate, flaked, leathery, smooth on both sides. Flowers lateral, solitary, on long, smooth falks. Fruit nearly globular, furred by a few lobed style, and therefore, like the following, referred by Vahl to *Lightfootia*.

4. P. integrifolia. Willd. n. 4.—Leaves somewhat coriaceous, oblong or obovate, emarginate, nearly entire. Flowers-falks generally crowded together, single-flowered.—Native of the Mauritius. Branches cylindrical, smooth, ashy-coloured. Leaves alternate, flaked, pale green. Flowers axillary, sometimes many together at the axils of the upper leaves. Fruit oval, about the thickness of a very small hazel-nut.

5. P. ovoata. Lamarck Dict. v. 5. 626. Illustr. t. 465. f. 2.—Leaves oblong-falked, ovate. Flowers solitary, in a form of umbel.—Native of the same country. This new species of Lamarck's is distinguished by its obtusely oval, long leaves, notched with fiddle-shaped teeth at their edges, marked with lateral, parallel nerves, and flaked. Flowers forming an umbel. Fruit oval, small.

Native of Montserrat and the Mauritius. The branches of this shrub are round, warty and ashy-coloured. Leaves alternate, flaked, smooth on both sides. Flowers of a pale colour, small. Fruit resembling a black currant. This species is occasionally dioecious.

7. P. laciniata. Lamarck Dict. v. 5. 627. —Leaves very smooth, oblong-lanceolate, laciniated, very narrow.—Native of the Isle of Bourbon, from whence it was sent to M. Lamarck under the name of *P. tribulata*, who tells us the flowers of this species are unknown, so that it cannot with certainty be referred to the present genus.

**Proclamation**. Declaration, an instrument dispatched by the king, with the advice of his privy-council, whereby the people are advertised of something which his majesty thinks fit for them to know; and by which they are sometimes required to do, or not to do, certain things.

The word is of Latin origin, formed from *proclamare palam* & valde clamare.

Proclamations have the force of laws; but then they are supposed to be conformable with the laws already in being; otherwise they are superceded.

Thus, the established law is, that the king may prohibit any of his subjects from leaving the realm; a proclamation, therefore, forbidding this in general for three weeks, by laying an embargo upon all shipping in the time of war, will be equally binding as an act of parliament, because founded upon a prior law. But a proclamation to lay an embargo in time of peace upon all vessels laden with wheat (though in time of a public scarcity), being contrary to law, and particularly to statute 22 Car. II. cap. 13, the advisers of such proclamation, and all persons acting under it, found it necessary to be indemnified by a special act of parliament, Geo. III. cap. 7.

By the statute 31 Hen. VIII. cap. 8 it was enacted, that the king's proclamations should have the force of acts of parliament, a statute, says Judge Blackburne, which was circulated to introduce the most despotic tyranny, and which must have proved fatal to the liberties of this kingdom, had it not been happily repealed in the minority of its successor.

Promulgation is also used for a solemn denunciation, or declaration of war or peace.

War is an evil, and besides its being undertaken on just grounds, those who are concerned should take every method in their power for preventing it. Accordingly they should endeavour, by declaring their intentions to have recourse to the last remedy against injustice, by the use of open force, to impress the minds of their adversaries, and to excite fear, in order to induce them to adopt equitable and pacific measures. Such is one end of declaring or proclaiming war, after other means of securing uninterrupted conciliation have been ineffectual. This was the mode of proceeding adopted by the Romans, according to the regulations of their "Fecial" law. They first sent the chief of the "Feciales," or heralds, called "Pater patratus," to demand satisfaction of the people who had offended them; and if, within the space of 33 days, a satisfactory answer was not returned, the herald called the gods to witness of the wrong, and came away saying, that the Romans would consider what they had to do. The king, and afterwards the confederated...
used to ask the senate's opinion, and war being resolved on, the herald was sent back to the frontier, where he declared it.

A declaration of war being necessary as a farther trial for terminating the difference without the effusion of blood, by making use of the principle of fear for bringing an enemy to more equitable sentiments; it is, at the same time that it declares the resolution taken of making war, to set forth the cause of that resolution. This is, at present, the constant practice among the powers of Europe. After a fruitless application for justice, a nation may proceed to a declaration of war, which is then pure and simple. But if it be thought proper to avoid making it two several times, the demand of satisfaction, which the Romans called "rum repetitio," may be accompanied by a conditional declaration of war, notifying, that if justice be not done without delay, an immediate war will be the consequence. And then there is no need of a pure and simple declaration of war, the condition being sufficient, if the enemy delay to give satisfaction.

If the enemy, on either declaration, offer equitable conditions of peace, the war ought to be suspended, for when justice is done, all right of employing force is superseded, the use being permitted only for the necessary support of right. To these offers, however, are to be added securities; for we are under no obligation to suffer ourselves to be abused by empty proposals. The word of a sovereign is a sufficient security, whilst he has not disgraced his credit by any act of perfidy; and we should be content with it. As to the conditions in themselves, besides the essential subject, a reimbursement of the expenses may likewise be demanded in regard to the preparations.

The declaration of war must be known to the state against which it is made. This is all which the law of nations requires; yet custom having introduced some formalities, those nations which, by adopting the custom, have given a tacit consent to the formalities, are under an obligation of observing them, till they have publicly renounced them. Formerly the powers of Europe used to lend heralds or ambassadors to declare war; at present this is only done in the capital, the principal towns, or on the frontiers; ministers are appointed, and the communication, so easy and expeditious since the establishment of posts, soon spreads the intelligence.

Besides the foregoing reasons, it is necessary for a nation to publish the declaration of war for the instruction and direction of its subjects, in order to fix the date of the rights belonging to them from the moment of this declaration, and relatively to certain effects which the voluntary law of nations attributes to a war in form. Without such a public declaration of war, it would be difficult to settle, in a treaty of peace, those acts which are to be accounted the effects of the war, and those which each nation may consider as wrongs, for obtaining reparation. He who is attacked, and makes only a defensive war, need not declare it; the state of war being sufficiently determined by the declaration of the enemy, or his open hostilities. An act of aggression may, in some cases, be considered as a declaration of war. However, either from dignity, or for the direction of his subjects, a sovereign, though attacked at present, seldom fails of declaring war in his turn. If a nation against which a war has been resolved, will not admit any minister or herald to declare it, whatever the custom otherwise be, it is sufficient for the other nation to declare it within its own territories, and on the frontier, and if the declaration does not come to its knowledge before hostilities are commenced, the former can only blame itself. But no person being excepted from his duty, only because another has been wanting in his, we are not to omit declaring war against a nation because hostilities are commenced, because this nation had, on another occasion, attacked us without any declaration. That nation, in so doing, has violated the law of nature; and its fault is no warrant for us to be guilty of the like.

The law of nations does not impose the obligation of declaring war, for giving the enemy time to prepare itself for an unjust defence. The declaration need not be made till the army has reached the frontiers; it is even lawful to delay it till we have entered the enemy's territories, and occupied an advantageous position; yet it must always precede the commission of any hostility. Thus we provide for our own safety, and equally secure the end of the declaration of war, which is, that an unjust adversary may still seriously consider his measures, and avoid the horrors of war, by doing justice.

A sovereign who has entered a country, and declared war, may proceed to military operations; but, at the same time, the only legitimate cause of war (see War) should not be forgotten. The sovereign that declares war can detain neither those subjects of the enemy that are within his dominions at the time of the declaration, nor any of their effects; because they came into his country on the public faith. He should therefore allow them a reasonable time for withdrawing their persons and their property.

A sovereign should make the declaration of war public, not only to his own subjects, but also to neutral powers. This is necessary to vindicate his conduct in their estimation of it, as well as to obviate all difficulty, with regard to those commodities which neutral nations are carrying to the enemy, and which, in time of war, are called contraband. Declarations of war should either themselves express, or be accompanied with manifestoes that announce the reasons that induce and justify recurrence to arms, and also those general orders that relate to the conduct of the subjects of the state during the progress of the war. In a civilized age it may, perhaps, be thought unnecessary to observe, that in all publications of an authoritative kind, and that issue from the press under the sanction of government, all opprobrious words are to be avoided, together with every expression that indicates hatred, animosity, and rage, because they only degrade those who use them, and excite similar sentiments in the minds of the enemies.

Grotius says, that, according to the law of nations, two things are required to make a war solemn, or in due form, 1. That on both sides it should be by authority of the sovereign; 2. That it should be accompanied with certain formalities. These formalities consist in the demand of a just satisfaction, (rum repetitio,) and in the declaration of war, at least on the part of him who attacks, defensive war requiring no declaration, nor even, on urgent occasions, so much as an express order from the sovereign. Vattel's Law of Nations, b. iv.

Proclamation also denotes the act of notifying to the people the accession of a prince to the crown. The proclamation does not invest the prince with the regal authority; it supposes him already invested with it, and only gives notice of it to the people.

Proclamation of Estray. See Estray.
Proclamation of Exigent. See Exigent.
Proclamation of Attachment. See Attachment, and Commis of Rebellion.
Proclamation of a Fine, is a notice openly and solemnly given of it in the court of common-pleas, where it passed, and at all the assizes in the country, held within one year after the enacting it. See Fine.

These proclamations, at the assizes, are made on transcripts of the fine, sent by justices of the common-pleas to the justices of the assize, and of the peace.
PRO

PROCLUS, in a cafe of viot. See RIOT.

PROCLUS, in a Monastic Sense, is the acclamation of a friar or brother, by another brother, in open chapter, and in presence of the superior and community, for some external crime he has seen him commit.

PROCLUS, Writ of. See EXIGENT.

PROCLUS, in Biography, an eminent mathematician and philosopher of the Eclectic school, was born at Constantinople in the year 410 of the Christian era. He was instructed in grammar learning at Xanthius in Lycia, and from thence he was sent to Alexandria, where he studied eloquence and polite literature, with a view to qualify himself for the profession of the law. He, however, soon abandoned this, for the pursuit of the sciences properly so called. He learnt philosophy under Olympiodorus, and mathematics under Hero, and was distinguished by quickness of conception, and great strength of memory. He acquired a high reputation among his fellow students, by being able, at all times, to give them an accurate summary of the arguments of their master. After spending several years in the Alexandrian schools, Proclus went to Athens, where he first became acquainted with Syrian, to whom he attached himself. By him he was introduced to Plutarch, the son of Nellorius, an eminent teacher of the Eclectic philosophy, by whom he was conducted into the more recondite mysteries of the doctrine. Among other means of improvement he derived great benefit from the practice recommended by Plutarch, of drawing up, from his own recollection, compendious abridgments of the lectures which he had heard from his preceptor. Of his laborious application he afforded evidence at the age of twenty-eight, by having then written, besides several other pieces, his “Commentary on the Timæus of Plato,” abounding with much learning of the times. He was instructed by Plutarch’s daughter in the arts of divination, who inherited from her father many secrets of this kind. By these helps, and the diligent perusal of the writings of Plotinus, Porphyry, Jamblicus, &c., he became a complete master, not only of divine science, but of Theurgic powers. He hence became accomplished as a preceptor in the Alexandrian philosophy, and Syrian associated him with himself in the Platonic chair at Athens. It is said that he excelled all his predecessors in this department, and improved the Eclectic system by many new discoveries, and was the author of many opinions which had never before entered the mind of man, both on the subject of physics, and in the sublime science of ideas. His powers were highly extolled; he practised rigorous fasting, and spent whole nights and days in repeating prayers and hymns, that he might thereby prepare himself for immediate intercourse with the gods. He died when he was about the age of 83 years. In his writings, Dr. Enfield says he appears at once a man of learning and a fanatic. They contain a rude and undigested mass of materials, collected with bold variations from the Chaldæan, Orphic, Hermetic, Pythagoric, Platonic, and Aristotelian doctrines, and adorned with fictitious and allegorical, which, while they involve the subjects upon which the writer treats in thick darkens, discover great luxuriance of imagination. Among the works which Proclus left behind him are, books “De Providentia et Fatou,” “De decem Dubitationibus circa Providentiam;” and “Malorum Substantia;” Latin versions of which, from the Greek, were given by William de Morbek, chaplain to the archbishop of Corinth. Godfrey Olearius, and Hugo Grotius, published Latin versions of his Hymns to the Sun, to the Muses, and to Venus. His work “De Sphæra, five Circulae Cælestibus Libellus,” was copied in part from the Hageoge of Geminus, an astronomer of some distinction in the time of Cicero, and frequently published, but in its best form by Bainbridge, Savilian professor of astronomy at Oxford, in 1620. Many other pieces are enumerated in Enfield, some as published, some as still existing in M., and others no longer extant.

PROCONDYLUS, Πρωνιος, an appellation given to the first point of each finger. See EXTERMINITY.

PRO-CONFESSO, in Law. When, upon a bill exhibited in chancery, the defendant appears, and is in contempt for not answering, and in custody; upon an habeas corpus (which is granted by order) to bring him to the bar, the court affixes him a day to answer; which being expired, and no answer put in, a second habeas corpus is granted, and a farther day assigned; by which day, if he answer not, the bill upon the plaintiff’s motion shall be taken pro-confesso, or as allowed, unless cause be shown by a day, which the court usually gives. For want of such cause showed, upon motion, the substance of the plaintiff’s bill should be decreed, as if it had been confessed by the defendant’s answer; or, after a fourth insufficient answer made to the bill, the matter of fact not sufficiently answered unto, shall be taken pro-confesso.

By fl. 5 Geo. II. c. 25, it is enacted, that in order to prevent a defendant’s eluding justice, by abscending to avoid a subpena, where the defendant cannot be found to be served with process of subpena, and abscends (as is believed) to avoid being served with it, a day shall be appointed him to appear to the bill of the plaintiff; which is to be infested in the London Gazette, read in the parish church where the defendant last lived, and fixed up at the Royal Exchange; and if the defendant does not appear upon that day, the bill shall be taken pro-confesso.

PROCONNESIUM MARBOM, a name given by the ancients to a species of marble, called also neius and elpctrineus, and by the Cyzicium, from the works of a famous flatuary of that name, many of which were made of it. It was of a blueish white, slightly variegated with black; this colour usually running in small veins, and not unaptly resembling, in many instances, the course of the veins of a human body in the naked statues. It was also used in the fumptuous buildings of the Romans. See MARBLE.

PROCONSUL, a Roman magistrate, sent to govern a province, with a confular authority.

The proconsuls were appointed out of the body of the senate; and ordinarily, as the year of any one’s consular expiring, he was sent proconsul into some province.

The proconsuls had the same honours, &c., with the consuls themselves; except that they had only a letter and fasces before them.

The proconsuls did not ordinarily hear and determine processes in person, but had that office performed by their auxiliaries, or other judges, constituted or delegated by them.

As the proconsuls had the direction of justice, of war, and of the revenues, they had their several lieutenants in each capacity: these were called legati, and were ordinarily nominated by the senate.

The proconsular function only held a year. The charges of their journey, backwards and forwards, were borne by the public, and were called viaticum.

After the partition of the provinces between Augustus and the people, those who presided over the provinces of the people were called especially proconsuls. See Prefect.

Livy, lib. viii. and lib. xxvi. mentions two other sorts of proconsuls; viz. such as being consuls had their office prolonged beyond the time settled by law; and such were
were invested with this honour, either for the government of the provinces, or the command in war, who before were only in a private station. We also read of such as the senate created proconsuls without a province, merely for the command of the army, and the care of the military discipline; and such as entered on their proconsular office before they were admitted to the consulship, though deprived for this honour.

Proconsul, in our Ancient Law Books, is sometimes used for a justice in eye, or justice erant.

Procopius, in Biography, one of the later Greek historians, was a native of Cariaca in Palestine, where he obtained a high reputation as professor of rhetoric, and whence at length he repaired to Constantinople. In the reign of Justinian he engaged the confidence of the great general Belisarius, who made him his secretary, and took him in his company to the campaigns in Asia, Africa, and Italy. The emperor honoured him with the title of Illyricus, and raised him to the office of prefect of Constantinople. What his religion was is not certainly known, but Gibbon supposes he has been an occasional conformist to Chalcedony, with a secret attachment to paganism and philosophy. He died about the year 560.

Procopius was the author of a "History," in eight books, of the public events of his own time, divided into the Peric war, comprised in two books; the Vandals, in two books; the Gothic, in three: there is an eighth book, which is supplemental and miscellaneous, and comes down to the year 553. It is an elaborate and exact performance: the facts are collected from personal observation or enquiry, and are related with freedom, and intermixed with useful reflections. The characters of the different barbarous tribes which pressed upon the declining empire, are strongly painted. To these he afterwards added a ninth book, which is entitled "Anecdota," or Secret History; and in this Justinian and his empress, Theodora, are drawn with the most odious features; and of the latter, in particular, stories are told, which are a scandal to her sex, as well as to her high station. The books of Procopius on the Gothic war were published by Leonardo Aretino, in Latin, as his own, in 1470. His works were mutilated by the first Latin translators, and the Greek was not printed till 1607. A Paris edition was published by the Jefuit Claude Maltré in 1663, in two vols. fol. Gr. et Lat. with the omission of most of the anecdotes. These were afterwards published by Monnoye in the first volume of the Menagiana. Moreri, Gibbon.

Procopius-Rasa, or the Shorten, a famous leader of the Hufites in Bohemia, was, in early life, sent to study, and afterwards travelled in France, Italy, Spain, and the Holy Land. On his return he was obliged, against his will, to receive the tonsure, and it is said to be ordained priest; but when the war of religion in Bohemia broke out, he joined the Hufites under their great leader Ziska, and displayed so much courage and ability, that he obtained the confidence of that leader and of the party. After the death of Ziska in 1434, Procopius succeeded to the command of the Hufites, who were making war upon the Catholics with all the ardour of enthusiasm, exasperated to savage ferocity by the perfecution they had undergone. He obtained very great successes, and spread terror throughout a large part of Germany. The emperor Sigismund sent deputies in 1438 to treat with him, and Procopius professed himself willing to make peace, and even to procure Sigismund's election to the throne of Bohemia, provided the religious grievances of his party should be redressed, and the privileges of the country confirmed. An evasive answer being returned, arms were again resumed, and the Hufites laid waste Mihnia with fire and sword, and extended their ravages to the surrounding countries. When the council of Basile was convoked in 1435, Procopius issued a circular letter in Latin, addressed to all the sovereigns and states, setting forth the complaints of his party, and proposing a disputation between the Catholic and Hufite doctors on scripture grounds. In reply to which a crusade was published against the Hufites, and an imperial army marched into Bohemia, which ravaged all the barbarities of that party, but being alarmed at the approach of the heretic forces, fled with precipitation, bearing all their baggage and rich furniture as spoils to the enemy. In 1433 Procopius and some of the other leaders held several disputations without effect with the Catholics, and on their return hostilities were renewed. Procopius laid siege to Pilzen in Bohemia, but was obliged to raise it with great loss in 1434. He soon afterwards received a mortal wound, and died, leaving a name in his party for the greatness of his exploits, and the ferociousness of his manners. Some of his letters have been published in the last volume of the collection of ancient documents by Martenue and Durand. Univer. Hilt. Moreri.

Procopius of Gaza, celebrated as a scripture commentator, flourished under the reign of the emperor Justin I. He professed with great reputation over a rhetorical school in Gaza of Palestine, whence he derived his surname. There is still extant an eloquent funeral oration in praise of his talents and virtues, pronounced by Choricrus, his disciple and successor, when the infortunes of age obliged him to resign the rhetorical chair. This oration was published with a Latin version, by John Chriftian Wolf, and is inserted in the eighth volume of Fabricius's "Biblotheca Græca." Procopius applied himself to the study of the orthodox fathers and commentators of the holy scriptures, and he himself compiled commentaries on various books of the bible, which are now frequently referred to, and which are executed with considerable judgment, as well as in a polished style, and have been useful to succeeding writers. Thofe given to the world consist of "Commentaria in Ezechiel," published in Asia Minor in 1555: "Scholia in Quatuor Libros Regum et duos Chronicorum," translated into Latin from the Greek by Lewis Lavater, and published in Greek and Latin at Leyden: and "Variorum in Efsiam Prophetae Commentarium Epitome," 1580. It is not known whether he was the author of "Letters" written in an elegant style, in the collection of Greek Letters printed by Aldus, and ascribed to Procopius the sophist, or whether they were written by Procopius the historian. Moreri.

Procreation, Procreatio, the action of begotting and bringing forth children. See Generation.

Procus, in Botany. See Elastostoma.

Proctalgia, Proctitis, in Medicine, from πρόκτος anus, and ἁρπάζω, pain, a term employed by Sauvegrain to denote the varieties of disease affecting the anus, of which he enumerates several species, including inflammation, cancer, fistula, intertrigo, rhagades, hemorrhoids, prolapsus... Nefol. Method. clafs vii. gen. 32. The various kinds of inflammation and abscesses affecting this part of the body, are treated of in the article Fistula.

Proctor, Procurator, a person commissioned to act as proxy, or delegate, in behalf of another. See Procurator.

Proctor, Procurator, in the Civil Law, is an officer appointed...
pointed to appear in court, and manage the causes of parties who will make use of his procuration.

Anciently every body was obliged to appear in person; and when the affair happened to be drawn out to a great length, they were allowed to create a proctor, or proxy, in their cause. See Attorney.

But this was a favour only granted for a certain time, till towards the middle of the sixteenth century, when it was decreed, that all procuration should hold till revoked.

Proctors in the Common, are persons skilled in the civil and ecclesiastical laws, who exhibit their proxies, and make themselves parties for their clients, to draw up acts and pleadings, produce witnesses, prepare causes for sentences, and attend the advocates with the proceedings. They are about fifty in number; are admitted by the archbishop's fiat; and wear black robes, and hoods lined with white furs.

By 3 Jac. c. 5. no reascant convict shall præstiss in the civil law as proctor; but this was repealed by 31 Geo. III. c. 32, which introduces a new oath to be taken by Roman Catholics præstiss in the law; and by 5 Geo. II. c. 18, no proctor in any court shall be a justice of the peace, during such time as he shall continue in the business and practice of a proctor. Moreover, by 48 Geo. III. c. 149, every admission of any person to the office of proctor in any of the courts shall be upon a 2ol. 1amp. And every præstiss solicitor, attorney, notary, proctor, agent, or procurator, must take out a certificate annually; upon which there shall be charged, if he reside in the city of London or Westminster, or within the limits of the two-penny pot, in England, or within the city or town of Edinburgh, and shall have been admitted to his office three years, 10l.; if not so long, 5l. If he shall reside elsewhere, and have been admitted three years, 6l.; if not so long, 3l.

Proctor of the Clergy, are deputies, or representatives, chosen by the clergy of each diocese, two for each; and by the cathedral and collegiate churches, one for each, to fit in the lower house of convocation.

Proctors in the University, are two officers chosen from among the students, to see good orders and exercize daily performed there.

Proctor's Creek, in Geography, a river of Virginia, which runs into James river, N. lat. 37° 24'. W. long. 77° 36'.

Proctor's Point, a cape on the S. coast of the island of Antigua, E. of Falmouth harbour. N. lat. 17° 8'. W. long. 61° 29'.

Procubitores, among the Romans, an appellation given to the velites, baccal, when the enemy was near, they always formed the outguard.

Proculians and Sabini, in Antiquity, two famous sects which divided the Roman jurisprudence, forming two schools, and deriving their respective appellations from aulus Capito and auctius Labeo, belonged to these schools, which thus maintained their inveterate conflict from the age of Augustus to that of Adrian.

Proculls, in Geography, a town of Prussia; 10 miles S.S.E. of Memel.

Procumbent Leaves, in Botany, such leaves of plants as lie flat, or trailing on the ground.

Procunia, in Geography, a town of European Turkey, in Servia, formerly the capital of Dardania; the see of two archbishops, one Rafaian, the other Latin; 16 miles W. of Niia. N. lat. 43° 30'. E. long. 21° 50'.

Procuration, or Procuracy, an act or instru-

ment by which a person is empowered to treat, transact, receive, &c. in another's name, as if he himself were actually present.

When a man treats in behalf of another, the first thing is to examine his procuration or procuration.

Procuration is now little used in this sense, except in the case of a person who collects the fruits of a benefice for another.

Procuration, in the Canon Law, is used for the repast, or entertainment, annually given to church officers, or ordinaries, who came to visit in churches or monasteries, whether they were bishops, archdeacons, or visiting. Procuration was due to the pope's legate, and even to popes themselves, when they came into France; and the charge was comprised in the bulls then granted.

Complaints were frequently made to the pope of the excessive charges of the procurations of bishops and archdeacons; upon which they were prohibited by several councils and bulls.

That of Clement IV., mentioned in the Monastic, is very express; in which that pope tells us, complaint had been made, that the archdeacon of Richmond, visiting the diocese, travelled with one hundred and three horses, twenty-one dogs, and three hawks; and did grievously oppress a religious house with that vast equipage, that he caused the monks to spend in an hour as much as would have maintained them a long time.

Procuration is now used for a sum of money paid yearly by parish-priests to the bishop or archdeacon, in lieu of this entertainment, towards defraying the charge of their visitation.

These procurations were anciently such extravagating and oppressive, that several constitutions were framed by Langton and others to restrain them. • The last constitution of this kind by Stratford, by putting it in the choice of the incumbent, whether he would entertain the visitor in provi-
sions, or compound for it by a certain sum of money, was the cause of the custom generally prevailing afterwards, and which now universally obtains, of a fixed payment in money, instead of a procuration in meat, drink, provender, and other accommodation.

Procuration is due to the person visiting, of common right; and though originally due by reason of visitation only, yet the same may be due without actual visitation. The constitutions to which we have above referred, limit the payment, in provisions or money, to actual visitation, and warrant the denial of them when no visitation is held. Upon this a doubt has been raised, whether those archdeacons who are not permitted to visit, but are inhibited from doing it in the bishop's triennial visitation, have a right to require procurations for that year. Those who maintain the negative, found their opinion upon the express letter both of the ancient canon law, and of our own provincial constitutions. But others, who undertake to defend the rights of the archdeacons, allege, that though it might be reasonable that they lose their procurations, in case they neglect their office of visiting (which, by the way, was all that the ancient constitutions meant), yet that reason doth not hold, when they are restrained and inhibited from it; and that procurations are rated in the valuation of king Henry VIII., as part of the revenues of every archdeacon, who therefore pays a certain annual tenth for them; and the law could never intend the payment of the tenth part every year, if there had been any year in which he was not to receive the nine parts. These two arguments (says Dr. Gibson) are so strong in favour of the archdiocesan right,
right, the first in reason, and the second in law as well as reason, that it is needless to say more on that head.

Procurements are facultative only in the spiritual court, and are merely functions of the court of law. (L. Raym. 450.) And they may be levied by sequestration, or by other ecclesiastical process. (Gibb. 1546.) By the law of the spiritual court, forty years make a custom or prescription. (1 Peere W. 657. Str. 421.) If there be a parsonage and vicarage, or an endowment, only one is to pay procurations, but custom, or the endowment if extant, directs which of them is payable. Such a chapel as shall be included in the procuration of the mother church. (Lind. 223. Deg. p. 2. c. 15.) Churches newly erected shall be rated to procurations, according to the proportion paid by the neighbouring churches. (Gibb. 976.) Donatives and free chapels pay no procurations to any ecclesiastical ordinary, because they are not visitable by any. Deg. p. 2. 15.

Procuration, in Commerce, &c. When exchange is made in the name and for the account of a third person, by virtue of full power, and authority given by him, commonly termed "procuration," such bills (of exchange) may be drawn, subscribed, indorsed, accepted, and negotiated, not in the name or for the account of the manager or transferee of any or all of these branches of remittances, but in the name and for the account of the person who authorized them. See Power of Attorney, and Bills of Exchange.

PROCURATOR, Proctor, or Proxy, a person who has a charge, or office committed to him, to act in behalf of another. Thus the proxies of the lords in parliament, in our lawbooks, are called procurators.

The word is also used for a vicar, or lieutenant. Thus, in Petrus Blemensis, we read of a procurator regni.

Those who manage causes in Doctors' Commons, are also called procurators or prorogers.

The bishops are sometimes called procuratores eccelestiarum, and the representatives sent by the clergy to convocation, procuratores clerii.

In our statutes, a person who gathers the fruits of a benefice for another, is particularly called a procurator, and the instrument empowering him to receive the same, is termed a procuration.

Procurator is also a kind of magistrate, in several cities of Italy, who takes care of the public interests. There are procurators of St. Mark at Venice, at Genoa, &c.

Originally there was but one procurator of St. Mark at Venice; in 1442 the number was augmented to nine, when the senate made a decree, appointing, that, for the future, none should be admitted to the dignity, but after the death of some of the nine. But, in the necessities of the republic, the number was afterwards enlarged to forty; though of these there are only nine that bear the title of procurators, and whose place is regularly filled. They are administrators of the church of St. Mark, and of the revenues attached to it, the patrons of orphans, and the executors of testaments.

This office receives more lucre from the merit of those who discharge it, than from its authority. They are clothed in black, or violet, with ducal fleeces.

Procurator Mougerius, anciently was the advocate of a religious house, who was to solicit the interest, and plead the causes, of the society. See Advocate and Advouee.

Procurores Ecclesiae Parochialis, are the churchwardens, whose office is to act as proxies and representatives of the church.

Procurores, in the Roman Law, were such lawyers as assisted the plaintiff in proving, or the defendant in clear-

This was one condition requisite to give them the liberty of pleading; the other was the being retained by one party, or receiving a fee, which they termed mandatum.

Procurores Caesaris, among the Romans, were officers, often mentioned by Tacitus and Suetonius, who were sent by the emperors to every province, to receive and regulate the public revenue, and to dispense of it at the emperor's command. The procurator of Judea was invested with all the authority proper to the Proconsul, which fee; and, as the learned bishop Pearson observes on the Creed, art. 4, even with the power of life and death.

PROCYON, in Astronomy, a fixed star of the second magnitude, in Canis minor.

PROD, in Rural Economy, a term signifying a short spike. It also signifies a goad for driving oxen, and likewise a sharpened piece of stick for keeping thatch upon flacks, buildings, &c.

PRODANO, in Geography, an island in the Mediterranean, near the coast of Morea, anciently called "Sphenaria," 36 miles S.S.E. of Zante. N. lat. 37° 15'. E. long. 21° 24'.

PRODEGAS, a town of South America, in the province of Quito; 38 miles N.N.E. of Guayaquil.

PRODES HOMMES, q. d. wife or direcute men, in our Ancient Customs, a title given to the barons, and other military tenants, who were called to the king's council, and were to give advice according to the best of their prudence and knowledge.

PRODICTATOR, among the Romans, a magistrate who had the power, and did the office of a dictator. The Romans sometimes created a prodictator, in cases where they could not have a dictator. Fabius Maximus was prodictator.

PRODIGALITY is a term, the meaning and application of which are well known. We shall, therefore, under this head, only take occasion to observe, that, by the Roman law, if a man by notorious prodigality was in danger of waiving his estate, he was looked upon as non compos, and committed to the care of curators, or tutors, by the praetor. And by the laws of Solon, such prodigals were branded with perpetual infamy.

PRODIGY, in Mythological and Fabulous History, an event which really or apparently deviated from the ordinary course of nature, and which credulity and superstition interpreted as an omen or preface of good or ill fortune. (See PREMISE.) The history of paganism abounds with occurrences of this kind, and with an ample account of ceremonies which they were the occasion of introducing. An accidental, and sometimes a merely imaginary coincidence between the event, deemed a prodigy, and the circumstances that followed it, led the credulous to connect them together, and to consider the former as the cause, or at least as the preface of the other. The historians of antiquity, such as Livy, Dionysius Halicarnassensis, Pliny, Valerius Maximus, &c. &c. have recorded various occurrences of this nature, and the political uses to which they were applied by the crafty and designing. The prodigies treated of by the ancients, are reduced by Bannier into two classes. In the first, he comprehends those reputed miracles of paganism, which have been considered as inexplicable, without having recourse to a supernatural cause. Such have been reckoned the story of the Did Paroies, or household gods, related by Dionysius of Halicarnassus (lib. i.) that of Jupiter Ter-
nalis, which it was impossible to force from its place at the
time of building the Capitol; the adventure of Accius Na-
vius, who cut, as it is said, a fint hone with a razor, to
convince the incredulity of a king of Rome, who sighted
the augurs and the Tuscan divination; that of the veftal
virgin Æmilia, who drew water in a sieve; that of another
veftal, who with her girdle drew to shore a ship which had
been flared; and, to mention no more of a similar kind,
for they are numerous, and all equally incredible, that of
the shield which fell from heaven, under the reign of Numa
Pompliius. The prodigies of the fecond clas were purely
natural events, but being less frequent, and feeming to be
deviations from the ordinary course of nature, they were
acrefc to a superior cause by the credulous and superstiti-
sous. Such were various meteors, the appearances of fire
and light in the night, monstrous births of men or of animals,
flowers of blood, of stones, or of affes, and many other
things, which were natural, but the caufes of which were
not investigated or not understood. All these prodigies have
diminished in number, as a spirit of inquiry and know-
ledge have prevailed, and those which have not been ex-
plained have had secret caufes, which the most fagacions
and diligent inquirers have not been able to explore. To the
number of fuch incredible prodigies, fome writers have re-
ferred Constantine's luminous trophy of the crofs, which he
obferved above the meridian fun, and inscribed with the fol-
lowing words, by this, conquer, and which the emperor
either thought he faw, under the defufion of his fancy and
fenfes, or faid he faw, to anwer his own political purpofes.
The latter alternative is adopted by Mr. Gibbon. Hift. of

PRODROMUS, προδρόμος, literally denotes a fore-
runner, an harbienger. Hence,

PRODROMUS Morbus, among Physicians, is used for a leffer
difeafe, which preceeds, or forerunns, a greater.

Thus, a ftraightnes of the breath is a prodromus of a con-
fumption, &c. A vertigo is fometimes a prodromus of an
apoplexy.

PRODUCE, NET. See NET Produce.

PRODUCING, in Geometry, denotes the continuing a
right line, or drawing it out farther, till it have any affigned
length.

PRODUCT, in Arithmetic and Geometry, the fum of
two numbers, or the quantity arifing from, or produced by,
the multiplication of two or more numbers, lines, &c. into
one another.

Thus, if 6 be multiplied by 8, the product is 48.

In lines it is always (and fometimes in numbers) called
the reftangle, between the two lines multiplied by one
another.

PRODUCTION. See Generation, and Propaga-

tion.

Production, in Anatomy, a continuation or procfs.

PRODZELDEN, or PROCELDEN, in Geography, a
town of Germany, in Haffe-Darmiftadt; seven miles E. of
Miltengen.

PROEDEM, πραξήδημοί, among the Athenians, magiftrates
whofe businefs it was to propofe to the people the things they
were to deliberate upon and determine at every afsembley,
after which their offices expired.

They were fo called from the privilege they enjoyed, of
always having the firft seats at afsemblies. See Epi-

PROEM, PROEMIUM, a term anciently used for preface.

PROEMPTIFION, in Astronomy, that which makes the
new moons appear a day later, by means of the lunar equa-
tion, than they would do without that equation. See Me-

TEMPTOSIS.

PROERCA a Velho, in Geography, a town of Portu-
gal, in the province of Beira; 17 miles N.E. of Caftel-
Branco.

PROEROSIA, in Mythologv, a festival of Ceres, in-
stituted to her honour in Attica, and so called because it was
celebrated before fowing and tillmg; and the goddesse her-
self was called by the fame name.

PROFANATION, in Religion, the doing of fomething
which is difreceptful to holy or sacred things.

PROFANATION of the Lord's day. See SUNDAY.

PROFANE, a term used in opposition to holy, Sacred.
Except churches, and church-yards, all places are esteemed
profane. By the canon law, a fared chalice, or cup, be-
comes profane, by giving it a blow with a hammer.

Profane is alfo applied, in general, to all persons who
have not the fared character; and all things which do not
belong to the fervice of religion.

In this fene, Xenophon, Seneca, &c. are profane au-

tors. The heathen priests, pontiffs, &c. alfo pafs with us
for profane.

PROFANENESS denotes a difrecept paid to the name
of God, and to things and perfonfs consecrated to him. By
flatute 19 Geo. II. cap. 21. which repeals all former ones,
every labourer, foifer, or foldier, fhall forfeit l5. for every
profane oath or curfe; every other perfon under the degree
of a gentleman, 20; and every gentlemen, or perfon of su-
perior rank, 51. to the poor of the parish; and on a fecond
conviction, double; and for every fubfequent conviction,
tremble the fum forfeited, with all charges of conviction;
and in default of payment fhall be fent to the house of cor-
rection for ten days. Any juftice of the peace may confec
upon his own hearing, or the testimonie of one witneff; and
any confiable or peace officer, upon his own hearing, may
secure any offender, and carry him before a juftice, and there
convict him. If the juftice omits his duty, he forfeits 51.
and the confable 40s. And the act is to be read in all parish
churches and public chapels, the Sunday after every quar-
ter day, on pain of 51. to be levied from any juftice. By 22 Geo. II. c. 33. art. 2. all flag-officers, and
all perfonfs in or belonging to his majesty's ships or veflens of
war, being guilty of profane oaths, curfures, exclamations,
or other scandalous actions, in derogation of God's honour,
and corruption of good manners, fhall incur fuch punish-
ment as a court-martial fhall think fit to impofe, and as the
nature and degree of their offence ftall deferve. Besides this
punishment for taking God's name in vain in common dif-
course, it is enacted by flat. 3 Jac. I. cap. 21. that if in any
flag-play, interlude, or fhow, the name of the Holy Tri-
nity, or any of the perfonfs therein, be jeifally or profanely
ufed, the offender fhall forfeit 101. one moncy to the king,
and the other to the informer. See BLASHEMARY and

Teration.

PROFECTITIOUS. See Adventitious, and Goods.

PROFER, formed of the French professer, to produce, in
Laxa, the time appointed for the accounts of sheriffs, and
other officers, to be given into the exchequer; which, by
flat. 51 Hen. III. is to be twice in the year.

Profer is alfo used for an offer, or endeavour to proceed
in an action, by a perfon concerned to do.

Trinity term fhall begin the Monday next after Trinity
Sunday, whenever it fhall happen to fall, for the keeping of
the effigns, provers, return, and other ceremonies, here-
tofore in use. Stat. an. 37 Hen. VIII.

Prober the half mark. See HALF-mark.

PROFERT in Curia, in Laxa, is where the plaintiff in
an action declares upon a deed, or the defendant pleads a deed, he must do it with a pro\footnote{fer in curia}, to the end that the other party may have his own charges have a copy of it, and until that time he is not obliged to answer it.

PROFESSED Monk, or Nun, one who, having made the vow, is admitted of a religious order.

In this sense the word is used in opposition to novice.

PROFESSIO, PROFESSOR. See Viritudinis.

PROFESSION. Professor, in a monastic sense, the entering into a religious order; or an action whereby a person offers himself to God, by a vow of observing three things: viz. obedience, chastity, and poverty; which he promises inviolably to maintain.

This is called fanae religiosae profissio, and the person, a religious professed.

Persons are not admitted to make profession till after a year of probation.

PROFESSOR, in the Universitatis, a person who teaches or lectures, publicly, some art or science, in a chair established for that purpose.

The professors, in foreign universities, teach the arts, and have their classes of pupils; those in our universities only read public lectures in term-time.

Of professors we have a great number, some denominated from the arts they profess, as capistical professor, Hebrew professor, phylic professor, divinity professor, &c. Others, from those who founded the professorship, or assign'd a revenue for the support of the professor, as the Savilian professors of astronomy and geometry; the Lucasian professor of mathematics, Margaret professor of divinity, &c.

PROFESSOR, Regius. See Regius.

PROFICISCENDUM, Capitis Conducere ad proficiscendum. See Cytias.

PROFILE, in Architecture, the figure or draught of a building, fortification, or the like; in which are expressed the several heights, widths, and thicknesses, such as they would appear, were the building cut down perpendicularly from the roof to the foundation.

Whence the profile is also called the section; sometimes the orthographical section: and, by Vitruvius, also the figuration.

Profile, in this sense, amounts to the same with elevation; and stands opposed to a plan, or isometric figure.

Profile is also used for the contour, or outline of a figure, building, member of architecture, or the like; as a base, a cornice, &c.

Hence profiling is sometimes used for designing, or describing the member with rule, compas, &c.

Profile of a Fortification. See Fortification.

Profile, in Sculpture and Painting. A head, a portrait, &c. are said to be in profile, when they are represented sideways, or in a side-view.

As, when in portrait, there is but one side of the face, one eye, one cheek, &c. shewn, and nothing of the other. On almost all medals the faces are represented in profile.

PROFIT of Stock, in Political Economy, is that which is produced by means of a capital above its value. Capitals are in general confused or employed, with the view to gain by their employment. In the latter case, the capital is either lent to another individual, who consumes it, and repays it to the owner out of some other fund, with profit; or the capitalist employs his stock in the payment of such labour as produces more than the value of his capital. The first of these two ways of employing capital, though it may be beneficial to the capitalist, produces no advantage to the country. The second is that which yields the most regular and highest profits. A capital may be considered as a machine, by the use of which something is to be gained. The capitalist is the owner of the machine, and he who uses it for the purpose of producing something useful with it, is, as we have seen in the article Price, called the undertaker. The former has nothing to do but to lend it; the latter regulates its operations, and dipoles of its produce. When the functions of capital, undertaker, and labourer, exist in the same person, the whole produce of his flock and labour belongs to that individual: in general they are different persons. In either case we must distinguish the shares of profit enjoyed by the capitalist, undertaker, and labourers in their different capacities. The labourer returns for his wages something of greater value, and it is the surplus of this value which constitutes the profit of flock. The capital is restored to the capitalist, but the surplus or profit is divided between him and the undertaker. What the former receives for the mere act of lending his capital is called interest, what the latter gets for the management or enterprise, is called the profit of the undertaker. This profit is a reward, not only for his skill and trouble in the management of the undertaking, but also for the risk connected with the same. The rewards of an undertaker must always be more considerable than those of a common labourer; for otherwise he would prefer being a labourer, whose occupation is not attended with any hazard. But independently of this, the nature of his business entitles him to a higher reward. Moreover, in those who undertake the employment of another person's capital, certain requisites are looked for. They must be of talent, of judgment, and industry. Different undertakings require these qualities in different degrees, which cause a difference in their profits. Hence it is extremely difficult to ascertain the principles by which the profit of the undertaker is regulated. At any rate, the profit of flock ought to be greater than the usual rate of interest; so that the surplus above the interest ought to be sufficient to enable the undertaker to live according to his rank of life, and to do something to accumulate a capital for himself.

The market price of this profit follows the general rule of all market prices. As long as skilful undertakers are scarce, their profits are great, but when a country abounds with clever men in that line, their profits are small. When the profits of the undertakers are generally high, the rate of interest is also high. In that case the class of undertakers is increasing; they strive to deprive each other of capital, by offering a higher interest. Where the profits are small, the rate of interest is necessarily low. Wealth of Nations. Boileau's Political Economy.

PROFITS, Pernor of. See PERNOR.

PROFUVUS, in Medicine, difeases accompanied with fever, and with increased excretion of some fluid, naturally not bloody; whence the order of profuvia, in Dr. Cullen's arrangement of diseases, includes only two genera; the catarrh, or orbif excretion of mucus from the nos trils, throat, and bronchial passages; and defiyentery, with a morbid excretion of mucus, with or without blood, from the bowels. See his Nofol. Method, claff i. ord. v.

PROFUVUM, any kind of flux, or copious and liquid evacuation. Thus, profuvium venenit signifies a diarrhæa. Dr. Cullen, after Vogel, has used the word in the plural, to denote an order of febrile diseascs. See the preceding article.
PROFUNDUS, in Anatomy, a name given by Albinus, Hunaud, and others, to a muscle of the writ, generally known by the name of the perforans. These authors called, in the same manner, the perforator of others the sublimis.

PROGAL- INSECT, an animal nearly approaching to the gall-infect class, but differing from it in some respect, and called by this name from its resemblance to those creatures; as the creatures somewhat approaching to the fearab or beetle class, but not regularly of it, are called pro- faeraul.

Animals of this class pass a great part of their lives in the same manner with the gall-infects, fastened to the bark of a tree, and there remain motionless: some of them also, in the manner of the gall-infects, cover their young brood with their bodies; but they easily distinguishable as animals, in all the stages of their lives, and that in they differ from the others. The annular depressions of their bodies may in all their states be distinguished, especially with the help of a magnifying glass; whereas those of the gall-infects all disappear as they grow towards their adult bulk.

If the gall-infects are worthy of observation, on account of the great value of one species of them, the kernes; the progal-insects are at least equally so on the same account, since the cochlear belongs to this class.

The most common and observable species of the progal-insect class, is that of the elm.

PROGNOSIS, in Medicine, from προνοειν, before, and μαθειν, I know, the foretelling the event of any disease, or the approach of a disease.

There is no part of the science of medicine, which it is so difficult to teach by precept as the principles of prognostic; the application of which, at least, must be learned exclusively from experience of the ordinary progress and tendency of certain combinations of symptoms. The very young practitioner, and above all the pretender to medical knowledge, are, therefore, usually very deficient in these species of skill: with this difference, that the former daily multiples his knowledge by observation; while the latter, being devoid of principles, is incapable of improvement, unless he pos sesses an unusual share of sagacity and attention. For the power of anticipating the course of the symptoms of disease, must be founded on a knowledge of the nature of those symptoms; that is, of the actual state of the different organs of the body which they indicate. This, however, implies also that degree of knowledge of the structure and functions of the living body, which belong to anatomy and physiology, without which it is impossible that any clear indications can be inferred from certain symptoms: the structure of the machine, and its healthy mode of action, must be understood, before we can either appreciate or comprehend the derangements of its parts. It is upon a clear estimation, then, of the extent of mischief already done in any important organ, or likely to ensue from the violence of the action going on, which must be estimated from the symptoms, that a found prognosis can alone be founded: in other words, he who, from previous knowledge of the nature of the living body, and from greater opportunities, or what is still more important, from greater attention and accuracy in the discrimination of symptoms, acquaints himself most thoroughly with the actual nature of the disease, will be the ablest, not only to cure the disease, but to anticipate its changes and termination.

The danger or safety indicated by certain symptoms will be exactly in the ratio of the importance of the organs diseased, and of the degree of the morbid derangement which is actually produced, or the violence of the action which is going on in them, the tendency of which is to produce organic derangement. The affections of particular organs are distinguished, partly by the seat of pain, tumour, change of colour, &c. where these exist, but principally by the particular functions which are disturbed. For as physiology teaches us, that certain functions are performed by particular organs; so, where we have no opportunity, like the common mechanist, of examining the organs themselves, we must infer their derangement from the effects, defect, or unnatural performance of these functions. The three great organs, the functions of which are immediately necessary to the continuance of life, are the brain, the heart, and the lungs; whereas the functions of the nervous system, the circulation, and respiration, cannot be long suspended, without occasioning death; and death, in all cases, takes place from the cessation of one or other of those three functions. (See Death,) It is chiefly, therefore, from the violent disturbance of one or more of these functions, that the prognosis in acute diseases becomes unfavourable. In chronic diseases, however, where no organ immediately necessary to life may be affected, the prognosis must still be unfavourable, in consequence of the serious derangement of life, though important, organs, which are absolutely necessary to the constitution, and contribute to some of the purposes of life; as in organic diseases of the stomach, liver, spleen, mesentery, kidneys, bladder, uterus, &c. and even of the bones, muscles, and ligaments.

As we have detailed, under the head of each disease respectively, the symptoms which afford a favourable or unfavourable prognosis, it will not be necessary to enter at any length here into the particular prognostics, which the various circumstances of disease may give rise to. We shall, therefore, exemplify very briefly the mode in which the prognostics are deduced in violent diseases, from indications relative to the three great functions just mentioned.

In all febrile diseases, great disturbance of the functions of the brain, or common fenotum, is indicative of danger.

The existence of this disturbance is denoted by aberration of the intellectual functions; as by delirium, whether furious and noisy, or low and muttering; by stupor, loss of memory, and incoherence of thought. It is denoted also by morbid changes in the organs of sense; as by extreme facility to light, or by partial or total blindness; by the appearance of black spots, speck, sasses of light, &c. floating before the eyes; by cutaneous hearing, or by deafness; by perversion of taste, and of feeling as to external objects; by coma, or by great watchfulness. It is indicated, moreover, by a disordered state of volition and muscular motions; as by statics, subfinus of the tendons, and convulsions; by quavering of the eyes, distortions of the countenance, dilatation of the pupils; and by prostration, or a preternatural exertion, of the muscular strength. These are direct indications of the disordered state of the brain; the excess or over-acuteness of the faculties implying inflammatory excitement, the defect or abolition of them denoting pressure, oppression, or distension of the organ; the latter of which is often the consequence of the former state. These conditions of the brain can scarcely occur, without producing other indirect indications in different organs, which are necessarily influenced through the nervous system. Whence the symptoms just enumerated are commonly accompanied by various morbid states of the circulation, as indicated by the pulse: thus in the case of high excitement, the pulse is frequent, hard, strong, and sharp; and in the oppressed state of the brain, it is often preter-
naturally flow, irregular, and intermitting. The respiration is also disordered, in the latter case, from the impaired influence of the brain on the muscles of the chest, and becomes fluid, irregular, and stertorous. And the alimentary canal, also, suffers from the same sympathy, the stomach sometimes rejecting its contents by vomiting, whilst the bowels become exceedingly torpid. According to the greater violence and combination of such symptoms, or the inimical or absolute absence of all or many of them, the prognosis, as to the state of the brain, will necessarily be more or less favourable.

The lungs, however, are often affected primarily and idiopathically, by inflammation, tubercle, dropsy of the chest, obstructions in the trachea and air-tubes, &c.; when the prognosis will be principally collected from the disordered state of the functions of respiration. This function may be performed with various degrees of facility, or with various noises, as coughing, wheezing, rattling, piping, &c.; it may be performed more or less freely in different positions, as on the back, on one side, or only in the erect posture, when it is called orthopenia; it may be accompanied with much discharge by expectoration, as of mucus, pus, blood, fauces, &c.; or with pain in different parts of the chest; or with lividity of the face. And from these symptoms, together with other concomitant circumstances, as the absence or presence of acute fever, or of hectic fever, the state of fulness or emaciation, the long or short duration of the disease, the age and constitution of the patient, it will be decided whether the disease be pleurisy, peripneumony, phthisis, croup, hydrothorax, asthma, &c.; and the degree of danger, or the chance of recovery, will thus be estimated.

The circulation is much more frequently affected secondarily, than idiopathically, unless the local inflammations are deemed affections of the circulation. Inflammation is dangerous, in proportion to the importance of the organ which it attacks, and to the violence and rapidity of its progress. Two of its terminations, gangrene and suppurition, are extremely dangerous, when they take place in internal organs; and the prognosis is more or less favourable, according as the tendency to these is more or less manifest. Extreme violence of pain, and a long continuance of it, with continual fever, betoken the probability that suppuration will ensue; and when the pain, after such a continuance, begins to remit, while rigors or shiverings come on, it may be concluded that suppuration is begun. A sudden cessation of all pain, without any adequate cause, affords a most unfavourable prognosis in cases of acute inflammation, especially in the bowels, and other membranous parts; for it is commonly the signal of commencing mortification; and though the patient expostulates himself as perfectly comfortable, the sinking pulse will inform the physician that a few hours will probably terminate his life.

In chronic diseases, the prognosis is often less easily laid down, in consequence of the slow progress of the symptoms; but our principal guide, in forming it, will be an attention to the state of the functions, as leading to the fate of the disease. See Disease.

