"Regal is, secondly, a spinet organized, or rather a small organ of two or three stops placed under a key'd instrument, very common in Spain and Italy. In France this kind of instrument is called a psaltier." Craig, an organ-builder in London about the middle of the last century, furnished organs of this kind to many harpichords and spinets in a virginal form. Snetzler, when he first came hither from Stralsburg, was employed by Shudi to organize his harpichord.

But regal in all Roman Catholic countries is a portable organ used in processions, carried by one person and played by another. We have seen that the made of this kind of organ at Naples. The pipes are of reeds, for the lightness of carriage.

In the list of Edward VI. and queen Elizabeth's musical establishments in the Sloane MSS. at the British Museum, among the instrument-makers, the regal-maker is allowed 20l. yearly. And in our own memory there was an office in one of the chapel royal under the title of "tuner of the regale," but it was abolished, and united to some more useful officer in the chapel.

In the supplement to the folio Encyclopaedia, we are told that the regal is a portable organ, which has no pipes, or at most such as are very short, the tones being produced by reeds. This we believe to be the truth. The instrument is sometimes so small as to be set on a table.

REGAL Psith. See ROYAL Psith.

REGAL Smit. See SUTI.

REGALE, in the French Jurisprudence, is a right belonging to the king over all benefices in that kingdom.

The regale consists in enjoying the revenues of bishoprics, during the vacancy of their fees, and of presenting to the benefices dependent on them, which become vacant during that time, and till such a feecesse have taken the oath of fidelity, and have procured letters patent, to secure him from the regale.

The enjoyment of the fruits of the fee is called the temporal regale; that of presenting the benefices, the spiritual regale.

Some refer the origin of the regale to the time of Clovis; and say, the clergy granted this privilege to the king upon his defeating the Vifigoths; others allege, that pope Hadrian I. gratified Charlemagne with it, in a council held in Rome. It is observed by others, that the regale was originally no more than a ward, or administration; and that the kings were only depositaries of the fruits of the vacant bishoprics; and appointed ecclesiomy to look to them during the vacancy.

It is added, that the kings of the first and second race never enjoyed any such privilege; and that it was only introduced in the twelfth century, in favour of investiture.

Whatever was the origin of the regale, it occasioned a very
very important and warm debate between Lewis XIV, and pope Innocent XI, which began about the year 1678, and was carried on with great animosity and contention for several years after. Lewis was devious, that all the churches in his dominion should be subject to the regale. Innocent pretended, on the contrary, that his claim could not be granted with such universality; nor would he consent to any augmentation of the prerogatives of this nature that had formerly been enjoyed by the kings of France. Lewis summoned, for letting this dispute, the famous assembly of thirty-five bishops, and as many deputies of the second order, which met at Paris in the year 1682, and which extended the regale to all the churches in France, without exception. In this convocation the ancient doctrine of the Gallican church, that declares the power of the pope to be merely spiritual, and also inferior to that of a general council, was drawn up in four propositions, which were solemnly adopted by the whole assembly, and were proposed to the whole body of the clergy, and to all the universities through the kingdom, as a sacred and inviolable rule of faith.

REGALE, Regalia, a magnificent treat, or entertainment, given to ambassadors, or other persons of distinction, to entertain or do them honour.

REGALIA, in Law, the royal rights or prerogatives of a king.

These are reckoned by civilians to be six. 1. Power of judicature. 2. Power of life and death. 3. Power of war and peace. 4. Maitres les goods, as waifs, esclaves, &c. 5. Afferiments. 6. Minting of money.

REGALIA is also used for the several parts of the apparatus of a coronation: as the crown, the sceptre with the crofs, sceptre with the dove, St. Edward's Hafl, four several swords, the globe, and the orb with the crofs, &c. used at the coronation of our kings.

REGALIA of the Church, are those rights and privileges which cathedrals, &c. enjoy by grants, and other concessions of kings.

Regalia is sometimes also used for the patrimony of a church; as, regalia Sancti Petri. And more particularly, for such lands and hereditaments as have been given by kings to the church.

These regalia, while in possession of the church, were subject to the same services as all other temporal inheritances; and after the death of the bishop they reverted to the king, till he invested another with them; which, in the reigns of William the Conqueror, and some of his immediate successors, was frequently delayed, and as oft did the bishops make complaint of it, as appears from Malmbury, Neuburgien, &c.

This last author says, that great complaint was made against Henry II. "Quod episcopatus vacantes, et prvenientia percipere commoda, diu vacare voluit, et ecclesiasticus potius utibus applicanda in sicum reedit." REGALIA FaHsa is used for the bishop's doing homage, or fealty, to the king, when he is invested with the regalia. Thus Malmbury, in Ascham: "Regalia pro more illis temporis faciens principi vii. kalend. Octobris Cantuariae addidit."

REGALITIES. See Royalties.

REGAN, in Geography, a town of Peru, in the province of Kerman, and district of Normanhier, on the frontier of Kerman to the eait, which district is about 50 miles in length, and in breadth from 30 to 80. This district is bound on the N. and S. by a range of mountains, those to the S. being covered with snow during the greater part of the year. The soil is fertile, the district populous, and well watered by streams from the mountains, and the climate hot in the plain, but cold on the mountains. The Afghans were lately expelled from this district by the Persians, who invaded different tribes of Balouches to occupy the deserted villages.

Regan is a neat little town, surrounded by a mud wall, within which the cattle of the inhabitants are driven every night for protection. The fort is quadrangular, the wall high and in good repair, and flanked with bastions; with one gate, constantly guarded for preventing the entrance of strangers. The capital of Normanhier is Kookooh, which is the residence of the governor, and built in the same style as Regan, but larger, and surrounded by a deep ditch. Before the expulsion of the Afghans, a city, called Bumm, was considered as the frontier town of Peru in this quarter. This city is strongly fortified by a high mud wall, flanked with towers, surrounded by a deep and broad dry ditch, with one gate; and it has a bazar tolerably supplied with dates, milk, and fruit. The ruins of Bumm testify that it was formerly of much greater extent than it is at present. The forests are said to have thrown water to an amazing height, and the gardens, which appear to have been walled in, and adorned with elegant summer-houses, produce the most delicious pomegranates. Kinmeir's Geog. Memoir of the Persian Empire, 1813.

REGARD of the Forest, the oversight, or inspection, of it; or the office and province of the regarder; which is, to go through the whole forest, and every bailiwick of it, before the holding of the securions of the forest, or justice-fee, to see and enquire of the trepassers in it, and for the survey of dogs. A court for this purpose is to be held every third year. See EXPEDITION, and FOREST.

"Ad vivendum, ad inquirendum, ad certificandum, &c." See Regarder.

Regard is also used for the extent of the regarder's charge, i.e. for the whole forest; or all the ground that is parcel of it.

REGARDANT, in Heraldry, is underfoot of a lion, or other beast of prey, borne in a posture of looking behind him, with his face towards his tail.

Others apply it to a beaft, which only shews the head, and some part of the neck, as moving from out of some division of the coat into another. He bears azure, three bends, or, in a chief, argent, charged with a lion regardant, gules.

REGARDANT Cultain, or Regardant to the Manor, denotes an ancient servient or retainer to the lord; thus called, because charged to do all base services within the manor, to see the same freed of all filthy and loathsome things that might annoy it, &c. Coke upon Littleton, fol. 120.

REGARDER of a Forset, Regadorer Forsefes, an ancient officer of the king's forest, whole business was every year, upon oath, to make a regard, i.e. to take a view of the forest limits; also to enquire of all offences and defaults committed by the foresters within the forest, and of all the concealements of them; and whether the other officers did execute their respective duties or not.

Manwood refers this institution to king Henry II. but Spelman thinks the name, at least, was given since; and that they were the same with those officers called custodes regales.
REGATTA, a name given at Venice to a kind of exhibition on the water, in which the gondoliers contend for superiority in the art of rowing their gondolas.

A splendid entertainment, under this appellation, was exhibited on the Thames in 1775.

REGAU, in Geography, a town of Austria; 12 miles W. of Steyr.

REGO CONSULTO, in Law, is a writ illumed from the king to the judges, not to proceed in a cause which may prejudice the king, until he is advised. A rego consulto may be awarded, not only for the party to the plea, but upon suggestion of a stranger, on cause shown that the king may be prejudiced by the proceeding, &c.

REGO Quo Ratu Canam. See Querela.

REGEL, or REGL, in Astronomy, a fixed star of the first magnitude, in Orion’s left foot.

REGELBRUN, in Geography, a town of Austria; seven miles N. of Bragg.

REGEN, a river which rises on the borders of Bohemia, and runs into the Danube, near Ratibon.—Also, a town of Bavaria, on the above-named river; 40 miles E. of Ratibon.

REGENERATED TARTAR. See Tartar, Regenerated.

REGENERATION, in Theology, the act of being born again by a spiritual birth, or becoming a child of God: or it is that change of heart and life experienced by a person, who forsakes a course of vice, and sincerely embraces a life of piety and virtue.

When an infidel is converted, baptism is always administered as a sign of regeneration.

The term is also used to signify the change of state that takes place at the resurrection. Matt. xix. 28.

REGENSBERG, in Geography, a town of Switzerland, in the canton of Zurich, situated on a mountain, and surrounded with walls in the year 1687: it is the principal place of a bailiwick formerly subject to the dukes of Austria; 6 miles E. of Baden.

REGENSBERG. See Ratibon.

REGENSTAF, a town of Bavaria, in the principality of Neuburg; seven miles N. of Ratibon.

REGENSTEIN, a town of Welphalia, in the bishopric of Halberstadt; seven miles W. of Quedlinburg.

REGENSTORF, or Old Regensberg, a bailiwick of Switzerland, in the canton of Zurich, which derives its name from that of an ancient cattle, destroyed in 1443.

REGENT, REGENS, a person who governs a kingdom during the minority or absence or incapacity of a king.

In France, the queen-mother has the regency of the kingdom, under the title of reine-regent, while the king is a minor. Some have urged, that women, being incapable of succeeding to that crown, were incapable of the regency; but custom has declared in their favour.