PROGNOSTICS of the Weather. See Weather.

PROGRAMMA, a term denoted a letter sealed with the king's seal.

Programma is also a college term, signifying a billet, or advertisement, pulled up, or given into the hand, by way of invitation to an oration, or other college ceremony: containing the argument, or so much as is necessary for the understanding of it. Programmas are sent to invite people to afeit at declamations, dramatic performances, &c.

Vol. XXVIII.
PROGRESSION.

Whence it follows, that the sum of a progression beginning from 0, is subduple the sum of so many terms, all equal to the greatest.

PROGRESSION, Geometrical, is a series of quantities increasing or decreasing, in the same ratio, or proportion; or it is a series of quantities that are continually proportional; or which increase by one common multiplier, or decrease by one common divisor: which common multiplier or divisor is called the common ratio. Thus, \( a, a r, a r^2, \) \( a r^3, a r^4, \&c. \) or \( a, \frac{a}{r}, \frac{a}{r^2}, \frac{a}{r^3}, \&c. \) and in numbers, 1, 2, 4, 8, 16, 32, 64, \&c. or 729, 243, 81, 27, 9, 3, 1, make a geometrical progression.

1. In every geometrical progression, the product of the two extreme terms is equal to the product of the two intermediate terms equidistant from the extremes; as also, if the number of terms be uneven, to the square of the middle term. For example: let \( a, ar, ar^2, ar^3, \&c. \) continued to \( y, \) the last term, be such a series; then \( y \frac{y}{r}, \frac{y}{r^2}, \frac{y}{r^3}, \) will be the four last terms; and \( ax = ar \frac{y}{r} = ar, \) \( a \frac{y}{r} = ar^2 \times \frac{y}{r^3}, \&c. \) And, in numbers,

\[
\begin{array}{cccc}
3 & 6 & 12 & 24 \\
12 & 6 & 3 & \\
288 & 288 & 288 & \\
\end{array}
\]

2. If the difference of the first and last term of a geometrical progression be divided by a number less by unit than the denominator of the ratio, the quotient will be the sum of all the terms except the greatest; hence, by adding the greatest, we have the sum of the whole progression.

In the preceding series, \( \frac{y-a}{r-1} + y = \frac{y-a+yr-y}{r-1} = r. \) For the sum of a series of geometrical proportionals, wanting the first term, or the sum of all the consequents, is equal to the sum of all but the last term, or the sum of all the antecedents, multiplied by the common ratio. Thus, \( ar + ar^2 + ar^3, \&c. + \frac{y}{r^2} + \frac{y}{r^3} + \frac{y}{r^4} + \frac{y}{r^5} + \frac{y}{r^6} + \frac{y}{r^7} + \frac{y}{r^8} + \frac{y}{r^9} + \frac{y}{r^{10}}; \) Therefore \( s = a + ar + ar^2 + ar^3, \&c. + \frac{y}{r^2} + \frac{y}{r^3} + \frac{y}{r^4} + \frac{y}{r^5} + \frac{y}{r^6} + \frac{y}{r^7} + \frac{y}{r^8} + \frac{y}{r^9} + \frac{y}{r^{10}}; \) If it be a deceasing series, whose sum is to be found, as of \( y + \frac{y}{r} + \frac{y}{r^2} + \frac{y}{r^3}, \&c. + ar^2 + ar^3 + ar + a; \) and the number of terms be supposed infinite, then \( a, \) the last term, will be equal to nothing; consequently the sum of such a series \( s = \frac{y}{r-1}; \) which is a finite sum, though the number of terms be infinite.

Thus \( \frac{1}{1} + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16}, \&c. = \frac{1}{2} \) \( \frac{1}{2} \).

In a progression of five terms, beginning with \( 3, \) the denominator being likewise \( 3, \) the greatest term will be \( 243. \) If, then, the difference of the first and last term \( 240 \) be divided by \( 2, \) a number less by \( 1 \) than the denominator, the quotient \( 120, \) added to \( 243, \) gives \( 363, \) the sum of the progression.

Hence, 3. The first or least term of a progression is to the sum of the progression, as the denominator lessen by \( 1, \) to its power likewise lessen by \( 1; \) the exponent of which power is equal to the number of terms. For, if the number of terms be \( n, \) the exponent of \( r \) in the last term will be \( n - 1. \) Therefore \( y = ar^{n-1}; \) and \( y = ar^{n-1} + ar^n; \)

\[ s = \frac{y^2 - a}{r - 1} \]

and \( s = \frac{y^2 - a}{r - 1} + a : -1 = \frac{y^2 - a}{r - 1} - 1. \)

Thus, supposing the first term \( 1, \) the denominator \( 2, \) and the number of terms \( 8, \) the sum will be \( 255. \)

4. Hence, also, the difference between the last term and the sum, is to the difference between the first term and the sum, as unity to the denominator. Wherefore, if the difference between the first term and the sum be divided by the difference between the last and the first term, the quotient is the denominator.

From art. 2. it appears, that \( s - a = \frac{s-a}{s-a} \times \frac{s-a}{s-a} \); therefore \( s = \frac{s-a}{s-a}; \) or, \( s = \frac{s-a}{s-a}. \)

As a right line, or figure, may increase continually, and never amount to a given line or area; so there are progressions of fractions which may be continued at pleasure, and yet the sum of the terms be always less than a given number. If the difference between their sum and this number decrease in such a manner, that by continuing the progression it may become less than any fraction, how small soever, that can be asigned, this number is the limit of the sum of the progression, and is what is understood by the value of the progression, when it is supposed to be continued infinitely. These limits are analogous to the limits of figures, and they mutually affilt each other. The areas of figures can, in many cases, be no otherwise expressed than by such progressions; and when the limits of figures are known, they may sometimes be advantageously applied for approximating to the sums of certain progressions.

Thus, for instance, let the terms of any progression be represented by the perpendiculars \( A, B, C, K, H, L, \) &c. standing at a given distance on the base \( A D \) (Plate XIII., Analysis, fig. 5.); and let \( P N \) be any ordinate of the curve \( FNE \) falling over the extremities of those perpendiculars. Suppose \( AP \) to be produced; then according as the area \( APMF \) has a limit to which it may approach continually, but never exceed, or may be produced till it exceed any given space; there will also be a limit of the sum of the progression, or it may be continued till it exceed any given number. For supposing the rectangles \( FB, EC, KH, LI, \) &c. completed, the area \( APNF \) will always be less than the sum of those rectangles, but greater than their sum after the first; therefore, the area \( APNF, \) and the sum of those rectangles, either both have limits or both have none. The same is to be said of the sum of the ordinates \( A, B, C, K, H, L, \) &c. and of the sum of the terms of progression represented by them. If the curve \( FNE, \) for example, be the common hyperbola, \( b \) its centre, \( bP \) the asymptote, and \( AB \) equal
equal to $6/A$; if $A F$ represent unity, the series of ordinates will represent the progression $1, 2, 3, 4, 5, \ldots$ which may therefore be continued till it exceed any given number, as the hyperbolic area may be produced till it exceed any given space. But if $F N \perp$ be an hyperbola of any higher order, so that the ordinates $PN$ be reciprocally as any power of the base $bP$, whose exponent is greater than unity, the area $APNF$, and the sum of the progression represented by the series of ordinates, will have limits. Hence there is always a limit of the sum of the fractions that have unity for their common numerator; and the squares, cubes, or any other powers of the numbers $1, 2, 3, 4, \ldots$ whose exponents exceeded unity for their successive denominators.

When the area $APNF$ has a limit, we may not only conclude that the sum of the progression, represented by the ordinates, has a limit; but when the former limit is known, we may by it approximate to the value of the latter; and vice versa, when the limit of the progression is given, the limit of the area may be found.

Progressions of fractions may be found at pleasure, that shall have assignable numbers equal to the limit of the sum of the terms. Thus a series or progression of any number of quantities continually decreasing being given, their successive differences form a new series of terms, the sum of which from the beginning is always equal to the excesses of the first term of the first series above its last term. For instance, if $A, B, C, D, \ldots$ be the terms of the first series, it is manifest, that the sum of the difference of $A$ and $B$, $B$ and $C$, $C$ and $D$, and so on, is the excess of $A$ above $E$. If the terms of the first series decrease in such a manner, that by continuing the progression they may become less than any quantity that can be assigned, then the first term of the first series is the limit of the sum of the second series. In like manner, the difference of the alternate terms of the first series, as of $A$ and $C$, $B$ and $D$, $C$ and $E$, and so on, form a new progression of terms, the sum of any number of which is equal to the excess of the sum of $A$ and $B$, the first and second term of the series, above the sum of the last and penultimate terms; and the sum of $A$ and $B$ is the limit of the sum of the new series. In general, if a progression be formed by taking the difference of the first term $A$ and the term whose place in the series is expressed by any number $n$ of the second term $B$, and that whose place is $n + 2$, and so on; then will the limit of the sum of this new progression be equal to the sum of the terms $A$, $B$, $C$, $D$, and so on, which precede that term whose place is expressed by $n$. In this manner progressions may be found at pleasure, which may be continued without end, and have given numbers for the limits of their sums.

For example, let the first series be $1, 2, 3, 4, \ldots$ &c. the successive differences of the terms of which are $2, 1, 1, 1, \ldots$ &c. and the limit of the sum of this progression will therefore be $1$. If we multiply each term of this last series by 2, that the first term may be unit, we shall have $1, 2, 3, 4, \ldots$ &c. the denominators of which are the triangular numbers, unity being the common numerator, and the limit of the sum of this progression is $2$. The successive difference of the terms of this latter series being each multiplied by $1/2$, that the term of the new series may be unity, give $1, 2, 3, 4, \ldots$ &c. which have the pyramidal numbers for their successive denominators; and the limit of the sum of this progression is $2$. In the same manner, the limit of the sum of the fractions having unity for their common numerator, and the figurate numbers of any order designated by $m$ for their successive denominators, is found to be $m - 1$.

The same series $1, 2, 3, 4, \ldots$ &c. being again assumed, the difference of the alternate terms are $2, 1, 1, 1, \ldots$ &c. the limit of the sum of which progression is $1/2$. Dividing each term by 2, the limit of the sum of $1/2, 1, 1, 1, \ldots$ &c. is $1/4$. If we take the differences of the first term, and that whose place is $m$, the second term, and that whose place is $m + 1$, &c. the common numerator of those differences will be $m - 1$; and their successive denominators, the product of $x \times m, 2 \times m + 1, 3 \times m + 2$, and the limit of the sum of this progression is the sum of as many terms as $1 + 2 + 3 + \ldots + m - 1$, &c. as there are units in $m - 1$. Now if each term of the new progression be divided by $m - 1$, that unity may be the common numerator, the terms $1/m, 1/(2m + 2), 1/(3m + 2)$ &c. will arise, the limit of which is equal to the sum of the fractions $1/1, 1/2, 1/3, \ldots$ &c. (continued till their number be $m - 1$) divided by $m - 1$. In like manner, by assuming other alternate, or any equivalent terms of the series $1, 2, 3, \ldots$ &c. we may form new progressions, the value of which may be found. Thus, if we take the terms $1, 3, 4, 5, \ldots$ &c. falling over three terms, and divide the successive differences of the terms by 96, we shall have the series $1, 1/3, 1/18, 1/140, \ldots$, which is equivalent to the series $C$, given by Mon. de Moellert, in the Philosophical Transactions, N° 353, p. 351; viz. $C = 1 + 14/5 + 55/10 + 140/11$. Thus, if we take the alternate terms of the series $1, 3, 4, 5, \ldots$ &c. above mentioned, and divide the successive differences of the terms by 2, we shall have the series $5/30, 9/120, 13/356$, &c. which is equivalent to the series $5/18, 9/120, 13/356$, &c. mentioned in the said Philosophical Transactions, and marked $A$, the sum or limit of which, by the foregoing rules, is $1/2$. See Maclaurin's Fluctuations, art. 356, where there is an error of the press, in p. 296. 11 and 15; for the series in which 11 is said to be $m$ Monnot's series $B$, is the series $A$, p. 651, of the Philosophical Transactions, N° 353, aforesaid; fo in line 15, for $A$, read $B$.

This may suffice to shew how the sums of progressions so derived may be found. We refer, for the farther application of these principles, to the aforesaid Treatise of Fluctuations, art. 357, &c. Mr. Stirling's Treatise of the Summation of Series ought also to be consular, as he has improved the method of approximating to the value of progressions, which often arise in the solution of problems. See also Mr. de Moivre's Miscellanea Analytica, and particularly the supplement to that work. Methodus Differentialis, viv Tractatus de Summatione et Interpolatione Serierum infinitarum, Lond. 1730, 4to.
PRO

PROGYNASMATA, προγνασμάτα, in Antiquity, certain preparatory exercises performed by all those who offered themselves to contend in the Olympic games.

PROHIBITED Goods, in Commerce, such commodities as are not allowed to be either imported or exported. See CONTRABAND.

PROHIBITIO de vaño directa parti, in Law, is a writ judicial, directed to the tenant, prohibiting him from making waife upon the land in controversy, during the suit. It is sometimes also directed to the sheriff.

PROHIBITION, Prohibition, the act of forbidding, or inhibiting any thing.

It is the prohibition of the law that makes the sin; a testator frequently bequeathes things with a prohibition to alienate.

Prohibition, in Common Law, denotes a writ issued out of the chancery, the king's bench, common pleas, or exchequer, to forbid some other court, either spiritual or secular, to proceed in a case there depending, upon fiction, that the cognizance thereof belongeth not to that court.

It is now usually taken for that writ which lieth for one who is implicated in the court of Chancery, for a cause belonging to the temporal jurisdiction, or the cognizance of the king's courts; by which, as well the party and his counsel, as the judge himself, and the registrar, are forbidden to proceed any farther in that cause.

Prohibitions, in Music, during the seventeenth century. The church style, during that period, was much changed, not only by the imitations of dramatic music, and the introduction of instruments, but by writing in tranposed keys, and supplying the deficiencies in the scales, which too strictly adhered to the species of octave, and modes of the church, had occasioned. Indeed, before this time, there was no decision of keys, either in sacred or secular music, according to our present rules of beginning and ending upon the chord, major or minor, of some determinate note of the scale. The prohibitions were so numerous in the writings of the old theorists, that if the most regular modern compositions were tried by such rules as culminated at the beginning of the last century, they would appear extremely licentious. No part was to be extended above or below the staff, or five regular lines, on which it was written; the combination of chords was never to be broken by moving in an unrelative harmony; and the intervals of the sharp seventh, the triton or sharp fourth, false fifth, sharp second, and even the major fifth, were prohibited. Indeed, an excellent composition might now be produced, merely from ancient dispositions.

Prohibito, in the Italian Music, is a term applied to such parts of a piece as are not proper, or according to just rules. Thus, interniculo prohibito is every interval in melody that does not pass the ear easily or naturally, to give it some pungency; such are the tritones, the fifth major, the seventh, ninth, &c. though, under certain circumstances, even these have pleasing effects; in that by their hardness they render the subsequent concords more agreeable.

PROJECTILE, or Project, in Mechanica, a heavy body, which, being put into motion by an external force impelled upon it, is dissipated from the agent, and left to pursue its course.

Such, e.g., is a stone thrown out of the hand or a sling, an arrow from a bow, a bullet from a gun, &c.

PROJECTILES, the cause of the continuation of the motion of, or what it is determines them to persist in motion, after the first cause ceases to act, has puzzled the philosophers. See Motion and Communication.

The Peripatetics account for it from the air, which, being violently agitated by the motion of the projecting cause, e.g., the hand and sling, and forced to follow the projectile, while acceleratéd in it, deœs, upon the dissipation of the projectile, prefs after it, and prostrates it forward, to prevent a vacuum.

The moderns account for the motion of projectiles on a much more rational and easy principle; it being, in effect, a natural consequence from one of the great laws of nature; viz. that all bodies, being indifferent as to motion or rest, will necessarily continue the rate they are put into, except so far as they are hindered, and forced to change it by some new cause.

Thus a projectile, put in motion, must continue to move eternally in the same right line, and with the same velocity, were it to meet with no resistance from the medium, nor had any force of gravity to encounter.

The doctrine of the motion of projectiles is the foundation of all gunnery.

PROJECTILES, Theory of, is that branch of mechanics which relates to the motion, velocity, range, &c. of heavy bodies projected into space by any external force.

This subject may be considered under two distinct heads, viz. 1. With reference to bodies moving in void space, or, as is usually said, in a non-refilling medium; and 2. When the body is projected into a refilling medium, as air, water, &c.

Of the Theory of Projectiles in vacuo.—As the curve described by a projectile in void space depends upon its initial velocity and the law of acceleration which a body would in this case observe in its fall towards the earth by the action of gravity, and as the latter was not known till the discovery of it by Galileo, it follows a fortiori that the real path of a projectile was also unknown before the time of this celebrated philosopher, who not only determined the true nature of the curve, shewing it to be the common parabola, but he examined also various circumstances relative to its motion. He showed how to ascertain the impetus for any range and elevation, and how the range was to be found when the impetus and elevation were given; and the elevation from the range and impetus. He demonstrated also, that the velocity of the projectile in any point of the curve, is equal to that which would be generated by a heavy body in falling, though one-fourth of the parameter to the diameter at that point; that the greatest range, the impetus being the same, is when the angle of elevation is 45°; and that the ranges are equal for angles equally above and below 45°; limiting his enquiries, however, in all these cases to the horizontal plane only.

Torricelli, the worthy pupil of so great a master, pursued the subject still farther, and investigated all the circumstances of a projectile, with reference to the inclined plane; and, amongst other very interesting properties he discovered, that the locus of the vertices of all the parabolas described by a body thrown from the same point, with the same velocity, but with different degrees of elevation, was itself a parabola, of which the point of projection was the focus. In fact, the theory of projectiles in non-refilling mediums has received very little addition since the time of Torricelli, except so far as regards simplicity; but, in this respect, it has received great improvement in the hands of more modern mathematicians. We shall endeavour to condense all the most important propositions connected with this theory in the short space possible, in order that we may enter more at length on the subject when we come to consider it with reference to the resistance of the air, which is, in fact, the only useful case; for though there
there is not perhaps any branch of mixed mathematics, which presents a more elegant and interesting theory than that of projectiles in a non-refilling medium, it unfortunately happens also that there is none, in which theory and practice are more at variance with each other, in consequence of rejecting the air’s resistance, which is so great, that, in many cases, the computed range exceeds the real range obtained in practice, by more than twenty miles.

Prop. I.—If a body be projected into a non-refilling medium, either parallel, or any way inclined to the horizon, it will, by this motion, combined with that resulting from the action of gravity, describe the curve of a parabola.

Let a body be projected from A, (Plate XXXVI. Mechanics, fig. 7.) in the direction AD, with an uniform velocity, which would carry it over the equal spaces AB, BC, CD, &c. in equal portions of time, and BE, CF, DG, &c. the spaces through which a heavy body would descend by the force of gravity in those times; then it follows, from the principles of the composition of motion, that the body would be found at the end of these portions of time in the points E, F, G; or that its path will be the curve A E F G H passing through those points, and which is to be demonstrated to be a parabola.

Let t, T, represent the times the body would take in passing over any two of those spaces AB, AD; then since the motion in this direction is uniform, we have

\[ AB : AD :: t : T \]

therefore

\[ A B' : A D' :: t' : T' \]

but

\[ BE : DG' :: t' : T' \]

by the laws of falling bodies; therefore

\[ A B' : A D' :: BE : DG \]

which is a known property of the parabola.

Cor. 1.—The velocity in the direction AD being uniform, the horizontal velocity is also uniform; and it is to the former as the cosine of the angle HAD of elevation to radius.

Cor. 2.—The velocity in the direction of gravity at any point F, is to the first projectile velocity, as 2 CF to AC. For this velocity would carry the body over 2 CF in the same time by the law of falling bodies, but in the same time the projectile velocity would carry the body over the space AC; therefore the former velocity is to the latter as 2 CF : AC.

Cor. 3.—Let PA be the height due to the first projectile velocity, or that space through which a heavy body must fall to acquire a velocity equal to that of projection, and DG be an ordinate equal to PA; then the velocity in the direction of gravity at G, will be equal to the projectile velocity at A; but it has been shewn that these velocities are to each other as 2 DG to AD, therefore, being equal at this point, we have 2 DG or 2 PA = AD, whence AD' = 2 DG x 2 PA, or DG' = 4 PA x DG, consequently PA = 4 of the parameter of the diameter at A; and, therefore,

\[ A B' = 4 A P \times B E \]
\[ A C' = 4 A P \times C F \]
\[ A I' = 4 A P \times I H \]
\[ \text{&c.} = \text{&c.} \]

Cor. 4.—Hence again it follows, that the velocity of a projectile in the direction of the curve, or of its tangent, at any point, is equal to that which would be generated by gravity in a heavy body falling through \( \frac{1}{2} \) of the parameter at that point. Whence, and from the known property of the direction of a parabola, it appears, that if from the direction of the parabola the several lines HE, HE, &c. be drawn perpendicular to H, H, &c. (fig. 8.) then the velocity of the projectile in the direction of the curve, at any point E, is always equal to the velocity acquired by a body falling through HE.

Cor. 5.—It follows also from this property, that the motion of the projectile in the direction of the curve, is the same as the velocity of a body at the vertex of the parabola, at which point also the projectile is at its greatest height above the point of projection.

From these properties we may readily draw the geometrical construction for the determination of the range, elevation, or impetus, any two of them being given.

Prop. II.—Having given the velocity, or the height due to the velocity, and the angle of elevation, to find the range upon any given plane passing through the point of projection; whether parallel or oblique to the horizon.

Let PA (fig. 9.) be the height due to the velocity, or that through which a body must fall to acquire a velocity equal to that of projection, the direction of which let be A I; and A H the given plane.

From P draw PQ, making the angle A P Q = the angle Q A R; take A I = 4 A Q, and draw H I parallel to PA, so that H A = be the range required.

For the triangles A P Q, A I H, are similar, and therefore A P : A Q = \( \frac{1}{4} A I \) : I H, whence \( \frac{1}{4} A P = PA, I H \), or \( A I = 4 PA \times I H \); therefore H is a point in the parabola by cor. 3. above.

Cor. —Draw Q V parallel to A H, and V will be the vertex of the parabola, which will give the greatest height, \( V n \), of the projectile above the plane by cor. 4. and which, since \( V n = Q R \), is equal to \( \frac{1}{4} \) of I H.

Prop. III.—Given the range and impetus, to find the angle of elevation.

On PA, the height due to the impetus, describe a segment to contain an angle equal to A R Q, or a A P, and take A R = \( \frac{1}{4} \) A H; and draw Q R parallel to A P, cutting the circle in Q Q', so that A Q = or A Q', be the direction required.

For since the angle A Q P = A R Q, and P A Q = A Q R, because of the parallels A P, Q R, it follows that the angle A P Q = Q A R; and since \( A R = \frac{1}{4} A H \), \( A Q = \frac{4}{4} A I \); therefore A Q is the direction required, as is obvious from the preceding proposition.

Cor. 1.—Hence it follows, that there are always two angles of elevation which give the same range, except when the two points Q Q' coincide, or when the angle P A H is bisected, in which case the range is the greater possible, as is obvious.

Cor. 2.—Hence the greatest range for the horizontal plane, is when the angle of elevation is 45°.

Cor. 3.—Hence also, when it is required to determine the greatest range with a given impetus, we must bisect the angle P A H, which will be the angle of direction, from which the range will be found as in prop. 2.

Prop. IV.—Having given the range and elevation, to find the height due to the velocity.

Draw A P perpendicular to the horizontal line A B; take A R = \( \frac{1}{4} \) A H; also draw Q R parallel to A P, and from Q draw Q P, making the angle A Q P = A Q R, and the point P, where this line cuts A P, will give the height due to the projectile velocity; as is obvious from the demonstrations given above.

The above propositions include all the most important cases relating to projectiles, when the plane passes through the point of projection; we shall therefore only add another for
for the case in which the plane does not pass through that point.

Prop. V.—Given the direction and velocity, to find the point where the projectile meets a plane given in position.

Let A P (fig. 12) be the height due to the velocity, A I the direction, and B C the plane. Produce B C to meet D P in D, D P being perpendicular to A P, which produce to cut the plane B C in B. Make the angle R A F = R A P, and A F = A P, and join D T, and from the centre B, with the distance B P, describe a circle cutting D F in N; join B N, parallel to which draw F C, which will cut the plane in the point C required.

For draw E C perpendicular to D P, then since A P = A F, by construction, F is the focus of the parabola; also

\[ DB : DC :: BN : CF, \]

and

\[ DB : DC :: BP : CE. \]

But B N = B P, therefore C F = C E, and consequently the point P is in the parabola.

And it is obvious, that the same construction applies to the preceding propositions, the only difference being, that the points A and B in those cases coincide.

Cor.—When the point is given on the plane, and the elevation or impetus is required, it is obvious that the construction is then the same as in prop. 2, or prop. 3, whether the plane passes through the point of projection or not.

From the preceding constructions it will be easy to compute the several cases trigonometrically.

Let A P = m, then \( v = 2 \sqrt{gm} \), the time of flight = \( t \), \( 16 \frac{1}{2} \) = \( g \), the greatest height \( n = b \). Make \( A I \), for the sake of abridging the expressions, the angles B A I, B A H, and H A I, respectively equal to \( a, b, c \).

Then \( A I = tv \); and as \( \sin A H I (= \cos b) : \sin c \)

\[ :: \frac{\sin c}{\cos b} \cdot tv = IH = g t^2, \] by the laws of falling bodies = \( 4 b \), by cor. 5, prop. 1; hence \( \frac{\sin c}{\cos b} \)

\[ tv = g t^2 = 4 b; \] whence we draw \( \frac{v}{g} = \frac{\cos b}{\sin c}, \) and \( t = \frac{v}{g} \).

Again, as \( \sin A H I (= \cos b) : \sin H I A (= \cos a) \)

\[ :: \frac{\cos a}{\cos b} \cdot tv = \frac{\cos a}{\sin c} \cdot g t^2 = \frac{\cos a}{\sin c} \cdot \frac{v^2}{g} = \frac{\cos a}{\sin c} \cdot \frac{\cos a}{\sin c} \cdot \frac{4 m}{\sin c} = \frac{4 b}{\sin c}. \]

From which, it is obvious, we may readily find \( t, v, m, \) or \( b \), when the range \( r \) is given; as we may also the angle of elevation and the inclination of the plane, when these are to be determined.

When the plane is horizontal these expressions become more simple, for in that case \( \cos b = 1 \), and \( \angle a = \angle c, \) whence the above become \( r = \frac{\cos a}{\sin a} \cdot \frac{v^2}{g} \),

\[ g t^2 = \frac{\cos a}{\sin a} \cdot \frac{v^2}{g} = \frac{\cos a}{\sin a} \cdot 4 m = \frac{\cos a}{\sin a} \cdot 4 b. \]

And these, again, by substituting \( \sin a \) \( \cos a = \frac{1}{2} \sin 2 a, \) and \( \tan a = \frac{\sin a}{\cos a} \), are rendered still more simple, particularly those which relate to the angle of elevation. We have

Thus

\[ r = \frac{g t^2}{\tan a} = \sin 2 a \cdot \frac{v}{2} = \sin 2 a \cdot 2 m \]

\[ \sin a = \frac{g t}{v} = \sqrt{g b} = \frac{tv}{4 b}. \]

Cor. 1.—From the last value of \( r \) it is obvious, that in the horizontal plane the range varies, the impetus being the same, as the sine of the double angle of elevation, and, therefore, that it is the greatest when that angle is \( 45^\circ \), or when the angle subtended by the impetus and plane is bisected; and the same is also true in the latter sense for the oblique plane.

Cor. 2.—And in both cases, all angles equally above and below which gives the maximum range, will give equal ranges, as may be readily deduced from the preceding formulas.

Cor. 3.—All other things being the same, the range varies as \( v^2 \), as or the square of the velocity, as does also the greatest height of the projectile above the plane.

Cor. 4.—The time of flight varies as the velocity, or as the impetus.

For more on this subject, see Robins's Gunnery, Hutton's Traicts, and Burrow's Theory of Gunnery, contained in his Relfutation of the Inclinations of Apollonius.

Theory of Projectiles in Resisting Medium.—We have already observed, that the doctrine of projectiles in a non-resisting medium, is only to be considered as an elegant theory, which is, in fact, almost entirely useless in practice, in consequence of its not taking any account of the resistance of the air; it being only with very small velocities, that there is any tolerable agreement between experiments and the computed ranges. But when the velocity is at all considerable, the resistance becomes very great, and such as to render the parabolic theory of no practical use whatever. The inaccuracy of those authors who have treated the subject upon the supposition of the resistance of the air being inconsiderable, will easily appear from what is established by Robins in his New Principles of Gunnery, where he has shewn that this resistance to a cannon ball amounts to more than twenty times the weight of the ball. What errors may not be expected from an hypothesis which neglects this force as inconsiderable? In effect, it will not be difficult to shew, that the track described by the flight of shot or shells, is neither a parabola nor nearly a parabola. For by that author's experiments it appears, that a musket-ball of three-fourths of an inch diameter, fired with half its weight of powder from a piece forty-five inches long, moves with a velocity of nearly 1700 feet in a second. Now, by the common parabolic theory, if this ball flew in the curve of a parabola, its horizontal range at \( 45^\circ \) would be found to be about seventeen miles. But from practical writers, as Diego Ufane, and Merettenus, it appears, that this range is short of half a mile; so that a musket-shot at \( 45^\circ \) elevation, with a reasonable charge of powder, flies not with the upper part of the distance it ought to do, if it moved in a parabola.

Nor is this present diminution of the horizontal range to be wondered at, when it is considered that the resistance of the air to this bullet, when it first leaves from the piece, amounts to one hundred and twenty times its gravity.

Again, if the flight of the heaviest shot, in common use for land service, as of iron bullets of 24 lb. weight, be examined, it will appear, that such a shot, with a full charge of powder, has a velocity of 1650 feet in a second. And the horizontal range at \( 45^\circ \) of this shot, would, according to the parabolic hypothesis, be about sixteen miles; but by the experiments of St. Remy it appears, that the range is really short
short of three miles; which is not one-fifth of the distance it ought to fly, if it described the curve of a parabola.

And this deviation from the parabola happens not only in these great velocities, but in such as are much less; thus in velocities of about 400 feet in a second, by several experiments it appears, that the range of a leaden bullet of three-fourths of an inch in diameter, fired at different elevations with this velocity, did not at all answer the common theory. So that it sufficiently appears that any theory, which depends upon the supposition of the insconsiderableness of the air’s resistance to projectiles, is useless.

Indeed, the inaccuracy of this hypothesis almost appears at sight, even in projectiles flown enough to have their motion traced by the eye; few there are who do not discern through a curve manifestly shorter and more inclined to the horizon than that in which they ascended, and the highest point of their flight, or the vertex of the curve, is much nearer to the place where they fall on the ground, than to that whence they were at first discharged. These things cannot be a moment doubted by any one, who in a proper situation views the flight of flues, arrows, or shells, thrown with any considerable velocity.

What is here advanced may be confirmed from the constant observation of all who are conversant in the practice of throwing shells, viz. that the ranges at elevations below 45°, constantly exceed the ranges at elevations above 45°, which are respectively at an equal distance from 45°. But it is known that in the parabolic hypothesis there ought to be equal; which is a farther proof of the fallacy of this hypothesis.

There is also a singular phenomenon in the motion of bodies projected with considerable force, which shows the great complication and difficulty of this subjeet; which is, that bullets in their flights are not only depraved beneath their original direction by the action of gravity, but are also frequently driven to the right or left of that direction by the action of some other force.

If it was true, that bullets varied their direction by the action of gravity only, then it ought to happen that the errors in their flight to the right or left of the mark they were aimed at, should increase in the proportion of the distance of the mark from the piece only. But this is contrary to all experience; the same piece which will carry its bullet within an inch of the intended mark, at ten yards distance, cannot be relied on to ten inches in one hundred yards, much less to thirty inches in three hundred yards.

Now this inequality can only arise from the track of the bullet being incurved sideways, as well as downwards: for, by this means, the distance between the incurved line, and the line of direction, will increase in a much greater ratio than that of the distance; these lines being coincident at the mouth of the piece, and afterwards separating in the manner of a curve from its tangent, if the mouth of the piece be considered as the point of contact.

This is put beyond dispute by the experiments made by Mr. Robins; who informs us, that having taken a barrel carrying a ball of three-fourths of an inch diameter, and fixing it on a heavy carriage, he satisfied himself of the truth of its direction, by firing at a board 14 by 1 foot square, at the distance of one hundred and eighty feet, and missed it but once in sixteen successful shots. Now the same barrel being fixed on the same carriage, and fired with a smaller quantity of powder, so that the shock on the discharge would be much less, and consequently the direction less change, he found that at seven hundred and sixty yards distance the ball flew sometimes one hundred yards to the right of the line it was pointed on, and at other times one hundred yards to the left. He found, too, that its direction in the perpendicular line was not less uncertain, it falling one time above two hundred yards short of what it did at another; although by the nicest examination of the piece after the discharge, it appeared not to have the least started from the position it was placed in.

If it be asked what can be the cause of a motion so different from what has been hitherto supposed? It may be answered, that the deflection in question must be owing to some power acting obliquely to the progressive motion of the body, which power can be no other than the resistance of the air. And this resistance may perhaps act obliquely to the progressive motion of the body, from inequalities in the reflect surface; but its general cause is doubtless a whirling motion acquired by the bullet about its axis; for by this motion of rotation, combined with the progressive motion, each part of the bullet’s surface will strike the air in a direction very different from what it would do if there was no such whirl; and the obliquity of the action of the air arising from this cause will be greater, according as the rotary motion of the bullet is greater in proportion to its progressive motion. Principles of Gunnery in Tracts, vol. i. p. 149, &c.

Latter, on the contrary, attributes this deflection of a bullet to its figure, and fearlessly at all to its rotation: for, if the bullet was perfectly round, though its centre of gravity did not coincide with its centre of magnitude, the deflection from the axis of the cylinder, or line of direction sideways, would be very inconsiderable. If such a ball goes to the right or left of an object, it is certain that the object does not lie in the same vertical plane with the axis of the piece. But if it be not round, it will generally go to the right or left of its direction, and so much the more, as it goes farther from the piece. He infers from his reasoning on this subject, that cannon-shot, which are made of iron, and rounder and less susceptible of a change of figure as passing along the cylinder than those of lead, are more certain than musket-shot.

There is another circumstance, however, which appears to us to account for the irregular motion of shot, which is the windage; for the ball not exactly hitting the bore of the cannon, and the explosion of the powder not taking place exactly in the axis of the gun, it must necessarily happen, that in the motion of the ball along the barrel, it strikes sometimes one side and sometimes another of the bore, and that it will, therefore, be elevated or depressed, or be thrown to the right or left of the object, according to the point at which it was laid in contact with the mouth of the cannon.

That this is the true cause of the irregular motion we are speaking of, is made pretty evident from an experiment reported by M. Guyton, in vol. viii. of the Memoirs of the National Institute. In this experiment the bore of the cannon was slightly conical, the greater part being at the breech, where the cannon was charged with a leaded bullet, as in a rifle gun, and which consequently must undergo a slight change in its form in passing through the bore of the piece, so that there was no windage, and the consequence was the most complete regularity in the flight of the shot, the deviation being scarcely perceptible in the longest ranges.

Another experiment is reported in the same Memoir, which it is important to detail, because it contradicts a sort of hypothesis which has been almost universally admitted, and in some measure justified by experiment; namely, that the less the windage, the greater the range, all things else being the same; but it appears from the experiments above alluded to, that the medium range of a number of experiments, in which the
the windage was reduced to half a millimeter, was only about half the range with a windage of a millimeter; but that the ranges again decreased by diminishing farther the size of the shot; so that the millimeter, answering to about \(1/3\) of an English inch, seems to be the best suited for giving the greatest range. This experiment appears to be at variance with the one mentioned above by the same author, and also with some other of his experiments made with balls of new construction, which M. Guyton calls "bullet a bague de plomb," which are constructed so as to prevent any windage, by a collar of lead fixed across the middle of the ball; with these, though their weight was nearly double that of a common shot, the range was in some cases greater, and in very few less, than with the common ball, the charge and everything else being exactly the same. The former anomaly, therefore, both M. Guyton and M. Prony endeavoured to account for, by the protrusion of the vertical diameter of the shot, and the consequent friction between the ball and the bore of the cannon, both of which appear to have been brads in these experiments; and which friction they suppose to be so much greater than that between lead and brass, as to be sufficient to account for the great defect in the ranges in the former case; we are doubtful, however, how far this may be considered as a satisfactory explanation.

The most complete set of experiments made with a view of obtaining a rational theory of projectiles in air, are those of Dr. Hutton, which were carried on at Woolwich during the years 1775, 1783, 1784, 1785, 1787, 1788, 1789, and 1791, the objects of which were very various, and some of the results highly important. The latter are thus enumerated by the author in the second vol. of his "Tracts," lately published.

1. It is made evident by these experiments, that powder fires almost instantaneously, so that nearly the whole of the charge fires, though the time be much diminished.

2. The velocities communicated to the shot of the same weight, with different quantities of powder, are nearly in the subduplicate ratio of those quantities. A very small variation, in defect, taking place when the quantities of powder become great.

3. And when shot of different weights are fired with the same quantities of powder, the velocities communicated to them, are nearly in the reciprocal subduplicate ratio of their weights.

4. So that, universally, shots which are of different weights, and impelled by the firing of different quantities of powder, acquire velocities which are directly as the square roots of the quantity of powder, and inversely as the square roots of the weight of the shot nearly.

5. It would, therefore, be a great improvement in artillery, to make use of shot of a long form, or of heavier matter; for thus the momentum of the shot, when fired with the same weight of powder, would be increased in the ratio of the square root of the weight of the shot.

6. It would also be an improvement to diminish the windage; for by so doing, one-third or more of the quantity of powder might be saved.

This, however, must be understood only to be true within certain limits. See the experiments of M. Guyton, above referred to.

7. When the improvements mentioned in the two last cases are considered as both taking place, it is evident that about half the quantity of powder might be saved, which is a very considerable object. But important as this saving may be, it seems still to be exceeded by that of the guns: for thus a small gun may be made to have the effect of one, of two, or three times its size, in the present way, by difcharging a long shot of two or three times the weight of its natural ball, or round shot; and thus a small ship might discharge shot as heavy as those of the greatest now made use of.

The objects of the latter courses of experiments are thus detailed; viz. to ascertain.

1. The velocities with which balls are projected by equal charges of powder, from pieces of the same weight and calibre, but of different lengths.

2. The greatest velocities due to the different charges of powder, the weight and length of the gun being the same.

3. The greatest velocity due to the different lengths of guns; to be obtained by increasing the charge as far as the resistance of the piece is capable of sustaining.

4. The effect of varying the weight of the piece; every thing else being the same.

5. The penetration of balls into blocks of wood.

6. The ranges and times of flight of balls, with the velocities, by striking the pendulum at various distances, to compare them with initial velocities, for determining the resistance of the medium.

7. The effects of wads, of ramming, of windage, &c. &c.

We cannot of course enter in this place into any detail relative to the manner of performing these experiments, nor even of the results of them; indeed, they are not all necessarily connected with our subject, but rather belong to the general article GUNNERY; but as they have been published since that article in the present work was written, we have thought it right to give a short abstract of the experiments in this place, but for farther particulars on some of the subjects, we must refer the reader to the work itself; others will be found illustrated at some length under the articles Penetration, Resistance, Whirling Machine, Initial Velocity, &c.

We shall here merely adopt the author's expression for the resistance of the air, as deduced from these experiments, and thence determine the ranges, times of flight, &c. of projectiles according to that hypothesis.

Theorem.—The resistance of the air to a ball projected into it with any considerable velocity, is expressed by the formula

\[ r = \left( \frac{1}{.0000757565} v^2 - 0.0175 v \right) \theta. \]

But for the smaller velocities, \( r = 0.0000424 d^2 \theta \) will be a sufficiently near approximation, where \( r \) represents the resistance in avoirdupois pounds, \( d \) the diameter of the ball in inches, \( v \) the velocity in English feet. See Hutton's Tracts, vol. iii. p. 232; see also our article Resistance.

Proviso 1.—To determine the height to which a ball, projected perpendicularly upwards, will ascend, being resisted by the atmosphere.

Putting \( s \) to denote any variable and increasing height ascended by the ball; \( v \) its variable and decreasing velocity there; \( d \) the diameter of the ball, its weight being \( w \); \( m = 0.0000757565 \), and \( n = 0.0175 \), the coefficients of the two terms in the above theorem. Then \( (m v^2 - n v) d^2 \) will be the resistance of the air against the ball in avoirdupois pounds, to which, if the weight of the ball be added, then \( (m v^2 - n v) d^2 + w \) will be the whole resistance to the ball's motion, and consequently \( \frac{(m v^2 - n v) d^2 + w}{w} \) is the retarding force. (See Acceleration and Retardation.) Hence the general formula \( v = \frac{2 g f x}{}\) (given under the former of these articles)
articles) becomes \( v = 2 \cdot g \times \frac{(m \cdot v^2 - n \cdot v)}{w} \)
making \( v \) negative, because the velocity is decreasing, where
\( g = 16 \text{ ft. per sec.} \), or \( 16 \text{ ft.} \), the descent of a body in one sec-
ond by gravity.

Hence \( x = -\frac{w}{2g} \times \frac{v^2}{(m \cdot v^2 - n \cdot v)} \times \frac{w}{2g \cdot m \cdot d^2} \). The fluent of which being taken, and
\( v^2 - \frac{n}{m} \cdot v + \frac{w}{m \cdot d^2} \)
corrected for the instant of the first velocity \( V \), when \( x = 0 \), gives
\( x = \frac{w}{4 \cdot g \cdot m \cdot d^2} \times \left\{ \frac{1}{2} \log \left( \frac{V^2 - n\cdot V + \frac{w}{m \cdot d^2}}{q} \right) - \frac{1}{2} \log \left( \frac{V^2 - n\cdot V - \frac{w}{m \cdot d^2}}{q}\right) \right\} \),
where \( q = \frac{n}{2m} \), and \( p^2 + q^2 = \frac{w}{m \cdot d^2} \).

But as part of this fluent, denoted by \( \frac{p}{q^2} \) the differ-
ence of the two arcs to tan. \( (V - p) \) and \( p \) is always very small in comparison with the other preceding terms, it may be omitted without any material error in practical cases; in which case we have
\( x = \frac{w}{4 \cdot g \cdot m \cdot d^2} \times \text{hyp. log.} \left( \frac{V^2 - n\cdot V + \frac{w}{m \cdot d^2}}{m \cdot d^2} \right) \)
for the greatest height to which the ball will ascendl in air; supposing its density uniformly the same as at the earth's surface. Now for the numerical value of the general co-
efficient \( \frac{w}{4 \cdot g \cdot m \cdot d^2} \), and the term \( \frac{w}{m \cdot d^2} \); because the mass
of the ball to the diameter \( d \) is \( 5.236 \cdot d^2 \), if its specific gravity
be \( \delta \), its weight will be \( 0.5236 \cdot d \); therefore \( \frac{w}{d} = 0.5236 \cdot d \), and \( \frac{w}{m \cdot d^2} = 69.259 \cdot d^2 \); this divided by \( 4.9 \) or \( 0.44 \),
gives \( \frac{w}{4 \cdot g \cdot m \cdot d^2} = 0.102 \cdot d \) for the value of the general co-
efficient, to any diameter \( d \), and specific gravity \( \delta \). And if we farther suppose the ball to be cast iron, the specific gravity
of which, or the weight of a cubic inch, is \( 2.685 \text{ lb.} \), it becomes \( 290.6 \cdot d \) for that co-efficient; also \( 69.259 \cdot d^2 = 18600 \cdot d = \frac{w}{m \cdot d^2} \) and \( \frac{n}{m} = 231.5 \).

Hence the preceding fluent becomes
\( x = 290.6 \times \text{hyp. log.} \left( \frac{V^2 - 231.5 \cdot V + 18600 \cdot d}{18600 \cdot d} \right) \)
\( x = 669 \cdot d \times \text{com. log.} \left( \frac{V^2 - 231.5 \cdot V + 18600 \cdot d}{18600 \cdot d} \right) \)

which is a general expression for the altitude in feet ascended by an iron bullet, whose diameter is \( d \), and projectile velocity \( V \).

Example 1. — Suppose a ball of cast iron, whose diameter
is two inches, and, therefore, its weight \( 1 \text{ lb.} \), to be pro-
jected upwards with a velocity of \( 2000 \text{ feet per sec.} \), to find
the greatest height to which it will ascend.

Here, substituting for \( d \), \( w \), and \( V \) their respective values, we have

Vol. XXVIII.

\[ \text{Proj.} \]
art. 24, it appears, that in most of them at an elevation between $45^\circ$ and $30^\circ$, the time of flight is nearly equal to $\frac{4}{3}$ of the square root of the range in feet, in which respect it nearly agrees with the similar rule for the time of flight in the parabolic theory, at the angle of $45^\circ$ for the greatest range, which time, it is well known, is equal to $\frac{4}{3}$ of the square root of the said range in feet. Whence it is probable, that with the help of a few other ranges at several elevations, some general relations might be evinced between the ranges, and the times of flight, with the tangents of the elevation.

"But such experiments and enquiries as these, unfortunately it is no longer in my power either to procure, or by any means to promote; and we can, therefore, only endeavour to render, without them, what service we can to the trade, and to philosophy, by such means as are in our power.

"There are some few theoretical principles which it may be useful to notice here, as first mentioned by professor Robinson. Thus balls of equal density, discharged at the same elevation, with velocities which are proportional to the square roots of their diameters, will describe similar curves; because then the resistances will be in proportion as the momentum or quantity of motion. For the resistance $r$, is $d^2v^2$ nearly; $d$ being the diameter, and $v$ the velocity. But $v$ being as $\sqrt{d}$, $v^2$ will be as $d$; consequently $d^2v^2$ will be as $d^3$; that is, $r$ is as $d^3$. But the momentum is as the magnitude or mass, which is as $d^3$ also, the cube of the diameter. Therefore the resistance is proportional to the momentum, when the velocity is as $\sqrt{d}$, or the square root of the diameter of the ball. In this case, then, the horizontal velocity at the vertex of the curve will be proportional to the terminal velocity, also the ranges, and heights, and all other similar lines in the curve, will be proportional to $d$, the diameter of the ball. And this principle may be of considerable use; for thus, by means of a proper series of experiments on one ball, projected with different velocities and elevations, tables may be constructed, by which may be ascertained the motions in all similar cases."

The following table, deduced partly from theory, and partly from experiment, may be found of use by analogy in many cases.

</table>

This table contains, in the first column, the velocity, in feet, of a 24lb. shot, projected at an angle of $45^\circ$; the second column shows the distance, in yards, to which the ball would go, in vacuo, on an horizontal plane; the third column contains the distance to which it will range through the air, considered all of the same density as at the earth's surface; the fourth shows the same ranges corrected for the diminution of the air's density as the ball ascends, and is, therefore, called the corrected range; and the fifth column shows the height to which the ball rises in the air, or the height of the vertex of the curve above the plane.

By this table it appears, what an immense difference there is between the motions through the air and in void, especially with the large velocities. It is seen that the ranges through the air, instead of increasing in the duplicate ratio of the initial velocities, as in non-refracting space, really increase slower than those velocities, in all the actual cases of military service; and in the most useful cases, viz. from 800 to 1600 feet, they increase nearly as the square roots of the velocities. A set of similar tables, made with the same shot at other elevations, would nearly complete what might be done by theory, as well as useful and necessary for practice.

To use the foregoing Table.—Suppose it were required to find the dimensions of the path described by a 12lb. shot, discharged with 1600 feet velocity, at an elevation of $45^\circ$ degrees. Here, recollecting that the curves are similar, and their corresponding lines proportional to the diameters of the shot, when these are discharged with velocities that are to one another as the square roots of the same diameters; we must, therefore, first find what velocity of the 24-pound shot, or tabular ball, corresponds to the 1600 feet velocity of the 12-pounder, in this manner. The diameters of the two balls being 4.403 and 5.546, it will be as $\sqrt{4.403}$ : $\sqrt{5.546}$ :: 1600 : 1760, the corresponding velocity of the 24-pounder; which being sought in the table, the range and height answering to it are there found to be 2386 and 692; therefore, $\sqrt{5.546} : 4.403 :: 2386 : 1894$ yards the range, and $5.546 : 4.403 :: 692 : 549$ yards the altitude. That is, the range is about 1,5 of a mile, and the height about $\frac{1}{3}$ of a mile.

Again, to find the range and greatest altitude of a 30lb. ball, projected with 1500 feet velocity. The diameter of the 9-pound ball being 4 inches, we have $4 : \sqrt{5.546} :: 1500 : 1760$, to which, in the table, correspond 2543, and 650, for the tabular range and altitude. Then $5.546 : 4 :: 2543 : 1699$ the range is 3 miles nearly.

$5.546 : 4 :: 650 : 491$ the height is 3 miles nearly.

The same table may also serve for computing the ranges of mortar shells. For this purpose, we have only to find what must be the initial velocity of the 24-pound shot, corresponding to the projected velocity of the shell. This must be deduced from the diameter and weight of the shell, by making the velocity of the 24-pounder such, that the ratio of its weight to the resistance may be the same as in the shell.

This, to find the range of the 15-inch shell, projected with the velocity of 2000 feet per second, at $45^\circ$ elevation. Here the diameter being 12.8, we have $12.8 : \sqrt{5.546} :: 2000 : 1317$, and as 178 : 149.4 :: 1317 : 115, the corresponding velocity of the 24-pounder; to which, in the table, answering the range 1930; then as 5.546 : $12.8 :: 1930 : 4455$ yards, or about 2$\frac{1}{2}$ miles the range. Hutton's Tracts, vol iii.

PROJECTING TABLE. See Table.

PROJECTION, in Mechanics, the action of giving a projectile its motion. See PROJECTILE.

If the direction of the force by which the projectile is put in motion, be perpendicular to the horizon, the projection
PROJECTION.

is said to be perpendicular, if parallel to the apparent horizon, it is said to be an horizontal projection; if it make an oblique angle with the horizon, the projection is oblique. The angle IAB (Plate XXXVI. Mechan. fig. 9.) which the line of direction A makes with the horizontal line AB, is called the angle of elevation of the projectile.

Projection, the art of forming the representation of a body upon a plane, by drawing straight lines through a given point or parallel from the contour, and from the intermediate lines of the body, if any; so as to cut the plane; then colouring the respective compartments, or each compartment, according to the degree of light, shade, and hue of the surfaces, or of each surface.

If the projection is made by drawing straight lines from a point, it is called a perspective representation; but if formed by parallel lines, it is called an orthography, or the orthographical representation, which is the subject of the present article, the former having been already given under the article Perspective.

Definitions.

1. The plane on which the object is represented, is called the plane of projection.

In orthographical projection, the rays by which the projection is formed, are here understood to be perpendicular to the plane of projection.

2. If the projection is made on a plane parallel to the horizon, or on a plane representing the horizon, it is called the plan of the object.

3. If the projection is made on a plane perpendicular to the horizon, or on a plane representing a vertical plane, it is called the elevation of the object.

4. The plane of position of an inclined line and a plane, is another plane passing along the line perpendicular to the plane.

5. The inclination of a line to a plane, is the angle on the plane of position comprehended between the line and the plane.