Regent is also used for a professor of arts and sciences, who holds a chair, or fee of pupils, in a college.

The foreign universities are generally composed of doctors, professors, and regents. Regent and scholar are relative terms. See Tutor.

Regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c.; those of philosophy are rather called professors.

REGENVALDE, in Geography, a town of Hinder Pomerania, on the Rega; 30 miles N.N.E. of Stargard. N. lat. 52° 49’. E. long. 15° 24’.

REGERENDARIUS, among the Romans, an officer who subscribed and kept a register of all petitions presented to the prefect. Piticus in voc.

REGESTOLA, in Ornithology, a name used by some authors for the martagel, or larger butcher-bird, a very small hawk, not exceeding the size of a common thrush, but very fierce and voracious. See Lanius Esculator.

REGETZ, in Geography, a town of Hungary; 18 miles S. of Czehan.

REGGE, a river of Holland, which rises near Enchede, and after passing by Gloer, Kylen, &c. joins the Veelt near Ommen.

REGGIO, Pietro, in Biography, a native of Genoa, who seems to have been the first Italian who gave our country a taste for the vocal refinements of his country. Before his arrival here, he had been in Spain, Germany, Sweden, and France. Besides refinements in florid song, he was much admired for his exquisite manner of accompanying himself on the lute. His first residence in England was at Oxford, where he published, in 1677, a small tract, entitled "A Treatise to sing well any song whatsoever." In 1684 his book of songs, in folio, the words chiefly from Cowley, appeared. We know not what were the tale and expression which rendered his vocal powers so captivating; but his airs are very dry and monotonous, and in as old an Italian taste as those of Lalli.

Reggio, in Geography, a city of Italy, capital of the department of the Crocold, and formerly of the duchy of Modena, the see of a bishop, suffragan of Bologna. It was founded by the Tuscan, and became a Roman colony under Lepidus the triumvir. It was destroyed by Alaric, and rebuilt by Charlemagne. Its number of convents is 16, and of inhabitants about 18,000. The cathedral contains many capital pictures and sculptures. The inhabitants of this city were the first of all the Italians, who in 1794 renounced their allegiance to their own sovereign, Hercules III., who fled to Venice, afterwards took up arms, and solicited the protection of Bonaparte. He took possession of the city, proclaimed the liberty of the inhabitants, and instituted a legislative committee, who took the oath of allegiance to the French republic. Reggio is the native place of the poet Ariosto; 14 miles W.N.W. of Modena. N. lat. 44° 41’. E. long. 10° 38’.

Reggio, a sea-port town of Naples, in Calabria Ultra, situated on the flats of Messina. The inhabitants carry on manufactures of stockings, gloves, and wafflecoats of thread or filk. This place is the see of an archbishop, founded by the patriarch of Constantinople, and contains two colleges and seven convents. The environs abound in oranges, citrons, mulberries, and grapes, with some sugar-canes. This town was called by the Greeks Rhegium, derived according to Diodorus from the Greek word Ῥήγιος, to break or tear, because Sicily was torn from Italy, either by the sea or an earthquake. It is very ancient, founded as some say by Jocalitus, son of Eolsus, king of Lipari, who entertained Ulysses; or, according to others, by the Calaeitians, who came hither from Euboea. The territory of the Rhegini was free and powerful, though sometimes governed by tyrants. In the Peloponnesian war they suffered much from their neighbours the Epizephyrian Loceri, and were distracted by internal contentions. In the time of Dionysius the elder they were very powerful and afforded their liberty, relieving an association with that tyrant, who demanded a daughter of the city. When Pyrrhus waged war against the Romans, the latter sent a legion for the protection of Rhegium; but the soldiers murdered the citizens and seized on the city. After the war the insurgents were taken by the Romans, and put to death for their treachery and cruelty. St. Paul, on his journey to Rome, passed through this city. In the year 1783 it was almost totally destroyed.
REGGIOLO, a town of Italy, in the department of the Mincio; 36 miles E. of Guaitalla.

REGHABILLE, a town of Africa, in the country of Wangara, situated on a lake. N. lat. 12° 47'. E. long. 18° 15'.

REGIA AQUA. See AQUA.

REGIA VITA. See VITA.

REGICIDE, REGICIDA, a king-killer. The term is also used for the act itself of murdering a king; of rex, king, and cida, I slay.

Regicide is chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution, of king Charles I.

REGIFUGE, REGIFIGIUM, a seat held in ancient Rome on the fifth of the calends of March, i.e. on our 24th of February, in memory of the expulsion of their kings, particularly of Tarquin's flying out of Rome on that day. Some will have the seat to bear this name from the rex furciferum, king of the faurutes, flying out of the comitia, or place of assembly, as soon as the fauruce was over, in imitation of the flight of Tarquin the Proud.

Some critics and antiquaries will have Regifium the same with Tufcia; others hold it to be different.

REGIMEN, in Medicina, from regno, I rule or govern, a rule or course of living, with regard to eating, drinking, clothing, and the like, accommodated to some disease, or particular course of medicine which the patient is under, or intended as a prevention of some threatening malady.

In many diseases, especially those of the acute or febrile classes, the regimen is often of equal, and sometimes of more importance than medicine: and there can be no doubt that the humoral physicians, by the introduction of a hot regimen in the treatment of febrile complaints, contributed to render these diseases more severe and fatal: and that the fulbility of a cool regimen has of late years very materially diminished the danger and mortality of these maladies. This change in medical practice has been, in fact, but a return to nature, and to Hippocrates, who taught this simple, but clear and rational principle, "contraria contrariis medentur," remedies should be of an opposite nature to diseases: that is to say, if the body is morbidly hot, cold is the remedy; if it is cold, the application of heat is necessary; if there is over-diffusion, inflammation, or plethora, evacuation must be resorted to: if depletion, we must supply nourishment: if there is thirst, the remedy is the free use of drink, and so forth. The clear inferences of nature (where they can be distinguished) are commonly infallible guides, as to the regimen to be purfued: but let not morbid habits and prejudices be mistaken for them. Thus in all fevers, small-pox, measles, scarlet-fever, catarrh, typhus, and the plague itself, the natural bias is for fresh air, coolness, light bed-clothes, clean linen, cold drink, light and merely liquid nourishment, in small quantities, or absolute abstinence, quietness of mind and body, relief from noise, strong light, and every species of excitement; and this is precisely the regimen, which experience has proved to be most beneficial in such diseases. Under the influence of such a regimen, where proper medicines are also employed, every symptom is rendered comparatively mild; the diftrefs of the sick is diminished, by the soothing of every morbid sensation; and the derangements, which would otherwise enflue, or be aggravated, in the more vital organs, as in the brain, lungs, and alimentary canal, are frequently altogether prevented.

It is sufficient to contrast the effects of the hot regimen, in febrile diseases, to the convinced of the truth of these observations. When a person afflicted with the species of fever, is confined in a close and heated apartment, in which the free circulation of air is prevented by closed doors and windows, curtains, &c. and is kept at the same time under a load of bed-clothes, and supplied with hot drinks, or even cordials of vinous and fermented liquors, with the view of inducing perspiration, the consequences are as follow. The whole train of symptoms is aggravated. The heat of the patient is raised considerably above the natural standard, notwithstanding the profuse perizations that are constantly bathing him; the pulse is excited to the highest febrile standard; the thirst becomes incessant to supply the unnatural waste of fluids; the mouth and lips become parched and furred; the head is in constant pain, with confusion of ideas, preventing all sound sleep, and occasioning distressing dreams, and at length delirium; the whole powers of the frame become prostrate, with disposition to fainting, on being moved, or on paling an evacuation by ftoof; and from this situation the recovery is extremely precocious. In cases of contagious fever, such as small-pox, measles, scarlet-fever, &c., the eruption is always greatly multiplied by this hot regimen, and all the symptoms are changed to what has been called a putrid type; the tongue, teeth, and lips, become coated with a black, clammy, and immoveable fur; purple spots appear on the skin; and the whole disease assumes the character of malignancy. There is one disease, indeed, which is truly the result of this hot regimen, which has made a considerable figure in the writings of physicians, who never dreamt that it was of their own creation; we allude to the military fever. See MILLARIA.

The above may perhaps be considered as the extreme of the picture, which is scarcely ever to be seen in the present day. But the greatest difficulty which a physician has ever now to overcome, in the majority of cases of feverish diseases, is to counteract the tendency of nurses and parents to the adoption of more or less of this pernicious system. The fatal luxury of must be taken away from all liquids, whether used internally or externally; the cheering breeze is deemed a death-bringing draught; and though the patient may die from the severity of a malignant fever, he must on no account run the slightest risk of catching cold; that is to say, the possible occurrence of a flight fore-throat, or a running at the nose, is to be avoided religiously, at the expense of aggravating both the sufferings and the danger, under a more formidable disease. The use of wine and cordials, in these diseases, is now confined to the poor and ignorant, and it is to be hoped, that the other parts of the hot regimen will not long be resorted to, at least among the more intelligent classes of society. See COLD as a remedy.

REGIMEN, in Chemistry and Alchemy, is the method of ordering and conducting any thing, that it may answer its intention.

Thus, regimen of fire is the method of making and ordering fire, and the degrees of it.

REGIMEN of the Work, that is, of the philosopher's stone, called the work of patience, is the rule and conduct to be observed to obtain protection.

There are three things, they say, to be chiefly regarded in the regimen of the work. The first, to administer a gentle easy heat at the beginning of the coction.

The second, to continue this external heat according to the season of the work, always observing four seasons, as in the common and astronomical year; the beginning being the winter, the proceeds the spring, then summer, and lastly autumn, which is the time of maturity and perfection of the stone;
Regimen.

It is to be added, that the work may not be begun in any season; but regard is to be had to the seasons of nature. Left the winter of the work be found in the summer of the year, &c. Which, however, is to be understood of the day in which the mercury is put in the ovum philosophicum, not of that when it is begun to be set at liberty from the prisons which nature had included it in.

The third is, that in augmenting the fire, the augmentation be not of a whole degree at once, the spirits being unable to bear such violence; but a degree is to be divided into four parts, and one part is to be taken at a time.