6. The plane on which any object is given, is called the primary plane.

7. A point on a plane is said to be given when its situation is known in respect of some given line, with regard to some fixed point in that plane.

8. The position of a line to a plane is said to be given when the limit of the line is given upon the plane, and when the angle which the line makes with its limit is known.

9. In the representation of figures, in planes inclined to the plane of projection, the situation of the figure, in respect to the intersection of its plane with the plane of projection, is supposed to be known. The intersection is, therefore, given on the plane of projection, and the space on the one side is to be considered as the original plane, while that on the other is the plane of projection.

Axiom.—If any point, line, or plane, coincide with the plane of projection, that point, line, or plane, so coincident, is both the original and the projection, of that point, line or plane.

Propositions.

1. The projection of a point is in a straight line drawn from the original point perpendicular to the intersection.

For, suppose a plane to pass through the original point perpendicular to the primary plane and to the plane of projection, the intersection of this plane with each of these planes will be perpendicular to the intersection of the primary plane and the plane of projection; but lines which are perpendicular to the same straight line, drawn from the same point, are in the same straight line, and, therefore, the projection of a point is in a straight line drawn from the original point perpendicular to the plane of projection.

II. The orthography, or projection of a straight line, is also a straight line.

For, let a plane pass through the original straight line perpendicular to the plane of projection, to intersect it; now the intersection of one plane with another is a straight line; therefore the orthographic representation is also a straight line.

III. All original parallel straight lines are represented by parallel straight lines.

IV. The orthographical representation of a line parallel to the plane of projection, is a line equal and parallel to its original.

V. The orthographical representation of a line parallel to the intersection, is a line equal and parallel to the original.

VI. The orthographical representation of a plane figure parallel to the plane of projection, is a figure equal and similar to the original.

VII. All planes perpendicular to the plane of projection, are represented as straight lines.

VIII. All straight lines in the primary plane perpendicular to the intersection, have their representations also perpendicular to the intersection.

IX. Every straight line in a plane perpendicular to the plane of projection, is represented by the intersection, or a part of the intersection, of that plane.

Problem I. Plate I. Fig. 1.

Given a point on a plane inclined to the plane of projection, to find the orthography of the point.

Let A B (fig. 1.) be the intersection, and let g' be the original point. Draw g' g perpendicular to A B, and through any other point D in A B, draw C E parallel to g' g; make the angle C D F equal to the inclination of the planes, draw g' C parallel to B D, and draw C E perpendicular to D F, cutting D F in i; make D E equal to D i; draw E g parallel to A B, then g is the representation of the point g'. For the representation of g' is in the line g' g; but it is also in the line E g; it will therefore be found in the intersection, g', of the lines E g and g' g.

Problem II. Fig. 2.

To find the orthography of a line on an inclined plane, the line being placed obliquely to the intersection.

Method I. Fig. 2.

Let A B be the intersection (fig. 2.), and b' b' the line. Find k and h the representations of the points k and h'; by problem I; join k h, and k h is the orthographic representation of the line required.

For since k is the representation of the point k', and k the representation of the point k, the extremities of the given line, the straight line k h, joining these two points, is the orthography of the line k h' by prop. I.

Method II. Figs. 3 and 4.

The intersection A B, the line E C, and the angle C D F, are here supposed to be the same as in fig. 1.

Let g' b' be the original line; produce g' b', (fig. 3.) to meet E C in C, and A B at i. Draw C k perpendicular to D F, cutting D F in k; make D E equal to D K, and join E i; then E i is the orthography of the line C I. Draw g' g parallel to C E, cutting E i at g; b' h parallel to g' g, cutting E i at h; then h g is the representation of h' g'.
Method 3. Fig. 4.

Let $g' h'$ be inclined the contrary way; find the orthography, $g'$ of the point $g'$, as in problem I., and join $g k$; draw $h' k$ perpendicular to $A B$, cutting $E i$ at $g$; then the intercepted part, $g h'$, is the orthography of $g' h'$, as required.

PROB. III. Fig. 5.

To find the orthography of a line perpendicular to the primitive.

Find $g$, the orthography of $g'$, by problem I.; draw $g C$ parallel to $A B$, cutting $C E$ at $C$; make $C K$ equal to the height of the line; draw $K O$ perpendicular to $F D$, cutting $D E$ at $D$; make $E F$ equal to $D O$; draw $E h$ parallel to $A B$, and $g h$ perpendicular to $A B$; then $g h$ is the representation of the line required.

PROB. IV. Fig. 6.

To find the orthography of a line inclined to the primitive, given the feet of the line and its inclination to the primitive.

Let $g' h'$ be the feet of the line; draw $g' p$ perpendicular to $g' h'$; and make the angle $g' h' p$ equal to the inclination of the line with its feet; find $g$ the orthography of $g'$; and $h$ the orthography of $h'$, by problem I.; also find $g p$ the orthography of the perpendicular $g' p$, and join $p h'$; then $p h'$ is the representation of the inclined line as required.

PROB. V. Fig. 7.

A parallelogram being given in the primitive, to find the representation of the parallelogram.

Let $g' h' k$ be the original parallelogram.

Find $g$, the orthography of $g'$, by problem I.; produce $g' h'$ to meet the intersection $A B$ in $l$; also produce $g' h'$ to meet the said intersection in $o$; join $g k$; and $g o$; produce $h' k$ to meet $A B$ in $m$; also produce $h' k$ to meet it in $n$; draw $m b$ parallel to $g k$, cutting $o g$ at $h$; also draw $n b$ parallel to $o g$, cutting $l g$ in $k$, and $m b$ at $i$; then $g h k$ is the orthographical representation of $g' h' k$.

In the same manner, the orthography of any plane figure in the primitive may be found, by producing the sides of the original figure.

PROB. VI. Fig. 8.

To find the orthography of a circle, draw the diameters $i' l$ and $b' k$ of the circle, the one parallel and the other perpendicular to $A B$, the intersecting line; find $i l$ and $b k$ the orthography of these diameters; and $i l$ and $b k$ will be the two axes of the ellipse, which is the orthographic representation of the circle.

PROB. VII. Fig. 9.

To find the orthography of a rectangular prism.

Find the representation $g h i k$ of the base by problem V.; then find $g l$ the representation of a line perpendicular to the primitive, by problem III.; draw $k m$, $i o$, $h n$, parallel to $g l$; through $l$ draw $l m$ parallel to $g k$, cutting $k m$ at $m$; and $l n$ parallel to $g k$, cutting $h n$ at $n$; latly, draw $m o$ parallel to $l m$, and $n o$ parallel to $l n$; and $m o n h$ will be the orthography of the fold.

PROB. VIII. Fig. 10.

To find the orthography of a right pyramid.

Find $g h i k$ the representation of the base $G H I K$, by problem V.; find $o$ the representation of $O$, the face of the apex, by problem I.; latly, find $g m$ the representation of the axis, by problem III., and join $m k$, $m i$, $m h$; then $k i h m k$ is the representation of the pyramid.

If the primitive and the plane of projection are at a right angle, the base of the object will be projected into a straight line, and all lines that are perpendicular will have their representations also perpendicular, and in height equal to that of the original fold.

Fig. 11. is the representation of a rectangular prism, fig. 12. that of a pyramid, fig. 13. the representation of a cylinder, and fig. 14. the representation of a cone, where the primitive and the plane of projection are at a right angle to each other.

Upon this simple principle the method of drawing planes and elevations depends.

PROB. IX. Plate II. fig. 1.

To find the orthography of any polygonal figure, the intersecting line, I., being given.

Let the polygon be a regular hexagon, $A B C D E F$; produce the side $A F$ to meet the intersecting line in $I$; also produce $A B$ to meet $I I$ in $I$; find the point $a$, the orthography of $A$, by problem I.; draw the diagonals $A C$, $A D$, $A E$, to meet $I I$ in $i'$, $i''$, $i'''$; join $a i'$ and $a i''$; draw $B i''$ perpendicular to $I I$, cutting $a i''$ at $b$, then $B b i''$ will be the representation of $B b i''$; also draw $F i''$ perpendicular to $I I$, cutting $a i''$ at $f$, and $f$ is the representation of $F$; therefore, $a b$ and $a f$ are the representations of $A B$ and $A F$; join $a i'''$, $a i''', a i'$; draw $b i'$ parallel to $a i''$, cutting $a i'$ at $c$, and $f e$ also parallel to $a i'$, cutting $a i'$ at $e$, draw $c d$ parallel to $a b$, cutting $a i''$ at $d$, and $c d$ parallel to $a f$; then $a b c d e f$ is the orthography of $A B C D E F$.

For, in the primitive figure, $B C$ and $F E$ are parallel to $A D$, and the opposite sides are parallel; therefore, in the orthographical figure, $b c$ and $f e$ are parallel to $a d$ or $a f$, and the remaining sides are parallel to their opposite sides.

PROB. X. Fig. 2.

Given the projection of an angle of a pentagon, and the project length of one of the sides containing the angle, to find the orthography of the whole figure, the intersecting line being given.

Let $I I$ be the intersecting line, $e a b$ the projected angle, and $a b$ the projected side; produce $a b$ to meet $I I$ at $i''$, and $a e$ to meet $I I$ at $i'''$; on $i'$ describe the segment $i A i'$ of a circle, to contain the angle of the two sides of a pentagon; that is, 108 degrees; draw $a A$ perpendicular to $I I$, cutting the are $i A i'$ at $A$; join $A F$, $A i''$; draw $b B$ parallel to $a A$, cutting $A i''$ at $B$; then upon $A B$ describe a pentagon, which will be the primitive figure; find the representations of the remaining parts as in the preceding problem, and $a b c d e f$ will be the orthography required.

PROB. XI. Fig. 3.

Given the intersecting and the inclination of a plane, and the projection of the intersection of that plane with another plane, and the inclination of the planes, to find the intersection of the second plane on the plane of projection.

Let $A B$ be the intersecting line of the first plane on the plane of projection; and let $A E$ be the projection of the intersection of the inclined planes. In $A B$ take any point $G$, and draw $G E$ perpendicular to $A B$, cutting $A E$ at $E$; produce $A E$ to $K$; make the angle $E G F$ equal to the inclination of the primitive to the plane of projection; through $E$ draw $E H$ perpendicular to $A E$; make $E H$ equal to $E F$, and join $H A$; draw $E I$ perpendicular to $A H$, cutting $A H$ at $I$; make $E K$ equal to $E I$, and join...
Join B K; make the angle B K D equal to the angle which the two planes make with each other; join D A, and D A will be the intersection of the second plane with the plane of projection.

**Pror. XII.** Fig. 4.

Given the intersection and inclination of a plane to the plane of projection, and the inclination of that plane to another inclined plane, and the angle which the inclined planes make with each other, to find the intersection of the second inclined plane with the plane of projection.

Let A B be the intersection of the first inclined plane with the plane of projection; and let A E be the intersection of the two inclined planes; draw E F perpendicular to A B, cutting A B at K; make the angle F K G equal to an angle of the plane; make K G equal to K E, and draw G F parallel to A B; draw D C perpendicular to A F; make F D equal to F G, and join D A; draw F I perpendicular to D A, cutting D A at I; produce A F to H, and make F H equal to F I; join B H, and make the angle B H C equal to the angle of the planes; then join C A, and C A is the intersection which was to be found.

**Pror. XIII.** Figs. 5, 6, 7, 8, 9.

To find the inclination of two adjoining planes of the regular solids.

Draw the base A B C, A B C D, or A B C D E, of the pyramid which forms one of the solid angle; draw the triangle B G C, the development of one of the sides of the pyramid; draw G F perpendicular to B C; bisect the angle A B C; and let the bisecting line meet G F in F, their point of concurrence; draw F H perpendicular to B F; from B, with the radius B G, describe an arc, cutting F H at H; draw F I perpendicular to B H, cutting B H at I; in F B make F L equal to F I; let F H and B C meet in M; also let F H and B A meet in K; join M I and K L; then K L M will be the angle of the plane as required.

As the sides of the tetrahedron are equilateral triangles, and as three of the triangles form each solid angle, both the base of the pyramid A B C, and the developed side B G C, will be equilateral triangles in fig. 5.

In the construction for fig. 6, as the sides of the hexahedron are squares, and as each solid angle is formed by three of the right angles, the base of the pyramid will be an equilateral triangle, and the vertical angle of the developed side will be a right angle.

In the construction for fig. 7, as each side is an equilateral triangle, and as four of the angles of the triangle form the sides of the solid angle, the base of the pyramid will be a square, and the developed side will be an equilateral triangle.

In the construction for the octahedron (fig. 7), as each side is an equilateral triangle, and as four of the angles of the triangle form the sides of the solid angle, the base of the pyramid will be a square, and the developed side will be an equilateral triangle.

In the construction for the dodecahedron, as each solid angle is formed by three planes, and as each of the planes is a pentagon, the base of the pyramid will be an equilateral triangle, and the vertical angle of the developed side will be equal to the angle formed by the two sides of a pentagon.

In the construction for the icosahedron (fig. 9), as each solid angle is composed of five faces, and as all the sides of the solid are equilateral triangles, the base of the pyramid is a pentagon, and the developed side an equilateral triangle.

In the construction for the dodecahedron, the angle of the pentagon was found by dividing a circle into five equal parts, and joining the chords of two adjoining parts, as A B, B C, fig. 8, N° 1; then, to obtain the vertical angle, draw A C as a base; bisect the angle A B C, which will also bisect the straight line A C in E; make E F equal to the half of B C, N° 2, and draw F G parallel to B C, cutting B D at G; make E G, N° 2, equal to E G, N° 1; and in N° 2 join G B and G C, which will give the vertical angle B G C.

**Pror. XIV.** Fig. 13.

To project the dodecahedron.

Find abed the orthography of one of the planes, by problem IX; find the angle which two contiguous planes of the solid make with each other, by problem XIII; find the intersection of each of the planes adjoining to the plane whose projection is found, by problem XII, and thus the three on the sides of the solid will be projected; then to project the planes adjoining the extremities of the arrises or edges a, b, c, d, e, suppose that contiguous with a, e, produce c d to meet the intersecting line I I' in i', and produce c e to meet I I' in i'; then having the projection of the angle c d e, and the projected lengths c e or d e of one of the sides, and the intersecting line i', i' of the plane of that side, find the orthography of the figure c d e in the whole figure, by problem X. In like manner, find the orthography of the figures m n o p q, e k l b, and the representation of the solid will be completed.

This new method of projection is not only more periphrastic, and requires fewer lines in the construction than that used by Brook Taylor, &c., but is also of universal application in every position, without the principle of dividing a line into extreme and mean ratio.

Not only architectural designs, but machinery drawing, depend upon orthographical representation; it enables the architect, engineer, or mechanic, to construct the objects intended to be executed. As drawings of every kind are greatly facilitated by a knowledge of the formation of bodies, so in drawing machines it is necessary to know the methods of representing any system of lines upon cylindrical and conic surfaces, as this knowledge will determine whether the lines represented are parallel to each other, or tend to a point.

In drawing of machinery, as in other kinds of orthographical representations, the object is represented upon two planes, one parallel, and the other perpendicular to the horizon.

As the faces of the different parts of a machine are generally in vertical planes parallel to each other, the elevation is also made on a vertical plane parallel to the faces of the work, or to the greatest number of faces, in order to facilitate the execution, as this position not only gives the nature of the parts, but is also convenient in ascertaining the magnitude of the lines in every direction in these planes, and the angles which the lines form with each other; for if the faces of the work stand at oblique angles with the projecting plane, there can be only one direction, namely, that of measuring in a vertical line, in which the true dimensions can be ascertained; every other will be fore-shortened, and the angles formed by the lines of representation will also vary from the original angles of the object.

As the axes of wheels are sometimes obliquely situated, it becomes necessary to represent them in various positions. The several kinds of representations are sections through the principal parts; as through the axis of a wheel, plans or horizontal projections, and elevations.

Though a plan and elevation are sufficient to construct any machine with proper attention, yet from the greater facility of comprehending the nature of the design, and applying the measures to practice, two elevations are sometimes given, particularly in a complex machine. One of these elevations expresses the parts in the longed horizontal dimension of the work, and the other represents the parts comprehended
comprehended in the breadth or horizontal extent of the work.

In the representation of a machine, the wheelwork is the most difficult of any part, except when the whole of the surfaces of the wheel are planes, with two or more faces parallel to the projecting plane, and all the other surfaces perpendicular to the said plane, as in this case the boundaries of the parallel planes are represented by figures similar to the original faces, and the whole of the other surfaces are projected into straight lines or circles. This case is so very simple, as not to require any directions; but if the wheel or its faces have an oblique position to the projecting plane, several considerations are necessary to effect a true representation.

A ground section through the axis of the wheel, placed at the required angle, with the intersection of the plane of elevation, and an elevation of the wheel on a plane parallel to the faces, will be required. It is likewise necessary to observe, that in this oblique projection all the parallel arista[?]s of any original object are represented by parallel lines, and all equal distances in the original object are represented by other distances equal among themselves; also all straight lines whatever in the original plane, divided into parts, are represented by a series of parts respectively in the same proportion. The ratio of any line is to its original, as radius to the colline of the inclination of the original line and the plane of projection. The representation of an original circle is an ellipse, and as the plane of projection is vertical, the elevation of an ellipse will be represented with its greater axis parallel to the intersecting line.

Having now premised a few of the leading principles, we shall proceed to the representations of wheelwork.

Example 1. Plate III.

Fig. 1, No 1, is the representation of the half of a water-wheel, on a plane perpendicular to the axis of the wheel. F G H is the arc of a circle representing the convex side of the ring; I K L is the arc of a circle representing the concave side; I, H, L, M, N, O, P, are the ends of the float-boards, fastened to the radiating pieces at the back, and the radiating pieces are fastened to the ring by mortice and tenon.

Fig. 1, No 2, is an elevation of the wheel upon a plane parallel to the axis; this shews the planes of the ring as straight lines; the float-boards are represented by I, H, L, M, N, O, P, which shew the radiating planes of the sides, and the outer edges which adjoin, and which range in a cylindrical form.

Fig. 1, No 3, is an elevation of the wheel upon a plane inclined to the axis; but the axis, in all the three positions, is supposed to be in a plane perpendicular to the plane of projection. The intersection of this plane is represented by the straight line E E.

In this it will be observed that all the circles are represented by ellipses, and that all the ellipses are proportional to each other, and the dimensions in the transverse axis are equal to those in the original object which they represent. The dimensions in the conjugate axis, oes, in the line E E, are diminished in the ratio of radius to the colline of inclination: oes, in all the planes which are perpendicularr to the axis of the wheel. Therefore in fig. 1, No 4, draw any two straight lines, making any convenient angle with each other: make E F equal to the transverse axis of the greatest ellipse, and E G equal to the conjugate in fig. 1, No 4, in E F make E b equal to the length of a float-board; bisect E b at k, and make E i and k f half the thickness of the ring; then l i will be the whole thickness: join G F, and draw h m, i n, k o, f p, parallel to F G, cutting G E at m, n, o, p; then E m is the length of the float-board in the drawing, and p is the thickness of the ring in the frame, to be transferred to the line E E; observing that the transverse axis is perpendicular to the line E E.

In fig. 1, No 3, draw the two similar and equal ellipses, which form the extremities of the outer edge of the float-boards, at the distance of E E, No 4, from each other about the same axis; these will contain the edges of the float-boards. One of these ellipses may be projected entirely round; as also the other in the same plane which forms the lower edges. The latter two ellipses will contain the ends of the float-boards which radiate to the centre of the wheel.

The edges of the float-boards ranging in the exterior cylindrical surface, might be found by drawing lines parallel to the axis from 1, H, L, M, N, O, P, &c. No 1, to the corresponding letters I, H, L, M, N, O, P, &c. No 3; but this method, though simple, does not give sufficient accuracy at the extremities of the transverse axis.

In order to obtain greater certainty, let A C B, No 5, be a semi-ellipse, equal to the half of the two ellipses which contain the edges of the float-boards, arranged in the exterior cylindrical surface of No 3; A B being the transverse axis, and E C the semi-conjugate: join A C and C B; bisect A C by a perpendicular g 2, cutting A C at 2; make g 2 equal to 2 A or 2 C. From the centre g, with the distance g 2, describe an arc 3 4, intersecting g C and g A at 3 and 4. Between the points of intersection divide the quadrant into as many equal parts as there are intended to be float-boards in a quarter of the wheel. Suppose it were required to place the first division at the point I of the ellipsis A C B; draw I E, cutting A C at y, and join y g, cutting the arc 3 4 at r; then the part of the arc 3 4 is a multiple being determined, and beginning at that part as a radius, cut off the equal arcs r k, k l, m n, n o, o p, p q; through the points r, k, l, m, n, o, p, q, draw g y, y r, r k, k l, l m, m n, n o, o p, p q; the radius of the circle represented by A C, cutting A C at y, z, s, t, u, v, w, x; through the points y, z, s, &c. draw the lines E I, E H, E L E, &c., cutting the circumference of the semi-ellipses at 1, H, L, &c., and the parts P Q, P O, P N, will be obtained with the greatest certainty, as well as the representations of the angles I E H, H E L, E M, &c. about the centre. Upon this principle the edges of the boards in the planes in which the ends of the float-boards are arranged, are found. The edges of the float-boards arranged in the cylindrical surfaces are all parallel to the axis; and the parts in the plane of position in which the axis of the wheel is poited are obtained from No 4.

The whole of this process is so very easy, that a little reflection will enable the reader to comprehend the principles clearly.

Example 2. In sphero-conic wheels.

Sphero-conic wheels are those of which the teeth project from the surface of a cone, and of which the working surfaces of the teeth tend to the apex of the said cone.

Hence the ends of the teeth of two wheels which work together will be found in a sphero surface, of which the apex of the cone is the centre of the sphere.

Fig. 2, No 1, is the section of a sphero-conic wheel H F E, and O P M L the section of the opposite teeth; G H E D, and N O L K, the sections through the opposite parts of the ring.

Fig. 2, No 2, the orthography of the wheel upon a plane parallel to the circles which form the arities of the ring. In No 1 and No 2, the point A represents the vertex of the conic surfaces from which the teeth project; the line R A, No 1,
PROJECTION.

$N^0 1$, represents the axis in the same straight line with the point $A$, $N^0 2$.

$Fig. 2$, $N^0 3$, is half the section of the wheel; $fig. 2$, $N^0 4$, is the orthography on a plane parallel to the axis; in $N^0 3$ and $N^0 4$, $AB$ and $AB$ are the axes parallel to each other; the points $A, A$, are in the perpendicular $A A$ to $A B$.

$Fig. 2$, $N^0 5$, is a whole section of the wheel. $N^0 6$ is the orthography projected upon a plane oblique to the axis.

In $N^0 2$, $N^0 4$, and $N^0 6$, the edges of the teeth in the conic surface of contact terminate in the vertex $A$; and the edges in the two concentric conic surfaces, each perpendicular to that ending in the point $A$, terminate in the points $B$ and $C$. These are all projected in the point $A$, $fig. 2$, $N^0 2$.

The three projections $N^0 2$, $N^0 4$, and $N^0 6$, have their axes in the same straight line, in order to find the representation of the teeth by drawing parallel lines to cut the representations of the corresponding circles.

In $N^0 2$, the representations of the original circles are also circles; in $N^0 4$ the representations of the original circles are straight lines, and in $N^0 6$, the representations of the original circles are ellipses. The section at $N^0 4$, determines the conjugate axis of each ellipse, the transverse being equal to the diameters of the original circles.

$Prob. XV.$ Plate IV. $fig. 1$.

Given the seat and altitude of a line on a plane, and the intersection of the plane with another plane, at a given angle, to find the sun's seat on the other plane, as also its angle of altitude.

Let $A C$, $fig. 1$, $N^0 1$ and $2$, be the seat of the line; $A B$ the intersection of the other plane. In $A C$ take any point $C$; draw $CD$ perpendicular to $AC$; draw $CE$ perpendicular to $AB$, cutting $AB$ at $B$. In $N^0 2$, draw $CH$ perpendicular to $BC$; make $CH$ equal to $CD$; make the angle $CBG$ equal to $MLK$, $N^0 3$, the inclination of the plane; draw $HG$ perpendicular to $BG$; make $BE$ equal to $BG$, and join $AE$; then $AE$ is the seat of the sun's rays on the other plane.

Draw $EF$ perpendicular to $AE$; make $EF$ equal to $GH$, and join $AF$; then $EAF$ will be the angle of altitude of the line on the other plane.

In $N^0 1$, the two planes are at right angles with each other; in this case the problem may be constructed without the quadrilateral $BCHG$; thus, having drawn $CE$ perpendicular to $AB$, cutting $AB$ at $B$; make $BE$ equal to $BD$, and complete the triangle $AEF$, as in $N^0 2$; then $AE$ is the seat of the line, and $EAF$ is the angle of altitude, as before.

This may easily be conceived, by supposing that upon the triangle $ABC$, $N^0 2$, the triangle $ACD$, and the quadrilateral $BCHG$, are raised perpendicularly, then $CH$ and $CD$ will coincide, and the point $D$ will turn the triangle $ABE$ upon $AB$, and the side $BE$, being perpendicular to $AB$, will describe a plane upon $BE$ perpendicular to the plane $ABC$; and because $BC$ and $BE$ are in the same straight line, $BC$ will be in that plane; and because the plane $BCHG$ is supposed to be raised perpendicular to the plane $ABC$ upon $BC$, the plane supposed to be described by $BE$ will be in the same plane with $BCHG$, which, raised perpendicularly to the plane $ABC$ upon $BC$, therefore, move the plane $ABE$ until $BE$ coincide with $BG$, supposed to be raised with the plane $BCHG$; the plane $ACD$, the plane $BCHG$, and the plane $ABE$, being thus supposed to be raised, turn the plane $AEF$ round $AE$, until $EF$ fall upon $GH$; then the point $F$ will fall upon $H$; and the straight line $AF$ will also be coincident with $AD$; for the triangle $AEF$ will be at a right angle with the triangle $ABE$, therefore $EF$ will be at right angles to the plane $ABE$.

$Prob. XVI.$ $Fig. 2$.

Given the seat and altitude of the sun's rays on a plane and the angle which the seat of a line parallel to the plane of projection makes with the seat of the sun's rays, to determine the inclination of the plane of shade obstructed by the original line with the plane of projection.

Let $AC$ be the seat of the sun's rays given upon the plane of projection; make $CAD$ equal to the altitude of the sun's rays; draw $CD$ perpendicular to $AC$; make $CAB$ equal to the angle which the seat of the sun's rays makes with the seat of the original line, which occasions a plane of shade; from $C$ draw $CB$ perpendicular to $AB$, and $CE$ perpendicular to $CB$; make $CE$ equal to $CD$, and join $BE$; then $BCE$ is the inclination of the plane required. Produce $CB$ to $F$; make $BF$ equal to $BE$, and join $AF$; then let the triangles $CDA, CBE, BAF$, be turned up, and $AF$ and $AD$ will coincide; and the triangle $BCE$ will measure the inclination of the plane $ABF$ to $CBA$.

This problem is of the utmost use in finding the shadows of parallel lines to planes in various positions, as also in finding the shadows of cylinders where the axis is parallel to the plane of projection; also in determining the points and lines of light and shade both in cylinders and cylindrical rings.

$Prob. XVII.$ $Fig. 3$.

Given the seat and altitude of a line; and the seat and altitude of the sun's rays, to determine the shadow of the line on that plane.

Let $HE$ be the seat of the line; make the angle $EBH$ equal to the altitude of the line, $viz.$ of $ABC$, $N^0 1$; $E$ being any point in $HE$; draw $EI$ perpendicular to $HE$; draw $EF$ parallel to the seat of the sun's rays; and draw $EG$ perpendicular to $EF$; make the angle $EGF$ equal to $EI$; make the angle $EGR$ equal to the complement of the sun's altitude, and join $HF$, which will be the shadow of the line required.

This problem will be found of the greatest use in finding the shadows of objects upon inclined planes.

$Prob. XVIII.$ $Fig. 4$.

Given the inclination of a line to two planes at right angles to each other, to find the seat of the line on each of the planes, and the intersection of the planes.

Let $ABC$, $N^0 2$, be the inclination or angle which the line makes with one of the planes, and $DEF$, $N^0 3$, the angle which it makes with the other plane.

From the angular point $B$, $N^0 2$, take $BC$ of any length, and from the angular point $E$, $N^0 3$, take $EF$ equal to $BC$. In $N^0 2$, draw $CA$ perpendicular to $AB$, and in $N^0 3$, draw $FD$ perpendicular to $ED$. In $N^0 1$, draw any line $HK$; and through $G$, any point in $HK$, draw $HI$ perpendicular to $GK$; make $GH$ equal to the line $DF$ of one of the angles of $N^0 3$, and $GI$ equal to the line $AC$ of the other, $N^0 2$; from $K$, with the radius $AB$, $N^0 2$, describe an arc, cutting $GK$ at $K$, and join $HK$ and $KI$; then $GK$ will be the intersection of the planes, and $KH$ and $KI$ will be the seats of the line on each plane.

In the following problem respecting shadows, two planes of
of projection are always supposed to be given, viz., the face of the rays of light on each of the planes, and the intersection of the planes, unless it be otherwise announced.

Practical Examples of Shadows.

Ex. 1.—To find the shadow of a rectangular prism attached to a wall, one of the sides of the prism coinciding with the surface of the wall.

Let \( H I K L M N \) (fig. 5) be the plan, the straight line \( HI LMN \) that of the wall, and \( I KLM \) that of the prism; and let \( ABCD \) be the elevation of the prism, and \( VW \) the intersection of the plane of elevation, and that of the ichnography parallel to \( HN \) and \( KL \) in the plan.

To find the shadow of any point \( B \) on the elevation, corresponding to \( L \) on the plan.

Draw the ichnography \( LN \) of a ray of light; also from \( B \) draw \( BF \), the elevation of the ray, at any given angle with the intersection \( VW \); join \( BL \); draw \( FN \) parallel to \( BL \), and the point \( F \) will be the shadow of the point \( B \) on the elevation.

In the same manner find \( E \) and \( G \) the shadows of the points \( A \) and \( C \), join \( EF \) and \( FG \), and \( ABCGFEA \) is the shadow required. Or thus:

Find the shadow \( F \) of the point \( B \) as before; draw the indefinite representations \( AE \) and \( CG \) of the extreme rays; then because the arisings or edges of the prism are parallel to the wall, or to the surface on which the shadows are thrown, the representations of the edges of the shadows will be parallel to the representation of the arisings on the plane of elevation; therefore draw \( FE \) parallel to \( AB \), and \( FG \) parallel to \( BC \); and \( AEFG \) will be the edge of the shadow, as before.

Ex. 2.—The shadow of fig. 6. is found in the same manner as in the last problem; the body which throws the shadow being a prism, having its planes parallel and perpendicular to the surface on which the shadow is thrown; \( ANMLC \) is therefore the outline of the shadow thrown by a prism, represended by \( FGH \) on the plan, and by \( AB \) on the elevation. The figure here introduced represents a cantiliver projecting from a wall.

Ex. 3.—To find the shadow of a cantiliver formed as in the last example, the plane of elevation being placed obliquely to the surface on which the shadow is thrown.

Let \( EFILK \) (fig. 7) be the representation of the surface on which the shadow is projected, placed obliquely to the line \( VW \), the intersecion of the orthographic planes; let \( FGH \) be the plane of the cantiliver, and let \( ABCD \) be the elevation of the cantiliver, the points \( A \) and \( D \) on the elevation corresponding with the point \( H \) on the plan; and the points \( B \) and \( C \) corresponding with the point \( F \) on the plan. The end of the cantiliver is represented by \( DEF \), and the root by \( CB \); the point \( I \) on the plan being represented by \( g \) and \( h \) on the elevation, and the point \( F \) on the plan by \( B \) and \( C \) on the elevation. To find the shadow of any corresponding lines \( FG \) and \( BB \); draw \( GL \), the parallel of the face of the fan's rays on the plane, meeting the shadowed surface \( EK \) in \( L \); draw \( LM \) perpendicular to \( VW \); from \( B \), the corresponding point of \( G \), draw \( BM \) the elevation of the ray; join \( BM \); draw \( G \) parallel to \( B \); draw \( MN \) parallel to \( AB \), and \( NO \) parallel to \( AD \); then \( BMNO \) will be the shadow required; for the representation of the two edges of the shadows are parallel to the representation of the two edges of the end of the cantiliver.

Ex. 4.—Let \( ABD \) (fig. 8) be the intersection of any vertical surface on which a shadow is to be thrown; and let \( BCD \) be the plan of a triangular prism projecting from that surface; also let \( GHIF \) be the elevation of the plane; find \( p \) the shadow of the perpendicular line as before, and join \( nG \), and \( pn \) is the shadow of the prism as required.

Ex. 5.—\( GHIKL \) (fig. 9.) is the elevation of several rectangular prisms joined to each other in the form of a pediment; \( GHIKL \) is the outline, and \( l m n \) the inner line forming the tympanum.

\( ABEF \) is the plane of the surface on which the shadow is to be thrown parallel to the intersecting line \( VW \); \( BCD \) is the plane of the pediment, of which the line \( CD \), representing the face, is parallel to \( AF \).

Draw \( GO \), \( HP \), \( IG \), and \( r \), the elevation of the rays; draw the ray \( D \) on the plane, meeting \( AF \) at \( v \); draw \( NO \) perpendicular to the intersecting line, cutting the rays \( HP \) and \( IG \) of elevation at \( P \) and \( G \); draw \( PO \) parallel to \( GH \); then \( GOPG \) will be the extremity of the shadow, the same as in example 1. To find the shadow from the inner edges \( l m n \); make \( n \) equal to \( GO \), or \( HP \), or \( IG \), as each of the points \( G, H, I, r \), is equally distant from the shadow; draw \( rs \) parallel to \( nL \), and \( r s \) parallel to \( nm \); and \( r s \) is the shadow from the under arisings of the inclined planes.

Ex. 6.—Fig. 10. is the shadow of several rectangular prisms crossing each other at equal angles; one of the faces of each is parallel to the plane on which the shadow is thrown, and also parallel to the plane of elevation; the opposite or parallel faces are attached to the plane on which the shadow is thrown, and, therefore, the other faces are perpendicular to the said plane. The shadows, therefore, are to be found in the same manner as in the last example, viz., by drawing indefinite rays from all the angular points on the elevation, and finding the length of one of them; then the rest is completed by parallel lines from the termination.

Ex. 7.—To find the shadow of a rectangular ring.

Find the point \( l \) (fig. 11.) the shadow of the centre \( k \); through \( l \) draw \( OP \) perpendicular to \( ki \); then with the radius of the interior circle describe the arc \( WXU \), meeting the said inner circle in \( W \) and \( U \); also from \( l \), with the radius of the exterior circle, describe the semicircle \( OQP \); draw \( OM \) and \( PN \) parallel to \( lk \), and these lines will touch the circle in \( M \) and \( N \); then \( MOQP \) is the exterior shadow required.

Prob. XIX.

To find the representation of the shadow on a prismatic solid, by a plane cutting the prism perpendicular to its arisings; given the elevation of the prism on a plane parallel to its arisings, and parallel to one of its sides; given also the figure of the plane which throws the shadow, with the section of the surfaces of the prism on that plane; likewise the sun's rays both on the plane and on the elevation.

Place the figure of the plane and the elevation so, that any two of their corresponding points, or parts, may be in a line perpendicular to the intersection. Draw the representation of the rays from all the angular points on the figure of the plane to meet the section line of the prism; draw the corresponding representations of the rays on the elevation, and from the points where the representations from the angles of the plane meet the section, draw lines parallel to the representations of the arisings of the prism to cut the corresponding rays on the elevation; then by joining the successive points, the shadow which was required is determined.
Examples. Plate V.

Ex. 1.—Let ABCD (fig. 1.) be the plane, and EF, FG, the intersections of two other planes at right angles to the plane ABCD, and let K L N O be the elevation of the prism; the lines ON, RM, and KL, representing the angles corresponding to the angular points G, F, E, on the section, that is to say, the point G is in the plane straight line with ON, the point F with RM, and the point E with KL. Also let KLMR represent the plane which is parallel to the plane of elevation, and let KP represent the plane of intersection.

Make KU equal to the breadth of the shadow at the bottom; draw the ray DI on the figure of the plane; draw DT perpendicular to KP, cutting KP at T, and T will represent the point which throws the shadow on the elevation; draw TQ, the ray of the sun, on the elevation; IQ parallel to DT, and US parallel to KP, cutting RM at S; join SQ; then KUSQVO will be representation of the shadow required.

The examples in this plate, as well as the five succeeding ones in the following Plate VI., shew the forms of shadows on the roofs of buildings, from chimney shafts and dormer windows of various forms.

Ex. 2.—Fig. 3. shews the shadow of a chimney shaft upon the roof of a house, the sides of the chimney shaft being parallel and perpendicular to the front.

Ex. 3.—Fig. 4. shews the shadow of a chimney shaft upon a roof which has two inclinations, the sides of the chimney shaft being situated as in example 2. The principles of performing these two examples are the same as in the preceding problem, and as illustrated in example 2. under the said problem.

Ex. 1.—To find the shadow of a chimney shaft on the roof of a house.

Find the indefinite shadow of the vertical line FL, fig. 5, No. 2, thus:

Let AC, fig. 5, No. 3, be parallel to FL; find BD as in prob. XXI.: draw FO, No. 2, parallel to BD, No. 3; now let the parallel of the orthography of the fun’s rays be given: from L draw LO, the orthography of the fun’s rays, and the point O is the termination of the shadow LO; produce FG and LM to meet each other in N; draw ON, and ON is the indefinite representation of the shadow of the edge LM of the top; draw the orthography MQ of the ray parallel to LO, cutting ON at Q: continue the intersection GH, and the edge ML of the top, to meet each other in P: draw QP, and QP is the indefinite representation of the edge of the top, and of the other vertical plane not seen; draw HR parallel to HO, and FOQRH will be the shadow required.

Ex. 2.—Fig. 6. is the shadow of a dormer window with a rectangular front, and the top inclined toward the front; find the indefinite shadow AG as in the last example, and the orthography EG of the fun’s rays, and join BG; and AGB is the shadow required.

Ex. 3.—Fig. 7, is the shadow of a dormer window with a pediment top: find AG the shadow of AE, as before; then DE being the next line that projects a shadow, A B is the intersection of the plane ABCDE; therefore, produce DE and BA to meet in F; join FG, which produce to H: find the termination H by the ray DH, and AGHDE will be the shadow required.

N.B. If the lines DE, EG, had been in the same straight line, or had formed a slanting angle instead of a re-entrant one, the upper side of the shadow would have been the same as in the last example.

4 C
"Ex. 4. — Fig. 8. exhibits the shadow of a dormer window with a femicircular head: find the shadow A1 of the perpendicular line AB; let O be the centre of the femicircular head; draw OL to touch the head of the window at A; and D is the point of contact; let it be required to find the shadow of any intermediate point, E, of the arc of the circle; now AB is the intersecation of the plane A B C D E F; therefore draw a chord E F, and produce A B and E F to meet each other in H; join H I; produce H I to K; and draw the orthography E K; and the point K will be the shadow of the point E: in like manner draw the chord D E, and produce D E and B A to meet each other in G; join G K; produce G K to L; and L will be shadow of the point D: draw a curve from the point I, through K to L, touching the straight lines A I and D L at the points I and L and A I K L D will be the shadow required.

Ex. 5. — Fig. 9. exhibits the shadow of a dormer window with a kirk-roof top; find the shadows M, K, L, of the points E, F, G, as in the last example; and A I K M E F G A will be the shadow required.

It is hardly possible to conceive any method more expeditious than the present, of finding the indefinite representation of the shadow by producing the line which throws it and the intersecation of the plane till they meet each other in the plane in which the shadow is thrown. This principle has never before been generalised, for though it was well known, that if the representation of the shadow of the extremity of a line projecting from a surface, and the representation of the intersecation of that line with the surface was found, the representation of the shadow of the line would be determined by joining the representation of the point to the representation of the shadow; yet the method of producing the representation of each successive line, and the intersecation of the plane which throws the shadow with the plane on which the shadow is to be thrown, or with the several planes on which the shadow is to be thrown, has never been known as a general rule. This method has great advantages over the common established one, which requires that the feet of every point of the line, or several lines, which throws the shadow, be represented in the plane or several planes on which the shadow is to be thrown, and also that the feet of the luminar be represented in the plane or several planes: this last mode is attended with great labour, when there are more planes than one.

It is true, that in perspective, when the vanishing line of a plane of shade is found, and the vanishing lines of the planes on which the shadows are thrown, the indefinite shadow of the line upon each plane will easily be found: but these vanishing lines are frequently inaccessible, and the construction of them is attended with great labour, and when more lines than one throw a shadow on several surfaces, the labour to find the vanishing line of each plane of shade, and the vanishing lines of the planes on which the shadows are thrown, is very great.

From the great importance of this method in the art of shadows, it will be proper to give a few more examples, in order to shew its univeral and expedition.

Ex. 6. — Fig. 1. Plate VI. No 1 is the elevation of a prismatic object, as the walls of a building, which form two prisms attached to each other; the lower prism is terminated with an inclined plane in the manner of a roof. The plan, No 2, shews the end of the higher prism, to which the lower prism is attached, to be at an obtuse angle with the plane of the front.

Let the ray B F, No 2, be drawn on the plan from the corner B, to meet the side C D at F; then F is the projected point of B on the plan: draw F g, the elevation of the point F, cutting the top of the lower wall at g; draw l m, the elevation of the sun's rays, as in the preceding examples; produce the intersecation h i of the inclined plane to meet the line b l, which projects the shadow in k; through the points k and g draw k g m, meeting the elevation of the sun's rays at m. Now, as the line l o of the top of the end of the prism projects the next shadow, produce l o and the intersecation i b to meet each other in n; draw m n, cutting the upper termination b q of the inclined plane at r; and f g m r h f will be the shadow required.

Ex. 7. — Fig. 2. No 1 is a plane representing the gable of a house, of which B A is the bafe; F G, G H, H U, are the intersecations of several planes; F G, parallel to B C, is the intersecation of a vertical plane, as the face of a wall; G H and H U are the intersecations of two inclined planes, forming two sides of a kirk roof. Now, to find the shadow by the intersecating points of the lines which project the shadow with the plane or which the shadow is thrown, it is evident that the line B C will project a shadow on the plane whose intersecation is F G parallel to F G; and as B C, No 2, represents B C, No 1, draw F q parallel to B C, cutting the lower inclined plane at q. Then, supposing the side B C also to throw a shadow upon the lower inclined plane, produce its intersecation H G, No 1, and the line B C, which throws the shadow, to meet in K; produce C B, No 2, to k, and draw K k parallel to B A, then through the points k and q draw k q r; draw C C from C, No 1, to C, No 2, parallel to B A, No 1; from the point C, No 2, draw the elevation C r of the sun's rays. C D, No 1, is the next line which throws the shadow still upon the lower inclined plane; therefore, produce C D and G H, to meet each other in M; draw M m parallel to B A, cutting B C at m; draw also the indefinite shadow r m, cutting the intersecation of the two inclined planes at s, No 2; then the line C D will also project a shadow upon the upper inclined plane; therefore, produce H U and C D, No 1, to meet each other in N; draw N n parallel to B A, cutting B C at n; draw the indefinite shadow n s; then d, No 2, being the corresponding point of D, No 1, draw the elevation of the ray d t, No 2, and the point t, No 1, will be the shadow of D, No 1. D E, No 1, is the next line which projects a shadow, and U is the intersecation of D E and H U, and u the corresponding point to U, No 1; therefore join t, n, and B p q r s t u will be the shadow required.

Ex. 8. — Fig. 3, represents an example similar to fig. 1, but with two inclined planes; the plan is here omitted, as it is only used in the project of the first ray; the ray G L, parallel to A B, is drawn at pleasure at any distance from F H, to meet the intersecation H P of the two adjoining planes in L; produce I H to meet the line A B, which throws the shadow in D; draw D L, and produce D L to S; draw the elevation of the ray B S; then B C is the next line which throws the shadow: produce B C and H I to meet each other in E; draw the indefinite shadow S E to cut the intersecation I Q of the two inclined planes at M; then B C will also project a shadow upon the upper plane; therefore, produce B C, and the intersecation I K of the upper plane, to meet each other in T; draw the indefinite shadow M T, cutting the top K R at N; then F G L S M N K will represent the project of the shadow by the edges A B, B C, of the plane A B C, as required.
or perpendicular to the first vertical plane F O P H, according
as the sides are parallel or oblique to the plane of represent-
ation.

Ex. 9.—Let A B C D E (Fig. 4.) be the figure of a gable, K L M N the upright of a wall, A B the bafe of the
gable, N M the bafe of the wall; and suppose that the
edge B C is joined to N K at any given angle, so that
the point B may coincide with the point N. Now let it
be required to find the shadow of the gable A B C D E
upon the wall K L M N, the side B C of the gable being
placed parallel to the edge N K of the wall.

As the vertical sides A E and B C of the gable are
parallel, the shadow thrown upon the plane K L M N will
also be parallel to the edge N K; therefore, taking N g
at pleasure, draw g h parallel to N K; then e being the
corresponding point of E, draw e h the elevation of a ray
of the fun, and the point h will be the shadow of the
point E. E D being the next line that projects the shadow,
produce E D and B C the interfection of the plane to meet
in F; find f the corresponding point of F, and draw the
indifinate shadow f f; find d the corresponding point of D,
and draw the elevation d i of a ray, cutting h f at i; C
being the concourse of the line which throws the shadow
with the interfection B C of the plane, find c the cor-
responding point of C, and join c i; then e i g h is the
shadow of the lines A E, E D, and D C.

Ex. 10.—A B C D E (Fig. 5.) represents the gable of
a building as in the preceding example, S T U V the up-
right wall and inclined side of a roof, F G and G I the
repective interfections of the wall and the roof; then, sup-
poling the edge E D of the gable to be attached to S B,
it is required to find the form of the shadow; the inter-
fecion F G of the plane being parallel to A B, the
breadth of the shadow will also be parallel; therefore,
taking the distance S n upon S V at pleasure, draw m o
parallel to S T; then b being the corresponding point of
B, draw the elevation b o of the ray. B C being the next
line which projects the shadow, produce the interfection
F G to meet B C in L; find l the corresponding point of
L, and draw the indifinate shadow o l, cutting b w at p;
B C now projects the shadow upon the inclined plane;
therefore, produce the interfection G I, and the edge B C
that throws the shadow, to meet K; find k the corre-
ponding point of K; through k and B draw the indifinate
shadow k i p; c being the corresponding point of C, draw
the elevation c q of a ray; find i the corresponding point
of I; join i q, which completes the shadow on both planes.

PROB. XXIV.

A cylinder being caped with a square abacus, jutting
alike over each side of the cylinder, to find the represen-
tation of the shadow; the elevation and plan being given, as
also the plan and elevation of the fun's rays.

Let A B C D (Fig. 6. No. 1.) be half the plan of the
abacus, E F G half the plan of the cylinder, H I J K the
elevation of the same, and L M N O that of the abacus, to
project the shadow of any point p in the elevation of the
abacus, p being its corresponding place on the plan; draw
the plan of the ray p q, meeting the semicircumference
E F G at q; also from p draw the indifinate elevation of
the ray e p g; and draw g f parallel to I J or H K, and q f
will be the shadow of the point p. Find as many other
points as may be necel'ary in the same manner; then,
through all the points thus found, draw a curve, which will
be the shadow required.

If the ray R T be drawn to touch the circle in V on
the plane, and if V W W', the elevation of V, be drawn, then
V W W' will be the line of separation of light and shade.

If the rays of the fun be in two planes, one perpendicular
to the plane of representation, but inclined 45 degrees to
the horizon, and the other equally inclined to the hori-
zon and to the plane of representation; that is to say,
making 45 degrees with each; then all the points q will be
in the circumference of a circle, whose diameter is equal
to the representation of the diameter of the cylinder.

Fig. 6, No. 2, shews the elevation completely shadowed.

PROB. XXV.

A cylinder being caped with another concentric cylinder,
to find the representation of the shadow, fig. 7, No. 1.
Proceed to find all the points q as in the last problem,
and a curve being traced through the points q will give the
shadow required.

The point p' on the elevation, corresponding to p on the
plan, may be thus found. Draw B R parallel to A C, and
A R perpendicular to A C; draw S S parallel to A R,
cutting B R at S. In L M make L p' equal to R S, and
p' will be the corresponding point of p. No. 2, shews the
elevation completely shadowed.

PROJECTION of the Sphere is the representation of all its
circles upon a plane, either by rays proceeding to a given
point, or parallel among themselves, passing through all the
points of these circles till they are intercepted by the said
plane.

When the rays are all parallel, the representation may be
formed by the rules of orthographical projection: we shall
take this case first.

PROJECTION of the Sphere, Orthographic. In orthogra-
phical projection, when the rays fall upon the plane of any
circle, they will form a cylinder, and if the plane of the
circle be parallel to the plane of representation, or in a sub-
contrary position, the projection of that circle will also be
equal to the original; but if the plane of the original
circle be parallel to the projecting rays, the repre-
sentation of the circle will be a straight line equal in length
to the diameter of the original circle.

PROB. I.

Given the major axis A B, and a point C in the curve
of an ellipsis, to find the minor axis, and thence to describe
the curve.

Fig. 1. Plate VII. Bisect A B in E; through E draw
F G perpendicular to A B; from C as a centre, with the
distance A E or E B, describe an arc, cutting F G at H,
and draw C H, cutting A B at I; make E F and E G
equal to I C and F G, and F G will be the minor axis
required.

This problem belongs to conic sections, but as its ap-
lication is requisite in the following problems, it is here
introduced.

PROB. II.

Given a great circle A B C of the sphere, and the or-
thographical representation of two points D and E, on the
surface; to determine the interfection of a plane passing
through the centre of the sphere, and through the original
of the points D and E, with the plane of the circle given.

Through the points D and E (Fig. 2.) draw A B; on
A B, as a diameter, describe a semicircle A F G B; draw
D F and E G perpendicular to A B; join F and G, and
produce F G and A B to meet in H; draw H I, cutting
the circle A B C in K; produce K I to meet the opposite
circumference
Definitions.

1. A primitive circle is a great circle of the sphere, on which the representations of all the other circles are formed. The primitive circle is always supposed to be given.

2. A point is said to be drawn in projection, when the intersection of a straight line with the primitive is given, by drawing the line from the given point in the circle to be projected perpendicular to the primitive.

Hence, if two points be given in the projection of a great circle, the whole circle will be determined, since the centres of all great circles pass through the centre of the sphere; every great circle must, therefore, pass through the centre of the primitive; three points will therefore be given, by which the original circle can be determined.

Prob. III.

Given two points D and E in the projection of a great circle, to find the representation of the circle.

Find CK (fig. 3.) the intersection of its plane, by problem II., and CK is the major axis of the ellipsis which represents the original circle. There is now given the major axis CK, and a point D or E, in the ellipsis; the minor axis LM being found according to problem I., the ellipsis CLKM may be described by the same, and the curve thus drawn will be the orthographical representation required.

Prob. IV.

Given the projection of a great circle of the sphere, and the point of projection of the intersection of that circle with another circle, and the inclination of the planes of these two circles, to find the representation of the other circle.