All the operations of the first regimen are occult and invisible: in the second regimen comes putrefaction, which, they say, is the first sensible change, flewing itself by its black colour.

Regimen, or Government, in Grammar, is that part of syntax or construction, which regulates the mutual dependency of words, and the alterations which one part of speech occasions in another, with regard to its genus, tense, or cafe, and thus it differs from concord, or the agreement which one word has with another, in gender, number, cafe, or person. See Concord.

The regimen, or government, is entirely arbitrary, and differs in all languages; one language forming its regimen by cafes, as the Latin and Greeks; others by particles in lieu of them, as the English by of, to, &c. the French, Spaniards, and Italians, by de, a, di, &c.

There are, however, some general maxims which hold good in all languages; as, 1. That there is no nominative cafe in any sentence but has a reference to some verb, either expressed or understood. Sometimes, indeed, the infinitive mood, or part of a sentence, is put as the nominative cafe to the verb; as in English, to see the sun is pleasant. These sentences, or clauses, thus constituting the subject of an affirmation, may be termed "nominative cafes."

2. That there is no verb, except in the infinitive mood, or the participle, but has its nominative cafe, either expressed or understood. Indeed, in languages which have proper accusatives, as the Latin, before infinitives there is an accusative, not a nominative cafe; as Seo Petrum esse doctum. The nominative cafe is commonly placed before the verb; but sometimes it is put after the verb, if it is a simple tense, and between the auxiliary and the verb, or participle, if a compound tense.

3. Two or more nouns, &c. in the singular number, joined together by one or more copulative conjunctions, expressed or understood, must have verbs, nouns, and pronouns, agreeing with them in the plural number. The conjunction disjunctive, however, has an effect contrary to that of the conjunction copulative; for as the verb, noun, or pronoun, is referred to the preceding terms, taken separately, it must be in the singular.

4. A noun of multitude, or signifying many, may have a verb or pronoun agreeing with it, either of the singular or plural number; but not without regard to the import of the word, as conveying unity or plurality of idea. In the application of this rule, we ought to consider whether the term immediately suggests the idea of the number it represents, or whether it exhibits to the mind the idea of the whole as one thing. In the former cafe, the verb ought to be plural; in the latter, it ought to be singular.

5. Pronouns must always agree with their antecedents, and the nouns for which they stand, in gender and number.

6. The relative is the nominative cafe to the verb, when no nominative comes between it and the verb; but when a nominative comes between the relative and the verb, the relative is governed by some word in its own member of the sentence; e. g. "he who prefers me, to Adam love my being, whom I am, and whom I serve, is eternal."

7. When the relative is preceded by two nominatives of different persons, the relative and verb may agree in person with either, according to the sense.

8. Every adjective, and every adjective pronoun, belongs to a substantive, expressed or understood. Adjective pronouns must agree in number with their substantives: nevertheless this rule admits of exceptions; e. g. the word means in the singular number, and the phrases "by this means," "by that means," are used by our best and most correct writers, viz. Bacon, Tillotson, Atterbury, Addison, Steele, Pope, &c. Campbell, in his "Philosophy of Rhetoric," has this remark on the subject before us: "No persons of taste will, I presume, venture so far to violate the pretenf ufage, and consequently to shock the ears of the generality of readers, as to say 'by this mean,' 'by that mean.'" Lowth and Johnson seem also to be against the use of means in the singular number. The distributive adjective pronouns, each, every, either, agree with the nouns, pronouns, and verbs of the singular number only. Adjectives are sometimes improperly applied as adverbs. An adjective pronoun, in the plural number, will sometimes properly associate with a singular noun. Although the adjective always relates to a substantive, it is, in many instances, put as if it were absolute, especially where the noun has been mentioned before, or is easily understood, though not expressed. Substantives are often used as adjectives: in this case, the word so used is sometimes unconnected with the substantive to which it relates; sometimes connected with it by a hyphen; and sometimes joined to it, as to make the two words coalesce. Sometimes the adjective becomes a substantive, and has another adjective joined to it. When an adjective has a preposition before it, the substantive being understood, it takes the nature of an adverb, and is considered as an adverb.

9. One substantive governs another, signifying a different thing, in the polleslive or genitive cafe; insomuch as that cafe always expresses the pollesliver, which must be governed by the pollesliver: as, "my father's house," "virtue's reward," &c. When the annexed substantive signifies the same thing as the first, and serves merely to explain or describe it, there is no variation of cafe; as "George, king of Great Britain, elector of Hanover, &c." Nouns thus circumstanced are said to be in apposition to each other: and nouns are not unfrequently set in apposition to sentences, or clauses of sentences. This rule does not hold so apparently in the modern as it does in the ancient languages; because the particles of, de, &c. which are the proper signs of the genitive cafe, are frequently used as prepositions. (See Genitives.) Substantives govern pronouns as well as nouns in the polleslive cafe; as "every tree is known by its fruit." Sometimes a substantive in the genitive or polleslive cafe stands alone, the latter one by which it is governed being understood. The English substantive has often an unpleasant sound, so that we make more use of the particle of to express the same relation: and in some cafes, we use both the substantive termination and the preposition of; as "it is a discovery of sir Isaac Newton's:" but when this double substantive, as some grammarians call it, is not necessary to distinguish the sense, and especially in a grave style, it is generally omitted. Except to prevent ambiguity, it seems to be allowable only in cafes which suppose the existence of a plurality of subjects of the same kind, as "a subject of the emperor's." But after all that can be said for the double substantive, as it is termed,
termed, it is the opinion of some grammarians, that it would be better to avoid the use of it altogether, and to give the sentence another form of expression.

10. Active verbs govern the objective (or accusative) case, as “Virtue rewards her followers.” In English, the nominative case, denoting the subject, usually goes before the verb; and the objective case, denoting the object, follows the verb active; and it is this order that determines the case in nouns; as, “Alexander conquered the Persians!” but the pronoun having a proper form for each of these cases, is sometimes, when it is in the objective case, placed before the verb; and when it is in the nominative case, follows the object and verb; as “whom ye ignorantly worship, him declare I unto you.” Verbs neuter do not act upon, or govern, nouns or pronouns. Part of a sentence, as well as a noun or pronoun, may be said to be in the objective case, or to be put objectively, governed by the active verb; and sentences or phrases under this circumstance may be termed “objective sentences or phrases.” The verb to be, through all its variations, has the same case after it as that which next precedes it; so that this subjunctive verb has no government, or case, but serves, in all its forms, as a conductor to the two cases, inasmuch that the two cases which, in the construction of the sentence, are the next before and after it, must always be alike. Passive verbs which signify naming, and others of a similar nature, have the same case before and after them; as “he was called Cesar.” It is evident also, that certain other neuter verbs, besides the verb to be, require the same case, whether it be the nominative or the objective, before and after them; such verbs are, to become, to wander, to go, to return, to appear, to die, to live, to look, to grow, to seem, to roam, and several others. The auxiliary he governs the objective case; as “let him beware.”

11. One verb governs another that follows it, or depends upon it, in the infinitive mood; as, “cease to do evil,” “learn to do well;” and the preposition to, though generally used before the latter verb, is sometimes properly omitted; as “I heard him say it,” instead of “to say it.” This irregularity extends only to active or neuter verbs; for many other verbs, when made passive, require the preposition to before the following verb; as “He was seen to go.” The infinitive is frequently governed by adjectives, subordinates, and participles; and this mood has much of the nature of a subjunctive, expressing the action itself which the verb signifies, as the participle has the nature of an adjective, so that the infinitive mood does the office of a subjunctive, in different cases, as in the nominative, “to play is pleasant,” and in the objective, “boys love to play.” The infinitive mood is often made absolute, or used independently on the rest of the sentence, supplying the place of the conjunction that with the potential mood, as “to confess the truth, I was in fault.” The preposition to, signifying in order to, was anciently preceded by for, as “what went ye out for to see?” but the word for before the infinitive, is now, in almost every case, obsolete.