Let CLKM (fig. 4.) be the projection of the circle given, and let the point F be the projection of the intersection of the two great circles. Join F1 and draw FN perpendicular to F1, cutting the primitive ABC in N; produce I F to O, and draw NO perpendicular to IN; through O draw PQ perpendicular to IO; produce IK to meet PQ in R, and produce IO to S; make OS equal to ON, and join RS; make the angle RST equal to the inclination of the planes of the two great circles, and let ST cut PQ in T; join TI, cutting the circle in U; produce UT to meet the opposite side of the circumference at V; then describe the representation of a great circle, by problem III., upon UV, as a transverse axis through the given point F in projection; and the original of the representation, UWVX, will form the given inclination RST, with the original of the circle represented by KMCN, and these two original circles will pass through the original of the point F, as was required.

It is evident that TF will be the foot of the common axis of the two great circles, because the original axis passes through the point I; and because the pole is in the common axis, and F is the foot of the pole, therefore F is the foot of another point in the axis. Again, because FI passes through the centre, and FN is perpendicular to FI, let FI be produced to meet the opposite parts of the circumference in Y and W; then YNW will be a semi-circle; if this semi-circle be turned round YW as an axis, the semi-circumference will describe the sphere surface, and FN will describe a lesser circle of the sphere perpendicular to the plane of the primitive; let the semi-circle YNW be turned round its diameter YW, until its plane become perpendicular to the primitive, then the straight line FN will be perpendicular to the primitive, and the point N in the perpendicular FN will be in the intersection of the two great circles in the surface of the sphere. Again, because NO is perpendicular to IN, and IN represents the axis; NO is a section of a plane perpendicular to the axis, and PO is also a section made by the plane; but OS is equal to ON, and CK is the section of the plane of the great circle and the primitive; let the triangle INO be raised upon I0, perpendicular to the plane of the primitive; also let the TSBR be turned round PO, until OR coincides with ON, then the point S will fall upon N, and the axis IN will be perpendicular to the plane of the triangle RST; from the point S: now since RC and TV are the intersections of the planes of the original circles, and because the plane RST is perpendicular to the axis, the angle RST is the measure of the inclination of the planes.

Prob. V.

About a given point E, as a pole, to draw the representation of a circle, at a given distance from the pole.

Join DE, (fig. 5.) and draw EF perpendicular to DE, meeting the circumference of the primitive in F, and join FI; make FG and FH equal to the distance of the original circle from the pole; join GH, cutting IF at O, and draw G K, ON, and HL perpendicular to IE, cutting KE at K, N, and L; make NP and NQ each equal to OG or OH; on PQ and KL describe the ellipsis P K Q L, which will be the representation required.

By this problem all the parallels of latitude may be drawn, and by problem IV. the meridians may be described; these two problems will, therefore, be sufficient to represent all the principal circles of the sphere.

By this kind of projection, either the convex or concave side of the sphere may be represented; this choice is peculiar to the orthographic projection; but in both these projections the circles will be inverted in respect of each other, since to project each, the eye must be turned on contrary sides of the surface, that is, to the convex and concave sides.

Example.—Fig. 6. shews the application of the preceding problems in the orthographic projections of the sphere; the first meridional representative circle is drawn according to problem III., the second according to problem IV., and all the remaining circles in facsimile, according to the same problem. The parallels of latitude are all drawn according to problem V. The objections to the orthographic method of projection are, that the distances of all the representative parallels of latitude are unequal from the pole, and the distances from all the representative meridians are also unequal, as they are reckoned from one parallel of latitude to another; that is, as they are measured upon any such parallel; and that the representative angles continue to increase by inequality from the line of position on each side of it to the circumference of the primitive circle.

PROJECTION OF THE SPHERE BY THE RULES OF PERSPECTIVE.

Let the primitive circle be called the plane of projection or picture, and let the centre of the primitive be also denominated the centre of the picture. The position of any circle to be projected is determined by a diameter of the primitive, and a straight line at right angles therewith. The eye is supposed to be fixed in this straight line, at a given distance from the centre, in order to view the circle to be projected. The eye and the given diameter of the primitive are supposed to be in a plane, both perpendicular to the primitive and to the original circle to be projected, and to pass through the centre of the said circle.

Definitions.
Definitions.

1. The plane passing through the perpendicular in which the eye is fixed, and through the given diameter, is called the vertical plane, or plane of position.

2. The given diameter is called the diameter of position, and produced to any indefinite length, is called the line of position: this diameter is, therefore, the intersept of the primitive and the vertical plane.

3. A great circle of the sphere in the plane of position, having a common centre with the primitive, is called the vertical circle.

In the practice of representing a circle of the sphere, the plane of position is folded upon the plane of the primitive circle, and, consequently, the circumference of the circle of position will coincide with the circumference of the primitive circle.

The position of the original plane to the plane of the picture is determined by producing the chord, which is the diameter of the circle to be projected, and the line of position, till they meet each other; and the angle thus contained is the inclination of the planes.

The distance of the centre of a vanishing line is determined by drawing a straight line through the point of sight, parallel to the diameter of the circle to be projected, until it meet in the line of position.

Prob. I. Method 1.

To project any oblique circle of the sphere, the eye being at any given distance from the primitive.

Let A B C D (fig. 7) be the primitive and the circle of position, and A C their common diameter, in which is the centre O; through O draw the straight line E B D perpendicular to A C; and let F G be the diameter of the circle to be projected; draw E F, cutting A C at j, and E G, cutting A C in g; produce F G and A C, till they meet in H; through H draw T U parallel to D B, and produce C A beyond each extremity towards I and N; draw E I parallel to H F; make H K equal to E I, H L equal to H G, and H N equal to H F. Upon L N, as a diameter, describe the circle L M N P; T U being the interfacing line of the plane of the original circle; L M N P the original circle itself, placed in its real situation; and H K the distance between the vanishing line, that is, from the eye to the centre of the vanishing line, and K the prime directing point: therefore, bisect g s, which is one of the axes in u; through u draw m p parallel to T U; draw K M and K P tangents to the circle, cutting T U at R and S; draw R m and S p perpendicular to T U; then m p and g s are the two axes, by means of which the curve, which is the representation of the circle required, will be described.

Method 2. Without using the directing point.

Fig. 8.—The same lines and point being used as before, except the original circle and directing point, and E G being found as before; bisect G F, the diameter of the original circle, in Q; from Q, with the radius Q G, or Q F, describe the semicircle G N F; bisect f g at u; through u draw m p parallel to T U; draw E U, which produces to meet G F in K; draw K N perpendicular to G F, cutting the circumference of the semicircle at N; in T U make H L and H M equal to K N; draw M I and L I, cutting m p in m and p; then g s and m p are the axes, as before.

Method 3. By the vanishing and interfacing lines.

Fig. 9.—The same lines and points standing as in the preceding method, excepting the semicircle G N F, the straight line E K, the points L and M in the interfacing line T U, and the axis m p of the representative circle; bisect G F in Q, as before; in T U make H R and H S equal to Q F or Q G; draw R I, H I, and S I; through I draw the vanishing line W X, which is in course parallel to U T; make H Z equal to H Q, and I W equal to I E, and draw Z W, cutting R I at b, H I at g, and S I at d; parallel to T U draw b a, b i through g, and c d from c; the points a, b, being in S I, and the points i and c being in K I; let a b and d e cut H I respectively at f and g; then a b c d represents a square, circumscribing the original circle; therefore draw the diagonal a c, and draw the ellipsis g h f i, which is the representation of the original circle.

Prob. II.

To find a representation of a great circle of the sphere.

Let A C (fig. 10.) be the diameter of position, as before, and G F the diameter of a great circle in the vertical plane, which will therefore pass through the centre O; and the plane of the great circle itself will intersect the primitive in the diameter B D, which is common to both, to the vertical circle and to the primitive, whether these two circles are coincident or placed at any angle with each other; and as B D will be at right angles to A C, the points B and D are points in the representative circle; draw E F, cutting A C in f; produce E G and A C to meet each other in g, then g f is one of the axes found as before; the axis g f and a point B or D of the curve being given, describe the ellipse b f i, by problem I. Orthographical Projection.

Prob. III.

To find the measure of the arc of an original circle, represented by the part a b of the representative circle f m g p.

Draw E g and E f (fig. 11.); produce E to F, and E g to G, and join G F; biseet G F in Q; draw E Q, cutting f g in q; and draw m a, which produces to meet T U in J; also draw q b, which produces to meet T U in K; then if H Q be taken as radius, H K will be the tangent of the angle represented by the portion b g of the representative circle; also H J, the tangent of the angle represented by the portion a g of the same. But the parts a g and g b make the whole representative arc a b; therefore the whole angle will be found by its tangents thus: draw H L perpendicular to T U; make H L equal to H Q; join J L and K L, and K L J will be the measure of the arc represented by the curve A B.

Demonstration.—For T U is the interfacing line of the plane, and J and K are the interfacing points of the lines represented by q a and q b; but the lines q a and q b are the representations of the radii. Now the point L, in the original plane, is the original of the centre; therefore J L K is the angle formed by the radii of the original circle.

If the measure of the angle b q e, which represents the supplement of the angle represented by b q a, be required; produce J L to M, and K L M is the measure of the angle represented by b q e.

Prob. IV.

To find the original measure of any arc of a representative great circle.

Let
Let $BF\perp FG$ (fig. 12.) be the representative great circle, of which it is required to find the original part $ab$.

Let $AC$ be the diameter of position, and $GF$ the diameter of the great circle in the vertical plane.

Produce $CA$ to $Z$; draw $EI$ parallel to $GF$, meeting $CZ$ in $I$; make $IZ$ equal to $IE$; draw $ZA$ and $ZB$; produce $Za$ to meet the primitive in $A'$, and $Zb$ to meet it in $B'$; then will $A'B'$ be the original arc represented by $ab$.

Again, let it be required to find the arc represented by the portion $ij$ of the other semicircle; draw $Zi$, cutting the opposite part of the primitive in $I$; also draw $Zj$, cutting the opposite part of the primitive in $J$; then $IJ$ is the original of $ij$, as was required to be done.

Demonstration.—For $BD$ is the intersecting line, and $WX$ the vanishing line; $I$ is the centre of the vanishing line, $Z$ is the place of the eye in the vanishing plane, and $B'G'B'JD$ is a circle in the original plane; therefore $a$ is the representation of the point $A$, according to the principles of perspective; which see.

This method, which is entirely founded on the principles of Brook Taylor, has never before this, to our knowledge, been applied to the projection of the sphere, (and so far it is new,) not even by authors who have professed to give complete treatises on perspective. The rule is quite universal, so that it may be used to any distance of the eye whatever; whereas, in the common method, by finding the poles in the stereographic projection, the eye must be confined to the surface of the sphere; or in other words, the pole will not be the point from whence two lines may be drawn, that will intersect corresponding parts of the original circle, and its representative. This problem, moreover, shows the vast superiority over particular methods, which require so much trouble to perform.

**Prob. V.**

Given the angle which the intersection of the plane of a great circle, and the vertical plane, make with the line of position, and the inclination of the plane of that great circle with the vertical plane; to find the intersection of the great circle on the plane of the primitive.

Let $AB$ (Plate VIII. fig. 1.) be the line of position, passing through the centre $O$ of the primitive; and let $AOC$ be the angle which the intersection of the plane of the great circle, and the vertical plane, make with the line of position. From any point $C$ in $OC$, draw $CD$ perpendicular to $OC$, cutting $AB$ produced in $D$; produce $BD$ to $F$; make $DF$ equal to $DC$; through $D$ draw $GH$ perpendicular to $BF$; make the angle $BFI$ equal to the inclination of the plane of the great circle with the vertical plane, and let $FI$ meet $GH$ at $I$; draw $IK$ through $O$, cutting the primitive in $J$ and $K$; and $JK$ is the intersection of the great circle required.

**Prob. VI.**

Given the inclination of the planes of two great circles, intersecting each other in the vertical plane, the angle which their common intersection makes with the line of position, and the inclination of one of them with the said vertical plane; to find the intersection of the other great circle.

Find the intersection $JK$ of the plane of the great circle, of which its inclination is given to the vertical plane, as in the preceding problem; make $IFL$ equal to the inclination of the two great circles, and let $FL$ cut $HG$ at $L$; draw $LN$ through the centre $O$, cutting the primitive in $M$ and $N$; then will $MN$ be the intersection required.

**Corol.**—Hence, in a series of great circles, intersecting each other in one common diameter in the vertical plane, if the successive inclinations of each two adjoining ones are given, the angle which their common intersection makes with the line of position, and the inclination of one of them with the vertical plane, each successive intersection will be formed by this problem. The present figure shows the intersection of the planes of twelve great circles placed at equal angles, viz., that of any two adjoining circles with that of any other two adjoining circles.

**Prob. VII.**

Two lines tending to an inaccessible point being given, through a given point to draw a third that shall tend to the same point.

Let $FP$ and $DH$ (Plate VIII. fig. 1.) be two straight lines, which approach nearer together, towards the parts $P$ and $H$, than at $F$ and $D$; and let $O$ be the point through which the other straight line is to be drawn. Join $OP$, cutting $DH$ in $D$, and draw $PHQ$ parallel to $OF$; find a fourth proportional to $FD$, $DO$, $PH$; and make $HQ$ equal to the fourth proportional; draw $OQ$, and $OQ$ is the line required.

This problem is useful in the construction of the two last problems, where the distances of the points of concurrence of the lines forming the angles with the line $GH$, might be so great as to render the drawing of the radial lines from $O$ impracticable; it is, therefore, introduced in order to remedy this inconvenience.

The diagram, No. 2, shews the construction of finding $PH$, as is generally done by means of a triangle.

**Prob. VIII.**

Given the angle which the common intersection of a great circle, and the vertical plane, make with the line of position, and the intersection of the plane of the great circle, to find the inclination of the said plane to the plane of the primitive.

Let $AB$ (fig. 2.) be the line of position, $CD$ the intersection of the great circle, cutting each other at the centre $O$. Make $BOG$ equal to the angle which the common intersection of the great circle and the vertical plane make with the line of position. In $OB$, or $OB$ produced if necessary, take any point $F$, and draw $GF$ perpendicular to $OF$; produce $OF$ to $H$, and $CD$ to $I$, if necessary, and draw $FL$ perpendicular to $CI$; make $FH$ equal to $FI$, and join $GH$; then $FHG$ will be the inclination of the plane of the great circle to the plane of the primitive, as was required.

Fig. 3. shews the inclinations of the planes of a series of great circles to the plane of the primitive, the planes being supposed to have a common intersection through a straight line in the vertical plane, and form equal angles with each other.

**Prob. IX.**

Given the intersection of a great circle, the inclination of its plane to that of the primitive, and the distance of the eye, to find the representation of the great circle.

**Method.**

Let $CD$ (fig. 4.) be the intersection given; produce $CD$ to $E$; make $OE$ equal to the distance of the eye; through the centre $O$ draw $FG$ perpendicular to $CD$; make the angle $OEG$ equal to the inclination of the plane of the great circle to the primitive; draw $GH$ parallel to $DC$;
DC; make \( GH \) equal to \( GE \), the distance of the eye; join \( DH \), cutting \( FG \) at \( I \); join also \( CH \), and produce \( CH \) to \( F \), and \( FI \) is the minor axis; then, having the minor axis \( FI \), and a double ordinate \( CD \), describe the elliptic curve; by problem I. Orthographic Projection of the Sphere.

It is evident, that \( DC \) is the intersecting line of the plane of the great circle, and \( GH \) the vanishing line of that plane; the method of finding the representation of the great circle is therefore reduced to a common perspective problem.

It most frequently happens in practice of the projection of the sphere, that the part of the great circle within the primitive, is all that is required to be represented. The following methods, by finding points in the curve, are very eligible for the purpose.

**Method 2.**

Let \( GH \) (fig. 5.) be the vanishing line, found as before; and since \( EC \) is the intersecting line, the semicircle \( ECD \) may represent the circumference to be projected, as well as the semicircumference of the primitive, for the two may now be supposed in a state of coincidence. Let \( GCD \), therefore, be supposed to be the semicircumference of the great circle to be represented. To find the representation \( a \), of any point \( A \) in the original circle, draw \( GI \) perpendicular to \( GH \); make \( GI \) equal to \( GE \); through the original point \( A \) draw \( AB \), meeting the intersecting line \( EC \) at any angle; through \( I \) draw \( IH \) parallel to \( AB \); join \( H \), and \( I \), cut \( H B \) at \( a \); then \( a \) is the representation of the original point \( A \). And in this manner, as many points may be found as will be sufficient to draw the curve.

**Method 3. Without the original circle.**

Let \( GH \) (fig. 6.) be the vanishing line, as before; make \( GH \) equal to \( GE \), the distance of the vanishing line, \( GOB \) being supposed to be previously drawn; join \( HD \), and produce it to \( B \); join also \( CH \), cutting \( GB \) at \( A \); through \( A \) draw \( FG \) parallel to \( D \), and draw \( DF \) and \( GC \) parallel to \( AB \); divide \( DF \) into any number of equal parts, say three; also divide \( DO \) into the same number of equal parts, viz. three; draw the lines \( MA, NA \); draw also \( BO \) and \( BP \); produce \( BO \) to meet \( MA \) at \( q \); and \( BP \) to meet \( NA \) at \( r \), then \( q \) and \( r \) are points in the curve.

In the same manner the curve \( AC \) may also be drawn, which completes the lower semicircle. And thus having a diameter \( AB \), and double ordinate, the curve is described.

Again, if it were required to represent the semicircle next to the eye, it is only dividing \( DO \) in the same manner, that is, the division will stand for both; then drawing a line parallel to \( AB \), and another parallel to \( DO \), to meet the line parallel to \( AB \); divide the line parallel to \( AB \) into three equal parts, viz. into the same number as \( DO \); draw lines through the points of division as before, which will give the representation of one of the upper quadrants: the other will be found in the same manner, and thus the whole curve is found geometrically.

**PROB. X.**

Through a given point \( P \), to draw the representation of a great circle making a given angle with the vertical plane passing \( P \).

Join \( OP \), (fig. 7.) and produce it both ways to \( S \) and \( N \); draw \( DE \) perpendicular to \( SN \); make \( OE \) equal to the distance of the eye; draw \( EP \), which produces to meet the circumference in \( L \); join \( LO \), and produce \( LO \) to meet the circumference of the primitive in \( M \); draw \( EM \) to meet \( SN \) at \( S \); draw \( LX \) perpendicular to \( LM \), cutting \( SN \) at \( X \); through \( X \) draw \( UV \) perpendicular to \( SN \); make \( XN \) equal to \( XL \). From \( N \), as a centre, with the radius \( XN \), describe the arc \( WXY \); make the angle \( XNZ \) equal to the inclination of the vertical plane passing through \( P \) with the plane of the great circle to be projected, and set \( N \) cut \( UV \) at \( Z \); draw \( ZO \), cutting the circumference of the primitive in \( O \); produce \( QO \) to cut the opposite part of the same in \( T \); through \( P \) draw \( ZK \); then describe an ellipse through the three points \( S, T, Q \), and touch the straight line \( KZ \) at \( P \), and the curve \( PQRS \) thus described will be the representation of the great circle required.

**Demonstration.**—Because \( SN \) is the intersection of the vertical plane passing both through the original pole and its representation \( P \), \( L \) will be the original pole; and because \( LM \) is a diameter of the vertical circle, \( M \) will be the other original pole. And because both the projected poles must be in the straight line \( NS \), at right angles to \( ED \), \( EM \) being drawn will project the other pole \( M \) at \( S \). Now the vertical plane, with all the lines and points therein, being turned round \( SN \) perpendicular to the primitive, and \( S \) plane being supposed perpendicular to \( LN \) passing through the pole \( S \), this plane will be perpendicular to the vertical plane; and since the primitive, by supposition, is also perpendicular to the vertical plane, the intersection of the plane thus touching the pole and the primitive will be perpendicular both to the intersection of the vertical plane with the primitive, and the intersection of the vertical plane with the plane touching the pole; and because the point \( X \) is the intersection of the plane touching the pole and the primitive on the vertical plane, therefore the point \( X \) is common to all the three planes; and therefore \( UV \), passing through \( X \) perpendicular to \( SN \), is the common section of these three planes; and therefore \( UV \) will pass through \( X \) perpendicular to \( SN \), being the common section of the three planes, and therefore through \( S \), \( T \), \( Q \). But the measure of the inclination of two planes is the angle contained by the common section of these two planes with a third plane perpendicular to both planes; and because each of these planes intersects \( UV \) at \( Z \) and \( X \), and the primitive at \( O \), \( OZ \) and \(OX \) will be the sections of these planes with the primitive; therefore the points \( Q \) and \( T \) will be the sections of the circle in the plane whose section is \( TZ \), and consequently the representation of that circle will also pass through the points \( Q \) and \( T \); but it will also pass through the representative poles \( S \) and \( P \); and because \( UV \) is the intersection of a plane drawn through the pole \( L \) perpendicular to the axis \( LM \), every line drawn from \( L \) to the intersection \( UV \) will be perpendicular to the axis \( LM \), and will touch the surface of the sphere at \( L \). But \( P \) is the representation of the original pole \( L \), and \( Z \) is the intersection of a tangent from \( L \); therefore \( ZP \) is the representation of a tangent at \( P \), and consequently the representation will pass through the points \( Q, S, T \), and touch the straight line \( KZ \) at \( P \).

By this problem all the meridians of the sphere may be drawn, so that their planes may be at given angles with each other, and may be regulated by the frill, which may be called the primary projection of the meridian.

**Scholium.**—In order to save trouble, and yet preserve sufficient accuracy, the following observations will enable the student...
PROJECTION.

student to simplify the operation, when only the portion TPQ is required.

The ellipses which is the representation of the great circle, has its minor axis passing through the centre O perpendicular to TQ, and its major axis parallel thereto; therefore a perpendicular drawn from the point O, will cut the curve TPQ into two equal and similar portions; consequently, if two straight lines be drawn from the line TQ perpendicular thereto, and equally distant from the centre O, till they are intercepted by the curve, these two intercepted perpendiculars are equal to each other; therefore from P draw a perpendicular to TQ, cutting it in a; in OT make Oa equal to Oa; and drawalso a c perpendicular to TO; make be equal to a P; then, through the points T, e, P, Q, draw a curve to touch KZ at P, and this curve will represent the feirgament of the opposite hemisphere, sufficiently near for the purpose of constructing any map. The points T, e, P, Q, are equivalent to five points, as the tangent at P is equivalent to two.

But if greater accuracy will be required, the curve may be traced round in the representative pole S, which will fly more of the ellipses, and consequently the degree of curvature required in the various points of the representation.

PROB. XL.

To find the representation of a circle in a plane perpendicular to the plane of projection, given the intersection of the circle, and the distance of the eye.

Method 1.

Let CD (fig. 8.) be the intersecting line, E the place of the eye; it is evident that since the plane of the original circle is perpendicular to the plane of projection, the vanishing line AE will pass through the centre of the primitive circle, parallel to the intersecting line CD. Make OE equal to the distance of the eye from the plane of projection; draw PL through O perpendicular to AE; join ED, and produce E D to L; join also EC, cutting PL at J; bisect CD in F. Take any vanishing point v; draw vF, which produce to H; make v1 on the vanishing line equal to v P; draw ID, and produce I D to H; join CI, cutting v1 H at G, then G H is the representation of a diameter of the original circle. In the same manner, by taking any vanishing point v and the distance v2 equal to vF, the diameter IK will be obtained; and as many diameters in the same manner, as will give a sufficient number of points for drawing the curve representing the original circle.

Method 2.

Fig. 9.—The intersecting line CD, the line of position OL, and the distance O E of the eye, being given as before; join ED, which produce to L; join also CE, cutting OL in J; then will the minor axis JL, and the double ordinate CD, describe an ellipsis by problem I. Orthographic Projection of the Sphere; and the curve will be the representation of the circle required.

Scholem.—The preceding problems shew several steps, in order to obtain a complete projection of all the circles of the sphere. By problems V. and VI. the intersections of all the great circles on the plane of the primitive are obtained. By problem VIII. the inclination of any plane may be found to the plane of the primitive, by the intersection of the plane and distance of the eye being given. By problem IX. the representation of any great circle may be obtained, when its intersection, the distance of the eye, and the inclination of the great circle to the plane of the primitive, are given. The same method may also be employed in finding the representation of a small circle. By problem X. the representations of circles perpendicular to the plane of projection are obtained.

Examples constructed on the foregoing problems.

Example 1.—Plate IX. fig. 1. is a projection of the meridians upon the plane of a meridional circle. In this the common axis falls into the plane of projection. The distance of the eye is three-fourths of the radius from the sphere. From the choice of this particular distance, the meridians will divide the diameter of position into equal parts very nearly. The figure also shews how each ellipsis is described by means of the axes. The representations for one half of the lower hemisphere are only shewn; the other half being the same, except that each is opposite to its correspontent.

Ex. 2.—Fig. 2. is a projection of the parallels of latitude upon the plane of the meridian, the distance of the eye being the same as in example 1. This figure shews the manner of describing the ellipses by their axes; the curves divide the circumference into equal parts, and also the diameter very nearly.

Ex. 3.—Fig. 3. is a complete projection of both the meridians and parallels of latitude upon a meridional plane, which combines both the first and second examples. The circumference of the primitive is divided into equal parts, by the representation of the parallels of latitude; the diameter AB is divided into equal parts very nearly, by the same curves; and the diameter CD into equal parts very nearly, by the meridians.

Ex. 4.—Fig. 4. represents a projection of the sphere, as in fig. 3; except that in fig. 3, all the circles of the sphere are elliptical, whereas in this figure they are circular; the diameters AB and CD being equally divided, as well as the circumference. This is what the constructors of maps are pleased to call the globular projection upon the plane of a meridian. Though this construction answers to the equality of parts in the circumference and diameters of fig. 3, yet the curves being all arcs of circles, are not in truth projections; the deformity in the compartments, particularly at the circumference, and near the pole, is obvious, when compared to the true projection, fig. 3.

Ex. 5.—Fig. 5. is a projection of the circles of the sphere upon the plane of the equator, the distance of the eye being the same as above, namely, three-fourths of the radius; the parallels of latitude divide each of the radii, which represent the meridians, into equal parts very nearly. This is what map constructors term the globular projection on the plane of the equator. Though constructions, as in figs. 4 and 5, are sufficiently near for practical purposes, the principle can only be obtained from the preliminary problems necessary in the construction of figs. 1, 2, and 3.

Ex. 6.—Fig. 6. shews the projections of the meridians, and all the parallels of latitude, according to the general principles of perspective projection; the distance of the eye from the plane of the projection, or primitive circle, being three-quarters of the radius, as in the preceding examples. The meridians are all projected according to problem IX. and as they are at $\frac{1}{4}$° distant from each other, answering to hour circles, the first meridian is described according to the angle which it is required to make with the vertical plane, and all the remaining meridians at $\frac{1}{4}$° from each other, beginning from the first on each side of it, and ending in $\frac{1}{4}$°. The meridian is thus divided into 12 equal parts, which give 24 angles at the pole in projection; and as all these pass through the centre of the primitive, they divide the remote concave semicircumference, as well as that of the nearer convex half. All the parallels of latitude are projected according to problem I; the distances of the parallels
parallels are 10° from each other, and are set off on the circumference from the pole on each side of it. By the choice of distance of the eye from the primitive, as employed in this example, the parallels of latitude are nearly at equal distances, reckoned along any straight line drawn from the pole; and the same distance will nearly take place, by producing the straight line upon the opposite side, as far as 40°, where indeed no more can be drawn upon the semicircle, which contains the pole. The picture here drawn as near the true figure as can be delineated so small a scale.

This projection ought to be employed, instead of what is improperly called the globular, which in fact is founded upon no principle of projection whatever. The choice of distance, which obtains this equality of division, is founded upon Rhenaldinus's property of the circle, which gives nearly equal parts upon the diameter. In short, we do not recollect any other projections made upon what is called the globular method, than those upon the meridian and equator, where, in the former case, the poles are in the primitive circle, and in the latter, in the centre of that circle; so that the globular method, which is only confined to these two cases, is a more imitation of perspective representation, the distance of the eye being three-fourths of the radius from the surface of the sphere. The only argument that can be used in favour of the globular method is, that circles are much more easy to describe than ellipses; but if ellipsographs were brought to general use, they might be described with considerable expedition, and the compartments of the projection would be less distorted.

This is the first specimen that has come to our knowledge of the application of the general principles of perspective to the projection of the sphere, in which pure geometrical principles only have been employed by any English author. It is hoped that the perspective student will reap considerable advantage from this application, in being able to generalize the science. The ingenious Mr. Martin, in his Mathematical Institutes, has given some algebraic rules, whereby certain points may be found by calculation; but such cannot be of any use to the student: for though, in an abstract point of view, the result by calculation is complete, or, if in some cases not quite exact, the error may be so reduced as to be left, no any allowable difference from truth; yet to apply the numbers thus resulting from the arithmetical operation, recourse must be had to a scale, in order to convert the number into measure, the accuracy of which must then depend upon the division of the scale, and the eye of him who takes the extent as pointed out by the number. The error in this way, when such distance is transferred to the sphere, will in general exceed that occasioned by the obliquity of intersections, besides being more liable to mistake; nor could a drawing be made entirely by calculation, as the time required would exceed all comprehension. This may, therefore, satisfy a few, whose curiosity leads them to delight in nothing but what comes to them in the symbolical language of algebra, but cannot be of the smallest service to the practical student.

Projection of the Sphere. Stereographic. The stereographic projection of the sphere is a perspectival representation of all the circles upon the plane of the primitive, the eye being confined to the surface of the sphere at the extremity of a radius perpendicular to the plane of the primitive.

The reader who has made himself master of the science of perspective, and its application to the projection of the sphere, as shown by the preceding article, will, of course, be able to represent any circle of the sphere stereographically; but when the eye is brought to the surface of the sphere, certain properties take place, which considerably abridge the labour; one of the most remarkable of these properties is the following.

Theorem 1.—If in a circle (fig. 7 and 8), the diameters A G and H I be drawn at right angles, and if D B be any chord, and A B and A D be joined, then let B cut H I at E, and let A D cut H I at F; the triangle A B D will be similar to the triangle A F E.

Demonstration.—Join B C; and because the angle A B C is in a semicircle, it is a right angle; and because the angles A D B and A C B at the circumference stand upon the same base A B, they are equal: and also in the triangles A G E and A B C, the angle C A B is common, and each of the angles A B C and A G E a right angle, therefore the remaining angle A E G is equal to the remaining angle A C B of the triangle A C B; but the angle A C B is equal to the angle A D B; therefore the angle A D B is equal to the angle A E F; and because the triangles A D B and A E F have the angle D A B common, and the angle A D B equal to the angle A E F, the remaining angle A B D of the one is equal to the remaining angle A F E of the other; therefore the triangle A B D is similar to the triangle A F E, which was to be proved; and thus also the triangle A B D is subcontrary to the triangle A F E.

Theorem 2.—If from any point A (fig. 9.) in the circumference of a circle A F B I G, a straight line A B be drawn to meet the circumference in B, and if through the point B, a tangent C D be drawn; and if the radius A E be also drawn, and the diameter F G perpendicular to A E, cutting A B in H; then if G F and D C be produced to meet each other in C, then will the angles C B H and C B H of the triangle C B H be equal to each other.

For D B I is an angle formed by the chord B I, and a tangent D B, and the angle B A I is formed in the alternate segment, therefore the angle D B I is equal to the angle B A I; and because the triangles A E H and A B I are right-angled at E and B, and the angle at A is common to both, the triangle A E H is similar to the triangle A B I; therefore the angle A H E is equal to the angle A I B; but the angle C B A is formed by the tangent B C and the chord B A, and B I A is the angle in the alternate segment; therefore the angle C B A is equal to the angle B I A; but the angle B I A was shown to be equal to the angle A H E; therefore the angle A H E is equal to the angle A B C; but the angles A H E and C B A are opposite; therefore the angle C B H is equal to the angle A H E; therefore also, the angle C B H is equal to the angle C B H, which was to be proved.

Scholium.—By theorem 1. it is evident that every circle of the sphere will also be represented by a circle, for the cone of rays will be cut subcontrary. The advantage is very great both in point of accuracy and expedition, in having only to draw circles instead of ellipses. By the second theorem it is evident that the angles which original circles form with each other, will be represented by equal angles; that is, every representational angle will be equal to its original. This is the reason why this particular distance of the eye is to be preferred in the practice to a greater, which, though less distorted, is more laborious and more liable to inaccuracy.

Theorem 3.—If in the circle A J I H (fig. 10.) the diameters A I and J H be drawn at right angles, and if O D be any radius of the circle, and A D be joined, and if
AD and OH be produced to meet each other in C, and if AB be drawn perpendicular to OD, meeting OC in B, then will BA be equal to BC.

For, draw AF parallel to JH, and then the angle AED is the angle in the alternate segment, therefore the angle FAD is equal to the angle AED; because OD is perpendicular to AB, or to the chord A E, A E is bisected; because GA is equal to GE and GD perpendicular to AE, and the angles DGA and DGE are right angles, the triangle DGA is equal and similar to the triangle DGE; therefore the angle DEG is equal to the angle DAG; but the angles FAD and DAB are alternate, therefore the angle FAD is equal to the angle DCB; but the angle DAG is equal to the angle DFG, and the angle DAG is equal to the angle DFB, therefore the angle DAB is equal to the angle FBA, therefore BA is equal to BC.

This theorem shews the coincidence of the general method of projecting the sphere by the rules of perspective in finding the original measure of any representative arc with that of the stereographic projection of the sphere: for if A be considered as the plane of the eye, D the plane of the circle to be projected, and if AD and JD be drawn to meet each other in C, it is evident that C is the projected pole of D, as shown by the rules of stereographic projection. Now, by the rules of perspective, AB may be considered as the parallel of an original plane, whose pole is the point D, B the vanishing point of lines perpendicular to the intersection, and C the place of the eye in the vanishing plane.

Theorem 4.—The plane of every great circle of the sphere divides the primitive into two equal parts, or passes through a diameter.

Demonstration.—Every great circle passes through the centre of the sphere; therefore the planes of any two great circles will bisect each other; but the primitive is a great circle of the sphere, and its centre is the centre of the sphere; therefore the plane of every great circle of the sphere will pass through the centre of the primitive, and therefore through a diameter.

In the following problems the vertical plane is always supposed to pass through a diameter of any great circle to be projected, and therefore the line of position is the foot of that diameter; therefore the diameter itself will always be projected upon the line of position.

Prob. I.

To find the representation of the axes or poles of a great circle, the foot of the axis being given in the line of position, and the inclination of the axis to its feet.

Let ABCDE (fig. 11.) be the primitive circle, FC the diameter of position, and E the place of the eye, in the diameter EB, at right angles to FC.

Make COD equal to the angle which the axis makes with its feet, and produce DO to A, then AD is the axis; draw the visual ray EA, cutting FC in P; also join ED, and produce ED and FC to meet in Q, then PQ is the representation of the axis, and consequently P and Q are the poles.

Prob. II.

To find the intersection of a great circle, given the line of position, the angle which the axis makes with the line of position, and the inclination which the plane of any great circle makes with the vertical plane.

Make COD (fig. 12.) equal to the angle which the axis makes with the line of position; from any point D in OD draw DG perpendicular to OD; produce OC to Q, and let QQ cut DG at G; make GO equal to GD; through G draw GJ perpendicular to OQ; make GQ equal to the inclination of the plane of the great circle with the vertical plane; through O draw JL, cutting the circumference in K and L, and KL is the diameter of the section required.

Corol. 1.—If the point D be in the circumference of the primitive, and if E D be produced to meet the line F Q, the point of concourse will be at Q; this appears from theorem 3, therefore the point Q is in the pole of the great circle.

Corol. 2.—If DO be produced to meet the opposite part of the circumference at A, and if A M be drawn perpendicular to A O, cutting OF produced at M; and if through M, MN be drawn perpendicular to O M; and if O M be produced to I, and if M I be made equal to MA, and KL be produced to N, and N I joined; and A E be drawn, cutting FC in P, and P N be joined, P N will be equal to NI; for MN and J G are at the same distance from the centre O, and are parallel to B O E, and the triangle M I N is equal and similar to the triangle G O J, therefore MP is equal to M I. See Prob. X., Perspective Projection, where it was shown that PN is a tangent to the curve at the point N.

Prob. III.

To find the representation of a great circle or any portion thereof, the intersection and the common representative diameter being given.

Let KL (fig. 13.) be the given intersection, and PQ the representative of the axis.

Bisect PQ by the perpendicular TS, and draw OS perpendicular to KL; from S, the point of concourse of the lines RS and OS, with the distance SP or SQ, describe the arc PKL, which is an arc of the representative of the great circle.

Demonstration.—For since the representation is a circle, and because it passes through the points K and L, the extremities of the intersection, the centre of the representation will be in the line QS; but the representation of the circle also passes through its poles P and Q; therefore the centre will be in the line TS; bisecting the representative axis PQ; but it is also proved to be in the line OS, it will therefore be at the point of concourse S of the lines TS and OS.

Corol.—Hence the centres of all the representative great circles which have PQ for their representative axis, will be in the line TS; since every representative circle passes through the points P, Q, they must therefore be in the line bisecting PQ.

Definition.—The line TS, bisecting the axis PQ, is called the locus of the centres of all the great circles which have the same representative axis.

Prob. IV.

Given a common representative diameter of two great circles, and the intersection of one of them, to find the representation of the two circles, so that their original planes may have a given inclination.

Method 1.

Let PQ (fig. 14.) be the common representative diameter, and KL the intersection. Find RM the locus of the centres; join KL; draw OS perpendicular to KL, meeting RM in S; join SQ, and from S, with the distance SQ, describe the arc KPL; make the angle SQR equal to the inclination of the planes of the two great circles from
from \( R \); with the distance \( RQ \) describe the arc \( QMPN \), then \( QKPL \) and \( QMNP \) will be arcs of the circles required.

**Demonstration.**—Join \( PR \) and \( PS \), then \( PR \) will be perpendicular to a tangent to the arc \( MPN \) at the point \( P \), and \( PS \) will be perpendicular to a tangent at the point \( P \), in the arc \( KPL \); but the tangents at the point \( P \) form an equal angle to the original angle; therefore the lines \( PR \) and \( PS \), which are perpendicular to these tangents, will form an equal angle; but the angle \( RQS \) is equal to the angle \( RPS \); therefore the angle \( RQS \) is equal to the angle formed by the tangents of the two great circles, that is, equal to the inclination of their planes.

This method is exceedingly useful in describing the representations of great circles, which have a common representative diameter, with compasses; but in many cases it is impracticable, owing to the centres running out to distances without limit, and consequently beyond the reach of any radius: but in the representation of the sphere, seldom more is required than the part of the representation of the great circle contained within the primitive. The instrument called the cyclograph will be much better adapted to the description of the arcs required: we shall therefore construct the problem as adapted to the use of the cyclograph, which perhaps is the most convenient of any that could be used for the purpose.

**Prob. V.**

Given the angle which the intersection of a great circle and the vertical plane make with the plane of projection, and the inclination of the plane of the great circle and the vertical plane, to describe the representation of the great circle.

Let \( HC \) (Plate X, fig. 1) be the line of position; through the centre of the primitive \( O \), draw \( DE \) perpendicular to \( HC \); make \( HOB \) equal to the angle which the common intersection of the vertical plane and the plane of the great circle make with the line of position, and let \( OB \) cut the circumference of the primitive in \( B \); draw \( BG \) perpendicular to \( OB \); and let \( BG \) meet \( HC \) in \( G \); draw \( GJ \) perpendicular to \( HC \); make the angle \( GHI \) equal to the inclination of the plane of the great circle and the vertical plane, and let \( HI \) meet \( GJ \) in \( I \): draw \( IO \), cutting the circumference in \( N \); produce \( NO \) to meet the opposite side in \( M \); join \( BE \), cutting \( HC \) in \( P \); through the point \( P \), and upon \( MN \) as a chord, describe the arc \( MPN \), thus: let \( A \), \( C \), \( N \), be the chord, \( B \) the given point through which the arc is to pass; lay a straight edge \( BD \) upon the points \( B \) and \( A \), and another, \( BE \), upon the points \( B \) and \( E \); fall them together at \( B \); then, supposing the angle \( DBE \) to be kept stationary while the two pieces are put in motion in the following manner, let the point \( B \) be brought to \( A \), and \( B \) laid upon \( C \), and let a pencil be fixed at \( B \); let the instrument be so moved, that \( BD \) may always be upon \( A \), and \( BE \) upon \( C \); and that the point \( B \) may describe a continued line from \( A \) to \( C \), and the line thus described will be the arc of a great circle, as required.

**Scholium.**—By this method every great circle of the sphere may be represented one after the other, and the plane of the one to be projected may either make a given angle with that which is projected, or a given angle with the vertical plane. The projected circles make the same angle with each other at the point of intersection, or the tangents at that point, that the original planes make with each other: thus the projected circles \( MPN \), \( KPL \), or their tangents \( PI \) and \( PJ \), as \( IH \) and \( JH \), which form the inclination of their planes, or the angle contained between the line of position \( PG \), and the tangent \( PJ \) to the circle \( KPL \), will be equal to the angle \( GHJ \).

**Prob. VI.**

Fig. 2.—About a given representative point \( P \), to describe the representation of a circle of the sphere, of which the original shall have the original of \( P \) for its pole, and be at a given distance from \( P \).

Join \( PO \), and produce \( PO \) to \( A \) and \( B \); draw \( OE \) perpendicular to \( AB \); and make \( OE \) equal to the radius of the sphere; draw \( EP \), and produce \( EP \) to meet the primitive in \( F \); then \( F \) is the original pole; make \( FC \) and \( FD \) equal to the distance of the circle from its pole; draw the chord \( CD \); draw \( CE \), cutting \( AB \) at \( e \); also draw \( DE \), cutting \( AB \) at \( d \); on \( ed \), as a diameter, describe the circle \( c \) \( d \) \( e \), which is the circle required.

**Scholium.**—By this problem the parallels of latitude may be described at any distance from each other, or at \( 10^\circ \), \( 20^\circ \), \( 30^\circ \), \( 40^\circ \), &c. from \( F \).

**Prob. VII.**

The representation of a circle of the sphere being given, to find the representation of its pole.

Let \( c \) \( d \) \( e \) (fig. 2.) be the representation of the circle given; and let \( G \) be its centre; join \( GO \), and produce \( GO \) to the primitive at \( A \) and \( B \), and let \( AB \) cut the representative circle in \( c \) and \( D \); join \( E \) \( c \), and produce \( E \) \( c \) to meet the primitive in \( G \); also join \( E \) \( d \), and produce \( E \) \( d \) to meet the primitive in \( D \); bisect the arc \( CD \) in \( F \); draw \( EF \), cutting \( AB \) in \( P \), then \( P \) is the pole required to be represented.

**Scholium.**—This problem is the converse of the former; but when the circles are all parallel, they have one common pole.

**Prob. VIII.**

Given the representative of a great circle, to find the vanishing line of its plane, the place of the eye in the vanishing plane, and the representation of the centre of the circle.

Let \( EFGH \) (fig. 3.) be the primitive circle, and \( AKBD \) the representation of the circle of the sphere; join \( OC \); draw \( OE \) perpendicular to \( OC \); make \( OE \) equal to the radius of the sphere, and the point \( E \) will coincide with the primitive circumference; produce \( OC \) to \( B \) and \( P \), cutting the representative circle in \( A \) and \( B \); draw \( EA \), and produce \( EA \) to meet the primitive circumference in \( G \); also draw \( EB \), and let \( EB \) cut the primitive circumference in \( H \), as in \( N \), or produce \( EB \) to meet the primitive circumference in \( H \), as in \( N \), and join \( GH \); produce \( BA \) to \( P \); draw \( ES \) parallel to \( HG \), meeting \( BP \) in \( S \), make \( SP \) equal to \( SE \); through \( S \) draw \( VL \) perpendicular to \( BP \); then \( VL \) is the vanishing line, and \( P \) the place of the eye in the vanishing plane.

Bisect \( HG \) in \( I \); draw \( IE \) cutting \( AB \) in \( J \); and \( J \) is the representation of the centre required.

**Scholium.**—This problem is general for all circles of the sphere, whether great or small; but in finding the representation of the centre of a great circle, the points \( I \) and \( J \) coincide in the centre \( O \) of the sphere; therefore, since \( HEG \) is a right angle, and because the points \( H \), \( E \), \( G \), are in the circumference of the circle \( GEH \), and \( HG \) is opposite to the right angle, \( HG \) is a diameter, which is, therefore, already bisected by the centre \( O \).

The particular construction, which may, therefore, be necessary in \( N \), in order to find the vanishing line, the place of the eye in the vanishing plane, and the representation of the centre, may be as follows:
PROJECTION.

Join O C; draw OE perpendicular to OC; make OE equal to the radius of the sphere; draw EA, and produce EA to meet the circumference in G; so far this agrees with the general construction, the difference takes place in the subsequent part. Join GO; draw ES parallel to GO, cutting BP in S; make SP equal to SE, then P is the place of the eye in the vanishing plane, VL the vanishing line, and O is the representative centre of the circle, represented by DE K.

PROB. IX.

Given the representation of a great circle, and a point in its circumference; from the given point to cut off a part of the said circumference, that shall represent a given portion of the original circumference.

Let EFGH (fig. 4.) be the primitive circumference, and AKD be the representation of the great circle, as in the preceding problem; find the vanishing line VL, P the place of the eye in the vanishing plane, and J the representation of the centre by the said point. Now let a be the given point; join J a; produce J a to L; join L P; make the angle L P V equal to the angle contained by the radii drawn from the extremities of the arc to the centre of the original circle; that is, in the same proportion to four right angles, that the original arc is of the whole circumference of which it is a part; join V J, cutting the circumference of the representative circle in b, then ab is the representative arc required.

Again, let it be required to represent an arc from the point e on the opposite part of the circumference of the representative circle; join e J; produce e J to L; join L P; make the angle L P V as before, and join V J; produce V J to meet the representative circumference in d; then ed is the arc required.

Lastly, let it be required to represent an arc of the original from the point b towards e; join b e; produce b e to V; join V P; make the angle V P R the same proportion of four right angles, that the original arc is of the whole circumference of the circle of which it is a part; join L J; produce L J to e, and be is the representative arc required.

PROB. X.

With the same data to find the original measure of any part of the representative circumference.

Let it be required to find the original measure of the arc represented by ab; join a J, and J b; produce J a to L, and J b to V; join L P and V P, and the angle L P V will be the measure of the original arc required.

In like manner it will be found, that L P V is also the measure of the arc represented by cd; and V P R is the measure of the arc represented by be; also O P L is the measure of the arc represented by a d.

Seclidian.—Thee problems are derived from the general principles of perspective. Those who have acquired the elements of that science will be at no loss to comprehend the above. However, in the stereographic projection of the sphere, P is the external pole; therefore, if in N° 2 lines be drawn from the point P, through the two points a and b, to meet the opposite side of the primitive circumference, the portion of the intercepted circumference will be equal to the original arc represented by ab; even this method may be derived from the principles of perspective.

The point P, in N° 1, is also the external pole of the lefser circle, but the original of the lesser circle cannot be obtained with the same facility. In this the intersecting line must be found; and the original circle requires to be put in its place in the original plane, and then the corresponding parts will be found in the same manner.

With respect to N° 1, the part ECG of the primitive is already the original of the representative part EAG.

PROB. XI.

Through a given point in the representation of the arc of a great circle, to describe the representation of the arc of another great circle, so that their original planes shall have a given inclination.

Let A B P be the given arc, and P the given point, and let C be the centre of the arc A PB; draw PC and PO; produce PO to H; and draw CH perpendicular to PH; produce HC to D, and make CPD equal to the inclination of the planes of the two great circles; from D as a centre, with the radius D P, describe E P G, then the original planes of the circles, represented by A PB, E P G, will have the inclination required.

Demonstration.—For the locus of all the circles is in a straight line perpendicular to PO, the line joining the centre of the primitive, and the given point; therefore, if the centres of one of the circles be known, (which is always easy, when the circle or any one of it is given,) the locus will be a perpendicular through that point; but C is the centre of the circle A PB, and D H passes through C perpendicular to PO; therefore D H is the locus of the centres; and because the tangents of these circles are perpendicular to PC and PD at the point P, CP will make the same angle with PD, that the tangents make with each other; but the angle formed by the tangents of these arcs is equal to the inclination of the planes of the original circles, therefore the representative circle A PB is described according to the data, as required to be done.

Seclidian.—By this problem the obliquity of the ecliptic may be represented at its proper angle with the equator; or in a spherical triangle an angle may be represented at a given point in the representation of one of its sides; the sides may be determined as in problem IV.; and thus all the cases in spherical trigonometry may be resolved by means of these two problems.

The following are examples shewing the use of the preceding problems in the stereographic projection of the sphere.

Ex. 1.—Fig. 6. Projection of the sphere on the plane of the meridian.

Ex. 2.—Fig. 7. Projection of the sphere on the plane of the equator.

Ex. 3.—Fig. 8. Projection of the sphere on the plane of the horizon.

This species of projection of the sphere is the most useful of all others, as it gives the angles equal to their originals, and as the measures of the angles and the different arcs concerned are so easily obtained.

As it is impossible to develop the surface of a sphere, so it is also impossible to represent its surface upon a plane without considerable distortion throughout the greater part of the representation, by any mode hitherto devised, or perhaps that can be devised. The original measures of distances and angles upon the surface of a sphere may, however, be obtained from any of the foregoing principles, as accurately as upon the sphere itself, and this is all that is indeed necessary in the solution of any question that may arise.

PROJECTION OF THE SPHERE, Gnomonical.

Definition 1.—When the eye is placed in the centre of the sphere as a projecting point, and if from thence rays be drawn through every point of any circle of the sphere, till they are intercepted by a plane, the figure traced out by the
the intersection of the rays is called the gnomonical projection of that circle, or the circle is said to be projected gnomonically.

2. If the several circles of the sphere be projected gnomonically, the representation is called a gnomonical projection of the sphere.

3. A straight line be drawn from the eye perpendicular to the plane of projection, until it meets the said plane, the point of concurrence with the plane is called the centre of projection, as in the stereographic projection.

4. If a plane be supposed to pass through the eye perpendicular to the plane of projection, and to the plane of any circle to be projected, the plane thus so placed to each is called the vertical plane.

5. The intersection of the vertical plane, and the plane of projection, is called the line of position.

Theorem 1.—Any great circle of the sphere is projected upon a straight line in the plane of projection.

For the centre of the sphere is a point common to every great circle; but the eye is placed in the centre of the sphere, therefore the eye is in the plane of every great circle; and, consequently, every such plane will be projected into its intersection with the plane of projection.

Theorem 2.—The projecting rays passing through any small circle form the surface of a right cone. Since the eye is situated in the centre of the sphere, it cannot be in the plane of any small circle; and since the centre of the sphere, and the centre of a small circle, is in a straight line drawn perpendicular to the plane of the said circle, the rays proceeding from the eye to all points of the circumference of any circle will therefore form the surface of a right cone.

Theorem 3.—Every small circle of the sphere is projected upon a conic section. For the rays form the surface of a cone, and the surface of the cone of rays is terminated by the plane of projection; therefore the section of the intercepted rays will be a conic section, which will either be the ellipse, parabola, or hyperbola.

Prob. I.

Given the centre O, the line PO of position, the inclination of the intersection of a great circle of the sphere, and the vertical plane with the plane of projection, the inclination of the plane of the great circle with the vertical plane, and the radius of the sphere, to draw the representation of the great circle.

Draw OE (fig. 9.) perpendicular to PO; make OE equal to the radius of the sphere, and OEP equal to the complement of inclination of the intersection of the great circle, and the vertical plane with the plane of projection; produce PO to C; in PE take any point A, and draw AB perpendicular to PE, meeting PC at B; make BC equal to BA; draw BD perpendicular to PC, and make the angle BCD equal to the inclination of the plane of the great circle with the vertical plane; join DP, and produce DP to F, and the straight line DF will be the representation of the great circle required.

Scholium 1.—The greater part of this construction is independent of the projection of the sphere, as the same angle DPF, or the opposite one, GPF, would take place, whatever were the distance of the eye; the direct radial OE only determines the distance OP, which would otherwise be variable.

2. It is evident, that with the same data, except a change in the inclination of the plane of the great circle and the vertical plane, the straight line, which is the representation of the great circle, will always pass through the point P:

thus, if the inclination of several great circles of the sphere were B CH, BCD, BCI, BCJ, BCK, their respective representations would be HPQ, DPF, IPN, JPM, KPL.

3. It is also to be remarked, that if BP be the meridian of a plane, and if the angle BPE be equal to the latitude, and the angles BCI, BCD, BCH, &c. on the one side, as also BCI, BCK, &c. on the other side, be respectively 15°, 30°, 45°, &c. on each side, that is, each angle 15°; then BG will be the 12 o'clock line, and all the others on each side of it the hour lines of a horizontal dial.

4. This construction is not only necessary in the gnomonic projection, but also in the orthographic and stereographic projections, in finding the intersections of all great circles with the plane of the primitive.

5. The gnomonic projection of the sphere would be very eligible for general practice, if all the small circles could be projected with the same facility as the great ones; but as the small circles (except those that are parallel to the plane of projection, which are circles) are projected into ellipses, hyperbolas, or parabolas; it is generally confined to the use of dialing, where it is necessary that the hour lines should be straight, and where few curve lines are employed, seldom more than the follices being represented.

Prob. II.

To project any small circle of the sphere, its diameter being given as a chord to the circumference of the great circle.

Let FG (fig. 10.) be the diameter of the circle to be projected, and O the line of position; draw EO perpendicular to OG; draw EF, EG; produce EF to meet G in F; also let EG meet OG, if possible, in g; bisect fg at j; take half of the difference of the lines EF and EG, and let it in the major axis fj, from j to i; and from j to h; then h and i are the points of the ellipses; through j draw kl perpendicular to fj; from i or h as a centre, with the distance ig or fj, describe an arc at k, and another at k, then kl is the minor axis; then about the two axes fj and kl describe the ellipses, and it will represent the circle required.

But if EG (fig. 11.) be parallel to O, they will not meet each other; let this be the case, then the cutting plane will be parallel to the side of the cone, and consequently the projection of the small circle required will be a parabola; produce EF to meet g in f, and take any distance, for the abscissa of the curve; let kE bisect the angle FEG; draw ij perpendicular to Ek, cutting EG, produced at L; and the axis kE of the cone at k; draw im perpendicular to ij; and through i draw ng perpendicular to if; from k, with the distance kl, describe an arc, cutting im at m; make in and ig each equal im; then with the abscissa ij, and double ordinate ng, describe a, the parabola, which will be the representation required.

A very easy method of finding points in the curve is the following:—Draw no parallel to if, and of parallel to ni; divide ni into three equal parts, and through the points of division draw straight lines to cut the former parallels, and the points r, s, of intersection will be in the curve; therefore through the points on, rs, sf, draw a curve, which is the representation of the circle.

But if EG (fig. 12.) meet O in P, the other side of the centre O, the representation of the circle will be a hyperbola; find the double ordinate ng, as in fig. 11.; then with the double ordinate ng, and the abscissa if, and major axis fp, describe a hyperbola, which is the representation
represenation required. The following method, by finding points in the curve, is very expeditious: divide $n_i$ into any number of parts of any proportion, say three equal parts; from the points of division draw lines to $P$; divide $n_i$ into the same number of parts of the same proportion; that is, because $n_i$ is divided into three equal parts, $n_i$ will also be divided into three equal parts; through the points of division draw lines to $f_i$; and the points $r_i$, of intersection will be in the curve.

Scholium.—Though every kind of projection furnishes the means of ascertaining the distances and angles concerned in the same, and though the representation of the whole surface of the sphere by means of a projection is the most eligible method of all others; yet, when a final portion is required to be represented, the method of developing the surface is preferable, not only on account of the development being more nearly similar to the spherical surface itself, but also on account of the distances being obtained by inspection only, or from a scale of equal parts; and though this method is only an approximation to truth, it is sufficiently for common use.

The impossibility of forming a true development of the spherical surface has already been observed: if, however, the sphere be supposed to be circumscribed by a polyhedron, the sides of the polyhedron, extended upon a plane, will be very nearly a true development of the surface.

In the approximating the development of the spherical surface, there are two different methods of considering the subject; one is, by supposing the polyhedral surface to confit of conic frustums, each touching the surface of the sphere in the middle; and the other is, by supposing the polyhedral surface to be composed of those of a cylinder, meeting each other in planes passing through the centre of the sphere, and intersecting each other in one common diameter, as an axis; and, because conic and cylindric surfaces are developable, the surface of the circumscribing polyhedron will also be developable; and, therefore, may be correctly represented. Now, supposing all the sides to be equal, and increased in number at pleasure, (the greater the number, the nearer will the surface of the polyhedron coincide with that of the sphere); and, consequently, any portion of the surface of the development of the surface of the polyhedron will be very nearly equal and similar to the corresponding portion of the spherical surface.

Each of these different methods of representing the spherical surface has its peculiar advantage and disadvantage, when applied to the art of map-making. The conic method of development is best adapted to represent countries to any extent, in the difference of longitude, or round the whole circumference of the earth, if required; to a certain extent in difference of latitude. And the cylindric method of development is well adapted to represent countries contained between any two parallels of latitude, but not to have any considerable difference of longitude.

Of these two different developments, the conic is attended with the least trouble, on account of the facility of determining the parallels of latitude in concentric circles, and the meridians in straight lines.

With respect to the application of the development of the conic surfaces in the construction of maps, a very excellent method is that given by the Rev. Patrick Murdoch, M.A., F.R.S., in vol. i. part. ii. of the Philosophical Transactions for the year 1788, read Feb. 9, as follows.

I. "When any portion of the earth’s surface is projected on a plane, or transferred to it by whatever method of description; the real dimensions, and often the figure and position of countries, are much altered and misrepresented. In the common projection of the two hemispheres, the meridians and parallels of latitude do intersect at right angles, as on the globe; but the linear distances are every where diminished, except only at the extremity of the projection; at the centre, they are but one-half their just quantity, and then the supercificial dimensions but one-fourth part; and in less general maps, this inconvenience will always attend the isometric projection.

"The orthographic by parallel lines would be still less exact; those lines falling altogether oblique on the extreme part of the hemisphere. It is useful, however, in describing the circumpolar regions; and the rules of both projections, for their elegance, as well as for their uses in astronomy, ought to be retained and carefully studied.

"As to Wright’s or Mercator’s nautical chart, it does not here fall under our consideration; it is perfect in its kind; and will always be reckoned among the chief inventions of the last age. If it has been misunderstood or misapplied by geographers, they only are to blame.

II. "The particular methods of description, proposed to be used by geographers, are so various, that we might, on that very account, suspect them to be faulty; but in most of their works we actually find these two blemishes, the linear dimensions visibly false, and the intersection of the circles oblique; so that a quadrilateral space shall often be represented by an oblique-angled rhomboid figure, whose diagonals are very far from being equal; and yet, by a strange contradiction, you shall see a scale of distances inserted in such a map.

III. "The only maps I remember to have seen, in which the last of these blemishes is removed, and the other leftened, are some of P. Schenk’s of Amsterdam; a map of the Russian empire; the Germania Critica of the famous professor Meyer, and a few more. In these the meridians are straight lines, converging to a point; from which, as a centre, the parallels of latitude are described. But, as that rule appears to be only an easy and convenient approximation, it remains still to be enjoined, what is the construction of a particular map, that shall exhibit the superficial and linear measures in their truest proportion? In order to which,

IV. "Let E,L,P (figure 13) be the quadrant of a meridian of a given sphere, whose centre is C, and its pole P; E,L,E,L, the latitudes of two places in that meridian, E,M their middle latitude. Draw L N, n, cotangents of the latitudes, the false of the middle latitude MF, and its co-tangent MT. Then, writing unity for the radius, if in CM we take $C = \frac{N}{n}$, and through $x$ we draw $x R$, $x r$ equal each to half the arc $L I$, and perpendicular to CM; the conical surface generated by the line $R r$, while the figure revolves on the axis of the sphere, will be equal to the surface of the zone that is to be described in the same time as the arc $L I$; as will easily appear by comparing that conical surface with the zone, as measured by Archimedes.

"And lastly, if from the point $i$, in which $r$ produced meets the axis, we take the angle $C T V$, in proportion to the longitude of the proposed map, as a measure, the fine of the middle latitude is to radius, and draw the parallels and meridians as in the figure, the whole space $S O Q V$ will be the proposed part of the conical surface expanded into a plane; in which the places may now be inferred according to their known latitudes and lengths.
PROJECTION.

To construct a map upon the principles of development.

Let $A J K$ (fig. 14. No. 1.) be a quadrant of a great circle of the sphere; divide the arc $A J$ into nine equal parts, and let $B$, $C$, $D$, $E$, $F$, &c. be the points of section; draw the radii $B K$, $C K$, $D K$, $E K$, &c. and the tangents $B b$, $C c$, $D d$, $E e$, $F f$, &c. Now suppose it were required to draw a map of the whole hemisphere, or the half on one side of the equator, for want of room. Draw $l l$, $N^o$ 2, and $A J$ perpendicular to $l l$; make $A J$, $N^o$ 2, equal to nine times the chord $A B$, or $B C$, or $C D$, &c. $N^o$ 1; from $A$, as a centre with the radius $A J$, describe the semicircle $l l$; divide the radii, $A l$, $A l$, each into six equal parts; let $B$, $C$, $D$, $E$, $F$, $G$, $H$, $I$, be the points which divide $A J$ into nine equal parts, and produce $A J$ to $Z$; in $A Z$, make $D d$ equal to $D d$, $N^o$ 1; $E e$ equal to $E e$, $N^o$ 1; $F f$ equal to $F f$, $N^o$ 1, &c.; and from the points, $b$, $c$, $d$, $e$, $f$, &c. as centres with the radii $B b$, $C c$, $D d$, $E e$, &c. describe the arcs $m m$, $n n$, $o o$, $p p$, &c.; divide each of the arcs, $B m$, $C n$, $D o$, $E p$, &c. into six equal parts, and through the corresponding points draw curves from the points of section in $A l$ to terminate in $J$; then the lines $m m$, $n n$, $o o$, $p p$, &c. will represent the parallels of latitude; and the other lines, which terminate in $J$, the meridians.

Another method, by which the parallels of latitude may be made to cut the circumference $l l$ perpendicularly, is the following: imagine straight lines to be drawn from the point $l$, and through the points $B$, $C$, $D$, &c. to meet the concave circumference in $m$, $n$, $o$, &c.; then the tangents from the points $m$, $n$, $o$, will give the centres. If any of the points, $m$, $n$, &c. are out of reach, each curve may be described through the three points $m$, $B$, $m$, and $n$, $C$, $n$, &c. This proc. is even more accurate in distant latitudes than the former.

Scelolium.—This is a very near development of the surface of the globe. All the meridians and parallels of latitude intersect each other very nearly at right angles; the successive quadrilaterals between any two meridians are nearly equal in area, and similar to those on the globe; and those adjoining the middle meridian $A B$ are almost exactly the same as their correspondents. Every parallel of latitude is equally divided by the meridians, as they are on the globe; and every parallel, as terminated by two meridians on the map, is of the same length exceedingly near as the corresponding part on the globe itself. It must, however, be observed, that the meridians are here represented of different lengths, all longer than those on the globe, except $A J$, the central one; but this is also the case with every kind of the projection of the sphere whatever: and in this respect it is even less defective, in the lengths of the meridians, than Murdoch's is with respect to the lengths of the parallels of latitude. However, since the middle meridian answers as a scale, the length of every meridian can be correctly ascertained. This map is perhaps, upon the whole, the most correct and the easiest to be constructed of any yet published. It may be employed in the construction of the largest maps, as well as in the smallest, and will be more exact as the difference of longitude is less.

In drawing a map of any particular country, the perpendicular $A J$, or the diameter of which $A J$ is a part, must be taken as near to the middle of the country as possible, as the parts nearer to $A J$ are more exact than those which are more remote, and because all the degrees of latitude

mishealing the western parts of Europe and Africa, the more known parts of North America, and the ocean that separates it from the old continent."

As the rule here given by Mr. Murdoch would be attended with too much trouble, he proposes a shorter method for practice, in a note at the bottom of page 588 of the same vol. and part referred to; which is, "make $C x$ to $C M$ as the arc $M L$ is to its tangent, and finish the map."

Mr. Martin, in the second volume of his "Young Gentleman and Lady's Philosophy," has given a rule, derived from a very well-known principle of the centre of gravity, in order to obtain the distance $C x$: the formula is $C x = C M \times L B$, which is very convenient in practice. He also gives an example, as applied to a map, in the same volume, which rule is thus:"

"In this new map, the extent or difference of latitude is $50^o$, equal to $L l$; therefore $M L = 25^o = 2.6179$ inches to a radius of 6 inches. (See Inst. 885.) Also, the fine $B L$ of the same arc is 2.5358 inches; therefore fay,

As the arc $M L = 2.6179 - 0.417953$

Is to its fine $B L = 2.5358 - 0.404099$

So is radius $C M = 6. - 0.78151$

$1.82250$

To the distance $C x = 5.8116 - 0.764297$"

The advantage gained by Mr. Murdoch's method of constructing maps is only in facility of description: for though the whole area is truly represented, yet the measure taken along the parallels of latitude are very incorrect, being nowhere equal to those of the sphere, except where the conic surface intersects that of the latter body. The conic meridians within the intersected part are less than the true meridians, and those on each side of the intersected part greater. This method, therefore, ought to be restricted not to exceed $30^o$ of difference of latitude; and in this case, it would be much simpler to take the surface of the cone, a tangent to the sphere in the parallel circle of middle latitude.

From the rule which Mr. Murdoch gives for finding the vertical angle $C f V$, may be derived that of finding the vertical angle of development, in order to cover any portion of the surface of a cone; the side of the cone, the radius of the base, and the degrees contained in the circumference of the base being given, Mr. Murdoch's rule is,

As radius

is to the sine of middle latitude,

So is the difference of longitude

To the vertical angle $C f V$.

But radius is to the sine of middle latitude, as the cotangent is to the cofine; therefore, as the cotangent is to the cofine of middle latitude, so is the difference of longitude to the vertical angle $C f V$. Now the cone, that would touch the sphere, has its side equal to the cotangent, and the radius of its base equal to the cofine; therefore,

As the side of the cone

Is to the radius of the base,

So is the number of degrees contained in the circumference of the base

To the vertical angle of development.
tude are exactly equal upon the line A J to those of the globe, and therefore any measurement with compasses can be more accurately ascertained.

Projection of Shadows. See Shadow.

Projection, in Alchemy, the cauing of a certain imaginary powder, called powder of projection, into a crucible, or other vessel, full of some prepared metal, or other matter; which is to hereby presently transmitted into gold.

Projection, Powder of, or of the philosopher's stone, is a powder supposed to have the virtue of changing any quantity of an imperfect metal, as copper or lead, into a more perfect one, as silver or gold, by the admixture of a little quantity of it.

The mark to which alchemists direct all their endeavours, is to find the powder of projection; which every one of them has been within an ace of, a hundred times.

For the characters, properties, virtues, &c. of this powder, &c. see Philosopher's Stone.

Projection, in Building. See Projection.

Projective Dialling, a manner of drawing, by a method of projection, the true hour-lines, furniture of dials, &c. on any kind of surface whatsoever, without any regard to the situation of those surfaces, either to declination, inclination, or inclination. See Dialling.

Projecture, in Architecture, the out-jettting, or prominency, which the mouldings and members have, beyond the plane or naked of the wall, column, &c.

These the Greeks call cephora, the Italians spori, the French saillol, our workmen frequently failings over, and the Latins projecta, from projectio, I cast forward; whence the English projecture.

Vitruvius gives it as a general rule, that all the projecting members in buildings have their projectures equal to their heights: but this is not to be understood of the particular members or mouldings, as dentils, coronas, the facies of architraves, the abacus of the Tuscan and Doric capital, &c. but only of the projectures of entire cornices, &c. The great point of building, according to some modern architects, consists in knowing how to vary the proportions of projectures, &c. agreeably to the circumstances of the building.

Thus say they, the nearness and remoteness, making a difference in the view, require different projectures; but it is evident the ancients had no such intention.

The projecture of the base and cornice of pedestals, M. Perrault observes, is greater in the antique than the modern buildings by one-third; which seems to follow, in good measure, from the ancients proportioning this projecture to the height of the pedestals; whereas the moderns make the projecture the same in all the orders, though the height of the pedestal be very different.

The reason of this change, which the moderns have made of the antique, the same author refers to a view of the appearance of solidity.

PRO INDIVISO, in Law, a possession or occupation of lands or tenements, belonging to two or more persons, of which none can say which is his several portion, each having the whole, &c. as carpenters before partition.

PROKOPHEVA, in Geography, a town of Ruffia, in the government of Irkutsk, on the Kirenga; 40 miles S. S. E. of Kirensk.

PROLABIUM, in Anatomy, the red part of the lip, intervening between the common skin and the mucous membrane, and forming the very margin of the mouth.

PROLAPSUS, or PROCIDENTIA ANI, denotes, in Surgery, a very distending complaint, in which a tumour is produced at the anus by a defecant and protrusion of the rectum, or that bowel which forms the lower termination of the intestinal canal. It is not, however, the whole of this intestine which protrudes, but only a part of its internal membrane which becomes inverted and passes out at the anus, forming a red, soft, flatish, circular tumour. (Schacher de Morb. a Situ Intestinor. Haller, Difp. Chirurg. Selecit. tom. iii. p. 14.) Levret, in paffing his finger into the vagina of a patient, who had had for twenty years a bleeding, livid, fetid swelling, as large as one's fist, and occasioned by a prolapsus ani, found the vagina and uterus both in their natural situations; a circumstance which could not have been, had the whole of the rectum been concerned in the protrusion, as is commonly suppos'd. Traité des Polypes. p. 162.

A protrusion of the internal membrane of the rectum is frequently observed in children, affected with teneimus, or dysentery, or tortured with a fit of the stone, or undergoing the operation of lithotomy. Women, having internal hemmorhoids, and in the violent efforts of labour, are also subject to the same accident. Smellie's Midwifery, vol. iii.

In the early and most simple stage of this difease, the swelling may be easily reduced by compressing it with the fingers, and the reduction may be maintained by the application of a bandage, which will keep up moderate pressure. The majority of patients get into the habit of affllicting themselves in the preceding way. But if the disorder be chronic, if the reduction of the swelling be neglected, if the protrusion occur again from the slightest causes, or the tumour continue exposed to the effect of the external air, the protruded part acquires a larger size, its surface puts on a fungous appearance, and ulcerates and bleeds. By degrees the health is impaired; digestion is disturbed; the patient becomes languid; and the loss of blood weakens and ultimately destroys him. Such was the fate of a child eight years of age, who was afflicted for more than six months with a prolapsus ani, which could not be kept reduced. The tumour, without being absolutely painful, was incessantly bleeding, and the child died of hectic complaints. Bunning, ob. 62, centur. 2. p. 198.

Another child, ten years of age, but strong and robust, living in the country, had for upwards of a year a prolapsus ani, forming rather a hard swelling two or three inches in length. Laffius succeeded in reducing it by making rather forcible preflure, which the surgeons, who had previously seen the patient, had been afraid of putting in practice. The cure was complete immediately the reduction was accomplished, nor were any other steps necessary. Pathologi Chirurgicales, tom. ii. p. 133.

When a prolapsus ani is chronic, the internal membrane of the rectum, being exposed to the contact of the air, puts on a fungous thickened appearance, and ulcerates and bleeds. The consequence is an habitual weakness, sometimes accompanied with impossibility of reducing the tumour, or of keeping it reduced, provided it has acquired from long duration a considerable volume. In this alarming state of the complaint, the old writers recommended the cautization of the surface of the tumour. (Ætius, Terra- bibi. quart. ferm. 2. cap. 7. p. 760. Vegetius, Mulo medi- cina, lib. iii. cap. 11.) Amongst the moderns, Laffius is also a strong advocate for such practice. It is known, says he, that the membranous lining of the rectum sometimes partly, or
or totally floughs, in consequence of gangrenous inflammations, in persons labouring under prolapsus ani and internal highly painful hemorrhoids. Many cafes prove, adds this writer, that patients have been cured after such floughing, whether brought on by the interference of the practitioner, or the salutary operation of nature, provided the inflammation has been sufficiently great to detach a part, or the whole of the internal membrane in the form of flouches, together with some of the hemorrhoideal swellings. Cheifelden, Anatomy, seventh ed. p. 158. Tulpinus, cap. 17. lib. iii. Med. Essays of Edinburg, vol. v. p. 554. Cowper, Anatomy of the Human Body, tab. 39. fig. 7. Levret, Traité des Polypes, p. 162.

With respect to the plan of cauterizing bleeding, ulcerated, invertebrate, irreducible cafes of prolapsus ani, it is not to be expected that it will now meet with any approbation amongst the surgeons of this country, who, being well acquainted with the mode of flopping hemorrhage by ligatures and compression, would have no fear of attempting the extirpation of such a disease with the knife.

A prolapsus ani is mostly owing to too violent and repeated exertions of the rectum itself, excited by some source of irritation about the extremity of this intelle. Thus, the too frequent employment of acoetic medicines, the action of which particularly affects the large intestines, often occasions the above consequence. The same thing results from small worms, known by the name of aercides, and which, lodging about the lower part of the rectum, occasionally cause excessive irritation. Habitual colicences, hemorrhoids; in a word, every thing which, by stimulating the rectum, excites too violent an action of this intelle, may induce the complaint under consideration.

Authors of surgical works have, not uncommonly, recommended fomenting the prolapsed part with emollient and antifeptic decoctions, before making an attempt to reduce it. They even advise the operator, for the purpose of succeding with more ease, to cover his finger with linen, smeared with wax and oil. But all such preparations are useless, and, when a surgeon is called to a patient affected with a prolapsus ani, the greatest service he can render, is to put back the displaced part, as quickly as possible, into its natural situation, without leaving the intelle exposed to the dangerous effects which may arise during the time waited in employing fomentations, &c. Also, as much greater manual dexterity can be made use of, when the fingers are perfectly uncovered, than when they have greasy gloves on, it is best not to follow the latter method. However, if it should be judged proper to cover the hands with any thing, a piece of fine cotton will best anfwer the purpose.

The patient being in bed, lying upon his side, or, what is better, on the abdomen, while his buttocks are raised rather higher than the rest of the body, the surgeon is to make strong, but equal preffure, with the palm of his hand on the lower portion of the prolapsed intelle. By continuing such preffure, the intelle may, in general, be easily reduced. But if this plan should not suffice, the upper part of the protruded intelle must be comproffed with the fingers of one hand, while the lower part is preffed upward by the palm of the other one. In this way we are almost sure to succeed. It is true, that if, in consequence of having too long delayed the reduction, or from some other cause, the gut has become much swollen and inflamed, it will be impossible to reduce the part before such symptoms have been subdued. For this purpose it may be proper to take some blood from the patient, in such quantity as his strength will allow. The intelle may also be fomented with a warm solution of the acetate of lead, (faccharum fuiturni.) When the swelling has been diminished by these means, there will be no difficulty in replacing the parts, by purifying the plan already explained.

The greatest difficulty is not the returning of the intelle, but keeping it in its place. The latter object often gives a great deal of trouble. For, after the bowel has frequently descended, the sphincter sometimes becomes too weakened, that it can no longer keep the part supported. Hence, the complaint not only recurs whenever the patient goes to stool, but even whenever he walks, or places himself in an erect posture, of which there are many examples.

Different bandages have been devised for supporting the anus after its reduction. But it is not an easy matter to invent one, which is in every respect adapted to what such an inconvenience requires. A comprefl, doubled several times, is usually applied to the anus, and supported in this position by means of a T bandage. In many cafes, this method of keeping up the intelle answers very well. A machine was invented by Mr. Gooch, which has the double advantage of supporting the intelle more securely than any other with which we are acquainted, and of allowing the patient to take a great deal more exercise than he could do without its affifiance. See Gooch's Surgery.

Elatic gum pellaries were invented a few years ago by M. Bernard, an ingenious artist, who employed this substance for making various articles used by surgeons. The instrument which we have just mentioned, conflits of an oblong oval body, rounded at one end, and terminating at the other in a narrow, rather long neck, with a flat border at its extremity. The body of this instrument, when introduced into the intelle beyond the sphincter, dilates and supports the gut, while the sphincter embraces its neck, and the border of this part of the instrument hinders it from ascending too far up the rectum. A ftring is also attached to the edge, which tends to prevent the occurrence. This pellary is very smooth, and, conseqently, cannot do any injury to the parts. It is also very light, being only composed of a very thin, though tolerably folid, fubfance. As it is pierced at its termination, it does not impede the discharge of air, which might otherwise incommodate the patient.

When the intelle is protruded at the time the patient is at stool, the part is to be immediately replaced. This the patient should accustom himself to do without affifiance, and then the bandage, or pellary, is to be applied. In order to strengthen the sphincter ani and adjacent parts, the weaknches of which muft, in the majority of cafes, be regarded as the entire cause of the difeafe, the patient should take preparations of bark and feed, make use of the cold bath, and frequently have cold water dafhed against his buttocks and loins. Astringent infufions, particularly such as are composed of an infusion of gall-nuts, or oak-bark, are also very ferviceable. A small quantity of alum, or fugar of lead, has sometimes been added to these infufions; but, in general, all additions of saline fubfances are to be deemed improper, because falks usually produce an irritation of the intelle.

A much more serious disorder has been confounded with the prolapsus ani; viz. one, in which a confiderable portion of the colon, cæcum, and even sometime of the ileum, becomes everted and pushed out at the anus. Former practitioners confidered this occurrence in the fame point of view as the difeafe of which we have just been treating. In this cafe, they believed that the whole of the rectum became everted, in consequence of the relaxation of the sphincter and levatores ani, and that it then drew after it other por-

Vol. XXVIII.
PROLAPSUS.

Prolapsus of the Uterus. See Exopthalmia.

Prolapsus Uteri. This diffusing complaint presents itself in two different degrees; in one the uterus descends more or less into the vagina; in the other it protrudes entirely out of this passage, and hangs down between the patient's thighs. A prolapsus uteri may happen, either out of the time of pregnancy, during this period, or at the moment of parturition. Women, who are not pregnant, but who have a large pelvis, are in the habit of carrying or lifting heavy weights, and have already had several children, are particularly subject to the present disorder. It may readily be distinguished by an inspection of the parts. The body of the uterus fills the cavity of the vagina, at the orifice of which the os tincæ may be felt. The patient feels in her groins and about the pelvis dragging pains, which are exasperated by walking, but subside entirely when she keeps her bed, and the uterus has been pushed back with the finger, and kept there with the assistance of a pessary.

If this first degree of the disorder be not obviated, the uterus protrudes altogether from the vagina, and presents itself externally, which may happen either by degrees, or all on a sudden. The uterus, when thus protruded, forms a red oblong tumour, larger above than below, and terminating in the transverse opening of this viscus. The patient can neither walk nor sit down; she experiences pain in the groins and lumbar region; and has difficulty of voiding her urine and faces. The vagina becomes inverted, and one part of the fuscus of the bladder being drawn slowly outward, covers the anterior and inferior part of the tumour to which it is adherent. A prolapsus uteri of this description degenerates into a chronic diseafe, which may continue for several years, if not rectified on its first occurrence. (Saviard, ob. 13. & c. p. 49.)

When it has exiled a long while, its reduction can only be effected gradually, by the patient being confined to a horizontal position in bed, by low diet, and by daily covering the swelling, which is hard, thick, and almost insensible, with linen wet with an emollient decoction. As soon as the size of the uterus is a little diminished, an attempt is to be made to replace it by pulling it from below upwards, which operation may be facilitated by raising the pelvis, and taking care to have the bladder and rectum empty. Should the reduction be accomplished, the uterus is to be maintained in its natural situation with a pessary.

When the uterus protrudes completely from the vagina at the period of delivery, and at the moment when the woman makes the most violent efforts, no attempt should be immediately made to reduce the part, a thing that would also be impracticable. It would only be fatiguing the mother and child with useless trials. On the contrary, we ought to support the uterus, gradually dilate its orifice, bring the labour to a conclusion, and carefully extract the placenta. When delivery has taken place, the womb contracts, its size is lessened, and the reduction can then be easily effected. Fabricius, de Foetu vivi extraectione, utero prolapso. Vide Haller, Disputat. Chirurg. felectae, tom. iii. p. 431.

About the fourth or fifth month of pregnancy, and sometimes rather later, the uterus, by means of its weight, becomes displaced; and in women who have a large pelvis, and have already had several children, protrudes more or less out of the vagina. The patients experience a sense of heaviness about the rectum, dragging pains in the groins and lower part of the back, and weakness and prostration of strength. At length they are attacked with constipation and retention of urine, which complaints increas as the prolapsus uteri increases. Speedy relief is here essentially required, and the proper mode of procuring it, is by making the patient keep her bed, where the mulit endeavour to void her urine, and the uterus is to be pushed back with the finger, in order to avoid a recurrence of the retention of urine, which is occasioned by the pressure of the womb on the neck of the bladder.

A woman, twenty-six years of age, and four months with child, flipped and fell down while carrying a heavy burden on her shoulders. At the instant she felt a violent pain in the loins and region of the pubes, accompanied with an absolute inability to void her urine. An ignorant practitioner being called to assist her, prescribed diuretics, instead of introducing a catheter and drawing off the urine. For twelve days the patient suffered inexpressible pain, without being able to discharge a drop of fluid from the bladder, and she at last fell a victim to the ignorance of her
her medical attendant. After death the uterus was found in a state of prolapsus in the vagina, and its cervix protruding at the vulva. The bladder was so considerably dilated, that it was two feet long, and one broad, and contained twenty pints of water. "Patet adeoque luculentissime," says the writer of this case, "quam summis illi mediæ, ad multorum hominum detrimentum, proximiam suæ excitaret, qui chirurgiam negligent." Kuhn, Differt. de Uteri Lâpifu, Gedani 1753, in 4to. Vide Differt. Chirurg. felêcte, Haller, tom. iii. p. 587.

Girls are seldom afflicted with a prolapsus uteri. The disease, however, may take place slowly in them, in consequence of violent exertions.

There is an example on record of a young girl becoming pregnant, and being delivered of a child, notwithstanding she had a prolapsus uteri, which had existed a long time. When she was fourteen, and had her menses upon her, she made a considerable exertion to throw a bundle of herbs over a wall. She felt at the moment a very acute pain in the loins and lower part of the abdomen. The next day the uterus had descended into the vagina, and protruded at the vulva. This young woman lived six years with the complaint, which gradually became worse. At the age of twenty-two she married, but for the space of twenty years never conceived. At length the act of generation was consummated, and the period of pregnancy passed over without any material indispersion. At the time of parturition a very considerable portion of the uterus protruded at the vulva, in form and size resembling a large melon. It was hard and elastic, and seemed as if it had become adherent to the labia, so closely did they embrace it. As the cervix uteri did not dilate, it became necessary to divide it at two opposite points, in order to make the requisite room for the extraction of the child, which was dead. Delivery was followed by no serious consequences: the lochia were discharged in abundance. An attempt was made to reduce, gradually, the uterus which had been so long displaced, by keeping the patient in bed, and using emollient fomentations and the vapour bath. She only purged this treatment, however, one week, and then resumed her ordinary work.

The uterus continued in the same state as it was before pregnancy, with this exception, that its displaced part became rather longer and more clyndrical. This woman, at the age of fifty-three, ten years after her delivery, still enjoyed good health, and followed her usual country-work. Tracté des Maladies de la Vellie, par M. Chopart, tom. ii. p. 73.

It is generally admitted, that a prolapsus uteri is exceedingly difficult to reduce and keep up in patients who are fat; while, in thin women, the reduction and support of the displaced part can be managed with much less trouble.

For the preceding short and accurate account of the prolapsus uteri, we are indebted to M. Laffl. See Pathologie Chirurgicale, tom. ii.

PROLAPSIUS of the Vagina. See VAGINA.

PROLATE, in Geometry, an epithet applied to a spheroid produced by the revolution of a semi-ellipsoid about its longer diameter.

If the solid be formed by the revolution of a semi-ellipsoid about its shorter diameter, it is called an oblate spheroid; of which figure is the earth we inhabit, and, perhaps, all the planets too; having their equatorial diameter longer than the polar. See SPHEROID.

PROLATIO Major et Minor. Prolation, in the beginning of figurative counterpoint, was the manner of regulating the value of notes by signs at the beginning of a movement, which determined whether long notes were to be regarded as perfect or imperfect, that is, whether ternary or binary, equal to three notes of the next degree, or 2. Points which answer that purpose now were not then in use. The ternary notes in triple time were called perfect, as we have often observed elsewhere, and the binary, or common time, imperfect. See MODAL SIGNS, or MODUS, as they were called.

In the MS. of Waltham Holy Cros, there is a tract entitled "Regula Magistri Thomae Wallingham; de figuris compositis et non compositis, et de Cantu perfecto et imperfecto, et de Modis." And this comprehensive little tract does not promise more than the author has performed; as the simple and compound figures or notes, their perfect and imperfect powers, the moods and every thing that concerned the time and measure of such music as then fulfilled, is very well explained; particularly the moods and signs of prolataion, which we do not recollect to have been represented in any other authors equally ancient. His chapters on refris or pauses, on the signs of perfection and imperfect in the notes, and of the alteration of their value, by position or colour, are very instructive.

The signs of prolation at first were confined to four; two for perfect or triple time, and two for imperfect or common time. The circle with a point of perfection in the centre, thus C, was the sign for the great mode perfect, in which all long notes were equal in duration to three of the next shorter in degree. The simple circle, unaccompanied by the point, was used for notes of a shorter duration, but with the same triple power. These two moods may be compared with our present measures of 6 and 4, where each note is occasionally rendered perfect, or equal to three others, by a point, instead of the general augmentation implied by the circle, which the old masters placed at the beginning of a movement.

The signs of imperfect, or, as we now call it, common time, were these c, C, which differ but little from those in present use for dupla proportion, or an equal number of notes in a measure; where each longer note is only equal to two of the next shorter kind. This seems to us even clearer than Morley's account "of the prolation of the more, and the prolation of the less—the prick of perfection, &c." which his old English darkens instead of illustrating.

PROLECTATIO, a word used in chemistry to express an extraction of the finer substanances of a mixed body by the attenuation of the subter particles; so that these, being rarefied, separate spontaneously from the rest, and leave the grosser and less valuable part in form of a residuum behind.

PROLEGOMENA, formed of προειρήματι, I preface, or πρεισχο, in Philology, certain preparatory observations, or discourses prefixed to a book, &c. containing something necessary for the reader to be apprized of, to enable him the better to understand the book, to enter deeper into a science, &c.

The generality of arts and sciences require some previous instructions, some prelegomena.

PROLEPSIS, προειρήματι, or anticipation, a figure in Rhetoric, by which we anticipate, or prevent what might be objected by the adversary.

It serves likewise to conciliate the audience, while the speaker appears defirous to represent matters fairly, and not to conceal any objection which may be made against him. Thus, it may perhaps be objected, &c. You will ask, &c. But some man will say, How are the dead raised, or with what body do they come? Thou fool, that wiihst thou were, &c. Where the objection is turned into an argument against the adversary, as in the last instance, it is called anti tropo, or

inverso.
inseparable. Where it is rejected as insufferably absurd, it is called apodictic.

PROLEPTIC, προεφθαλμός, denotes a periodical disease, which anticipates, or whose paroxysm returns sooner and sooner every time; as is frequently the case in agues, &c.

PROLES, Lat. in English progeny, are such issues as proceed from a lawful marriage; though if the word be used at large, it may denote others.

PROLIFER, in Botany, a word sometimes used in specific names, or in definitions, to express either a greater assemblage of flowers, in one common integument, than is usual in the genus; witness Dianthus prolifer; or, more frequently, a preternatural luxuriance of growth in the herbage or inflorescence of any plant.

PROLIFIXITY, in Medicine, something that has the qualities necessary for generating. See Fecundity.

PROLIXITY, in Dicouns, the fault of entering into too minute a detail; of being too long, prolix, and circumstantial, to a degree of tediousness.

Prolixity is the vice opposite to concisefns and laconism.

Prolixity is a fault commonly charged on Guicciardini, Gaffendus, &c. See Method.

PROLOCUTOR of the Convocation, the speaker or chairman of that assembly.

The archbishop of Canterbury is, by his office, president or chairman of the upper house of convocation. The prolocutor of the lower is an officer chosen by the members the first day of their meeting, and is to be approved by the higher.

It is by the prolocutor their affairs, debates, &c. are to be directed; and their resolutions, meffages, &c. delivered to the higher house; by him all things propounded to the house are read, suffrages are collected, &c. See Convocation.

PROLOGIA, προλογία, in Antiquity, a festival celebrated by the inhabitants of Laconia, before they gathered their fruits. The Romans also celebrated a feast of the same kind.

PROLOGUE, Prologus, in Dramatic Poetry, a discourse adressed to the audience before the drama or play begins.

The word is formed from προλογία, προλογίου, fore-speech, formed of πρό, and λόγος, fermo.

The original intention of the prologue was to advertise the audience of the subject of the piece, and to prepare them to enter more easily into the action; and sometimes to make an apology for the poet.

The prologue is of a much more ancient standing than the epilogue. The French have left off the use of prologues, except in their operas; those few they now and then make having nothing in them of the genuine prologue, as bearing no relation to the subject, but being mere flourishes or harangues in praise of the king, &c.

In the ancient theatre, the prologus was properly the actor who rehearsed the prologue; the prologue was esteemed one of the dramatis personae, and never appeared in the piece in any other character; so that the learned are surprized to find Mercury, in Plautus' Amphitryon, speaking the prologue, and yet acting a considerable part in the play afterwards.

The prologue, therefore, among them, was a part of the piece; indeed, not an effential, but an necessary part. With us the prologue is no part at all; but something entirely distinct and separate: with them the drama was opened with the appearance of the prologue; with us it is not opened till after the prologue is retired; with us, therefore, the curtain is kept close till after the prologue; with them it must have been withdrawn before.

Hence proceeds a still more considerable difference in the practice of the prologue; for with us the prologue speaks in his real or personal character; with them, the prologue spoke in his dramatic character.

With us, he always directs his speech to the audience, considered as in a play-house, to pit, box, and gallery; with them, he ought, in propriety, to have spoken as to a chorus of by-standers, or persons to be present at the real action; but this being in good measure inconsistent with the design of the prologue, their persons spoke in the dramatic capacity to the audience in its principal capacity; which was an irregularity that either the good fortune, or the good sense, of the moderns have freed them from. They had three kinds of prologues; the first, ἠριστοπλογος, in which the poet delivered the argument of the piece; the second, τοιοτόπος, in which the poet recommended himself, or his piece, to the people; the third, ἄστειος, in which objections were obviated, &c.

PROLONGED FACE. See Face.

PROLUSION, Proloco, in Literature, a term applied to certain pieces, or compositions, made previously to others, by way of prelude or exercise.

Diodore calls the Culex of Virgil, and his other opulenta, prolusions; because written before the great ones. The prologues of Strada are very ingenious pieces. The famous M. Huet, bishop of Avranieres, had all Strada's prologues by heart.

PROMACHIA, προμαχία, in Antiquity, a festival in which the Lacedaemonians crowned themselves with reeds.

PROMALACTERION, the name of the first apartment in the hot baths of the ancient; this was a hot and close room, in which the person was kept a while before he plunged at once into the warm water.

PROMB, in Geography, a town of Austria; nine miles W. of Tauffkirchen.

PRIME, or Prone, or Ponge-mou, a city of the Birman empire, and capital of a district, situated on the Irrawaddy; containing, as it has been said, above 30,000 inhabitants. Their number, as Col. Symes was informed, was greater than that of Rangoon, and their market was better supplied. This city is renowned in Birman history, as having been the scene of many long feiges and bloody conflicts. It has no remarkable buildings; some of its streets are of considerarble length, and they are infested by a great number of dogs, and the inhabitants, men, women, and children, crowd into them to indulge their curiosity at the sight of an European, expressing their astonishment by loud laughis, and clapping of hands, but intending no contempt or offence; respect and kindness to strangers being inculcated by parents, as well as sanctioned by the practice of the Birmans. At the upper end of the present city are the ruins of the ancient port of Prome, which had been a small pentagon, constructed of brick, and, from its situation, very strong. The modern fort is nothing more than a pali-faded inclosure, with earth thrown up behind it. Low hills on the cahern side approach the town, in which the rains have formed channels down to the river, that are crossed by wooden bridges. The town has several yards for the accommodation of stone-cutters, who are employed in manufacturing flags for pavements, and slabs and vases for the use of temples, out of a fine free-lime which is found in its vicinity. Adjacent to the town there is a royal menagerie of elephants, consisting of two rows of lofty well-built stables, in which these animals are lodged during the rains. The city of Prome, and the province in which it stands, are the jaghirs, or estates, of the second son of the king, who derives his title from them. Prome is sometimes called Terrec-
Terreckettare, or single skin; and the Birmans have an old legendary tale concerning the origin of this name; it is related, that a favourite female slave of Tutub-mangoe, or the mighty sovereign with three eyes, importuned her lord for the gift of some ground; and being asked of what extent, replied in familiar terms with the crafty and amorous Elfa, when she projected the site of ancient Carthage. Her request was granted, and she used the same artifice. The resemblance of the stories is curious. Col. Symes informed, that the ruins of a large fort and city, much surpassing the present, stood about a league easterly of the town. Prome is 165 miles N.N.W. of Rangoon. N. lat. 19°. E. long. 95°. Symee's Ava, vol. ii.

PROTHEUS, in Ancient Astronomy, was the name of a constellation of the northern hemisphere, now called Hercules, or Ergonaïs.

PROTHEUS, in Mythology, the son of Japetus, one of the Titans, and Clymene according to Hesiod, or of Themis according to Eschylus, whom the poets feign to have formed men of clay, and animated them by fire fole from heaven; at which Jupiter being angry sent Mercury to chain him to mount Caucasus, and to set a vulture to his liver, which grew again as fast as it was devoured.

This fable is variously related by different authors. Prometheus, as some say, being a man of subtle and crafty genius, attempted to impose upon Jupiter in a facetious, and thus to find out whether he was really worthy to be reckoned a god. Having for this purpose slain two oxen, he filled one of the skins with the flesh, and the other with the bones of the victims, the latter of which was chosen by Jupiter. The god resolved to be revenged upon all mankind, deprived them of the use of fire; but Prometheus, with the assistance of Minerva, who had already aided him by her advice in forming the body of a man of tempered clay, got up to heaven, and approaching the chariot of the sun, stole from thence the sacred fire, which he brought down to earth in a furula. (See Hor. Od. 3. i. 2.) Jupiter, incensed at this scheme and audacious enterprise, ordered Vulcan to form a woman, endowed with all perfections, whence she was called Pandora. (See her story under Pandora.) Jupiter failing to enflame and seduce Prometheus by this artifice, ordered Mercury to carry him to mount Caucasus, and chain him to a rock, where an eagle was eternally to prey upon his liver. This part of the history of Prometheus, and his subsequent deliverance either by Hercules or Jupiter himself, abounds with fictions, which are supposed to contain some ancient facts under this fabulous disguise. M. Bannier supposes that this is merely a continuation of the history of the Titans. Prometheus, as he conjectures, was not exempt from the perfections which harassed the other Titans. As he returned into Scythia, which he durst not quit so long as Jupiter lived, that god is said to have bound him to Caucasus. This prince addicted to astrology, frequently retired to mount Caucasus, as to a kind of observatory, where he contemplated the stars, and was, as it were, preyed upon by continual pining, or rather by vexation, on account of the solitary and melancholy life which he led. This is supposed to have given rise to the fable of the eagle or vulture that incessantly preyed upon his liver. Herodotus, however, alleges, that Prometheus was put in prison for not being able to stop the overflowing of a river, which from its rapidity was called the eagle; or at least that he was obliged to fly with a part of his subjects to the mountains to escape the inundation, till a traveller, represented by Hercules, undertook to dam it up by a mount, and to kill the eagle, as it may be said, by making its course regular and uniform; thus Prometheus was delivered by this hero from his prison, or retreat. The inhabitants were at this time savage and without laws; Prometheus, who was a polite and well-informed prince, taught them to lead a more rational life, instructed them in agriculture, phyfiæ, &c., and thus gave rise to the hyperbolical expressions of his having formed a man, whom Minerva, the goddess of sciences, animated. Laëntius explains this fable by supposing that Prometheus was the first who taught the art of making statues of clay; whence he is said to have invented the art of flintary. As to his theft of fire, some authors say, that this part of the fable had its rise from his having taught man the use of fire. Diodorus Siculus says that he discovered combustible materials fit for kindling and maintaining fire. Bannier is of opinion, that the origin of this fiction was, that Jupiter, having ordered all the fires where iron was forged to be put out, left the Titans should make use of it against him, Prometheus, who had retired into Scythia, there established good forges; hence came the "Calybes," those excellent blacksmiths; perhaps Prometheus also, not thinking to find fire in that country, brought some thither in the flail of the furula, in which it may be easily preserved for several days. (See Furula.) As for the two oxen which Prometheus is said to have slain, that he might impose upon Jupiter, this part of the fable is said to be founded upon his having been the first who opened victims with a view of drawing omens from the inspection of their entrails. According to Le Clerc, Prometheus is the same with Magog, the former being the son of Japetus, and the latter the son of Japhet and grand-son of Noah. Both Prometheus and Magog settled in Scythia; the latter invented or improved the art of founding metals, and of forging iron, which the poets attributed to Prometheus; and Diodorus too says that he invented several instruments for making fire. The appellation Magog signifies vexation, as Prometheus was gnawed by a vulture.

If we rely on the statement of Sir Isaac Newton, Prometheus was nephew to the famous Sesostris, who, according to his account, lived about the time of the Argonauts, a few years before the Trojan war. As that prince had accompanied his uncle in his expedition, he was left by him upon the Mount Caucasus, with a part of his troops, to preserve the conquests he had made in Scythia. Admitting this to be the case, Prometheus would be an Egyptian originally, and his deliverer would be Hercules the Argonaut, the son of Alcmena. But many of the ancients, and particularly Hesiod, represent Prometheus as one of the Titans.

The learned Bryant adopts the opinion of those who consider Prometheus and Noah as the same person. Prometheus raised the first altar to the gods; he constructed the first ship, and transmitted to posterity many useful inventions. He is supposed to have lived in the time of the deluge, and to have been guardian of Egypt at that season. His influence was limited to that region; because the Egyptians, like the people of Phoeis, Argos, Thessaly, and Dodona, confined the deluge to the boundaries of their own country. Hence we may plainly see the perils which are alluded to under the character of Prometheus. He was the same as Osiris; the same also as Dionysus, the famous husbandman, planter of the vine, and inventor of the plough. (Bryant's Analysis of Mythology, vol. ii. 253.) Prometheus received divine honours, or at least rite as were assigned to the heroes; accordingly Paulæus tells us (in his Attica), that Prometheus had an altar in the academy itself, and that games were instituted
instituted to him, which consisted in running from that altar to the city with torches that were to be kept perpetually burning.

**PRO**

PROMIESZ, in Geography, a town of Lithuania; 35 miles W. of Troki.

**PROMISE, in Law,** is, when, upon a valuable consideration, a man binds himself by his word, to do or perform such an act as is agreed on with another: it is in the nature of a verbal covenant, and wants nothing but the solemnity of writing and sealing to make it absolutely the same. See COVENANT and ASSUMPT.

**Promise,** in Moral Philosophy, is a kind of social transaction between two parties, in which some declaration is made, or assurance given, on the part of one to the other, which brings us under an obligation to act or not to act, from which we should otherwise have been free. What makes a promise is, that it be expressed by one party to the other with understanding, and with an intention to become bound, and that it be accepted by him, and the expression, if it is not accompanied with understanding and will to engage, never makes a promise. Such an obligation never flows merely from declaring a resolution or intention. The intention to perform the promise, or not to perform it, whether the intention be known to the other person or not, makes no part of the promise; this is a solitary act of the mind, and can neither constitute nor dissolve an obligation. A promise must mean more than a declaration of resolution or intention; and the whole difference is, that the one relates to the present, the other to future time. When I say I intend to do an action, I affirm only a present fact—but to promise is to declare that such a fact shall be done, or that such and such events shall happen. In this case, it is not enough to acquit me from the charge of falsehood, that I intend to do what I promise, but it must be actually done, agreeably to the assurances given. After declaring a resolution to do an action, a man is under no obligation actually to do it, because he did not say he would; his word and veracity are not engaged; and the non-performance cannot infer the guilt of violating truth. On the contrary, when a person declares he will do any action, he becomes obliged to do it, and cannot afterwards omit it, without incurring the imputation of declaring falsehood, as really as if he declared what he knew to be a false or present fact; and in much the same manner as he would have done, if he had pretended to know, and had accordingly attempted, that a certain event would happen at a certain time which yet did not then happen. There is, however, a considerable difference between this last case, and the falsehood implied in breaking promises and engagements; for the object of these is something, the existence of which depends on ourselves, and which we have in our power to bring to pass; and therefore, here the falsehood must be known and willful, and entirely imputable to our own neglect and guilt. But in the case of events predicted which are not subject to our dominion, the blame, as far as there may be any, must arise from pretending to knowledge which we really want, and affecting absolutely what we were not sure of.

To promise, then, being to affect a fact dependent on ourselves, with an intention to produce faith in it and reliance upon it, as certainly to happen; the obligation to keep a promise is the same with the obligation to regard truth; and the intention of it cannot be, in the sense some have affected, to will or create a new obligation; unless it can be pretended that the obligation to veracity is created by the mere breath of men every time they speak, or make any professions. If, indeed, we mean by creating a new obligation, that the producing of a particular effect or performance of an external action becomes fit, in conseqence of some new situation of a person (or some preceding acts of his own) which was not fit before; it may be very well acknowledged; nor is it in any thing in the least mysterious. Thus, performance becomes our duty after a promise, in the same sense that repentance becomes our duty in conseqence of doing wrong, reparation of an injury in conseqence of committing it, or a particular manner of conduct in consequence of placing ourselves in particular circumstances and relations of life. As a confirmation of this account, if any confirmation were necessary, it might be observed, that false declarations in general, and violations of engagements, admit of the same extenuations or aggravations according to the different degrees of solemnity with which they are made, and the different importance of the subjacts of them.

The account above given of the nature and obligation of a promise, is very different from that of Mr. Hume in the third volume of his "Treatise of Human Nature;" and with respect to the obligation of a promise, it is somewhat different from archdeacon Paley's mode of reasoning in his "Principles of Moral and Political Philosophy," vol. 1.