12. In the use of words and phrases which, with respect to time, relate to each other, a due regard to that relation should be observed. Thus, instead of saying, “the Lord hath given, and the Lord hath taken away,” we should say, “the Lord gave, and the Lord took away.” To prefer subjunctive in the time of verbs; and also of words and phrases, says Mr. L. Murray, in his excellent treatise on Grammar, we must recollect that, in the subjunctive mood, the present and the imperfect tenses often carry with them a future sense; and that the auxiliaries should and would, in the imperfect time, are used to express the present and future, as well as the past. With regard to verbs in the infinitive mood, says the same popular author, the practice of many writers, among whom are some of the most respectable, appears to be erroneous. They seem not to advert to the true principles which influence the different tenses of this mood. The following rules will, according to our author’s judgment, be found pernicious and accurate. “All verbs expressive of hope, desire, intention, or command, must invariably be followed by the present and not the perfect of the infinitive.” Instead of the phrase, “the last week I intended to have written,” though common, the infinitive being in the past time, as well as the verb which it follows, it ought to be, “the last week I intended to write;” for how long forever it now was since I thought of writing, “to write” was then present to me, and must be considered as present, when I bring back that time, and the thoughts of it. Some writers on grammar, however, maintain that the former sentence is correct and grammatical, because, as they affect, it simply denotes the speaker’s intention to be hereafter in possession of the finished action of writing; but this reasoning admits of the following answers, according to the statement of Mr. Murray. The phrase “to have written” is, in English grammars, the established past tense of the infinitive mood, and as incontrovertibly the past tense of the infinitive in English, as fertitul is the past tense of the infinitive in Latin; nor can any writers be warranted in taking such liberties with the language, as to contradict its plainest rules, for the sake of supporting an hypothesis. Moreover, these writers might, on their own principles, and with equal propriety, contend, that the phrase “I intended having written,” is proper and grammatical; but by admitting such violations of established grammatical distinctions, confusion would be introduced, the language would be disorganized, and the most eccentric systems of grammar might be advanced, and plausibly supported. In short, says our author, the phrase “I intended to have written,” appears to involve the following absurdity: “I intended to produce hereafter an action or event, which has been already completed.” Some may hastily infer from the rule above stated, and from the near relation between the verbs to defere, and to wish, that the latter verb, like the former, must invariably be followed by the present of the infinitive. But when any one considers, that the act of deferring always refers to the future, and that the act of wishing refers sometimes to the past, as well as sometimes to the future, he will perceive the distinction between them, and that, consequently, the following modes of expression are strictly justifiable: “I wished that I had written sooner,” “I wished to have written sooner;” and he will be perfectly satisfied, that the following phrases must be improper: “I desired that I had written sooner,” “I desired to have written sooner.” Mr. Murray, having considered and explained the special rule, respecting the government of verbs, expressive of hope, desire, intention, or command, proceeds to state and elucidate the general rule, on the subject of verbs in the infinitive mood. “This rule,” he says, “is founded on the authority of Harris, Lowth, Campbell, Pickbour, &c.; and we think, too, on the authority of reaen and common sense. “When the action or event, signified by a verb in the infinitive mood, is contemporary or future, with respect to the verb to which it is chiefly related, the present of the infinitive is required; when it is not contemporary, nor is the infinitive in the infinitive mood, is contemporary or future, with respect to the verb which to the infinitive mood is a verb of a time antecedent, contemporary, or future, with regard to the governing or related verb. When this simple point is acknowledged, there will be no doubt in his mind, respecting the
form which the infinitive verb should have. A few examples may illustrate these positions. If I wish to signify, that I rejoiced at a particular time, in recollecting the sight of a friend, some time having intervened between the seeing and the rejoicing, I should express myself thus: "I rejoiced 
then to have seen my friend." The seeing, in this case, was evidently antecedent to the rejoicing; and therefore the verb which expresses the former, must be in the perfect of the infinitive mood. The same meaning may be expressed in a different form: "I rejoiced that I had seen my friend;" or, "in having seen my friend;" and the student may, in general, try the propriety of a doubtful point of this nature, by converting the phrase into these two correspondent forms of expression. When it is convertible into both these equivalent phrases, its legitimacy must be admitted.—If, on the contrary, I wish to signify, that I rejoiced at the sight of my friend, that my joy and his presence were contemporary, I should say, "I rejoiced to see my friend;" or, in other words, "I rejoiced in seeing my friend." The correctness of this form of the infinitive may also, in most cases, be tried, by converting the phrase into other phrases of a similar import.

The subject may be still further illustrated, by additional examples. In the sentence which follows, the verb is with propriety put in the perfect tense of the infinitive mood: "It would have afforded me great pleasure, as often as I reflected upon it, to have been the messenger of such intelligence." As the message, in this instance, was antecedent to the pleasure, and not contemporary with it, the verb expressive of the message must denote that antecedence, by being in the perfect of the infinitive. If, on the contrary, the message and the pleasure were referred to as contemporary, the subfrequent verb would, with equal propriety, have been put in the present of the infinitive: as, "it would have afforded me great pleasure, to be the messenger of such intelligence." In the former instance, the phrase in question is equivalent to these words; "if I had been the messenger;" in the latter instance, to this expression; "being the messenger."

To assert, as some writers do, that verbs in the infinitive mood have no tenses, no relative distinctions of present, past, and future, is inconsistent with just grammatical views of the subject. That these verbs associate with verbs in all the tenses, is no proof of their having no peculiar time of their own. Whatever period the governing verb allumes, whether present, past, or future, the governed verb in the infinitive always respects that period, and its time is calculated from it. Thus, the time of the infinitive may be before, after, or the same as, the time of the governing verb, according as the thing signified by the infinitive, is supposed to be before, after, or present with, the thing denoted by the governing verb. It is, therefore, with great propriety, that tenses are alluded to verbs of the infinitive mood. The point of time from which they are computed is of no consequence; since present, past, and future, are completely applicable to them.

It may not be improper to observe, that though it is often correct to use the perfect of the infinitive after the governing verb, yet there are particular cases, in which it would be better to give the expression a different form. Thus, instead of saying, "I wish to have written to him sooner," "I then wished to have written to him sooner," "I will one day wish to have written to him sooner," it would be more perspicuous and forcible, as well as more agreeable to the practice of good writers, to say; "I wish that I had written to him sooner," "I then wished that I had written to him sooner," "He will one day wish that he had written to him sooner."

13. Participles have the same government as the verbs from which they are derived; as, "I am weary with bearing him," &c. They should be considered, however, that participles are sometimes governed by the article; for the present participle, with the definite article the before it, becomes a subjunctive, and must have the preposition of after it. This rule arises from the nature and idiom of our language, and from as plain a principle as any on which it is founded; namely, that a word which has the article before it, and the possessive preposition of after it, must be a noun; and, if a noun, it ought to follow the construction of a noun, and not to have the regiments of a verb. It is the participial termination of this fort of words that is apt to deceive us, and make us treat them as if they were of an amphibious species, partly nouns and partly verbs.

The same observations, which have been made respecting the effect of the article and participle, appear to be applicable to the pronoun and participle, when they are similarly associated. When a subjunctive is put absolutely, and does not agree with the following verb, it remains independent on the participle, and is called the "cafe absolute," or the "nominative absolute;" but when the subjunctive preceding the participle agrees with the subfrequent verb, it loses its absolutenes, and is like every other nominative.