This ingenious writer deduces the obligation of performing promises, not from any innate moral principles, of which a sense of obligation is supposed to be one, but from the necessity of such a conduct to the well-being, or, indeed, the existence, of human society. Men act, he says, from expectation; expectation is, in most cases, determined by the assurances and engagements which we receive from others; and if no dependence can be placed upon these assurances, no judgment could be formed of many future events, nor should we know how to regulate our conduct with respect to them. Confidence, therefore, in promises, is essential to the intercourse of human life; and there could not be this confidence, if men were not obliged to perform them: the obligation, therefore, to perform promises is essential to the fame end, and in the same degree. Next to the nature and obligation of promises, the next subject of inquiry is the sense in which they are to be interpreted. If the terms of a promise admit of more senses than one, it is obvious that the promise is to be performed in that sense in which the promise is apprehended at the time that the promise was received.

Advertising to the account that has been just given of the obligation of promises, it will appear that this obligation has been thought to depend upon the expectations which we knowingly and voluntarily excite. Consequentially, any action or conduct towards another, which we are sensible excite expectations in that other, is as much a promise, and creates as strict an obligation, as the most express assurances. This is the foundation of "tacit promises."

A person may either simply declare his present intention, or accompany his declaration with an engagement to abide by it, which constitutes a complete promise. In the first case, the duty is satisfied, if he was sincere at the time of the declaration, though he may afterwards change his purpose; but in the latter case, a person has parted with the liberty of changing. Another inquiry of importance in relation to this subject, pertains to the variety of cases in which promises are not binding. Promises are not binding, where the performance is impossible. Here, however, the promisor is guilty of a fraud, if he be privately aware of the impossibility at the time of making the promise: and if the promisor himself occasions the impossibility, it is a direct breach of the promise. Promises are not binding, where the performance is unlawful. Of this there are two cases; one, where unlawfulness is known to the parties at the time when the promise is made; and the parties are not obliged to perform what the promise requires, because they
were under a prior obligation to the contrary: the guilt of such promises lies in the making, not in the breaking of them. The other case is, where the lawfulnefs was not known, or did not exif, at the time of making the promise; there the lawfulnefs becomes a condition of the promise, and when the condition fails, the obligation ceases. It appears in this connection to be a matter of importance, that no persons should ever give a promise which may interfere in the event with their duty. The reason is obvious: because, when this interferences occurs, their duty must be discharged, though at the expense of their promise, and, not unfiiily, of their good name. The specific performance of promises is reckoned a perfect obligation; and it has been laid down by many caufuits, in opposition to what is above afferted, that where a perfect and imperfect obligation clash, the former is to be preferred. Paley thinks that there is no reason for this opinion; but that of two contradictory obligations, the one which is prior in point of time ought to prevail. It is the unlawfulnefs of the performance, and not any unlawfulnefs in the subject or motive of the promise, which destroys its validity. Again, a promise does not lose its obligation, merely because it proceeded from an unlawful motive. A promise cannot be deemed unlawful, where it produces, when performed, no effe beyond what would have taken place if the promise had never been made: and this is the single cafe in which the obligation of a promise will justify a conduct, which, unless it had been promised, would be unjust. Moreover, promises are not binding, where they contradict a former promise; because the performance is then unlawful. Promises are not binding before acceptance, that is, before notice given to the promisee; for where the promise is beneficial, if notice be given, acceptance may be presumed. In this case the promisee has not done, that which constitutes the effence of a promise: that is, he has not voluntarily excited expectation. Promises are not binding which are released by the promisee. Erroneous promises are not binding in certain cafes: as, where the error proceeds from the mistake or misrepresentation of the promisee; and when the promise is underfiold by the promisee to proceed upon a certain supposition, or when the promisee apprehended he fo understood it, and that supposition turns out to be false.

It has been long controverted among moralists, whether promises be binding which are extorted by violence or fear? The solution of this question will depend upon this circumstance, whether mankind, upon the whole, are benefited by the confidence reposed in such promises? This, on many occasions, is a doubtful point, and accordingly the obligation of such promises is doubtful. With regard to promises extorted through fear, Cicero observes (De Off. i. iii. c. 29, 30.) “If you do not pay to robbers the sum you promised as a ransom for your life, you are guilty of no dishonesty, not even though you were sworn to do it.” We have the following anecdote in Ramfay’s Life of Viscount Turenne, which evinces his high senfe of honour. As he was coming home one night, he fell into the hands of robbers, who flopped his coach near Paris. On his promising them 100 louis d’ors to let him keep a ring of much lefs value, they returned it; and one of them had the boldness to go to his house the next day, and, in the middle of a large company, to whisper him, and demand the performance of his promise. The viscount ordered the money to be paid him, and before he related the adventure, he allowed the robber time to escape; adding, that a promise ought to be kept inviolable, and that an honest man should never break his word, though given to knaves. For other particulars relating to promises, we refer to Price on Morals, p. 260, &c. Grove’s System of Moral Philosophy, vol. ii. Paley’s Principles, &c. vol. i. Reid’s Essays, eff. v. See Contract, Covenant, Fidei- lity, and Vow.

PROMISSORY NOTE. See Note, and Bill of Exchange.

By 48 Geo. III. c. 149, the tamp duties upon bills, &c. which were imposed by 44 Geo. III. c. 98. (which last act had repealed the former duties) were repealed; and by schedule, part i, the following stamp duties are imposed; viz. upon every

Inland bill of exchange, draft, or order, for the payment to the bearer, or to order, either on demand, or otherwise, of any sum of money amounting to £40, or exceeding £51.

Exceeding £51. and not exceeding £30.

£50, £40, £30, £20, £10, £5, £1.

Not exceeding £3,000.

£1, 0 0

Inland bill, draft, or order, for the payment of any sum of money, though not payable to bearer or to order, if the same shall be delivered to the payee, or some person on his behalf,

The same duty as on a bill of exchange for the like sum, payable to bearer or order.

Inland bill, draft, or order, for the payment of any sum of money, weekly, monthly, or at any other flated periods, if made payable to the bearer, or to order, or if delivered to the payee, or some person on his behalf; where the total amount of the money thereby made payable shall be specified therein, or can be ascertained therefrom,

And where the total amount or the money thereby made payable shall be in infinite,

The same duty as on a bill for the sum expressed only.

And the following instruments shall be deemed and taken to be inland bills, drafts, or orders, for the payment of money within the intent and meaning of this schedule, and the foregoing act, viz.

“All drafts or orders for the payment of any sum of money, by a bill or promissory note, or for the delivery of any such bill or note, in payment or satisfaction of any sum of money; where such drafts or orders shall require the payment or delivery to be made, to the bearer or to order, or shall be delivered to the payee, or to some person for his behalf.

““All receipts given by any banker, or other person, for money received, which shall entitle, or be intended to entitle, the person paying the money, or the bearer of such receipts, to receive the like sum from any third person.

““And all bills, drafts, or orders for the payment of any sum of money out of any particular fund, which may or may not be available; or upon any condition or contingency, which may or may not be performed or happen; if the same shall be made payable to the bearer or to order, or if the same shall be delivered to the payee, or to some person on his behalf.

Foreign bill of exchange, (or bill of exchange drawn in, but payable out on an inland bill of Great Britain,) if drawn singly, the same amount and not in a set,

Foreign
PROMISSORY NOTES.

Foreign bills of exchange drawn in fets, according to the custom of merchants; for every bill of each fet, where the sum made payable thereby shall not exceed 100l. £ s. d.

Exceeding 100l. and not exceeding 200l. 0 1 0
200l. - 500l. 0 3 0
500l. - 1,000l. 0 4 0
1,000l. - 3,000l. 0 5 0
3,000l. - 10,000l. 0 1 0

Exemptions.

"All bills of exchange and bank post bills issued by the governor and company of the bank of England.

"All bills, orders, remittance bills, and remittance certificates, drawn by commissioned officers, masters, and surgeons in the navy, or by any commissioner or commissioners of the navy, under the authority of the 35 Geo. III. c. 94.

"All bills drawn pursuant to any former act of parliament, by the commissioners for victualling the navy, or by the commissioners for managing the transport service, and for taking care of sick and wounded seamen, upon and payable by the treasurer of the navy.

"All drafts or orders for the payment of any sum of money to the bearer on demand, and drawn upon any banker, or person acting as a banker, who shall rif ide or transact the business of a banker, within ten miles of the place where such drafts or orders shall be drawn; provided such place shall be specified in such drafts or orders; and provided the same shall bear date on or before the day on which the same shall be issued; and provided the same do not direct the payment to be made by bills or promissory note.

"All bills, for the pay and allowances of his majesty’s land forces, or for other expenditure liable to be charged in the public regimental or district accounts, which shall be drawn according to the form now prescribed, or hereafter to be prescribed by his majesty’s orders, by the paymasters of regiments or corps, or the chief paymaster or deputy paymaster and accountant of the army depot, or by the paymasters of recruiting districts, or by the paymasters of detachments, or by the officer or officers authorised to perform the duties of the paymastership, during a vacancy, or the absence, suspension, or incapacity of any such paymaster as aforesaid, save and except such bills as shall be drawn in favour of contractors or others who furnish bread or forage to his majesty’s troops, and who by their contracts or agreements shall be liable to pay the stamp duties on the bills given in payment for the articles supplied by them.

"By the same act of 48 Geo. III. c. 149. sched. part 1. a duty is imposed upon every licence to be taken out yearly by any banker or bankers, or other person or persons, who shall issue any promissory note for money payable to the bearer on demand, and allowed to be re-issued, of £ s. d.

And also upon every promissory note for the payment, to the bearer on demand, of any sum of money not exceeding £ s. d.

Exceeding 1l. 1s. and not exceeding 2l. 2s. 0 0 4
2l. 2s. - 5l. 5s. 0 1 0
5l. 5s. - 20l. 0 1 6
20l. - 50l. 0 3 0
50l. - 100l. 0 4 0

Which said note not exceeding 2l. 2s. may be re-issued, after payment thereof, as often as shall be thought fit; and the said notes for any sum exceeding 2l. 2s. and not exceeding 100l., may be re-issued from time to time after payment thereof, until the expiration of three years from the date thereof, but not afterwards.

Promissory note, for the payment, in any other manner than to the bearer on demand, of any sum of money.

Amounting to 40l. and not exceeding 5l. 5s. 0 1 0
Exceeding 5l. 5s. - 30l. 0 1 6
30l. - 50l. 0 2 0
50l. - 100l. 0 2 0

These notes are not to be re-issued after being once paid.

Promissory note, for the payment, either to the bearer on demand, or in any other manner than to the bearer on demand, of any sum of money.

Exceeding 100l. and not exceeding 200l. 0 4 0
200l. - 500l. 0 5 0
500l. - 1,000l. 0 7 6
1,000l. - 3,000l. 0 10 0
3,000l. - - 1 0 0

These notes are not to be re-issued after being once paid.

Promissory note, for the payment of any sum of money by instalments, or for the payment of several sums of money at different days and times, so that the whole of the money to be paid shall be definite and certain, as on any promissory note payable after date, for a sum equal to the whole amount of the money to be paid.

And the following instruments shall be deemed to be promissory notes within the meaning of this schedule, viz.

"All notes promissory of the payment of any sum or sums of money out of any particular fund, which may or may not be available; or upon any condition or contingency, which may not be performed or happen; if the same shall be made payable to the bearer or order, and if the same shall be definite and certain, and not amount in the whole to 20l.

And all receipts for money deposited in any bank, or in the hands of any banker or bankers, which shall contain any memorandum or agreement importing that interest shall be paid for the money so deposited.

Exemptions from the Duties on Promissory Notes.

"All notes promissory of the payment of any sum or sums of money out of any particular fund which may or may not be available; or upon any condition or contingency which may not be performed or happen, where the same shall not be made payable to the bearer or order, and also where the same shall be made payable to the bearer or order, if the same shall amount to 20l., or be indefinite.

"And all other instruments, bearing in any degree the form or style of promissory notes, but which in law shall be deemed special agreements, except those hereby expressly directed to be deemed promissory notes.

But fuch of the notes and instruments here exempted from the duty on promissory notes, shall nevertheless be liable to the duty which may attach thereon, as agreements or otherwise.

"Exemption as before for the governor and company of the bank of England.

And if any such bills or drafts for 40l. or upwards, by this act intended to be flamped, shall be written or printed on vellum, parchment, or paper, not duly flamped as aforesaid, or with a lower flamp than by this act directed, the full duty shall be charged upon the person who shall draw or make,
make, and utter and negotiate the same. 31 Geo. III. c. 25. f. 6.

By 48 Geo. III. c. 149. the former duties upon promissory notes and bills of exchange are repealed, excepting arrêrs: And new duties are by that act imposed, and divers new regulations relating to those intruments enacted. And thefe new duties are by f. 3. of this act, placed under the care of the commissirioners for the flamp duties.

By f. 12. if any perfon shall, after the expiration of one calendar month from this act, make and issue, or cause to be made and issued, any bill, draft, or order for the payment of money, to the bearer on demand, upon any banker or bankers, or any acting as such, which shall be dated on any day subsequent to the day on which it shall be issued, or which shall not truly specify the place where it shall be issued, or which shall not fall within the exception contained in the schedule (A) annexed to 44 Geo. III. c. 98. or that annexed to this act, unless the fame shall be duly flamped as a bill of exchange, according to the law in force when the fame shall be issued, such perfon shall forfeit 100l.; and if any perfon shall knowingly take any such bill, draft, or order, in payment of, or as a security for the sum therein mentioned, he shall forfeit 20l.; and if any banker or bankers, or any acting as such, take any such bill, &c. in payment of, or as a security for the sum therein mentioned, he shall for such a sum forfeit 20l.; and if any banker or bankers, or any acting as such, upon whom any such bill, &c. shall be drawn, shall pay or cause to be paid the sum of money therein expressed, or any part thereof, knowing the fame to be post-dated, or knowing that the place where it was issued is not duly specified or set forth therein, or knowing that the fame does not in any other respect fall within the said exception, then such banker, &c. shall forfeit 100l. for every offence, and moreover shall not be allowed the money so paid, or any part thereof, in account.

And by f. 11. the making, signing, issuing, or causing to be made, signed, or issued, or accepting or paying, or causing or permitting to be accepted or paid, any bill of exchange, draft, or order, or promissory notes for the payment of money liable to any of the duties of this act, without the outline being duly flamped, render those so making, &c. liable to a penalty of 50l.

And where any promissory or other note payable to the bearer on demand shall not exceed 5l. 5s. and be marked with a flamp duty of 3d. and also where such note shall exceed 5l. 5s. and not exceed 30l. and be marked with a flamp duty of 6d. or shall exceed 30l. and not exceed 200l. and be marked with a flamp to denote the respective duties hereby imposed, shall be paid by the perfon who made and signed, and first issued and negotiated the fame, and at the place where the same was first issued; such perfon may, notwithstanding flumping payment, from time to time, as often as there shall be occasion after every such payment thereof, but not otherwise, again issue such note in like manner as the same was first issued; and every such note which at any time shall be paid by any perfon other than the perfon making or issuing the same, or at any place other than the place of issuing the same, in pursuance of any direction, nomination, or appointment, for the payment thereof, contained or expressed in or upon such note, shall be taken to be thereupon wholly discharged, vacated, and satisfied, and shall be no longer negotiable, but shall be cancelled. And if any perfon shall again issue any such note, or if the perfon named or described therein for the payment thereof shall neglect or refuse to cancel the same after payment as aforesaid, he shall forfeit 20l. And if any such note shall not be cancelled, but shall be again issued or negotiated, there shall be paid the like duty which shall appear to have been charged theretofore before the first issuing, or by this act charged thereon as aforesaid; which duty shall be charged on the perfon who shall again issue or negotiate the same. 31 Geo. III. c. 25. f. 7.

But notes payable to the bearer on demand, not exceeding 5l. 5s. and 30l. stampt with the respective duties of 6d. and 12. as before directed, may be again issued and negociated by the perfon making or issuing the same, notwithstanding such notes have been presented to and paid by him, or by any other perfon in pursuance of any such direction, nomination, or appointment as aforesaid, or otherwise howsoever; and so from time to time as often as occasion may require.

f. 8.

And all such notes reissued as aforesaid, shall be the property of the perfon holding the same, in like manner as upon the first issuing thereof. 31 Geo. III. c. 25. f. 9.

By f. 15. it is provided that the bank of England shall be exempt from these duties, upon paying as a compensation the yearly sum of 42,000l., provided that the said compensation shall be reduced to 4000l. when they cease to issue promissory notes for less than 2l.

By f. 15. after the 10th of October, 1808, it shall not be lawful to issue any promissory notes payable to the bearer on demand, hereby charged with a duty, and liable to be reissued as aforesaid, without taking out a licence yearly for that purpose, to be granted by two or more commissioners of stamps for the time being, or by some perfon deputed in that behalf by them or the major part of them, on payment of the duty charged thereon in the schedule hereof annexed: and a separe licence shall be taken out for every town or place where any such promissory notes shall be issued, by, or by any agent or agents for any bank or other perfon; except that one licence yearly shall be sufficient for all the towns or places where any such banker or other perfon shall have established a branch of his bank, or have employed an agent for the issuing of such promissory note, previously to this act, so that every such town or place shall be notified to the stamp-office, and be specified in the first licence to be granted in pursuance of this act, and that an affidavit of the fact shall be transmitted to the stamp-office at the time of applying for such licence; and every such licence shall specify the proper name or names, and place or places of abode of the perfon or persons to whom the same shall be granted, and also the name of the town or place, towns or places where, and the name of the bank, firm, or title, under which such notes are to be issued; and where any such licence shall be granted to persons in partnership, the same shall specify and set forth the names and places of abode of all the persons concerned in the partnership, whether all their names shall appear on the promissory notes to be issued by them or not; and in default thereof, such licence to be absolutely void: and every such licence which shall be granted between the 10th of October, and the 11th of November, shall be dated on the 1st of October; and if granted at any other time, on the day on which granted; and every licence to continue in force from the day of the date till the 10th of October following, both inclusive.

By f. 18. those applying for such licences shall produce and leave with the proper officer, a specimen of the promissory notes proposed to be issued, and if any one by himself or his agent shall issue any such promissory note, allowed to be reissued as aforesaid, without a licence, or at any other town or place, or under any other firm or title, than shall be specified in his licence, he shall forfeit for each offence 100l.

By f. 20. where any such licence shall be granted to any persons
persons in partnership, the same shall continue in force for
the issuing of promissory notes under the firm or title therein
specified, till the 10th of October inclusive, notwithstanding
any alteration in the partnership.

If any person shall write or sign, or accept or pay, or
cause the same to be done, any such bill, note, draft, or
order, liable to any of the duties aforesaid, without being
first duly stamped as aforesaid, he shall forfeit 20l. f. 10.
39 Geo. 3. c. 107.

But by 37 Geo. III. c. 136. the holder of any bill of ex-
change, promissory or other note, draft or order, made after
the 12th of July, 1797, and liable to any stamp duty, which
shall be stamped with a stamp of a different denomination
than is required by the aforesaid acts, if the same be
of equal or superior value, may produce the same to the com-
missioners or officers of stamps within the times hereafter
mentioned, who shall, upon payment of the duty imposed
by the above acts, and the penalty hereafter mentioned over
and above the said duty, stamp the same, and give a receipt
for such penalty and duty on the back thereof, which shall
be valid. f. 5.

And if the same be produced to the said commissioners
before payable, according to the tenure and effect thereof,
it shall be stamped on payment of the duty, and the penalty
of 40l.; but if payable before the production thereof, then
the same shall not be stamped, but on payment of the duty
and the penalty of 10l. Id. f. 6.

Provided always, that no person shall have power by
virtue of this act to make any bills of exchange, promissory
or other notes, drafts, or orders for the payment of money,
in any other manner than they might lawfully have done be-
fore the passing thereof. 31 Geo. III. c. 25. f. 11.

The aforesaid duties to be under the management of the
commissioners of the stamp duties. f. 18. 39 Geo. III.
cy. 107. f. 23. 41 Geo. III. U.K. c. 10. f. 4.

And all vellum, parchment, or paper, by this act liable
to any stamp duty, shall be stamped before the same be
written or printed upon, and shall not be stamped afterwards
under any pretence whatsoever. 31 Geo. III. c. 25. f. 19.

Persons counterfeiting or forging any stamp hereby di-
rected to be made use of, shall be guilty of felony without
benefit of clergy. f. 29.

And all powers given by any former act relating to the
stamp duties, shall extend to these acts. 31 Geo. III. c. 25.
cy. 10. f. 9.

By 48 Geo. III. c. 149. f. 21. after the passing of this
act, no promissory notes for the payment of money, made
out of Great Britain, or purporting to be made out of
Great Britain; or purporting to be made by or on the
behalf of any person or persons resident out of Great Britain,
whether the same shall be made payable in Great Britain or
not, shall be negotiable, or be negociated, or circulated, or
paid in Great Britain, unless the same shall have paid such
duty, and be stamped as the law requires for promissory notes
of the like tenor and value made in Great Britain; and if
any person shall circulate or negociate, or offer in payment,
or shall receive or take in payment any such promissory note,
or shall demand or receive payment of the whole, or any
part of the money mentioned in such promissory note, from
or on account of the drawer thereof in Great Britain, the
same not being so duly stamped; or if any person or per-
sons in Great Britain shall pay or cause to be paid the sum
of money expressed in such note, not being so duly
stamped, or any part thereof, either as drawer, or in pur-
fuance of any nomination or appointment for that purpose
therein contained, the person or persons so offending shall
forfeit for each offence 20l. This not to extend to promissory
notes made and payable only in Ireland.

And by 43 Geo. III. c. 139. if any person within any
part of the united kingdom of Great Britain and Ireland
fel[d]ly make, forge, or counterfeit, or cause or procure to
be falsely made, forged, or counterfeited, knowingly aid
or abet in the false making, forging, or counterfeiting, any
bill of exchange, or any promissory note, undertaking, or
order for the payment of money, purporting to be the bill
of exchange, promissory note, undertaking or order for the
payment of money, of any foreign prince, state, or coun-
try whatsoever, or of any minister or officer employed in
the service of any foreign prince, &c. or of any person or
company of persons resident in any foreign state or country,
or of any body corporate or politic, and body in the na-
ture of a body corporate and politic, constituted by any
foreign prince or state, with intent to deceive or defraud his
majesty, his heirs and successors, or any such foreign prince,
state or country, or any person or company of persons
whomsoever, or any body corporate and politic, or body in
the nature of a body corporate and politic whatsoever, whe-
ther the same be respectively resident, carrying on business,
constituted or being in any part of the united kingdom, or
in any foreign state or country; and whether such bill, note,
or order be in English or in any foreign language, or partly
in one and partly in the other; or if any person shall,
within any part of the said united kingdom, tender in payment
or exchange, or otherwise utter or publish as true, any such
bill, forged, or counterfeited bill, note, undertaking, or
order, knowing the same to be false, forged, or counter-
feited, with intent to deceive or defraud his majesty, &c. or
any foreign prince, state, or country, or any person,
or company of persons, or any body corporate and politic,
or body in the nature of a body politic and corporate as afo-
resaid, then every such offender shall be deemed guilty of felony,
and on conviction shall be transported not exceeding fourteen
years. f. 1.

No person shall, within the united kingdom, engrave, cut,
etch, derape, or by any other means make or knowingly
aid in the engraving, &c. or by any other means making in or
upon any plate, any bill of exchange, or any promissory note
or undertaking, or order for the payment of money, pur-
porting to be the bill, note, undertaking, or order of any
foreign prince, state, or country, or of any minister or
officer employed in the service of any such prince, &c. or of
any person or company of persons, resident in any foreign
state or country, or of any body corporate and politic,
or body in the nature of a body corporate and politic, con-
stituted by any foreign prince or state, or any part of any such
bill, note, undertaking, or order, without an authority in
writing for that purpose from such foreign prince, &c. or
from some person duly authorized to give such authority,
shall within any part of the said united kingdom, without
such authority as aforesaid, by means of any such plate,
or by any other device or means, make or print any such
foreign bill, note, undertaking, or order for the payment
of money, or any part thereof, or knowingly, willfully,
and without lawful excuse, (the proof thereof shall be upon the
party accused), have in their custody any such plate or de-
vise, or any impregnation taken from the same; and if any
person shall offend in any of the aforesaid, he shall be
deemed guilty of a misdemeanor and breach of the peace,
and being thereof convicted, shall be liable for the first
offence to be imprisoned for not exceeding six months, or to
be fined, or to be publicly or privately whipped, or to suffer
one or more of the said punishments, and for the second
offence to be transported to any of his majesty's colonies for
the term of fourteen years: provided that nothing herein shall extend in any manner whatsoever to repeal or alter any law now in force for the prevention or punishment of the crime of forgery in any respect whatsoever, within any part of the said united kingdom. f. 2.

Any action or suit brought against any person for any thing done in pursuance hereof shall be commenced within three calendar months after the fact committed, and not afterwards, and shall be brought in the country or place where the cause of action shall arise, and not elsewhere; and the defendant in such action or suit may plead the general issue, and give this act and the special matter in evidence; and if it shall appear to be done in pursuance hereof, or if any such action or suit shall be brought after the time limited, or in any other country or place, then the jury shall find for the defendant; and if upon the trial, a verdict shall pass for the defendant, or the plaintiff become non sui, or discontinue, or upon demurrer judgment be given against the plaintiff, the defendant shall recover treble costs, and have the like remedy for the same as any defendant hath for costs of suit in other cases by law. f. 9.

PROMONTORY, in Geography, a high point of land, or rock, projecting into the sea; the extremity of which to the sea-ward is usually called a cape, or head-land.

PROMOTERS, Promoters, in Law, those persons who, in popular and penal actions, do prosecute offenders in their name and the king's; and are entitled to part of the fines and penalties for their pains.

Thee, among the Romans, were called quadruplatores, or delatores; in English also, informers.

Sir Thomas Smith observes, that promoters belong chiefly to the exchequer and king's bench. My lord Coke calls them turpitudin hominum genus. 3 Inst.

PROMOTER. See Inquisition.

PROMPT PAYMENT, ready money. See Payment.

In many cases there is a discount for prompt payment.

PROMPTER, in the Drama, an officer posted behind the scenes, whose business it is to watch attentively the actors speaking on the stage, in order to urge and put them forward when at a stand, to correct them when amiss, &c. in their parts.

PROMULGATED, Promulgated, Promulgatus, something published, or proclaimed.

In this sense we say the Jewish law was promulgated by Moses: the promulgation of the new law was chiefly effected by the apostles and disciples.

PROMULGATION of Laws. See Law.

PROMOTION, in Rhetoric, as Fable.

PRONAOΣ, προαος, in the Ancient Architecture, a porch to a church, palace, or other spacious building.

PRONATION, in Anatomy, that motion of the upper extremity, in which the radius is carried across the ulna, and the palm of the hand turned to the ground. See Pronator and Extremities.

PRONATOR, a name given to two muscles of the forearm.

The pronator radii teres (epitrochlea-radicen) is situated obliquely on the anterior and upper part of the fore-arm, and extends from the internal condyle of the humerus to the middle of the outer surface of the radius. It is elongated and flattened, and larger at the humeral than at the radial end. Its anterior surface is covered, in the two-thirds next to the humerus, by the fascia of the fore-arm; in the rest of its extent by the supinator longus, the radial extensors, and the radial artery and nerve. The posterior surface covers the brachialis internus and the flexor sublimis, the median nerve, and the ulnar artery. The outer edge of the pronator teres lies, in that half which is next to the humerus, in the brachialis internus, and is separated from the supinator longus by an interval, in which the tendon of the biceps, the humeral artery, and the median nerve are placed.

The other half of this edge is concealed by the supinator longus, and the radial extensors: it is parallel to the front edge of the supinator brevis, which it covers a little. The inner edge is connected, in the upper two-thirds, to the outer margin of the flexor radialis; in the other third it is unattached. The humeral extremity is fixed to the front of the internal condyle, and strongly connected to the flexor radialis.

It has also a small attachment to the coronoide processes of the ulna, by a few fibres separated from the rest of the muscle by the median nerve. It passes obliquely across the forearm, from the ulnar to the radial side, growing smaller in its course, and is fixed to the middle of the radius by a broad and thin tendon, which turns round the front of the bone, to reach the outer edge. This tendon runs for a short time on the front of the muscle, then enters into its substance, and is continued as far as the middle. The flabby fibres come from the condyle of the humerus, from the septa which separate the muscle from the flexor radialis and the sublimis, and from the fascia of the forearm. From all these points they pass to the tendon just mentioned, and inclose it.

By drawing the radius across the front of the ulna, this muscle turns the palm of the hand to the ground. If the radius is held firm by the supinators, the pronator teres will bend the elbow-joint.

The pronator quadratus (cubito-radicen) is a square muscle, situated deeply in the anterior part of the carpal end of the forearm, and extending straight from the ulna to the radius. Its anterior surface is covered by the flexor profundus, the flexor longus pollicis, the flexor radialis, the ulna and radial arteries. The posterior surface is fixed to the lower fourth part of the anterior surface of the radius, and to the same length of the ulna; in the interval of the bones, it lies on the interosseous ligament. Of the four edges of this muscle, the superior and inferior present nothing remarkable. The external is fixed to the lower fourth part of the edge of the radius, and the internal to the same length of the corresponding edge of the ulna.

A broad aponurosis, arising from the edge of the ulna, covers the inner portion of the anterior surface. Flabby fibres arise from this aponurosis, and from the surface of the ulna, and terminate on the anterior surface of the radius: they are slightly oblique from within outwards, and from above downwards.

Its effect must be simply that of drawing the end of the radius across that of the ulna, and consequently turning the palm of the hand towards the ground.

PRONG, the blade or fork part of an implement of the fork kind, that lays hold of the foil or subfusce to which it is applied. The term is sometimes likewise applied to the tool itself.

PRONG-HEX, a term used to express an implement to boe or break the ground, near, and among the roots of plants, with. It consists of two hooked points, of fix or seven inches long, which, when struck into the ground, lift and remove it the same depth as the plough; and thus answer both the ends of cutting up the weeds, and opening the land close to the rows of grain.

The ancient Romans had an instrument of this kind, which they called the bidens; but they were afraid of its use in their fields and gardens, and only used it in their vineyards.
PRONKCHNA, in Geography, a town of Russia, in the government of Upha; 36 miles E. of Buzuluk.

PRONOMÆA, a word used by some naturalists to express what is usually called the trunk, or proboscis in insects; an inwardly somewhat resembling the trunk of an elephant, which most of those small animals are provided with, for the extracting the juices of plants, &c. destined for their food.

PRONOMUS of Thebes, in Biography, the inventor, according to Pausanias, of a flute, upon which three different modes could be played.

PRONOUN, PRONOMEN, in Grammar, a part of speech used instead of a noun, or name, as its substitute or representative. Whence the denomination; from pro, and nominem; q. d. for noun, or name. Accordingly, pronouns are subject to the same modifications with substantive nouns, of number, gender, and case. As it would have been disagreeable to have been always repeating the same name, there are words invented in all languages, called pronouns, to save the necessity thereof, and to stand in the place of names: as I, thou, he, &c.

As nouns are the marks or signs of things, pronouns are the signs of nouns. Father Buffier, however, says, that pronouns are real nouns or names; and that all the difference between what the grammarians call nouns and pronouns, is, that the former are more particular, and the latter more general. They are called pronouns, because used in the place of particular nouns; indeed, sometimes they do not fill the place of nouns entirely, but need other words to affil them, to express the object spoken of; such, e. g. arc,whoever, whatsoever, &c. which do not express any determinate object of which a thing may be affirmed, unless accompanied with another word, especially a verb: as, whoever labour, deserves a reward.

These, father Buffier calls incomplete pronouns, to distinguish them from those which express an object completely: as I, thou, he, &c.

Pronouns have three cases: the nominative, the genitive, or possessive, like nouns; and moreover a case, which follows the verb active, or the preposition, expressing the object of an action, or of a relation, which, says bishop Lowth, may be properly enough called the objective case.

Pronouns are distinguished into three several forms, viz. pronouns of the first, the second, and the third person, according as the subject of the construction is the speaker himself, the party addressed, or some third object different from both. As this third person may be absent, or unknown, the distinction of gender here becomes unnecessary; and accordingly, in English, it has belonging to it the three genders, he, she, it.

The grammarians ordinarily distinguish pronouns into four classes, with regard to their different signification, formation, &c. viz. pronouns personal, relative, possessive, and demonstrative; to which may be added indeterminate pronouns.

PRONOUNS, Personal, are those used in lieu of names of particular persons; such are, I, thou, he, she, ye, they.

Our personal pronouns have a case, which answers to the accusative of the Latin; I, me, he, him, we, you, they.

PRONOUNS, Relative, which Father Buffier calls modificatory, or determinative, are those placed after nouns, or other pronouns, with which they have such affinity, that without them they signify nothing; such are qui, who, that, &c. Frequently the noun or pronoun with which the relative is joined, is understood.

For the proper disposition of the relative pronouns, in the structure of sentences, see Sentence.

PRONOUNS, Possessive, are those which denote the enjoyment or possession of any thing, either in particular or in common: as, mine, thine, his, &c.

These are pure adjectives, and only differ from the rest by the relation they bear to pronouns, whence they are derived, and by some particular inflections which they have in some languages.

PRONOUNS, Demonstrative, which serve to indicate or point out the subject spoken of: as, this, that, &c.

PRONOUNS, Indefinite, are those which express their subject indeterminately: as, whoever, any, &c. These coincide with what father Buffier calls incomplete pronouns.

Pronouns are likewise divided into substantives and adjectives.

To the first belong, I, thou, he; to the second, my, mine, who, what, &c.

Pronouns may also be considered in two flats: the first, or foregoing flat, as I, we; the second, or following one, as me, us.

Mr. Harris distinguishes pronouns, which, he says, are words invented to supply pointing or indication by the finger or hand, called δείκτια, into demonstratives and adjectives.

Prepositive pronouns are those which are capable of introducing or leading a sentence, without having reference to any thing previous, and are divided into three orders, called the first, the second, and the third person.

Subjunctive pronouns are those which serve to subjoin one sentence to some other which is previous, as who, which, that, &c. and may be distinguished from other pronouns, as they are not only substantives, but also connectives. They include the powers of the three orders into which the prepositive are distinguished, having superadded the peculiar force of connective.

Hermes, chap. 5.

PRONOUNCING, Pronunciation, in Painting, the marking and expressing the parts of all kinds of bodies with that degree of force necessary to make them more or less distinct and conspicuous.

Thus the painters, in speaking of a piece, say, these or these parts of well pronounced; which is a metaphorical way of speaking; as when we say, that a man who talks well has a fine pronunciation.

PRONSDORP, in Geography, a town of the duchy of Holland; 8 miles E. of Segeborg.

PRONSK, a town of Russia, in the government of Riazan; 28 miles S. of Riazan. N. lat. 54° 14'. E. long. 30° 30'.

PRONTIA LAPIS, a name given by the writers of the middle ages to a foill, of which they relate several extraordinary things; but their relating it to the head of a tortoise, and giving it the virtue of preserving people from injuries by lightning, seem to make it plain that the word is only a corrupt spelling of the brontia of the ancients, of which Phyl has related the same things.

This was a species of chalcedon, supposed to fall from the clouds in thunder-forms. See Brontë.

PRONUNCIATION, Pronunciation, in Grammar, the manner of articulating, or sounding, the words of a language, represented to the eye by writing, and orthography.

From the definition it would seem, that the pronunciation were only the image of the orthography: but as we pronounce before we write, and only write to express what we pronounce, it is more just to lay down the pronunciation as the rule and model of orthography.

Pronunciation makes much the most difficult article of a written grammar; in effect, a book only expressing itself to the eyes in a matter that wholly concerns the ears,
cafe seems next akin to that of teaching the blind to disting-

guish colours.

Hence it is, that there is no part so defective in the gram-
mars as that of the pronunciation; for the writer has fre-
quently no term by which to give the reader an idea of the
found he would express; for want of a proper term, there-
fore, he frequently substitutes a vicious or precarious one.
Thus the French grammarians frequently tell us that the
vowels a, e, i, &c. are pronounced, in French, the same
as in Latin; never considering, that there is not any known
and determinate pronunciation of the Latin; but each na-
tion, now, pronounces the Roman characters in the Latin,
the same as it pronounces those fame characters in its own
language. Thus the Latin cessus is pronounced by the
English, sakis, and by the Italians, tekbeous, &c.
Hence it appears, that the relation between sounds and
characters, as well as between things and words, is purely
arbitrary and national.

Indeed, Plato seems of a contrary opinion, and will have
a natural relation between words and the things they ex-
press, as there is a natural relation between the signs made
by mutes, and the things they would imitate: so that, ac-
cording to Plato, to every separate word there must be a
separate motion of the mouth relative to the action expres-
sed by the word.

Whether or no there might be such a thing in the primi-
tive language, we dare not undertake to say; but it is cer-
tain, such a relation would require a facility of contortions
in the mouth, to which we are strangers.

To give a just and precise idea of the pronunciation of a
language, it seems necessary to fix, as nearly as possible,
all the several sounds employed in the pronunciation of that
language: this Mr. Lodwick has done, in his attempt to-
wards an universal alphabet, where he enumerates forty-
three several simple sounds (some of them, indeed, strangers
to the English language); and F. Baffier, who gives thirty-
three several sounds in the French tongue, twenty-nine in
the Italian, thirty in the German, twenty-two in the Spanish,
and twenty-four in the English.

The French language is clogged with a difficulty in pro-
nunciation, from which most others are free; and it con-
stitutes in this, that most of their words have two different pronun-
ciations; the one in common prose, the other in verse. In
prose, et gr. they omit the pronunciation of the final s in
the plural of nouns, and of the t in the third person of the
plural of verbs, and of several other final consonants; but
in verse they pronounce all.

Thus, in a qui bon reverir ves mysu endormir? the final
s of muser is pronounced; and in mille et mille doceurs se fes-
bient attaches, the t of fembient is to be pronounced.

Add to this, that in verse they often found the sound of a great
many words; pronouncing creire for croire: but in poetry
the genuine pronunciation is retained.

PROUNCIATION is also used for the fourth and last part of
rhetoric, called delivery, which consists in regulating and
varying the voice and gesture agreeable to the matter and
words; so as more effectually to persuade and touch the
hearsers.

The pronunciation is of such importance, that Demof-
thenes called it the first, the second, and the third part of
elocution. By which he seemed to intimate, that he
thought the whole art of oratory did in a manner confess it.
And indeed, if he had not judged this highly necessary
for an orator, he would scarcely have taken so much pains
himself in correcting those natural defects under which he
laboured at first, in order to acquire it. For he had both
a weak voice, and likewise an impediment in his speech, to
that he could not pronounce distinctly some particular let-
ters. The former of which defects he conquered, partly
by speaking as loud as he could upon the shore, when the
sea roared and was boisterous; and partly by pronouncing
long periods, as he walked up hill; both which methods
contributed to strengthen his voice. And he found means
to render his pronunciation more clear and articulate, by
the help of some little flourishes put under his tongue. Nor
was he less careful in endeavoring to gain the habit of a
becoming and decent gesture, for which purpose he used to
pronounce his discourses alone before a large glafs. And
because he had got an ill custom of drawing up his shoulders
when he spoke; to amend that, he used to place them under a
sword, which hung over him with the point downward.

Quintilian defines the pronunciation, vocis, et vultus, et
corporis moderate cum vennfate; a decent agreeable manner
of managing the voice, gesture, and action of the whole
body.

Cicero somewhere calls it quaedam corporis eloquendi a
certain eloquence of the body; and in another place, serno
corporis, the language or speech of the body.

When we addres others by words, it is certainly an in-
tention to make some impression on those to whom we speak;
and it is certain, that the tone of our voice, our looks, and
gestures, interpret our ideas and emotions no less than words
do; nay, the impression they make on others is frequently
much stronger than any which words can make. The fig-
nification of our sentiments, made by tones and gestures, has
this advantage above that made by words, that it is the lan-
guage of nature. The connection is so close between cer-
tain sentiments, and the proper manner of pronouncing them,
that he who does not pronounce them after that manner,
can never persuade us that he believes, or feels, the senti-
ments themselves. His delivery may be such as to give the
lie to all he affirms. When Marcus Callidius accused one
of an attempt to poison him, but enforced his accusation in
a languid manner, and without any warmth, or earnestnesse
of delivery, Cicero, who pleaded for the accused person,
improved this into an argument of the falsity of the charge,
"An tu, M. Calidii, nit fingere, sic agere?" In Shakes-
ppear's Richard II. the duchess of York thus impeaches the
sincerity of her husband:

"Plead he in earnest?—Look upon his face,
His eye do drop no tears; his prayers are jest;
His words come from his mouth; ours, from our breast;
He prays but faintly, and would be denied;
We pray with heart and soul."

Pronunciation is the same with what we otherwise call
action; which see. Though if we attend to the proper
figuration of each of these words, the former respects
the voice, and the latter the gestures and motions of the
body. Some writers, particularly Mr. Henly, confound it
with elocution, which is a very different thing. That author,
when he styles himself reformer of the ancient elocution, means
of the ancient pronunciation.

There are three things which come under the pronunciation;
the memory, voice, and gesture. See each under its
proper article.

Augustus, to avoid being baulked by his memory, and at
the same time save the trouble of getting off by heart, used
to harangue from a writing; as we are told by Dio and Sue-
tonius.

In public speaking a proper attention to pronunciation or
delivery is, as we have already stated, of the greatest im-
portance; and the importance of it will further appear, if
we consider the principal objects which every public speaker
has
has in view. These are, first of all, to speak so as to be fully and easily understood by all who hear him; and, secondly, to speak with grace and force, so as to please and move his audience. For the attainment of the first object, the four chief requisites are, a due degree of loudness of voice, distinctness, slowness, and propriety of pronunciation. A public speaker, who wishes to be heard by all whom he addresses, should endeavour to fill with his voice the space occupied by the assembly. For this purpose, independently of the power of voice derived from nature, much depends on the proper pitch and management of the voice. Every man, says Dr. Blair, has three pitches in his voice; the high, the middle, and the low one. The first is that which he uses in calling aloud to some person at a distance; the low is when he approaches to a whisper; and the middle is that which he employs in common conversation, and which he should generally use in public discourse. It is a great mistake to imagine, that one must take the highest pitch of his voice, in order to be well heard by a large assembly. This is confounding two things which are different; loudness, or strength of sound, with the key, or note on which we speak. A speaker may render his voice louder without altering the key; and we shall always be able to give most body, most persevering force of sound, to that pitch of voice, to which we are accustomed in conversation; whereas by setting out on our highest pitch or key, we certainly allow ourselves to be compassed, and are likely to strain ourselves before we have done. We shall fatigue ourselves, and speak with pain; and whenever a man speaks with pain to himself, he is always heard with pain by his audience. Give the voice, therefore, full strength and swell of sound; but always pitch it on your ordinary speaking-key. Make it a constant rule never to emit a greater quantity of voice than you can afford without pain to yourselves, and without any extraordinary effort. As long as you keep within these bounds, the other organs of speech will be at liberty to discharge their several offices with ease; and you will always have your voice under command. But whenever you transgress these bounds, you give up the reins, and have no longer any management of it. It is an useful rule too, in order to be well heard, to fix the eye on some of the most distant persons in the assembly, and to consider ourselves as speaking to them. But it should be remembered, that in public, as well as in conversation, we may give delight and offence by speaking too loud; because the speaker has thus the appearance of one who endeavours to compel attention, by mere vehemence and force of sound.

Moreover, in order to be well heard and clearly understood, distinctness of articulation contributes more, perhaps, than mere loudness of sound. With this view, every public speaker should give every sound which he utters its due proportion, and make every syllable, and even every letter in the word which he pronounces, be heard distinctly, without straining, whispering, or suppressing any of the proper sounds. Further, in order to articulate distinctly, moderation is requisite with regard to the speed of pronouncing. Precipitancy of speech confounds all articulation, and all meaning; and yet the contrary extreme should be avoided; as a lifeless, dawdling pronunciation, which allows the minds of the hearers to be always outrunning the speaker, must render every discourse inipid and fatiguing. Rapidity of utterance in early life, however, is pardonable, as it is likely to find its own remedy in advanced age, and to prevent that tedious, tiresome drawl, which is often the attendant of prolonged life. After all, to pronounce with a proper degree of slowness, and with full and clear articulation, is the first thing to be studied by all who begin to speak in public, and cannot be too earnestly recommended. Such a pronunciation gives weight and dignity to a discourse. It greatly aids the voice by affording pauses and rests, and it enables the speaker to swell all his sounds both with more force, and with more music. It also affords in maintaining a due self-command; whereas a rapid and hurried manner is apt to excite that flutter of spirits, which is very injurious to right execution in the province of oratory. "Promptum sit os," says Quintilian, "non praecipue, modatum, non lentum."

After the attention now recommended to the pitch and management of the voice, to distinct articulation, and to a proper degree of slowness of speech, the public speaker should diligently study propriety of pronunciation, or the giving to every word which he utters, that sound, which the most polite usage of the language appropriates to it, in opposition to broad, vulgar, or provincial pronunciation. This is requisite, both for speaking intelligibly, and for speaking with grace or beauty. In this connection it is not improper to recommend a particular attention to the accent. To what has been already offered under the term Accent, we shall here add the following remarks of Dr. Blair. In the English language, he says, every word which consists of more syllables than one has one accented syllable. The accent rests sometimes on the vowel, sometimes on the consonant. Seldom, or never, is there more than one accented syllable in any English word, however long; and the genius of the language requires the voice to mark that syllable by a stronger percussion, and to pave more clearly over the rest. Having first learned the proper seats of these accents, it is an important rule to give every word just the same accent in public speaking, as in common discourse. In this respect many persons err; for, when they speak in public, and with solemnity, they pronounce the syllables in a different manner from what they do at other times. They dwell upon them, and protract them: they multiply accents upon the same word; from a mistaken notion, that it gives gravity and force to their discourse, and that it adds to the pomp of public declamation. Whereas, this is one of the great faults that can be committed in pronunciation, it makes what is called a theatrical, or mouthing manner, and gives an artificial affected air to speech, which detracts greatly both from its agreeableness and impressiveness. See Blair's Lect. vol. ii. Sheridan's Lectures on Elocution. See also the articles already referred to, viz. Accent, Articulation, Gesture, Voice, and also Elocution, Eloquence, Oratory, and Public Speaking.

The public speaker, as we have above said, has another object besides that of rendering himself intelligible, and that is giving grace and force to what he utters. For this purpose it behoves him to pay particular attention to emphasis, pauses, tones, and gestures. See each of these articles.

Pronunciation, in Painting. See Pronouncing.
PROOF, in Law, Logic, &c. denotes the mediums or arguments, used to evince the truth of any thing. See EVIDENCE.

Proofs, in the ecclesiastical courts, are obtained by witnesses examined, whose depositions are taken down in writing by an officer of the court. These are adduced after the defendant’s answer upon oath, if he denies or extenuates the charge. If afterwards the defendant has any circumstances to offer in his defence, he must also propound them in what is called his “defensive allegation,” to which he is intitled in his turn to the “plaintiff’s answer” upon oath, and may at thence proceed to proofs as well as his antagonist.

By the French law, a literal proof, or proof in writing, called also dead proof, probatio mortua, is preferable to a testimonial, or proof viva voce, by witnesses. The ordinance de Moulins excludes all proof by witnesses for loans of above 1000 livres.

The proof of crimes was anciently effected among our ancestors divers ways; viz. by duel or combat, fire, water, &c.

The proof by red-hot iron was very frequent; the accused, to purge himself, was here obliged to make an oath, as he touched the iron. The formula, ceremonies, prayers, &c. made on this occasion, are still extant in the notes at the end of the Capitularies of Charlemagne. See ORDEAL.

This custom was abrogated by the emperor Frederick; but it still obtains in Mingrelia, as we are told by Lamberti, in his relation infected in Thenevot’s voyages.

If they cannot have proof of a crime, a crocs is laid at the bottom of a cauldron full of boiling water, out of which the accused is obliged to fetch it with his naked hand and arm: this done, the arm is put in a bag tied, and sealed, and three days after opened; when, if there be no marks of the burn or scald, the accused is declared innocent.

In the kingdom of Siam, to have proof of a crime, the party is obliged to wash his hands in boiling oil, or to walk on burning coals; from either of which he must come out untouched to be reputed innocent.

Sometimes they oblige the two contending parties to plunge under water; and he who stays there longest, gains the cause; and sometimes to swallow a grain of rice, prepared and charmed by their doctors: he who is able to swallow it, is declared innocent, and carried home in triumph; and the accuser punished. This looks like an imitation of what was done among the Jews to have proof of adultery.

The proof by combat is likewise said to subsist among the Mingrelians. See COMBAT.

PROOF, in Artillery. See PROVING GUNS, GUNPOWDER, and POWDER-TRYERS.

PROOF, in the Sugar Trade, a term used by the refiners in sugar for the proper state of the dissolved sugar when it should be let to harden.

The process in the bringing of sugar to this state may be understood by performing the whole work in little in this manner: take six pounds of coarse, or unreduced sugar; dissolve it over the fire in six pints of lime-water; add to this the whites of four eggs beat up to a froth, stir the whole together; then boil the liquor to a higher consistence than a syrup, or till, when exposed to the cold, it will concretize into grains. This is what the sugar-bakers call proof. Pour this syrup into an earthen mould, with a hole at its bottom; stop the hole, and let the vessel in a moderately warm place. The sugar in a few days will set and harden; then open the hole at the bottom, and lay over the top of the sugar some tobacco-pipe clay, made into a soft pap with water. The clay must be afterwards wetted at times, and the water from among it will gradually be foaked up by the sugar, and running through it will wash away the treacle without dissolving the grained part. And thus all the treacle will by degrees be drained out of the mals, and a loaf of white sugar procured. See SUGAR.

Proof Spirits, among Difillers. See SPIRITS.

PROOF, Bread. See BEAD.

PROP, in Rural Economy, a term used to signify a shore or support, set up for the purpose of subserving any thing in its proper situation, as a wall, building, tree, or plant. They should always be sufficiently strong for the purpose intended, whatever it may be, and be so placed, that they may stand securely and without giving way. When used for trees that have been transplanted, they should likewise be so secured at the top part, as to prevent their rubbing and injuring them. It has been remarked by Dr. Darwin, that as the bark is the only living part of the tree, it is liable to receive much injury from its contusion, by the pressure of the props against it, or by the Irregularity of the bandage which holds it to them. He hence concludes, that as the internal wood of a tree is not alive, he many years ago fastened one prop, by a strong nail, to each fruit tree of a small orchard which he then planted, and found the tree supported with much less apparent injury than in the usual manner by three props and adopted cordage. But as moly fruit-trees are extremely apt to be affected with canker, by being injured in this way by nails or other means, it should probably be adopted with caution for them, especially as where proper care is taken in fixing the supports, the business may be effected without any danger of the trees being hurt in the usual mode.

PROPAGATION, PROPAGATION, the act of multiplying the kind, or of producing the like in the way of natural generation. See GENERATION.

Propagation is also applied to the raising of trees or plants from buds, &c. as well as to animals.

PROPACHIO, in Geography, a town of Illyria; six miles E. of Capo d’Illyria.

PROPÆMPTIC, PROEMPTIC, in Poetry, a poem in which are exprefsed ardent wishes and solemn vows for the safety of a person going upon a journey or voyage. Such is that of Horace, lib. I. od. 3, addressed to Virgil on his setting out for Athens. It was otherwise called appemptic. See PROEMPTIC.

The word is derived from πρεμπτειναι, I found forward, or accompany on the way.

PROPER, PROPRIUM, something naturally and essentially belonging to any being.

The school philosophers, after Porphyry, distinguish four kinds of props, or modes of propriety, which are expressed in the following verse.

"Eft mediens, bipis, caneeceans, ribilihilique."

The first, called proprium primo modo, what agrees to a single species, but not to all the individuals; this they call soli, sed non omni. As, to be a geometerian, a physician, a divine, &c. which are things proper to man, but not to all men.

The second, proprium secundo modo, is what agrees to the whole species, but agrees likewise to another; which they call omni, sed non soli. Thus, to have two feet is proper to a man, but is likewise proper to a bird.

The third, proprium tertio modo, is that which agrees to a single species, but not at all times; omni & soli, sed non fener.
per. As to grow grey, according to Porphyry, is proper to a man, but it is to an old man.

The last and highest, proprium quarto modo, is that which alone agrees to one kind, to all the individuals of it, and at all times; omnis, fuit, &c. Thus, the faculty of laughing is proper to man, of neighing to horses, &c. And it is this that Porphyry calls the true proper.

The first three species are only accidents of the fifth vulgar predicatable, to which they directly belong.

The fourth is an universal agreeing to every individual, or subject of predication of any species in such manner as to be always found absolutely in the species alone, but not at every determinate time; thus man alone is naturally rife; not that he is always laughing, but that he has the faculty of laughing at all times.

Proper, in respect of words, denotes their immediate and peculiar signification, or that directly and peculiarly attached to them.

In which fenfe the word flands opposed to figuraiue, and metaphorical.

Proper is also used, in a Moral Sense, to denote something that is usually found in things; as their particular, or specific virtues, &c.

In which fenfe we say, magnanimity is the proper virtue of heroes.

Proper is also used for the natural qualities necessary to succeed in a thing.

In which fenfe we say, people of a hot vigorous temper are proper for the army; the cold and phlegmatic are proper for study. The Romans became less proper for war, in proportion as they grew more learned and polite.

Proper, in Grammar, is also applied to nouns or names, which are distinguished into proper and appellative.

Man is the appellative, Peter the proper name.

The proper name among Christians, is that imposed at baptism. See Baptism, and Name.

Proper Feud. See Feud.

Proper Fraction. See Fraction.

Proper, in the Civil Jurisprudence, is used in opposition to acquired, for an inheritance derived by direct or collateral succession.

By the old French laws, a tellator can only dispose of one-fifth of his proper effects; the paternal relations inherit the paternal propria, and the maternal the maternal ones: so that propria always turn to the line whence they proceed.

The origin of the law which fixes the difference between proper goods and acquitils, is not known; neither the Greeks nor Romans having ever made any such distinction. Indeed it seems founded on this principle of natural equity, that men are uniformly defirous to preserve and attach to their family the goods which they have received from their forefathers, and transmit them to those defending from the same flock.

Proper sometimes also stands as a reduplicative, serving to mark or define a thing more expressively and formally. In this sense we say, Jesus Christ came to redeem the world in his proper person. The king did such and such a thing of his own proper motion.

Proper Motion. See Motion.

Proper Object. See Object.

Properna, in Geography, a town of Prussia, on the Frisch Nerung; 15 miles N.E. of Elbing.

Propertius, Sextus Aurelius, in Biography, a Roman poet, was a native of Umbria, and flourished in the reign of Augustus, by whom, and by Mecena, he was favoured, and who, in his turn, makes their praise a frequent theme of his verse. Little is known of the history of this poet; Ovid places him between Tibullus and himself. His father was of the equestrian order, and lost his life in Perussia, among other partisans of Antony. The confiscation of his property followed, and young Propertius came to Rome, where he obtained the patronage of the great. It is not exactly known when he died, but it has been conjectured to have happened about the year 1 B.C. He has always been ranked among the most eminent of the Latin elegists; four books of his elegies are remaining. He is often compared with Tibullus, but is not so natural or pathetic, and is more learned, various, and ornamented, abounding in allusions to fable and mythology. He is elegant and ingenious, but frequently obscure. His amatory pieces are addressed to a single object of passion, whom he calls Cynthia, which is the poetical name of a Roman lady named Holiba or Holitia, and with whom his connection, if real, appears to have been of the licentious kind. The editions of the Elegies of Propertius, both separately and in conjunction with those of Tibullus, are very numerous: among the best are those of Bouilly, 1702; Vulpiaus, 1755; Burmann, 1785.

Property, or Propriety, Proprietats, that which constitutes or denominates a thing proper; or it is a particular virtue or quality, which nature has bestowed on something, exclusive of all others.

This colour is a property of, light, extension, figure, divisibility, and impenetrability, are properties of body.

Property, or Propriety, in Law, denotes dominion, or the highest right a man can have to a thing; and such as no ways depends on any other man's courtsey.

In this sense, none in our kingdom have the property of any land: or tenements, except the king, in right of his crown; all other lands being of the nature of fee, and held of the king either mediatly or immediately. See Fee.

Property, or propriety, however, is used for that right in lands, tenements, &c. which common perons have: importing as much as usile dominium, though not directum; and consisting in the free use, enjoyment, and dispossession of all their acquisitions, without any control or diminution, save only by the laws of the land.

The original of private property is probably founded in nature: the earth and all things in it became the general property of all mankind, exclusive of other beings, from the immediate gift of the Creator (Gen. i. 28.); and while the earth was thinly inhabited, it is reasonable to suppose, that all was in common among them, and that every one took from the public flock, to his own use, such things as his immediate necessity required. However, this communio of goods seems to have been applicable, even in the earliest ages, only to the substance of the thing, and not extended to the use of it; for, by the law of nature and reason, he who first began to use it, acquired in it a kind! of transient property, that lasted as long as he was using it, and no longer: or, the right of possession continued for the same time only that the act of possession lasted.

The first objects of property were the fruits which a man gathered, and the wild animals he caught; next to these the tents or hovels which he built, the tools he made use of to catch and prepare his food; and afterwards weapons of war and offence. Many of the savage tribes of America have not even now proceeded any farther; for they are said to reap their harvest, and return the produce of their market with foreigners into the common board or treasury of the tribe. Stocks and herds of tame animals soon became property: Abel, the second son of Adam, was a keeper of sheep; sheep, oxen, camels, and ailes, composed the wealth of
of the Jewish patriarchs, as they do all of the modern Arabs. And as the world was first peopled in the East, where water was scarce, wells were, at an early period, made property. See Gen. xxi. 25. xxvi. 18.

In process of time it became necessary to form notions of more permanent dominion; and to appropriate to individuals not the immediate use only, but the various substance of the thing to be used. The labour of cultivation and art of agriculture by degrees introduced and established the idea of a more permanent property in the soil than had been before received and adopted. And as occupancy gave the right to the temporary use of the soil, so occupancy gave likewise the original right to the permanent property in the substance of the earth itself; which excludes every one else but the owners from the use of it. On this head Grotius and Puffendorff insist, that this right of occupancy is founded upon a tacit and implied assent of all mankind, that the first occupant should become the owner: and Barbeyrac, Titius, Mr. Locke, and others maintain, that there is no such implied assent, neither is it necessary that it should be: for that the very act of occupancy alone, being a degree of bodily labour, is, from a principle of natural justice, without any consent or compact, sufficient of itself to gain a title. However, it is agreed on both sides, that occupancy is the thing by which the title was in fact originally gained; every man feizing, to his own continued use, such spots of ground as he found most agreeable to his own convenience, provided he found them unoccupied by any else.

Property, both in lands and moveables thus acquired by the first taker, remained in him, by the principles of universal law, till such time as he does some other act which swears an intention to abandon it; for then it becomes, naturally speaking, publici juris once more, and is liable to be again appropriated by the next occupant. But this method of one man's abandoning his property, and another's feizing the vacant possession, could not long subsist in fact. Mutual convenience introduced commercial traffic, and the reciprocal transfer of property by sale, grant, or conveyance. The most universal and effectual way of abandoning property is by the death of the occupant; in which case all property must cease, conferring men as absolute individuals, and unconnected with civil society. But such a constitution would be productive of endless disturbances; the universal law of almost every nation (which is a kind of secondary law of nature) has either given the dying perfon a power of continuing his property by disposing of his possessions by will, or the municipal law declares who shall be the heir of the deceased, or the doctrine of escheats is adopted. Thus we see, that though the origin of property is founded in nature, the modifications under which it now exists, the method of preferring it to the present owner, and of translating it from man to man, are entirely derived from society; and are some of those civil advantages, in exchange for which every individual has renounced a part of his natural liberty.

Long after the institution of many other species of property, when a country became populous, and tillage began to be practised, land became vested in a permanent occupant. The first partition of an estate which we read of was that which took place between Abraham and Lot, and that was one of the simplest possible. In Caesar's account of Britain, there are no traces of property in land; little of it in the history of the Jewish patriarchs; none of it found among the nations of North America; and the Scythians are said to have appropriated their cattle and horses, but to have left their land in common. Hence we may infer, that the more permanent property in land was posterior in all probability to civil government and laws, and therefore settled by these, or according to the will of the reigning chief. When, and by what gradations, land, which alone by our laws is called "real" property, and which, in the earliest period of time, was unquestionably common, was taken out of the common, and appropriated with an exclusive right to the owner, has been a subject of dispute.

Some, as we have already stated, maintain, that the occupant was allowed by the joint consent of mankind to retain it; whilst others annex property to the labour bestowed on the land during the period of occupancy. However this be, the real foundation of our right is the "law of the land." As it was the intention of God, that the produce of the earth should be applied to the use of man, this institution could not have been fulfilled without establishing property; and, therefore, such an establishment must have been consistent with his will. The land could not have been divided into separate property, without leaving it to the law of the country to regulate that division; it is, therefore, consistent with the same will, that the law should regulate the division, and, consequently, "consistent with the will of God," or "right," that any individual should possess that share which these regulations assign him. By whatever circuitous train of reasoning, says archdeacon Paley, you attempt to derive this right, it must terminate at last in the will of God: the straightforward, therefore, and shortest way of arriving at this will, is the belt. But if the right of property be made to depend upon the law of the land, it seems to follow, that a man has a right to keep and take every thing, which the law will allow him to keep and take; and this, in many cases, will authorize the most flagitious chicanery. To obviate this difficulty, the following distinction is proposed. With the law, we acknowledge, refises the disposals of property; so long, therefore, as we keep within the design and intention of a law, that law will justify us, as is the case in foro conscientiae, as in foro humano, whatever be the equity or expediency of the law itself. But when we convert to our purpose a rule or expression of law, which is intended for another purpose; then we plead, in our justification, not the intention of the law, but the words; that is, we plead a dead letter, which can signify nothing; for words without meaning or intention have no force or effect in justice, much less words taken contrary to the meaning and intention of the speaker or writer.

The institution of property is, upon the whole, beneficial; and the principal advantages accruing from it are such as follow: it increases the produce of the earth, by subjecting it to cultivation; it preserves the produce of the earth to maturity; it prevents contentions; and it improves the convenience of living, by enabling mankind to distribute themselves into distinct professions, and by encouraging those arts, by which the accommodations of life are supplied. With few exceptions, therefore, it may be affirmed, that even the poorest and the most provided, in countries where property and the consequences of property prevail, are in a better situation, with respect to food, raiment, houses, and what are called the necessaries of life, than any are in places where most things remain in common. Inequality of property, in the degree in which it exists in most countries of Europe, undoubtedly considered, is an evil; but it is an evil, which flows from those rules concerning the acquisition and disposal of property, by which men are incited to industry, and by which the object of their industry is rendered secure and valuable. If there be any great inequality unconnected with this origin, it ought to be corrected.

The laws of England are, in point of honour and justice, extremely watchful in ascertaining and protecting the right of property. Upon this principle the great charter has declared,
clared, that no freeman shall be disquieted or defiled of his freehold, or his liberties, or free customs, but by the judgment of his peers, or by the law of the land. And by a variety of ancient statutes, viz. 5 Edw. III. c. 9. 25 Edw. III. mut. 5. c. 4. 28 Edw. III. c. 5; it is enacted, that no man’s lands or goods shall be seised into the king’s hands against the great charter, and the law of the land; and that no man shall be disinnuered nor put out of his franchises or freehold, unless he be duly brought to answer, and be forejudged by course of law; and if any thing be done to the contrary, it shall be redressed, and holden for none. So great is the regard of the law for private property, that it will not authorize the least violation of it; no, not even for the general good of the whole community.

The objects of dominion or property are things, as contradistinguished from persons; and things are by the law of England distributed into two kinds, viz. things real and things personal. Things real are such as are perpetual, fixed, and immovable, which cannot be carried out of their place, as lands, tenements, and hereditaments of all kinds; things personal are goods, money, and all other moveables, which may attend the owner’s person wherever he thinks proper to go. Hence property is divided into personal and real.

Moreover, the rights of personal property may be considered as in possession or in action. Those in possession are liable to two species of injuries, viz. the deprivation of that possession by unjust and unlawful taking them away, or unjustly detaining them, though the original taking might be lawful; and the abuse or damage of the chattels, whilst the possession continues in the legal owner.

Rights of property in action are such as are founded on, and arise from contracts, which are either express or implied: the former fort includes debts, covenants, and promises; and the latter are either such as are necessarily implied by the fundamental constitution of government, to which every man is a contracting party, or such as do not arise from the express determination of any court, or the positive direction of any statute; but from natural reason, and the just construction of law.

Real property is liable to various kinds of injury, the principal of which are the following, viz. outlawry, trespas, nuisance, waif, subtracion, and disturbance; which see respectively. Blackl. Com. books ii. iii.

There are three manners of right or property, viz. absolute, qualified, and poorefolly. See TITLE.

For offences or crimes against private property, see LAND.

MALICIOUS MISCHIEF, and FORGERY.

PROPERTY, Landel, Valuation of. See Valuation of Land.

PROPERTY, Literary. See LITERARY.

PROPERTY by Prerogative, is that property in personal chattels, a right to which may accrue either to the crown itself, or to such as claim under the title of the crown, as by grant or by prerogation; such are all tributes, taxes, and customs; all forfeitures, fines, and amercements due to the king, which accrue by virtue of his ancient prerogative, or by particular modern statutes; wreck, treasure-trove, waifs, &c. and other animals known by the denomination of game. See GAME.

PROPERTY, Right of, jus proprietatis, is that which is vested in a man without either possession, or even the right of possession. This is often spoken of under the name of the mere right, jus servitutis; and the estate of the owner is, in such cases, said to be totally divested, and put to a right. A person thus circumstanced may have the true ultimate property of the lands in himself; but by his own negligence, the solemn act of his ancestor, or the determination of a court of justice, the presumptive evidence of that right is strongly in favour of his antagonist, who has thereby obtained the absolute right of possession.

Incumbents have not the property of benefices, they have only the enjoyment of them. The monks have a long time disputed whether they had the property of the bread they eat, or only the use.

One may give the property of an estate, yet retain the usufruct; in which case, by the death of the usufructuary, the usufruct is confounded to the property.

In the law of England, strictly speaking, which is called an estate in lands and tenements is termed a property in personal chattels; the law considering the first as permanent, the other as temporary and precarious.

PROPHETY, Prophecy, a prediction, made by divine inspiration.

One of the strongest evidences for the truth of revealed religion, is that series of prophecies which is preferred in the Old and New Testament; and a greater service, says an excellent writer, could not be done to Christianity than to lay together the several predictions of scripture with their complements, to shew how particular things have been foretold, and how exactly fulfilled. A work of this kind was dehired by the lord Bacon (vide de Augustinis Scientiarum, lib. ii. cap. 11), and he entitles it the History of Prophecy; in which he proposes, that every prophecy of the scripture be fort with the event fulfilling the same throughout the ages of the world, both for the better confirmation of faith, and for the better illumination of the church, touching those parts of prophecies which are yet unfulfilled; allowing nevertheless, that latitude which is agreeable and familiar unto divine prophecies, being of the nature of the author with whom a thousand years are but as one day, and therefore they are not fulfilled punctually at once, but have springing and germinant accomplishment throughout many ages, though the height or fulness of them may refer to some one age. A work of this kind has been actually executed by the learned Bishop Newton in his “Discretion on Prophecies,” in three vols. 8vo. to which we refer, as containing a detail of all the prophecies in the Old and New Testament, with an account of their accomplishment.

With regard to the credibility of prophecy, it may be observed in general, that it is not at all incredible that God should, upon special occasions, foretell future events; and, if he affords an extraordinary revelation of his will to mankind, that he should attest its divine original by this kind of evidence; an evidence which, if the prophecies point to the events, and the events correspond with the prophecies, is in the highest degree conclusive and convincing. No previous conjecture or accidental coincidence is sufficient to counteract and invalidate this kind of evidence.

As to most of the scripture prophecies, they comprehend such a variety of particulars: they so minutely describe distant events, to be accomplished in circumstances which no human sagacity could foresee or conceive likely to occur; and they accord so exactly with the facts to which they refer, that there is no way of evading the conclusion, but by either denying the premises that such prophecies were ever delivered and recorded, against which fact and history militate, or by pretending that what we call predictions are only histories written after the events had happened, in a prophetic style and manner. But it is alleged in answer to this absurd plea, that there are all the proofs and authorities, which can be had in cases of this nature, that the prophets prophesied in one age, and that the events happened in another and sub-

---

PRO
frequent age; and we have as much reason to believe these, as
we have to believe any ancient matters of fact whatever;
and by the same rule which leads us to deny these, we may
as well controvert and contradict the credibility of all an-
cient history; but, besides, Christian writers undertake
to prove the truth of prophecy, and consequently the truth of
revelation, not by an induction of particulars long ago fore-
told and long ago fulfilled, the predictions of which may be
supposed to have been written after the histories, but
by instances of things which have confessedly many ages ago
been foretold, and have in these latter ages been fulfilled, or
are fulfilling at this very time; so that there is no pretense
for affording such prophecies to have been written after the
events; but it must be acknowledged that the events many
ages after correspond exactly with the predictions many ages
before. The evidence, therefore, which prophecy furnishes
in favour of the truth of religion is a growing evidence; and
the more prophecies are fulfilled, the more testimonies there
are and confirmations of the truth and certainty of divine
revelation. One of the greatest difficulties in Chriftianity
turns upon the manner of completion of the scripture prop-
hecies. In the prophecies of the Old Testament are fre-
quent predictions of the Messias; which the writers of the
New frequently urge to the Jews and heathens as fulfilled in
Jefus Chrift; and on this principle evince the truth of his
mission; but these texts, thus urged from the Old, in the New
Testament, are sometimes not to be now found in the Old;
and at other times are not urged in the New in the
literal and obvious sense which they seem to bear in the Old;
whence most of the Chriftian commentators, divines, and
critics, ancient and modern, judge them to be applied in a
secondary, typical, allegorical, or mystical sense. Thus,
Gr. St. Matthew, (if we allow the authenticity of the two
first chapters of his gospel, see Matthew,) after an ac-
count of the conception of the Virgin, and the birth of
Jefus, says, “All this was done that it might be fulfilled
which was spoken by the prophet, saying, Behold a Virgin
shall be with child, and shall bring forth a fon, and they
shall call his name Emmanuel.” But the words, as they
stand in Isaiah, whence they are supposed to be taken, do,
in their obvious and literal sense, relate to a young woman
who was to bring forth a child in the days of Ahaz; as
appears from the context, and as is owned by Grotius, Huetius,
Caltalio, Curellus, Epiphanes, Hammond, Simon, Le
Clerc, Lamy, &c.

This prophecy, then, not being fulfilled in Jefus, in the
primary, literal, or obvious sense of the words, is suppos-
ed, like the other prophecies cited by the apollos, to be ful-
filled in a secondary, typical, or allegorical sense; i.e., this
prophecy, which was first literally fulfilled by the birth of
the prophet’s fon in the time of Ahaz, was again fulfilled
by the birth of Jefus, as being an event of the same kind,
and intended to be signified either by the prophet, or by
God, who directed the prophet’s speech. Grotius observes
this to be the cafe in most, if not all, the prophecies and
citations quoted from the Old in the New Testament; and
Doddwell, with Sir John Marham, refers even the famous
prophecy in Daniel, about the seventy weeks, to the time of
Antiochus Epiphanes; shewing, that the expiriptions
taken thence by Chrift, and urged by him as predicting the
destruction of Jerusalem by the Romans, have only in a se-
condary sense a respect to that destruction.

And even that famous prophecy in the Pentateuch, “A
prophet will the Lord God raise up unto thee, like unto me;
to him shall ye hearken,” which St. Luke refers to as
spoken of Jefus Chrift, is by Simon, Grotius, Stillingfleet,
PROPHECY.

applied them in their literal meaning to the Messiah. Mr. Whiston, in his sermons preached at Boyle's lecture in 1707, had supported the same sentiment before Baltus. He condemns all allegorical explanation of the prophecies of the Old Testament cited in the New, as weak, enthusiastic, &c. and adds, that if a double sense of the prophecies be allowed, and there be no other method of shewing their completion than by applying them secondarily and typically to our Lord, after having been in the first and primary intention long ago fulfilled in the times of the Old Testament, we lose all the real advantages of the ancient prophecies, as proofs of Christliarity.

He therefore sets up a new scheme in opposition to it; he owes it, taking the present text in the Old Testament for genuine, it is impossible to expound the apostles' citations of the prophecies of the Old Testament on any other than the allegorical foundation; and therefore, to solve the difficulty, he is forced to have recourse to a supposition contrary to the sense of all Christian writers before him, viz. that the text of the Old Testament has been greatly corrupted since the apocalyptic age by the Jews. His hypothesis is, that the apostles made their quotations out of the Old Testament rightly and truly from the Septuagint version, which, in their time, was in vulgar use, and exactly agreed with the Hebrew original; and that as they made exact quotations so they argued justly and logically from the obvious and literal sense of the said quotations, as they then stood in the Old Testament; but that, since their times, both the Hebrew and Septuagint copies of the Old Testament have been so greatly corrupted, and so many apparent disorders and dislocations introduced in them, as to occasion many remarkable differences and inconformities between the Old and New Testament in respect to the words and sense of those quotations.

As to the manner in which these corruptions were introduced, he says, the Jews, in the second century, greatly corrupted and altered both the Hebrew and Septuagint, especially in the prophecies cited by the apostles, to make their reasoning appear invidious; that, in the third century, they put into Origen's hand one of these corrupted copies of the Septuagint; which Origen miltaking for genuine, inserted in his Hexapla, and thus brought into the church a corrupted copy of the Septuagint; and that, in the end of the fourth century, the Jews put into the hands of the Christians, who, till then, had been almost universally ignorant of the Hebrew, a corrupted copy of the Hebrew Old Testament.

The disagreement, then, between the Old and New Testament, in respect to the said quotations, he contends, has no place between the genuine text of the Old Testament, (now no where existing,) but only between the present corrupted text of the Old and New Testament; and, therefore, to justify the reasonings of the apostles, he proposes to restore the text of the Old Testament, as it stood before the days of Origen, and as it stood in the days of the apostles; from which text, thus restored, he doubts not, it will evidently appear, that the apostles cited exactly, and argued justly and logically from the Old Testament. But this scheme of accomplishing prophecies labours under difficulties at least as great as the allegorical scheme. Its foundation is incredible, and its superstructure, from first to last, precarious. In effect, it is inconceivable, that the Old Testament should be so corrupted; and it may be even made appear, that the Hebrew and Septuagint disagreed in the times of the apostles: to add to this, that the means by which he proposes to restore the true text will never answer that end; nor has he himself, from all the means he is yet possessed of, been able to restore one prophetic citation, so as to make that feem literally, which before only seemed allegorically applied.

In 1710, archdeacon Claggett animadverted on this notion of Whiston, and undertook the vindication of those Christian commentators, who had explained some prophecies concerning the Messiah, as not solely relating to him, in a treatise, entitled "Truth defended, and Boldness in Error rebuked."

Upon this head it may be observed, that the double sense of prophecies, for which some have zealously contended, and which others have as strenuously opposed, ought not to be underfoot, as if a prophecy equally and indifferently referred to many persons or events; or as if, literally referring to a lower person, it was only figuratively and allegorically to be interpreted of the Messiah (for a passage only capable of being accommodated to him is not by any means a prediction of him); but it is to be explained, as that it may appear the Messiah was principally intended, and the prophecy literally referred to him, though it might in part be applied to some other person; and might have been understood as referring to that inferior person alone, if farther light had not been thrown upon it, by comparing other prophecies, or by the testimony of those whom, on other accounts, we have reason to regard as authentic interpreters. Nevertheless, it must be acknowledged, that though the tracing of the Messiah in such prophecies may serve to illustrate the unity of design, which is a considerable additional proof of the truth of a revelation, yet the mainsense is to be laid upon such prophecies as evidently and solely relate to the Messiah and his kingdom, rather than on those which are capable of reference to other persons or events.

The learned and judicious Dr. Clarke has given double senses of several passages in the four gospels: Matt. xx. 1, &c. Matt. xxiv. 6, &c. The celebrated Mr. Locke has quoted, in his admirable preface to his Commentary on the Epistles, a passage from the learned and judicious Mr. Sel- deu, to show that no text of scripture has more than one meaning, which is fixed and limited by the connection; and yet Mr. Locke has, in some few instances, contended for double senses of one and the same text. 2 Cor. iii. 6. Gal. iv. 21, &c.

There are, it is said, several persons, who would be pleased with double senses, and who would be glad to have the truth and authority of them established and confirmed. Such are all mythical divines and enthusiasts, who plead for double, or manifold senses of the holy scriptures: the Papists also contend for many senses of holy scripture, because they are thus greatly helped in the proof of a number of their peculiar tenets: the Jews are highly delighted with manifold senses of scripture: and the enemies of revelation are glad to see Christians pleading for double senses, because, as they conceive, it affords the greatest advantage to them and their cause. In this number we may reckon Mr. Collins, Mr. Woolaston, and the author of "Christianity as old as the Creation," and the author of "Christianity not founded in Argument."

Collins's "Discourse on the Grounds and Reasons of the Christian Religion" was published in 1724; and in this publication he revived the objections of Falsatus, and other early writers, who had endeavoured to prove that the prophecies of the Old Testament had no direct relation to Jesus Christ. We refer to Leland's "View of the Deistical Writers," and to Fabricius's "Lux Evangelica," for an account
account of the several answers which were published to this, and to another work of the same author, entitled "The Scheme of literal Prophecy considered." Bishop Warburton also, in the sixth book of the "Divine Legation of Moises," has answered what Collins had objected against a second sense of prophecy; and in the first volume of Dr. Jortin's "Remarks on Ecclesiastical History," we have some very judicious observations, both concerning prophecy in general, and concerning a double sense of some prophecies.

Dr. Sykes, in his "Connection between Natural and Revealed Religion," has a whole chapter, to shew that the ancient prophecies contained only one sense. The author of an "Essay concerning the Unity of Sense," to shew that no Text of Scripture has more than one fingle Sense," prefixed to Dr. Benfon's Paraphrase on St. Paul's Epistles, and contained in bishop Watfon's Collection of Theological Tracts, vol. iv., has particularly examined this subject, obviated the difficulties that attend the interpretation of particular passages, evinced the advantage which his hypothesis affords him for this purpose, and answered the objections that have been urged against it.

Dr. Newton, late bishop of Bristol, at the conclusion of his "Dissertations" already mentioned, has shewn how the argument from prophecy avails in proof of the truth of divine revelation. Waving any reference to those prophecies that received their full accomplishment in ancient times, and confining the attention to those of later ages, you can have no reason to doubt of the truth of prophecy, and consequently of the truth of revelation, when you see infinances of things, which could no ways depend upon human conjecture, foretold with the greatest clearness, and fulfilled hundreds of years afterwards with the greatest exactness. Nay, you see prophecies, the latest of which were delivered about 1700 years ago, and some of them above 3000 years ago, fulfilling at this very time, and cities, countries, and kingdoms, in the very same condition, and all brought about in the very same manner, and with the very same circumstances, as the prophets had foretold.

You see the descendants of Shem and Japheth ruling and enlarged in Asia and Europe, and perhaps in America, and the curse of servitude still attending the wretched descendants of Ham in Africa. You see the posterity of Ishmael multiplied exceeding, and become a great nation in the Arabians; yet living as wild men, and shifting from place to place in the wilderness; their hand against every man, and every man's hand against them; and still dwelling an independent and free people, in the presence of all their brethren, and in the presence of all their enemies. You see the family of Esau totally extinct, and that of Jacob subsisting at this day; the Shepherds departed from Judah, and the people living no where in authority, every where in subjection; the Jews still dwelling alone among the nations, while the remembrance of Amalek is utterly put out from under heaven. You see the Jews severely punished for their inidelity and disobedience to their great prophet like unto Moses; plundered from off their own land, and removed into all the kingdoms of the earth; oppressed and spoilt evermore, and made a proverb and a byword among all nations. You see Ephraim so broken as to be no more a people, while the whole nation is comprehended under the name of Judah; the Jews wonderfully preferred as a distinct people, while their great conquerors are everywhere destroyed; their land lying desolate, and themselves cut off from being the people of God, while the Gentiles are advanced in their room. You see Nineveh so completely destroyed, that the place thereof is not, and cannot be known; Babylon made a desolation for ever, a possession for the bitttern, and pools of water; Tyre become like the top of a rock, a place for fifters to spread their nets upon; and Egypt a base kingdom, the basest of the kingdoms, and all tributary and subject to strangers. You see of the four great empires of the world the fourth and last, which was greater and more powerful than any of the former, divided in the western part thereof into ten lesser kingdoms; and among them a power with a triple crown drawn from the first, with a mouth speaking very great things, and with a look more fount than his fellows, speaking great words against the most High, and changing times and laws. You see a power cast down the truth to the ground, and prosper and flourish, and destroy the holy people, not regarding the God of his fathers, nor the defer of times, but honouring Mahabzim, gods-protectors or saints-protectors, and causing the priests of Mahabzim to rule over many, and to divide the land for gain. You see the Turks stretching forth their hand over the countries, and particularly over the land of Egypt, the Libyans at their feet, and the Arabsians still sleeping out of their hand. You see the Jews led away captive into all nations, and Jerusalem trodden down of the Gentiles, and likely to continue so until the times of the Gentiles be fulfilled, as the Jews are by a confent miracle preserved as a distinct people, for the completion of other prophecies relating to them. You see one who opposeth and exalteth himself above all laws divine and human, sitting as God in the church of God, and showing himself that he is God, wherefore coming is after the working of Satan, with all power, and signs, and lying wonders, and with all deceivableness of unrighteousness. You see a great apathy in the Christian church, which confits chiefly in the worship of demons, angels, or departed saints, and is promoted through the hypocrisy of liars, forbidding to marry, and commanding to abstain from meats. You see the seven churches of Asia lying in the fame forlorn and desolate condition that the angel had signified to St. John, their candlestick removed out of its place, their churches turned into moques, their worship into superition. In short, you see the characters of the beast and the false prophet, and the whore of Babylon, now exemplified in every particular, and in a city that is feated upon seven mountains; so that if the bishop of Rome had fat for his picture, a greater resemblance and likenes could not have been drawn.

Prophecies, False, are those delivered by persons pretending extraordinary commissions from God, to raife jealousies in the people; or terrify them with impending judgments, &c. Such perfons are punifhable at common law as impostors. This was a capital offence by Stat. 1 Edw. IV. cap. 12. which was repeaie in the reign of queen Mary. By statute 5 Eliz. cap. 15. none shall publish or set forth any false prophecy, with an intent to raife sedition, on pain of 100l. for the first offence, and a year's imprisonment; and for the second offence to forfeit all his goods and chattels, and suffer imprisonment during life; the prosecution to be within fix months. (2 Inst. 128, 129.) To prophesy when the king shall die, hath been anciently held to be treafon. Roll. Rep. 88.

Prophecyings, a name given to certain assemblies held by the ancient Puritans in this kingdom; where alternately, says Mr. Hume, as moved by the spirit, they displayed their zeal in prayers and exhortations, and raised their own enthusiasm, as well as that of their audience, to the highest pitch, from that Jacob contageon, which has so mighty an influence on holy fervour, and from the mutual emulation which arose in those trials of religious eloquence. Such dangerous societies, as the historian calls them, had been suppreffed by queen Elizabeth; and the ministers in the Hampton-Court conference moved king James I. for
their revival. But the king sharply replied, "if you aim at a Scottish presbytery, it agrees as well with monarchy as God and the devil. There Jack and Tom and Will and Dick shall meet and cenfuse me and my council. Therefore I reiterate my former speech: Le Ross'. Stay, I pray, for one seven years, before you demand; and then, if you find me grow purrifer and fat, I may perchance hearken to you. For that government will keep me in breadth, and give me work enough." Such were the political considerations, which determined the king in his choice among religious parties. Hume's Hist. of England, vol. vi. p. 14. 8vo.

PROPHET, Prophecy. ὁ προφήτης, a person inspired by God with the knowledge of future events, and commissioned to declare his will, &c. to the world.

The word is derived from the Greek ὁ προφήτης, said of ὁ προφήτης, to whom also the Latins derive their oraci, spoken.

Among the canonical books are those of sixteen prophets; four of which are denominated the greater prophets, viz. Isaiah, Jeremiah, Ezekiel, and Daniel; so called from the length or extent of their writings, which exceed those of the others; viz. Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Haggai, Zechariah, and Malachi; who are called the lesser prophets, from the shortness of their writings.

The writings of the prophets form one of the three divisions of the canon of the Old Testament; and to these already enumerated, called the books of the latter prophets, are added those of the former prophets; viz. Joshua, Judges, Samuel, and Kings.

The Jews only reckon three greater prophets; Daniel they exclude as no more to be ranked among the prophets than David; but that both the one and the other foretold many important things, but because their manner of life differed from that of the other prophets; David being a king, and Daniel a peer.

In the Greek church, the lesser prophets are placed in order before the great ones; apparently because many of the lesser prophets are more ancient than the greater.

Among the Greeks, too, Daniel is ranked among the lesser prophets. In the forty-eighth chapter of Ecclesiasticus, Ifaiah is particularly called the great prophet; both on account of the great things he foretold, and the magnificent manner in which he did it.

Spinoza says, the several prophets prophesied according to their respective humours: Jeremiah, e. g. melancholy and dejected with the miseries of life, prophesied nothing but misfortunes.

Dacier observes that among the ancients, the name poet is sometimes given to prophets; as that of prophet is, at other times, given to poets.

PROPHETS, Sons of the, in Scripture History, an appellation given to young men who were educated in the schools or colleges under a proper master, who was commonly, if not always, an inspired prophet, in the knowledge of religion and in sacred music, and thus were qualified to be public preachers, which seems to have been part of the business of the prophets on the Sabbath-days and festivals. That such colleges or schools existed even from the earliest times of the Hebrew republic, is evident from many parts of the sacred history. In these the candidates for the prophetic office, removed altogether from an intercourse with the world, devoted themselves entirely to the study and exercises of religion; and over each of them some prophet of superior authority, and more peculiarly under the divine influence, prefigured as the moderator and preceptor of the whole assembly. It is probable, that God generally chose the prophets, whom he inspired, out of these schools.

Although the Sacred History affords us but little information, and that in a cursory manner, concerning their institutions and discipline; we nevertheless understand that a principal part of their occupation consisted in celebrating the praises of Almighty God in hymns and poetry, with choral chants accompanied by stringed instruments and pipes. A remarkable passage to this purpose occurs in 1 Sam. x. 5–10. Saul being nominated king, and, pursuant to the command of God, consecrated by a solemn anoint, a company of the prophets, as Samuel had foretold, descending from the mount of God (that being the place in which the sacred college was situated) met him; and preceded by a variety of musical instruments, prophesied; upon hearing which, he himself, as if actuated by the same spirit, immediately joined them, and prophesied also. The same thing again occurred to him as related in 1 Sam. xix. 20–24. Concerning the nature of this mode of prophesying all are agreed, understanding by it the celebration of the praises of God, under the impulse of the Holy Spirit, with music and song. (See also 1 Chron. xxv. 1–3.) From these insinuates it sufficiently appears, that the word "Nabi" was used by the Hebrews in an ambiguous sense, and that it equally denoted a prophet, a poet, or a musician, under the influence of divine inspiration. To these we may add the prophetees, Miriam the sister of Aaron, and Deborah, who were distinguished by that title, not only because they pronounced the oracles of Jehovah, but on account of their excellence in music and poetry; singer arts, which were united by the Hebrews, as well as by all other nations, during the first ages of society. See Hebrew Music, and Hebrew Poetry.

PROPHETIC Poetry, denotes that species of poetry which is found to pervade the predictions of the prophets, as well those contained in the books properly called prophetical, as those which occasionally occur in other parts of the scripture. As to the peculiar character of the prophetic poetry, bishop Lowth observes, that this species of poetry is more ornamental, more splendid, and more florid than any other. It abounds more in imagery, at least in that species of imagery which, in the parabolic style, is of common and established acceptation, and which, by means of a settled analogy, always preferred, is transferred from certain and definite objects to express indefinite and general ideas. Of all the images proper to the parabolic style, it most frequently introduces those which are taken from natural objects and from sacred history; it abounds most in metaphors, allegories, comparisons, and even in copious and diffuse descriptions. It possest all that genuine enthusiasm, which is the natural attendant on inspiration; it excels in the brightness of imagination and in clearness and energy of diction, and consequently rises to an uncommon pitch of sublimity; hence also it often is very happy in the expression and delineation of the passions, though more commonly employed in the exciting of them; this indeed is its immediate object, over this it presides as its peculiar province.

With respect to the order, disposition, and symmetry of a perfect poem of the prophetic kind, no certain definition will admit of general application. Naturally free, and of too ardent a spirit to be confined by rule, it is usually guided by the nature of the subject only, and the impulse of divine inspiration. There are not wanting, it is true, instances of great elegance and perfection in these particulars. Among the shorter prophecies it will be sufficient to mention those of Balaam, each of which is possest of a certain accuracy
of arrangement and symmetry of form; they open with an
elegant exordium, they proceed with a methodical continue-
tion of the subject, and they are wound up with a full and
graceful conclusion. There are many familiar in flances in the
books of the prophets, and particularly in Isaias, which
deserve the highest commendation, and may, with propriety,
be claffed with the most perfect and regular specimen of
poetry. The following example is flected from that most
accomplished writer, and it is embellifhed with all the most
striking ornaments of poetry. The 34th and 35th chapters of
Aiahas contain a remarkable prophecy under the form of a
simple, regular, perfect poem, confifling of two parts, ac-
cording to the nature of the subject, which, as to its general
properties, is explained with the utmost perfefticity. The
first part of the prophecy contains a denunciation of ex-
traordinary punishment, indeed nothing short of total destruc-
tion against the enemies of the church of God; and, afterwards,
in consequence of this, a full and complete restoration
is promised to the church itself. For the development and
illustration of the whole, we must refer to Lowth, ubi
infra. As a specimen of a prophetic poem complete in all
its parts this learned author has flected one of the prophecies
of Balaam, of which he fays that the whole scope of the
Hebrew poetry contains nothing more exquifite or perfect.
This abounds in gay and splendid imagery copied imme-
diately from the tablet of nature, and is chiefly conpicious
for the glowing elegance of the fyle, and the form and
diverfity of the figures. Numb. xxiv. 5—9. Lowth's Le-
cures on the Sacred Poetry of the Hebrews, translated by
Dr. Gregory, pt. iii. See Hebrew Poetry.

For the peculiar character of each of the prophets, see
their respective names.

Prophetic Types. See Type.

Propitiatory, προπητιας, that part of the art
of medicine which directs the preventing or preferving
diseafes.

Propitiation, in Theology, is, as fome have
defined and repreffed it, a sacrifice offered to God to
avouge his wrath, and render him propitious.

Among the Jews there were both ordinary and public
sacrifices; as holocausts, &c. offered by way of thanksgiving;
and extraordinary ones offered by particular persons guilty
of any crime, by way of propitiation.

If it were a crime of ignorance, they offered a lamb,
or a kid; if done willingly, they offered a sheep; for the
poor, a pair of turtles was enjoined as a propitiation.

The Romil church believe the mafs to be a sacrifice of
propitiation, for the living and the dead. The reformed
churches allow of no propitiation, but that one offered by
Jesus Christ on the crofs.

There has been a considerable difference of opinion among
divines concerning the meaning of the term propitiation;
much more especially as it is used in the New Testament,
and refers to the fufferings and death of Christ; but whatever
effay any have afcribed to them as the
means of obtaining pardon for the penitent and establishing
their title to eternal life, it has been generally fupposed,
that they have been verbal declarations or memorial, that
God is propitious, and not the cause of a merciful dispo-
sition in God or the means of rendering him propitious,
who was before implacable. In this refeft, those who
maintain that sacrifices in general, and that of our Saviour
in particular, which they confider as a sacrifice, were a
proper expiation, or a real propitiation, affirm they neither were
nor could be proper expiations. On this subject many un-
found, not to fay unwarrantable, expreffions have
been used by controversial writers. Accordingly some have
taken occasion, from the redemption that is in Christ, to
repreff the bleffed God as being in himself implacable,
and that his inclination or disposition to shew mercy
was owing merely to Christ's interposing on our behalf. In
Scripture, the love of God and his compaffion to finners
are repreffed as the very spring of this constitution, and
the whole scheme of our redemption, whatever may be our
ideas of its nature, efficacy, and extent, is attributed to
the contrivance of the Father. Thus our Lord himfelf re-
preffes it: "God so loved the world, that he fent his
only begotten fon, that whoever believeth in him should not perifh,
but have everlasting life;" and to the fame pur-
pofe are the subsequent declarations of the apostles in all
their writings. But if God himfelf was originally disposed to
shew mercy, it may be added, how is then the death of
Christ a propitiation? Juft in the fame manner, fay the
divines, as a propitiation is accounted for under the Mofaical
conftitution. There God ftrictly a facred-meal (ol-fer-
ence), the term used for propitiation in Rom. iii. 25.; then
he requires that application be made to him as reducing
there, by sacrifice and by mediation of an high priest.
Thus also, God resolves to shew mercy to finners, determin-
ing at the fame time that his only begotten fon (not with-
out his own conftent) fhall suffer death, the penalty which
the original law hath denounced againft transgreflors;
merely to demonstrate his regard to the righteous function
of the law, and his difpleafure againft fin. Hence it has
been faid, Christ by dying for accomplifhing the purpose
of divine mercy, and in confequence of the appointment and
will of the father and fountain of mercy, may, with the
utmoft propriety and frileth, be regarded and defcribed as a
propitiation for our fins: inasmuch as by his fuffering
death he hath prevented or warded off thofe effets and
confquences of fin which would otherwife have befallen
the finner. In this fcheme, as the advocates of it fay, we fee
mercy, pure, unfolicited, unconftained, unprifted mercy
to finners; but God appoints that the mercy and favour,
and particularly the grant of eternal life, which he designs
for finners of a particular defcription and character, fhall
be conveyed to them or conferred upon them in this way,
viz. that Chrift fhall die as a sacrifice, and not as a priest,
for them. This being fupplanted, and Chrifa having com-
plied with it, his death and his mediation, originating in
the benevolence of the Dity and accepted by him, are
duly represented as the means of procuring for qualified
recipients the blessings which the Gofpel promises. For
different views of this subject, see the article Atonement.
See also Saffifice and Satisfaction.

Propitiation also gives the name to a solemn fcaf about
among the Jews, celebrated on the tenth of the month
Tifri, which is their leventh month, and answer to our
September.

It was instituted to preserve the memory of the pardon
proclaimed to their forefathers by Mofes on the part of
God; who thereby remitted the punishment due for their
worship of the golden calf.

Propitiatory, among the Jews, was the cover
or lid of the ark of the covenant; which was lined both
within and without with plates of gold; infomuch that
there was no wood to be fen.

Some even take it to have been one piece of maffe
gold.

The cherubins spread their wings over the propitiatory.
This propitiatory is faid by fome divines to be a type or
figure of Chrift, whom St. Paul calls the propitiatory
ordained from all ages. See Ark of the Covenant.

Propolasm, Proplasma, προπλασμα, is sometimes
used
PROPILIS, πρωπίλις, a thick, yellow, odorous substance, smelling like pseurox, nearly akin to wax, but more tenacious; with which the bees stop up the holes and cran-
ines of their hives, to keep out the cold air, &c.

These wary animals not only stop up in this manner all the cracks they can find, but even examine all the weak places of the hive, and will eat away a rotten or too weak part, and make up the deficiency with this propolis. Hence it derives its name from πρωπίλις, before the city.

This was elegantly seen in the case of some of M. Rea-
mur’s glafs hives, which were framed of wood, and had squares of glafs in their proper places; these squares of glafs were fastened in with slips of palfed paper. The bees finding this a much weaker part of the hive than any other, and capable of being eaten through by their en-
emies, soon gnawed to pieces all the paper and pafs, and covered those parts with the propolis in the place of that matter.

It might seem that the bees might use wax on this occa-
sion; but this would be no defence against those of their enemies, which devour and feed on wax; and nature has guarded them against thefe, by supplying them with a matter which spreads more easily, is of a greater tenacity, and fixes itself much more strongly in the small crevices than wax could do. It has been known from the earliest times, that the bees made use of this substance. Pliny mentions it, and tells us, that the authors of his time dis-
tinguished three kinds of it: the first they called merys, the second pseurox, and the third propolis. The falt of these names is only retained among the later writers, and seems to have fadet with the ancients for the pure substance, the other kinds differing from it only as they were more or less mixed with wax.

The propolis itself is a substance perfectly different from wax; it is found to be soluble in spirit of wine, or in oil of turpentine; and is soft and very extenfible when laid on by the bees, but grows hard afterwards; it may, however, even in its hardfelled state, be foftened by heat, even by that of the fingers, f0 as to acquire the ductility of wax; but more ropy and tenacious. Like wax it may be kneaded between the teeth, without any perceivable tale. In the mafs it is blackish, but femibrilliant when in thin plates. By all these observations it appears very plainly, that propolis is a true genuine vegetable resin, of the nature of many others which we have in common use. The authors who have treated of this substance, have described it very differently; George Pictorus, who has written of bees, fays that it is of a yellow colour, and an agreeable finell, like that of pseurox, and that it would spread when warmed properly. Pliny and the old authors describe it as being of a rank and strong smell, and being used as a succedaneum for gal-
num, and at present we usually find it of an aromatic and agreeable smell, resembling that of melilot, and balsam of Peru, or of the Banana poplar, infomuch that some rank it among the perfumes. The apothecaries, in some places, keep it as a medicine in their shops; but it is to be ob-
ferved, that it is very varifious in its nature; for, according to the defcription of authors, it is sometimes sweet and sometimes flaming. The truth is, that the bees, who col-
lect it as a thing to be used for a cement, not for food, are not over-curious what plants they gather it from; and hence in different hives it is found of very different colours and confiflencies. In general, the propolis is of a brownish-
red colour on the surface; the red sometimes predominating, sometimes the brown; but when broken it is yellowish, or approaching to the colour of wax. It very readily dif-
foles in spirit of wine or oil of turpentine; and this folution is of a fine gold colour, and will serve extremely well as a varnish to colour silvered picture-frames, or other the like work, into the appearance of gold. It gives a fine gold-like appearance, indeed, to any white metal of a polished surface; all that it wants is a little more brilliancy, which is easily given it by mixing a small quantity of malfich, or of fandarach, in the folution.

It is the general opinion of thofe who have studied bees, that the willow and the poplar are the trees which prin-
cipally furnish them with this resin, which, when it has pafed through their management, we call propolis. It is very certain, however, that thofe are not the only trees which afford it, fince the bees are not found to want this necessfary material for their work, in places where there are no trees of that kind in the neighbourhood of the hives.

Mr. Thorley declares, as he tells us likewife upon the fullest evidence, that the combs, both in their foundation and superstructure, are framed of nothing but pure wax. Be-
fides the ufe of the propolis already mentioned, there is an-
other very singular one, which must by no means be pafed over in filence: this is the embalming and preferving, by means of it, certain bodies which they know not how to dif-
pofe of otherwise. Notwithstanding the care that the bees take to guard the entrance of their hives, enemies of one kind or other will often get in: these usually fare very ill; for the bee’s fling is a weapon very capable of punifhing fuch an infufion, and the swarm is fo numerous, that it is not easy for the intruder to escape repeated wounds. When a creature of small fize has thus entered, and thus been killed for it, the bees with great care and pains carry him out; for they will bear no fmall degree of pain in the hive. It sometimes happens, however, that an unlucky fmall, particularly of the large naked kind, crawls into the hive; in this case he never ceases crawling over the combs fo long as he lives. It is no wonder that fuch cleanly creatures as the bees are highly enraged at this naffy visitor; they foon furrond and kill him with their wings; but then as he is a load too heavy to allow a poffibility of their carrying him out, they prevent the mischief attending the finking of the carcafe, by covering it over with a thick coat of this propolis, which perfectly well preferves it from putre-
faction.

The common garden fnail, with the shell, sometimes alfo visits these industrious and cleanly animals; and this creature they fecure in a different manner, and that at the expense only of a very fmall quantity of the propolis; but Reaumur had an opportunity of observing the method of destroying this enemy in a very accurate and easy manner, in one of his glafs hives. The fnail had entered the hive early in the morning, and after crawling about for fome time, had fixed itself to one of the glafs squares by the fame glutinous matter, by means of which it is frequently found fixed to old walls and trees; when the bees found their enemy thus fixed, they furronded him, and in a few minutes formed a border of propolis round the verge of the mouth of the shell: to this they continually added more and more, till they had formed a thick coat round it, that the fnail could never move from the place again.

The fnail is easily able to loosen the fetting with which it gives itself to any place, becaufe this is done by means of a gum, which water will difolve; therefore the firft shower of rain, or the moisture which the animal is able
to secrete from its own body, release it in this case; but the thinning which the bees use to fix the shell to the glass being a resin, this remains untouched by water, and must keep the animal fixed in its place till death, and even long afterwards. Reaumur’s Hist. Inf. vol. x. p. 77, &c.

Mr. Thorley observes, that he has frequently seen snails, within the boxes and at the back-window, moving about, changing their situation, and continuing at times for several days together, but not so much as a single bee afflicting the offensive animal, or offering the least reibilitance, but, on the contrary, humming or flying from him. He adds, that he has often observed snails coming out of the colonies, in no respect hurt or wounded, but in full health and vigour. Thorley’s Enquiry, &c. p. 136.

It seems probable, that the bees are not over-curious in the choice of the matter of the propolis; but that many vegetable resins indifferently serve for this purpose: it has been tried, however, whether they would use common turpentine, and some other of the resins in use among us by laying them before their hives; but without success. This is an experiment, however, that requires frequent repetition, since there are many feaons at which the bee has no occasion for this matter.

The propolis is by some esteemed sovereign in diseases of the nerves. It is also used to make holes in abbeilles; and being heated on the fire, its vapour is received for invertebrate coughs.

M. Vaquelin has analysed this substance. For this purpose 100 grammes of it were digested, for twenty-four hours, in very pure alcohol. The liquor acquired a deep red tint; and was thus filtered. Fresh spirit of wine was put to the residue, and left to digest again in the cold during twenty-four hours. As it had gained but little colour, a third quantity of alcohol was added to the marc, then boiled for a few minutes: and filtered quite hot. Six portions of alcohol were successively added to the marc and boiled: finally, to deprive it of the fat matters it retained from fragments of bees, as well as some vegetable substances and grains of sand, boiling sulphuric ether was poured on it, and the mass was pressed through a fine strainer. The residue dried, weighed 14 grammes.

To obtain the substance which had been dissolved by the alcohol, the whole quantity that had been employed in the different washings was collected, and passed through a fine strainer, which stopped all the matter precipitated by the cold. This residue was wrapped in unsized paper and pressed, when dried and melted, it weighed 14 grammes.

All the alcohol was then distilled and reduced to three-fourths of its quantity. The liquor which came over had an aromatic odour; but it did not render water turbid, nor was it acid. What remained in the retort was a deeper colour. Its precipitate by water wasropy, like the resins which are obtained by the same means. By diluting this liquor with water and boiling it, a resiform mass was obtained, on cooling, of a red-brown colour, semi-transparent, and very brittle, which weighed 57 grammes. The water in which this matter had been dissolved, contained an acid.

This resiform mass, or pure propolis, melts readily on the fire: it yields by distillation a volatile oil, white and of a very agreeable smell. The fixed part then acquires a deeper colour, and becomes firmer: it is soluble in fixed and volatile oils. It is a true resin, very similar to balsam of Peru, of which it contains the acid.

The 14 grammes of precipitate produced by cooling, were true wax, poffessing all its properties. It remains to be known whether this wax is actually mixed with the propolis by the bees; or whether, in collecting the latter with too little care, the wax is not united to the resin.

PROPOMA, a name given by the ancients to a potion prepared of honey and wine boiled together: the proportions were four parts of wine to one of honey.

PROPORTION, Proportio, in Arithmetic, the identity or similitude of two ratios.

Hence quantities that have the same ratio between them, are said to be proportional: e.g. if A be to B, as C to D; or E be to F, as G to H; and A to B is equal to C to D, or E to F, to G to H, are said to be in proportion, or are simply called proportionals.

Proportion is frequently confounded with ratio; yet the two have, in reality, very different ideas, which ought by all means to be distinguished.

Ratio is properly, that relation or habitude of two things, which determines the quantity of one from the quantity of another, without the intervention of any third; thus we say, the ratio of 5 and 10 is 2; the ratio of 12 and 24 is 2.

Proportion is the sameness or likeness of two such relations; thus the relations between 5 and 10, and 12 and 24, being the same, or equal, the four terms are said to be in proportion. Hence ratio exsists between two numbers; but proportion requires at least three.

Proportion, in fine, is the habit or relation of two ratios, when compared together; as ratio is of two quantities. See RATIO.

Proportion again is frequently confounded with progression. In effect, the two often coincide: the difference between them only consists in this, that progression is a particular species of proportion; in which the second of the three terms is a mean proportional between the other two, or has the same ratio to the third, which the first has to the second.

Add to this, that proportion is confined to three terms, but progression goes on to infinity (to that progression is a series or continuation of proportions); and that in four terms, 3, 6, 12, 24, proportion is only between the two couples 3 and 6, and 12 and 24, but the progression is between all the four terms. See PROGRESSION.

Proportion, as Dr. Clarke has shown in his correspondence with Leibnitz (see his "Works," vol. iv. p. 681, fol.), is sometimes confounded with quantity. Proportions, he says, are not quantities, but the proportions of quantities. If they were quantities, they would be the quantities of quantities, which is absurd. Also, if they were quantities, they would (like all other quantities) increase always by addition; but the addition of the proportion of 1 to 1, to the proportion of 1 to 1, makes still no more than the proportion of 1 to 1; and the addition of the proportion of 1 to 1, to the proportion of 1 to 1, does not make the proportion of 1 to 1, but the proportion only of 1 to 1. That which mathematicians sometimes inaccurately call the quantity of proportion is (accurately and strictly speaking) only the quantity of the relative or comparative magnitude of one thing with regard to another; and proportion is not the comparative magnitude itself, but the comparison of ratio of the magnitude to another. The proportion of 6 to 3 is 2. Proportion of 6 to 3 is 2.
to 1, with regard to that of 3 to 1, is not a double quantity of proportion, but the proportion of a double quantity, and in general, what they call "bearing a greater or less proportion", is not bearing a greater or less quantity of proportion or relation," but "bearing the proportion or relation of a greater or less quantity to another:" it is not a greater or less quantity of comparison, but the comparison of a greater or less quantity. Thus, also, the logarithmic expression of a proportion is not (as Leibnitz, &c.) a measure, but only an artificial index or sign of proportion; it is not the expressing of a quantity of proportion, but barely a denoting of the number of times that any proportion is repeated or complicated. The logarithm of the proportion of equality is 0; and yet it is as real and as much a proportion, as any other; and when the logarithm is negative, as −1, yet the proportion of which it is the sign or index, is itself affirmative. Duplicate or triplicate proportion does not denote a double or triple quantity of proportion, but the number of times that the proportion is repeated. The tripling of any magnitude or quantity once produces a magnitude or quantity, which to the former bears the proportion of 3 to 1. The tripling it a second time produces (not a double quantity of proportion, but) a magnitude or quantity, which to the former bears the proportion (called duplicate) of 9 to 1. The tripling it a third time produces (not a triple quantity of proportion, but) a magnitude or quantity, which to the former bears the proportion (called triplicate) of 27 to 1, &c.

Propotion is said to be continual, when the consequent of the first ratio is the same with the antecedent of the second; as, if 3 be to 6, as 6 to 12. The proportion is said to be discrete, or interrupted, when the consequent of the first ratio differs from the antecedent of the second; as, if 3 be to 6, as 4 to 8.

Propotion, again, is either said to be arithmetical, or geometrical; as the ratios are.

Proportion, Arithmetical, is the equality of two or more arithmetical ratios, or the equality of difference between three or more separate quantities.

Thus, 1, 2, 3, and 2, 5, 8, 11, 14, are in arithmetical proportion; because there is the same difference between the numbers compared, which are 1 to 2, and 2 to 3; or 2 to 5, and 5 to 8, &c.

If every term have the same ratio to the next, as the first has to the second, the terms are said to be in continual arithmetical proportion; as 5, 7, 9, 11, 13, 15.

If the ratio between any two terms differs from that of any others, the terms are said to be in arithmetical proportion discrete, or interrupted; as where 2 : 5 :: 6 : 9, the ratios of 5 and 6 being different from that of 2 and 5.

A series of more than four terms in arithmetical proportion forms an arithmetical progression; which fee.

1. If three numbers be in arithmetical proportion, the sum of the extremes is equal to double the middle term; thus, in 3, 7, 11, the sum of 3 and 11 is equal to twice 7, viz. 14.

Hence we have a rule for finding a mean arithmetical proportional between two given numbers; half the sum of the two being the mean required; thus, half the sum of 11 and 3, viz. 14, is 7.

2. If four numbers be in arithmetical proportion, the sum of the extremes is equal to the sum of the middle terms; thus, in 2 : 3 :: 4 : 5, the sum of 5 and 2 is equal to the sum of 3 and 4, viz. 7.

Hence, four terms in arithmetical proportion are all proportional, if taken inverely, 5 : 4 : 3 : 2; or alternately, thus, 2 : 4 : 3 : 5; or inversely and alternately, thus 5 : 3 :: 4 : 2.

3. If two numbers in arithmetical proportion be added to other two, the lesser to the lesser, &e. their difference is in a duplicate ratio, i.e. double that of the respective parts added; thus, if to 3 : 5 be added 7 : 9, the terms are 10 : 14; whole difference 4, is double the difference of 3 : 5, or 7 : 9. And if to this sum you add other two, the difference of the last sum will be triple the sum of the first two, and so on.

If two arithmetical proportionals be subtracted from two others in the same ratio, the less from the less, &c., the arithmetical ratio of the remainder is 0. Thus, from 9 : 7 taking 5 : 3, the remainders are 4, 4.

Hence, if arithmetical proportionals be multiplied by the same number, the difference of their products will contain the first difference as often as the multiplier contains unity; thus, 3 : 5, multiplied by 4, produce 12, 20, whose difference 8, is equal to 4 times 2, the difference of 3 and 5.

4. If two numbers in arithmetical proportion be added to other two in another ratio of the same kind, less by less, &c.; the sums are in a ratio which is the sum of the ratios added or multiplied; thus 2 : 4 and 3 : 9 being added, the sums are 5 : 13, whose difference 8, is the sum of 2 and 6, the difference of the numbers given.

Proportion, Geometrical, is the equality of two geometrical ratios, or comparisons of two couples of quantities.

Thus 4 : 8 :: 12 : 24; are in geometrical proportion; the ratio of 4 and 8 being equal to that of 12 and 24; i.e. 4 is contained as often in 8 as 12 is in 24. Again, 9, 3, 1, are in geometrical proportion; 9 being triple of 3, as 3 is of 1.

If, in a series of terms, there be the same ratio between every two terms, that there is between the first and second, they are said to be continual geometrical proportionals; as 1 : 2 :: 4 : 8.

If any two terms have a different ratio from that of the first and second, they are said to be in a disjunct, or interrupted geometrical proportion; as are 2 : 4 :: 3 : 6; where 2 is to 4, as 3 to 6; but not so as 4 to 3.

A series of progression of more than four geometrical proportionals is called a geometrical progression; which fee.

1. If three quantities be in continual geometrical proportion, the product of the two extremes is equal to the square of the middle term; thus, in 6 : 12 :: 12 : 24, the product of 6 and 24 is equal to the square of 12, viz. 144. Hence we have a rule,

2. To find a mean geometrical proportional between two numbers, &c. gr. 8 and 72.

Multiply one of the numbers by the other, and from the product 576, extract the square root 24; this will be the mean required.

3. To find a fourth proportional to three given numbers, &c. gr. 3, 12, 5; or a third proportional to two given numbers.

Multiply the second 12 into the third 5, in the first cæs; and in the latter multiply the second into itself; divide the product by the first 3, the quotient 20 is the fourth proportional sought in the one, or the third in the other.

The solution of this problem is what we popularly call the rule of proportion, or the golden rule, or the rule of three.

4. If four numbers be in geometrical progression, the product of the extremes is equal to the product of the two middle terms; thus, in 2 : 5 :: 4 : 10, the product of 10 and 2 is equal to that of 5 and 4; viz. 20. Hence,

5. If four numbers represented by a : b : c : d, be either
in arithmetical or geometrical proportion; they will also be in the same, if taken inversely, viz. \( d : e :: b : a \); or alternately, as \( a : c :: b : d \); or alternately and inversely, as \( d : b :: c : a \).

6. If the two terms of a geometrical ratio be added to, or subtracted from other two in the same ratio, the les to or from the les, &c. the sums or differences are in the same ratio: thus in 6 : 3 :: 10 : 5, where the common ratio is 2, 6, added to 10, makes 16, as 3 to 5 makes 8; and 16 : 8 is in the same ratio as 6 : 3, or 10 : 5. Again, if 16 be to 8 as 6 to 3, their differences 10 and 5 are in the same ratio.

The reverse of which proposition is likewise true; viz. if to or from any two numbers be added or subtracted other two, if their sums or differences be in the same geometrical ratio as the first two, the numbers added or subtracted are in the same ratio. Hence.

7. If the antecedents, or the consequents, of two equal geometrical ratios, 3 : 6, and 12 : 24, be divided by the same 3; in the former cafe, the quotients 1 and 4 will have the same ratio to the consequents, viz. 1 : 6 :: 4 : 24; and in the latter, the antecedents will have the same ratio to the quotients, viz. 3 : 1 :: 12 : 4.

8. If the antecedents or consequents of similar ratios, 2 : 6, and 3 : 9, be multiplied by the same quantity 6; in the former case, the factors 12 and 18 have the same ratio to the consequents, viz. \( 12 : 6 :: 18 : 9 \); and in the latter, the antecedents have the same ratio to the products, viz. \( 2 : 36 :: 3 : 54 \).

9. If in a geometrical proportion 3 : 6 :: 12 : 24, the antecedents be multiplied or divided by the same number 2, and the consequents be multiplied or divided by the same number 3; in the former case, the factors 12 and 18 have the same ratio to the consequents, viz. \( 12 : 6 :: 18 : 9 \); and in the latter, the quotients will be the same ratio to the products, viz. \( 6 : 18 :: 24 : 72 \), and 1 : 3 :: 4 : 12.

10. If in a proportion 4 : 2 :: 10 : 5, the antecedent of the first ratio be to its consequent, as the antecedent of the second to its consequent; then by composition, as the sum of the antecedent and consequent of the first ratio is to the antecedent or consequent of the first, so is the sum of the antecedent and consequent of the second to the antecedent or consequent of the second; viz. \( 6 : 2 :: 15 : 5 \), or \( 6 : 5 :: 10 \).

11. If in a proportion 6 : 4 :: 15 : 10, as the antecedent of the first ratio is to its consequent, so is the antecedent of the other to its consequent; then, by division, as the difference of the terms of the first ratio is to its antecedent or consequent, so is the difference of the terms of the second ratio to its antecedent or consequent, viz. \( 2 : 4 :: 5 : 10 \), or \( 2 : 6 :: 5 : 15 \).

12. If in a proportion 4 : 2 :: 6 : 3, as the antecedent of the first ratio is to its consequent, so is the antecedent of the second to its consequent; and as the consequent of the first ratio is to another number 8, so is the consequent of the second to another number 12; viz. \( 2 : 8 :: 3 : 12 \); then will the antecedent of the first be to 8, as the antecedent of the second to 12, viz. \( 4 : 8 :: 6 : 12 \).

13. If in a proportion 8 : 4 :: 12 : 6, as the antecedent of the first ratio is to its consequent, so is the antecedent of the second to its consequent; and as the consequent of the first ratio is to another number 16, so is another number 3 to the consequent of the second, viz. \( 4 : 16 :: 3 : 12 \); then will the antecedent of the second be to 16, as 3 to the consequent of the second, viz. \( 8 : 16 :: 3 : 6 \).

14. Suppose any four proportional quantities, viz. \( 3 : 6 :: 12 : 24 \); and any other four proportional quantities, \( 1 : 3 :: 9 : 27 \); if you multiply the several terms of the latter into those of the former, the products will likewise be proportional, viz. \( 3 : 18 :: 108 : 648 \).

15. If there be several quantities continually proportional, A, B, C, D, &c. the first A is to the third C, in a duplicate ratio; to the fourth D, in a triplicate ratio, &c. of the first A to the second B.

16. If there be three numbers in continual proportion, the difference of the first and second will be a mean proportional between the difference of the first and second term, and the difference of the second and third, and the first term.

Proportion, in Music, equality between two ratios. There are four kinds of proportion: arithmetical, geometrical, harmonical, and contra-harmonical. In order to comprehend all these proportions, it is necessary to understand the calculations with which authors have loaded the theory of music.

Proportion, Harmonical or Musical, is a third kind of proportion formed out of the other two, thus: of three numbers, if the first be to the third as the difference of the first and second to the difference of the second and third; the three numbers are in harmonical proportion.

Thus 2, 3, 6, are harmonical, because \( 2 : 6 :: 1 : 3 \). So also four numbers are harmonical, when the first is to the fourth as the difference of the first and second to the difference of the third and fourth.

Thus \( 24, 16, 12, 9 \), are harmonical, because \( 24 : 9 :: 8 : 3 \). By continuing the proportional terms in the first case, there arises an harmonical proportion, or series.

1. If three or four numbers in harmonical proportion be multiplied or divided by the same number, the products or quotients will also be in harmonical proportion; thus, if \( 6, 8, 12 \), which are harmonical, be divided by 2, the quotients \( 3, 4, 6 \), are also harmonical; and reciprocally their products by 2, viz. \( 6, 8, 12 \).

2. To find an harmonical mean between two numbers given; divide double the product of the two numbers by their sum, the quotient is the mean required; thus suppose 3 and 6 the extremes, the product of these is 18, which doubled, gives 36; this divided by 9 (the sum of 3 and 6), gives the quotient 4. Whence \( 3, 4, 6 \), are harmonical.

3. To find a third harmonical proportional to two numbers given.

Call one of them the first term, and the other the second; multiply them together, and divide the product by the number remaining after the second is subtracted from double the first; the quotient is a third harmonical proportional; thus, supposing the given terms \( 3, 4 \), their product 12 divided by 2 (the remainder after 4 is taken from 6, the double of the first), the quotient is 6, the harmonical third sought.

4. To find a fourth harmonical proportional to three terms given: multiply the first into the third, and divide the product by the number remaining after the second is subtracted from double the first; the quotient is a third harmonical proportional; thus supposing the given terms \( 9, 12, 16 \), a fourth will be found by the rule to be \( 24 \).

5. If there be four numbers disposed in order, of which one extreme and the two middle terms are in arithmetical proportion; and the same middle terms, with the other extreme, are in harmonical proportion, the four are in geometrical proportion: as here, \( 2 : 3 :: 4 : 6 \); which are geometrical; of which, \( 2, 3, 4 \), are arithmetical, and \( 3, 4, 6 \), harmonical.

6. If between any two numbers you put an arithmetical mean, and also an harmonical one, the fourth will be in geometrical proportion: thus, between 2 and 6, an arithmetical mean

\[ 4 \]
mean is 4, and an harmonical one 3; and the four 2:3:4:6, are geometrical.

We have this notable difference between the three kinds of proportion; that from any given number we can raise a continued arithmetical series increasing in infinitum, but not decreasing; the harmonical is decreasable in infinitum, but not increasable; the geometrical is both.

**Proportion, Centra-harmonical.** See CONTRA-HARMONICAL.

**Proportion, Extreme and Mean.** See EXTREME.

**Proportion, Inordinate.** See INORDINATE.

**Proportion, Reciprocal.** See RECIPROCAL.

**Proportion, Of Equality.** See EQUALITY.

**Proportion, Composition of.** See COMPOSITION.

**Proportion, Rule of.** See RULE.

**Proportion, Terms of.** See TERM.

Proportion is also used for the relation between unequal things of the same kind, by which their several parts correspond to each other with an equal augmentation, or diminution.

Thus, in reducing a figure into little, or enlarging it, care is taken to observe an equal diminution, or enlargement, through all its parts; so that if one line, e. g. be contracted by one-third of its length, all the rest shall be contracted in the same proportion.

The making of reductions of this kind is the great use of the proportional compasses.

**Proportion, in Law.** See PRO RATA and ONE-RANDA.

**Proportion, in Architecture.** denotes the just magnitude of the members of each part of a building, and the relation of the several parts to the whole; e. g. of the dimensions of a column, &c. with regard to the ordonnance of the whole building.

One of the greatest differences among architects, M. Perrault observes, is in the proportions of the heights of entablatures with respect to the thickness of the columns, to which they are always to be accommodated. See ENTABLATURE.

In effect, there is scarcely any work, either of the ancients or moderns, in which this proportion is not different; some entablatures are even nearly twice as high as others; yet it is certain, this proportion ought of all others to be most regulated: none being of greater importance, as there is none in which a defect is sooner spied, nor any in which it is more feebling.

Proportion is likewise understood of the magnitudes of the members of architecture, flats, or the like, with regard to the distance whence they are to be viewed.

The most celebrated architects are much divided in their opinions on this subject; some will have it, that the parts ought to be enlarged in proportion to their elevation; and others, that they ought to remain in their natural dimensions. See STATUE.

**Proportion, in Painting, is the just magnitude of the several members of a figure, a group, &c. with regard to one another, to the whole figure, the group, and the entire piece.**

Proportion makes one of the most important articles in the art of painting, the principal subject it is employed in being the human body: for which reason, the curious in that art will not be displeased with the following scheme of the rules and laws of it.

By the way let it be observed, 1. That to measure and set off proportions, they either divide the module into twelve parts, and subdivide each of these into four; or else they divide the face into three lengths of the nose, subdividing each length into twelve; or, lastly, divide the whole face into three, and subdivide each of those into four; which last method is what we shall here follow.

2. That the multiplicity of little measures is to be judiciously avoided, because they confound, and because they require great skill in architecture to hit justly.

3. That in measuring there be a regard had to the relief or juttings out of figures.

**Proportion, Rules of.** In the proportions of the human figure, regard is had to the age, sex, and quality. See FACE.

As to age, we consider the stages of it, infancy, youth, and manhood. For the first, at three years of age, we count five lengths of the face from top to toe; viz. from the tip of the head to the bottom of the belly, three; thence to the foot, two; breadth about the shoulders, one face one-eighth; and in the place of the hips, one face.

At four years, the height is six faces one-third; viz. from the top of the head to the bottom of the belly, three faces one-third; thence to the sole of the foot, three faces; the breadth about the shoulders, one face two-thirds; about the haunches, one face one-third.

At five years, the height of six faces one-half, one-third abated, the lower being shorter.

In youth, at twelve years, we have two proportions; the one from nature, which gives nine faces for the height; for the breadth about the shoulders, two faces; about the haunches, one face one-third; the other from the antique statues, as that of Laocoon, &c. which gives the height, ten faces one-half; the breadth from one shoulder to another, one face two-thirds; at the haunches one face two-thirds; at the place of the muscle called _opus externus_, two; at the thigh, one; the knee, two-thirds and one-half, a subdivision; and at the ankles, one-third.

In the state of manhood, when the proportions are arrived at perfection, we reckon the height ten faces; the first, from the top of the head to the navel; the second, to the hole in the neck between the clavicles; the third, to the pit of the stomack, called carpilago card'iiformis; the fourth, to the navel; the fifth, to the pyramidal muscles; thence to the knee, two faces two-thirds; and as much to the sole of the foot. The extent of the arms is the fame with the height; viz. from the tip of the long finger to the joint of the writh, one face; thence to the elbow, one face one-third; thence to the juncture of the shoulders, one face one-third; thence to the hole in the neck, one face one-third; in all, five heads; which, with the fifth of the other arm, give ten; the thicken of the arms to be adjusted by the quality or character.

As to the breadth of the figure seen frontwise, the width of the shoulders across the deltoides is two faces two-thirds; breadth of the pectoral muscles, to the juncture of the arm, two. About the haunches, where the oblique externi are, one face two-thirds, and the subdivisions. The thighs, at the biggest place, one. The knee one-third, three subdivisions one-half. The leg, at the thickest, two-thirds, and one subdivision. The extreme of the ankle one-third, one subdivision one-half. The feet, one-third, and one-half a subdivision. Their length, one face one-third, one subdivision. Others, measuring by the length of the whole head, make only eight heads in height and breadth, thus: the head, one; thence to the bottom of the breasts, one; thence to the navel, one; thence to the yard, one; thence to the middle of the thigh, one; thence to the lower part of the knee, one; thence to the small of the leg, one; thence to the bottom of the foot, one.

The breadth thus: from the end of the long finger to the writh,
In the rule of proportions, it is to be observed, that there is a difference in the contours of some parts, when put in different postures: thus, when the arm is bent, it is larger than when straight; and the same is true of the foot and knee, as is shown by Leonardo da Vinci.

Proportion, Rule of, in Arithmetic, a rule whereby we find a fourth proportional to three numbers given.

This is popularly called the golden rule, and sometimes the rule of three.

Proportion, Compsof, a name by which the French, and after them some English authors, call the secon. See its construction and use under the article Sector.

Proportions, Definite, in Chemistry, the limited proportions in which the elementary bodies combine, to form compound bodies.

When the constituents of any compound are presented to each other under the most favourable circumstances, they are found to unite in certain definite proportions. If one of the elementary bodies be in exceso, the proportions of the compound will not be varied, except by some definite quantity. The excess will always be found dilute from the compound. When metallic zinc is added to sulphuric acid and water, the oxyd of zinc, formed at the expense of the water, continues to be dissolved by the acid to a certain point, beyond which no more of the metal will be dissolved, whatever quantity may be present. If to a given quantity of nitric or muriatic acid, lime be added from time to time, the lime will be dissolved in the acid, forming a transparent solution. This, however, can go on only to a limited extent. Beyond this point, if more lime be added, it will fall to the bottom of the vessel, and will not be changed. If oxygen and hydrogen gases be mixed in any other proportions by volume, than one of the former to two of the latter, and exploded by the electric spark, the excess of the one will remain unchanged in its gaseous form. Numerous examples might be quoted to shew the truth of this law of mutual saturation, while very few, if any, can be adduced to prove the contrary. This law is found to be more conspicuous where the strength of chemical affinity is great, as in the oxidaion of metals, and the formation of salts.

It is rather remarkable, that chemists, with so many facts before their eyes, have frequently adopted a loose language, completely at variance with all these facts. We often read in chemical books, of salts having slight exceso of acid or base, and of metals oxysated by slight degrees; at the same time that they were aware, agreeably to the general opinion, that each of the salts afforded an uniform analysis, under whatever circumstances they were formed, and that each of the metals had a determined number of oxys, in each of which the doxes of oxygen were uniform.

No one seems to have investigated this important branch of chemical science, till the cause of limited proportions began to be sought for. We may with great truth affirm, that twenty years ago no chemist had an idea that the proportions of compound bodies would ever be obtained with more accuracy than is afforded by analysis. We may fee, that Bergman and Black were aware that bodies combined in limited doxes or proportions. Richter adopted numbers to express the quantities of each of the acids to saturate a given quantity of base. Mr. Higgins of Dublin, in a work entitled "A Treatise on Phlogiston," makes use of the language of atoms, or particles, in a way that proved he had a clear idea of the laws of definite proportions, but not to a greater extent than was known to Bergman and Black. So little had he any idea of its real importance, that he does not even dwell in particular upon it; so that nothing more is

known
known of his opinions, than what is gathered from the language used to shew the incoherence of the phlogistic theory. In some parts of his work he adopts a language very discordant with the laws of limited proportions, so much so, that if it had been found that bodies unite in any proportion, Mr. Higgins might have had an equal claim to prior discovery. 

What had hitherto been done in the theory of definite proportions, did not admit of being used to any advantage in chemical science. Mr. John Dalton of Manchester was the first who gave it a systematic form. Richter, although he found that the relative quantities of the acids to saturate a given quantity of base might be expressed by numbers, did not seem to be aware, that all bodies divisible of combination might be expressed by numbers, which would determine the ratios of the component parts. This theory, which has been strongly confirmed by facts, is as important in chemical science, as a knowledge of the laws of motion is to mechanical science.

It is worthy of remark, that many of our modern discoveries have been anticipated by the comprehensive mind of Sir Isaac Newton. In the latter part of the 3rd query to his Optics, at a time when so little was known of chemistry, he not only points out and develops the laws of chemical affinity, but he lays the foundation of the theory since discovered by Dalton, and to a certain extent embraced by the most eminent chemists of the present day. The passage is so remarkable, that we feel justified in giving a quotation of the most striking part.

After speaking of the laws of chemical attraction, he proceeds as follows (page 375.): "All these things being considered, it seems probable to me, that God in the beginning formed matter in solid, malleable, hard, impenetrable, moveable particles, of fixed sizes and figures, and with such other properties, and in such proportion to space, as might conduct to the end for which he formed them; and these primitive particles being solids, are incomparably harder than any porous bodies composed of them; even so very hard as never to wear or break in pieces: no ordinary power being able to divide what God himself made in the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away or break in pieces, the nature of things depending upon them would be changed. Water and earth composed of old worn-out particles, and fragments of particles, would not be of the same nature and texture now with water and earth composed of entire particles in the beginning. And, therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations and motions of these permanent particles, compound bodies being apt to break, not in the midst of solid particles, but where the particles are laid together, and only touch in a few points."

Although Sir Isaac Newton, with mathematicians in general, might conceive the infinite divisibility of matter, he seems to have been well aware, that in nature its divisibility is limited to the hard and impenetrable atoms to which he alludes in the above quotation. The idea of atoms which are hard and unchangeable appears very plausible, even in the aggregation of a mass of simple matter. We cannot well account for the change of volume from change of temperature, without supposing the body to be conjoined of atoms or particles, placed at different distances from each other, by the change of force existing in them, which is always the difference between the attraction of the atoms, and the repulsion of the caloric with which they are surrounded. How much more, however, the existence of definite atoms appears probable in the contemplation of a compound body. Nothing is more evident, than that the composition must commence with mallees of the elementary matter of some magnitude. If their magnitude were to vary under different circumstances, and to any extent arising from the infinite divisibility of matter, there would not only arise an infinite number of compounds of the same elements, from a variety in their proportions, but we should find compound bodies to vary even with the same proportion of their elements, owing to a different size in the integral particles. We find, however, in nature, that the proportions of bodies are definite, and we have no instance of compound bodies being different in their properties, when they afford the same analysis. Hence we have strong grounds to conclude with the great luminary of science, that matter is not infinitely divisible, and that all simple bodies consist of small mallees, which are called atoms, beyond which divisibility is impracticable, and that in the composition of simple matter the union takes place between these primitive atoms only, and not between any other mallees greater or less than them.

Mr. John Dalton, whose industry and patience can only be equalled by his ingenuity and profound thinking, began with the idea of primitive atoms, which combined with each other to form the different compounds. He supposes the simple atoms to be spherical, and that they can only combine to form atomic 1 to 1, 1 to 2, 1 to 3, and so on; the number of atoms of one element being some multiple by a whole number of the atoms of the other: so that it would be absurd to suppose that an atom can be divided, or that 2 can unite with 3, 3 with 4, and so on. It is from this impossibility that the proportions of bodies are limited. We will endeavour to illustrate this theory by several examples. Hydrogen is found to enter into compounds in less proportion than any known element; hence it is concluded to be the least of all the atoms of the known simple matter. On this account Mr. Dalton has fixed its weight at 1, or unit. If, in the composition of water, which appears to be the only compound of oxygen and hydrogen, we call the hydrogen 1, we must call the oxygen 7. The latter is therefore used to express the relative weight of the atom of oxygen. In the analysis of the first oxide of lead it is found to consist of 95 of lead, and 7 of oxygen, in 102 parts. It may be inferred that the relative weight of the atom of lead is 95, or 95 times heavier than hydrogen. Again, if galena, or the sulphuret of lead, which contains the least proportion of sulphur, afford on the analysis of 109 parts, 95 of lead, and 14 of sulphur, it is inferred that the atom of sulphur is 14 times heavier than hydrogen, and 14 will be therefore the number to represent the weight of an atom of sulphur. In burning carbon in oxygen gas, the bulk of the gas is not changed, but its specific gravity is increased from 14 to 19.4. This proves that the carbon, added to 14 of oxygen, to form carbonic acid, is 54. Hence the weight of the atom of carbon is rated by Mr. Dalton at 54. In like manner, the relative weights of the atoms of the other inflammable bodies may be found, knowing the quantity of oxygen with which they combine, and whether the oxy whole contains the least proportion of oxygen. If the oxide be the first oxide, and the oxygen 7, the weight of the inflammable base will be the number for its atom. If it be in the second stage of oxidation, then call the oxygen 14, and the weight of the inflammable base reduced to the same ratio will be the weight of the atom of the same. Of this we shall say more
P R O P O R T I O N S.

more hereafter. We will now point out the inferences to be drawn from the above facts, which will at once develope the beauty and importance of the atomic theory, as laid down by Mr. Dalton. The numbers being found for hydrogen 1, oxygen 7, sulphur 14, lead 95, and carbon 5.44; it will follow, that the proportions in which oxygen and hydrogen unite to form water, are 7 to 1. Lead and oxygen, to form the protoxyd of lead, will be 95 to 7; to form the deutoxyd of lead, 95 to 2 x 7. This will be obvious, since nothing less than a whole atom of oxygen, which is 7, can combine with an atom of lead; and hence the limitation of the proportions. We shall also see that lead cannot combine with sulphur, except in the proportions 95 to 14, 95 to 2 x 14, and so on, since no less than 14 of sulphur can be added or combined with the lead. Carbonic oxyd contains the least proportion of oxygen, and since the atom of carbon, if oxygen be called 7, must be called 5.4, we are to conclude that no less than 7 of oxygen can combine with 5.4 of carbon: this forms the carbonic oxyd. The next portion of oxygen must be 7 more, which will give 5.4 to 2 x 7. This gives the carbonic acid. All this was well known to chemists before the researches of Dalton, but he was the first to point out the means by which the composition of other compounds may be inferred, without the aid of experiment. The compounds we have just given are the results of experiment as regarding the least proportion, but the atomic theory will enable us to go farther. We have, in the above, for instance, no experimental data for the combinations of sulphur with oxygen, hydrogen, or carbon, nor for carbon with hydrogen. But it will be found that the numbers given will express the ratios of these compounds as correctly as those derived from experiment.

For instance; sulphur, when combined with oxygen in the least proportion, will be 14 to 7; the next stage will be 14 to 2 x 7, forming pyrosulphurous acid; the third, 14 to 3 + 7, which gives sulphuric acid. Sulphur, with hydrogen in the least proportion, will be 14 of sulphur to 1 of hydrogen, forming sulphuret of hydrogen. The compounds of carbon with sulphur will be 5.4 carbon to 14 of sulphur, the first compound; and 5.4 to 2 x 14, for the second; the latter gives the component parts of the volatile liquid, formerly called alcohol of sulphur, and now properly called superfulphuret of carbon.

It will appear from the above statement, that if by analogy we can obtain a number for each of the elementary bodies, which is only a distant approximation to the truth, these numbers will become corrected by trying them with all their different combinations, till they finally agree among themselves. This will fix the science of chemistry upon a mathematical basis. Experiment, which in chemistry was till lately considered the only test of truth, will be now considered as a rude approximation, minute accuracy depending upon calculation.

It will be obvious, that the number which will express the weights of the atoms of the compound bodies, will be equal to the sum of the weights of the elementary atoms. For instance, the weight of the atom of sulphuric acid will be 14 sulphur, added to 3 x 7 oxygen, equal to 35. In the same way, the weight of the atom of oxyd of lead will be 95 added to 7 = 102. The sulphate of lead will now be formed by 35 of sulphuric acid, added to 102 of oxyd of lead, equal to 137, which is the weight of the atom of this salt.

In order to give greater clearness to this theory, Mr. Dalton has used symbols to represent the elementary atoms, which he combines together to make compound symbols representing the compounds. The general character is a circle. The atoms are distinguished from each other by signs or letters placed within them. This method gives a much clearer idea of the constitution of bodies than can be conveyed by any language, particularly to those commencing the study of chemistry. Mr. Dalton's reason for using the circle as his general character is, from its near analogy to spherical particles of simple bodies. This idea holds good with binary and ternary compounds only; the quaternary compound being a tetrahedron, cannot be written upon paper, except by particular representation. In the representation of a salt, the symbol could not at all represent the form of the geometric solid which would be formed in nature, and therefore might as well be represented by some symbol in which the elementary symbols are more simple. For this purpose we would recommend, as the general character, the half of a square divided diagonally. The bodies are distinguished by figures within the half square of the inflammable bodies, that for oxygen being blank. If it should be confirmed that there are other bodies of the same class with oxygen, as is supposed by Sir Humphry Davy, they may be represented by placing letters in the half square.

The atomic theory, as advanced by Dalton, was for some years treated almost with ridicule. Some agreed with him so far as it admitted the doctrine of definite proportions, but did not hold with him in the atomic hypothesis, as regarded his numbers being the ratios in which the elements existed in any compound, although it completely explained the well-known fact of the neutrality of two salts, after mutual or double decomposition. Among his strenuous opponents, Sir Humphry Davy was not the least conspicuous. Previous, however, to writing his "Elements of Chemical Philosopy," he became a warm advocate for the doctrine of definite proportions, and adopted a set of numbers to express the relative proportions in which simple bodies combine.

What, however, is very strange, he denied the existence of definite atoms, or at least appeared to do so in some remarks which occur in his work. Yet he admits, that masses of some magnitude unite to form compounds, to which he gives the appellation of proportions. He uses this word precisely in the same sense in which Dalton uses the word atom, and if he had not particularly objected to this part of Dalton's theory, we should have thought he had entirely adopted it.

What does Sir Humphry mean by the word proportion, different from the idea conveyed by atom? Does he suppose that masses of different magnitudes, of the same simple matter, may unite to form a compound? This cannot be the case, since such data would establish the idea of an infinite number of compounds varying in their proportions, and an infinite number varying in their mechanical structure, from a difference in the magnitudes of the ultimate elementary masses. The idea of definite proportions cannot for a moment exist, without the admission of the fact, that compounds are never formed but by the union of atoms, which are unchangeable in their figure, weight, and dimensions. Nothing, therefore, can be more absurd, than to admit the doctrine of definite proportions, without admitting the existence of definite atoms.

The numbers of Sir Humphry's proportions agree with Dalton's in a few instances only. They each make hydrogen unity. Sir Humphry, for reasons bel known to himself, has doubled the weight of Dalton's oxygen, making it 15; and in order to make this agree with the combination of oxygen, he has nearly doubled the weights of the inflammable bodies. In order to make this arrangement explain the
the composition of water, he holds it to be composed of 2 atoms of hydrogen with 1 of oxygen, while Dalton holds them to be 1 to 1. His atom of azote, which is 26, is a little more than four times greater than Dalton's, which has obliged him to make nitric acid consist of 1 atom of azote and 5 of oxygen, and ammonia to consist of 1 atom of azote with 6 of hydrogen. It is difficult to imagine how so many atoms of hydrogen of such great elaticity should be retained upon an atom of azote, which has so little affinity for hydrogen. Dalton's atom of azote is 5, and he makes ammonia to consist of 1 atom of azote with 1 of hydrogen. His compounds of azote with oxygen are very simple, and agree with facts much better than by Humphry's numbers. Dalton's nitrous oxyd is formed by 2 atoms of azote with 1 of oxygen: his nitric oxyd by 1 of each. This explains the fact of nitrous oxyd being a heavier atom than nitric oxyd. Sir Humphry's numbers make nitrous oxyd the lightest of the compounds of azote with oxygen, which is inconsistent with fact.

Berzelius, a Swedish chemist, has established, by numerous experiments, the truth of the doctrine of definite proportions. He has given us a set of numbers almost entirely derived from his own facts. He, like Humphry, appears to reject the hypothesis of atoms, and makes use of the word volume in the same sense in which Dalton uses the word atom, and in which Davy uses the word proportion. His reason for adopting the word volume is founded on the pretended law of Gay Lussac, of gaseous bodies uniting in definite volumes. Hence Berzelius's numbers are the specific gravities of bodies in their gaseous form, under the same pressure. As for those bodies which do not assume the gaseous form at convenient temperatures, he determines the weight of their atoms by Dalton's method, and calls it the volume of the body, presuming, at the same time, that the same number would express the specific gravity of the body in the gaseous form. He begins his scale with oxygen, which he calls 16: that is, if any volume of oxygen be 16 in weight, the same volume of hydrogen will be 2.656; an equal volume of sulphur in the elastic form will be 201; a volume of phosphorus 167.5; one of arsenic 85.9, and of mercury 2531.6, and so on. Now, if all these bodies are capable of the elastic form at a moderate heat, it would, therefore, be important to know how far experiment would agree with this very ingenious idea. We see no reason why such an hypothesis might not be defended, if there were no attraction between the particles of gases, and if their repulsion were uniform. This would occasion the distance of the particles to depend upon the pressure of the atmosphere, the particles would stand at equal distances from each other, and the specific gravity of equal volumes would be as the weight of the atoms.

It would also follow from this law, that the compounds in the gaseous form would possess a specific gravity, which would be equal to the sum of the specific gravities of the elementary gases. There are many striking facts in favour of this law, but there seem to present many infurmountable objections to it. Fortunately, to a certain extent, the subject is within the reach of experiment; and we are happy to learn it will soon be put to the test. Should this hypothesis completely agree with experiment, Berzelius can have no better ground than Sir H. Davy for objecting to Dalton's doctrine of atoms. We can no more conceive how bodies should unite by volumes, than we can of any magnitude of one uniting to that of another. We have no influence of one grain or one ounce of one body uniting to any similar weight of another, to form a chemical compound. If the molecules or volumes which unite were indefinite, the proportions could not be definite. It must, therefore, be the same ultimate atoms, to which Newton alludes, and which Dalton maintains, that enter into combination to form compounds, in order that the proportions may be limited. The atoms of Dalton, the proportions of Davy, and the volumes of Berzelius, must, therefore, be the same, so long as they all advocate the doctrine of definite proportions.

Dr. Thomson has given an account of the Daltonian theory in his Annals of Philosophy, in which he has made great alteration in certain numbers. This principally arises from his taking different authorities for the analysis of compounds. He has fixed the atom of oxygen at unity. His reasons for this are plausible. Oxygen enters into combination more frequently than any other of the elements, and it will be easier to add unity than any other number. If hydrogen were unity, oxygen would be a number much encumbered with decimals. Since the publication of the elementary numbers, Dr. Thomson has made some alterations, particularly in the atom of azote. We shall subjoin a table, exhibiting the numbers of Dalton, Davy, Thomson, and Berzelius.

</table>

**Explanation of the Table.**

The first column contains the names of the elementary bodies; the second, the symbols; the third, the numbers of Dalton, in which he considers hydrogen unity; the fourth column contains the numbers adopted by Davy, in which hydrogen is considered unity, and oxygen a little more than the double of Dalton's; in consequence of which, almost all the other elementary numbers have been doubled. The fifth column contains the numbers prophec by Berzelius. He makes the number for oxygen 100. The sixth column contains the numbers prophec by Dr. Thomson. He fixes oxygen at unity: the rell of the numbers are derived from different authorities, and some from his own experiments.

The other three columns contain the numbers of Davy, Dalton, and Berzelius; the number for oxygen being reduced to unity.

These columns, with the sixth, serve to show how far the different authors agree. They will be found to correspond with sufficient exactness, to confirm the truth of the doctrine of definite proportions. It will be only by long comparing the elementary numbers with each other in the different compounds, that they can become perfectly correct. Analyis can only furnish a distant approximation to the truth of the numbers. Each elementary number will undergo greater correction, by tracing its progress through Vol. XXVIII.

All its combinations. In the four last columns it will be observed, that the numbers of one are sometimes about double that of another. This arises from a difference of opinion respecting the number of atoms combined. Berzelius conceives potash to be the second oxyc of potassium, and hence makes the number for potash 9.78; while the others, who consider potash as the first oxyc, make the number to be 5, nearly half the former.

It must be observed, that some difference of opinion prevails among these philosophers, which it will be necessary to explain. The substance in the table called chlorine is held by Sir Humphry Davy to be a simple body. Berzelius, and most other chemists, hold it to be a compound of what is called in the table muriatic radical and oxygen. The latter chemist is also of opinion, that azote is a compound of a peculiar bafe, which has been called nitric radical and oxygen. Davy's and Dalton's lift do not contain the latter, nor do Dalton and Berzelius admit the chlorine of Davy into theirs. They are, however, all introduced into one column to save room.

Berzelius makes use of letters and figures, instead of arbitrary symbols, to express his simple and compound bodies. These will be more familiar to the reader than the characters of Dalton, or those we have prophec. We shall, therefore, omit giving any other than those of Berzelius. With these we shall give some examples of the compounds, according to the opinions of each of these philosophers. These
are exhibited in the following table. The first column contains the names of the compounds. The second, third, fourth, and fifth contain the symbolic representation of each body, according to the opinions of each of the above philosophers. The figures which precede, or are placed over a symbol, express the number of atoms of Dalton and Thomson, the number of volumes of Berzelius, and the number of proportions of Sir Humphry Davy.

</tbody>
</table>

The preceding table contains only a very few of the compound bodies. In the present state of chemistry it would be impossible to give all the compounds correctly, for want of facts relative to the number of atoms in each compound, particularly in the salts. We have given this table to shew the method of combining the elementary symbols to express the compounds. When the constitution of all the compounds is known, a general list of the compounds expressed in a similar form might be of great importance to practical chemists, as it would not only shew the number of atoms or dozes in each compound, but the proportions of the elements in round numbers may be immediately known. If we refer to sulphuric acid in the table of compounds, we shall see that in all the columns it consists of 1 atom of sulphur and 3 atoms of oxygen. By Thomson's numbers, in which oxygen is unity, we find in the elementary table that sulphur is 2, which added to 3 atoms of oxygen, is equal to 5. This is the number for the atoms of sulphuric acid. In the table of compounds we find the second oxyd of copper to consist of 1 atom of copper, which in the table of simple bodies in Thomson's column, is 8, and 2 atoms of oxygen. These added, give 10 for the atom of black oxyd of copper. If now, we look in the table of compounds for sulphate of copper, we shall see that this salt is constituted by 2 atoms of sulphuric acid, 2 x 5, added to 1 atom of oxyd of copper 10, making 20 for the atom of sulphate of copper. This, however, gives the salt free from water of crystallization. According to Dr. Wollaston's scale, this salt in its crystallized form contains 36 per cent. of water, so that it would be complete when formed of 2 atoms of sulphuric acid = 10, 1 atom of oxyd of copper = 10, and 10 atoms of water = 11.43, the atom of water being 1, atom of hydrogen = 1.43, and 1 of oxygen = 1, making 1.143; the whole atom of salt being 10 + 10 + 11.43 = 31.43.

In the table of compounds, we find carbonic acid constituted by 1 atom of carbon = 77, added to 2 atoms of oxygen = 2, making 79. In the same table we find potehal formed by 1 atom of potasphium = 5, added to 1 oxygen = 1, making 6 for the atom of potehal. If, now, we look in the table of compounds for carbonic acid and bicarbonat of potehal, we shall find the former to consist of 7 1 atom
1 atom of carbonic acid = 2.77; and 1 atom of potash = 6; the whole atom of this salt being 8.77. The bicarbonate will be seen to consist of 2 atoms of carbonic acid = $2 \times 2.77 = 5.54$, added to 1 of potash = 6, together making 10.54 for the atom of bicarbonate.

These examples will be sufficient to show the importance of the atomic theory, particularly when we are in possession of a sufficient number of facts to form a complete table on a similar plan to those here given.

Before closing the present subject, a few observations may, with advantage, be added, on the value of the above doctrine as a means of improving the language of chemical science. Under the name Nomenclature its general application has already been noticed; but this, as will be now seen, is capable of still further extension than was then detailed. So complete is the system capable of being rendered, that if we merely remember the weight of the elementary atom of each acid and base of which a salt is composed, (a task by no means difficult,) the name of the compound alone will lead us to a knowledge of the proportions in which its ingredients are united. This, from what has been premised, will be obvious after a short illustration.

When one atom of acid and one atom of base are employed in the constitution of any particular salt, as of phosphoric acid and of lime, for example, the title of the resulting compound, as was explained under Nomenclature, is simply that of phosphat of lime. If two atoms of acid are present, it then becomes a super-phosphat, and if two atoms of base, a sub-phosphat. The addition of any farther number of particles may be conveniently registered by the aid of short prefixes derived from the Greek numerals. Thus, three atoms of either acid or base will be called a tria-phosphat (from $πυτρον$, tertius); four atoms, a tetra-phosphat (from $πυτρον$, quartus); five atoms, a penta-phosphat (from $πυτρον$, quintus); six atoms, a hexa-phosphat (from $πυτρον$, sextus); seven atoms, an hepta-phosphat (from $πυτρον$, septimus); eight atoms, an octo-phosphat (from $πυτρον$, octonum); nine atoms, an enneato-phosphat (from $πυτρον$, nonum); and ten atoms, a deca-phosphat (from $πυτρον$, decimun). The same source will furnish a sufficient means of distinction to any increased extent; but there are few instances in which this will be requisite, and had it not been for some recent researches of Mr. Dalton into the various combinations of the salt here quoted, it might almost have been doubted whether even so great a provision as the above would have been at all necessary. One addition remains yet to be made to the foregoing nomenclature, as a means of distinguishing salts with excess of base from those with an excess of acid. This is readily accomplished by retaining the word sub as a prefix to the former, and referring the names, as they stand above, without any alteration, to denote the latter. A compound of two atoms of phosphoric acid and one of lime, therefore, will be super-phosphat of lime, and three atoms of acid, and one of lime, tria-phosphat of lime. The combination of one atom of phosphoric acid with two of lime will, in like manner, be sub-phosphat of lime, and one of acid with three of lime, sub-tetra-phosphat of lime; and so of the remainder.

PROPORTIONAL, relating to proportion. Thus we say, proportional compasses, parts, scales, spirals, &c. See COMPASSES, &c.

PROPORTIONALS, in Geometry, are quantities, either linear or numerical, which bear the same ratio, or relation to each other.

Thus, if $3, 6, 12$, be proportional, then will $3:6::6:12$.

*To find a fourth proportional to three given lines, A B, A C, and B D (Plate XI. Geom. fig. 13.) draw an angle $\overline{FAG}$ at pleasure; from A let off the first of the lines to B; from A, the second, to C; and from B, to D, the third; draw $\overline{BC}$; and at D make an angle equal to $\overline{ABC}$; then is $\overline{CE}$ the fourth proportional sought; and $\overline{AB}=\overline{AC}::\overline{BD}::\overline{CE}$.

If a third proportional be required to two given lines, $\overline{A B}$ and $\overline{AC}$; make $\overline{BD}$ equal to $\overline{AC}$; i.e. let $\overline{AC}$ be repeated twice; then $\overline{A B}::\overline{AC}::\overline{BD}::\overline{CE}$.

To find a mean proportional between two given lines, $\overline{A B}$ and $\overline{BE}$ (fig. 14.), join the two given lines into one continued right line, and bisect $\overline{C}$. From $\overline{C}$, with the interval of $\overline{AC}$, describe a bisected $\overline{DE}$; and from $\overline{C}$ erect a perpendicular $\overline{BD}$; this is the mean proportional sought; and $\overline{A B}::\overline{BD}::\overline{BD}::\overline{BE}$.

The geometers have been these two thousand years in search of a method for finding two mean proportionals.

The ancients performed it mechanically, by the mefopab decribed by Eutocius; and many of them attempted to give the demonstration; some by the lodh loci, as Menecinus; others by the plain loci, as Nicomedes, Diocles, and, in our times, Vieta, and others by implicit motions, as Plato, Archytas, Pappus, and Sporus; others, on the contrary, by the decription of circles, as Hero and Apollonius, &c., but all in vain. See DUPLICATION of a CUBE.

To find a mean proportional between two numbers: half the sum of the two given numbers is an arithmetical mean proportional, and the square root of the product a geometrical mean proportional. See PROPORTION, ARITHMETICAL and GEOMETRICAL.

To find a mean harmonical proportional, see PROPORTION, HARMONICAL.

PROPORTIONALS, in Grammar. See NUMERALS.

PROPORTIONAL Compasses, an instrument consisting of two equal and narrow thin slips of metal, terminating at each extremity in a point, the slips being connected together by a cylindric pin, which, when they are made to coincide, is moveable along a slit through both pieces; so that the axis or centre of the pin, and the two extreme points of each piece, may be in the same straight line, and fixed at any point which will keep its situation in each of the pieces, whether the instrument be opened at any angle or shut.

The two surfaces of the instrument which appear when it is shut are called the fides.

The four parts of the instrument from the centre of motion are called legs.

It is evident from the definition given, that two legs will be equal to each other, and of the same invariable length, whatever angle these legs make with each other; and that the two which include the opposite angle will also be equal to each other, and their length also invariable at any angle formed by their legs.

Plate I. fig. 7. of Drawing Instruments, is the perspectival representation of a pair of proportionals; $a$ and $c$ are the two slips, coniuncted so as to turn round the centre of motion $a$, which remains in the same point of each slip $c$ or $d$; while the legs of the instrument are made to turn round it, but which may be moved when the adjoining surfaces of $e$ and $f$ are made to coincide, and thereby divide the length of the instrument in any proportion required.

Fig. 8. is another proportional compass, with an adjusting beam or screw, to contrived as to move the flider the smallest quantity required, or to keep the instrument fixed at any angle in dividing a line of equal parts.

The application of the proportional compasses with regard to the division of lines into any number of equal parts from 2 to 10, and the circumferences of circles into any number of equal
equal parts from 6 to 20, and with regard to being used as a scale, has already been shown under the article Compasses, as also some other applications with regard to its being used as a vector. In this article it is proposed to treat of its application to perspective, and some other branches of geometry and architecture, to which purposes it has never yet been applied.

**Problem I. Fig. 1.**

To set the proportional compasses in the ratio of a line divided into any two parts.