14. Adverbs, though they have no government of cafe, tense, &c. require an appropriate situation in the sentence, viz. for the most part, before adjectives, after verbs active or neuter, and frequently between the auxiliary and the verb.

15. Prepositions govern the objective cafe. Under this rule we may remark, that the prepositions to and for are often understood, chiefly before the pronouns, as "give me the book," for to me, &c. The preposition is often separated from the relative which it governs; as "whom will you give it to?" for to whom will you give it?" Some writers separate the preposition from the noun or pronoun which it governs, in order to connect different prepositions with the same word; but this kind of construction is always inelegant, and should generally be avoided. Different relations, and different tenses, must be expressed by different prepositions, though in conjunction with the same verb or adjective. Thus we say, "to converse with a person, upon a subject, in a house, &c." When prepositions are subjoined to nouns, they are generally the same that are subjoined to the verbs from which the nouns are derived. Many writers, as Dr. Priestley has observed, affect to subjoin to any word the preposition with which it is compounded, or the idea of which it implies, in order to point out the relation of the word, in a more distinct and definite manner, and to avoid the more indeterminate prepositions of and to: but general practice, and the idiom of the English tongue, seem to oppose the innovation. Thus many writers say, "averse from a thing;" but others use "averse to it," which is more truly English: "Averse to any advice," Swift. "The words averse and aversion," says Dr. Campbell, "are more properly conjoined with to than with from. The examples in favour of the latter preposition are beyond comparison outnumbered by those in favour of the former. The argument from etymology is here of no value, being taken from the use of another language. If, by the same rule, we were to regulate all nouns and verbs of Latin original, our present syntax would be overturned. It is more conformable to English analogy with to; the words dislike and hatred, nearly synonymous, are thus conjoined."

16. Conjunctions connect the same moods and tenses of verbs,
verbs, and cases of nouns and pronouns, as "Candour is to be approved and praised."

17. Some conjunctions require the indicative, some the subjunctive mood, after them. Those that are of a positive and absolute nature belong to the former class; e.g., "As virtue advances, so vice recedes." When something contingent or doubtful is implied, the subjunctive ought to be used, as "If I were to write, he would not regard it." See Subjunctive.

18. When the qualities of different things are compared, the latter noun or pronoun is not governed by the conjunction than or as, but agrees with the verb, or is governed by the verb or the preposition, expressed or understood; as "Thou art wiser than I," that is, "Than I am."

19. For the purpose of avoiding disagreeable repetitions, and of expelling our ideas in few words, an ellipsis, or omission of some words, is frequently admitted; e.g., instead of saying "He was a learned man, he was a wise man, and he was a good man," we say, availing ourselves of the ellipsis, "He was a learned, wise, and good man."

20. All the parts of a sentence should correspond to each other; so that a regular and dependent construction may, throughout, be carefully preferred. The following sentence is inaccurate; "He was more beloved, but not so much admired, as Cintihio," it should be, "He was more beloved than Cintihio, but not so much admired."

21. The regimen of verbs is frequently laid on different kinds of relations, according to custom or usage; which yet does not change the specific relation of each cafe, but only swells, thatcustom has made choice of this or that, according to fancy. Thus the Latins say, juvare aliquem, and epistolaris alicui, to help one. So the French say, faverir quelq'un, and fervrir a quelq'un, to serve one. Thus the English say, fight one, or fight with one. And thus, in Spanish, most of the verbs active govern indifferently either a dative or an accusative. Sometimes, also, the verb admits of several regimens; as praepare aliquem, or alicui; cripere morti aliquem, or aliquem à morte.

Indeed, the different regimen sometimes makes an alteration in the sense; in which, particular regard is to be had to the usage of the language. Thus, the Latin caverre alicui signifies to watch, or be careful of the preservation of any one; caverre aliquem signifies to beware of him.

There is one very common fault in regimen, which our accurate writers should be careful to avoid; viz., the using of two verbs that require different cafes together, as only governing one cafe; as in this example; after embracing and giving his blessing to his fon; where embracing requiring an accumulative, and giving a dative cafe, the regimen or construction of the first verb with the noun is irregular; embrace to a fon.

The same may be observed in nouns; as, I conjured him by the memory and the friendship be bore my father; where memory does not agree with be bore.

For an ample illustration of these rules by appropriate examples, and also of the exceptions which pertain to each respectively, we refer to Mr. Murray's English Grammar, vol. i. ch. 12. See Concord and Syntax.

Regimen, or Construction, State of, Status regiminis, a phrase used by Hebrew grammarians in contradistinction to the absolute state, or status absolutus. A noun in status absolute is that which does not govern either a genitive or any oblique cafe; and it is laid to be in regimen or in construction, when it does govern such cafe. Nouns of the former kind seldom undergo any change in the letters that form them, as מְדִינַת, just kings, whereas the latter either
guards succeeded that body under the same denomination which was raised by Charles II., soon after the restoration, the privates of whom were taken from the cavalier gentlemen, who had adopted the profession of arms, and followed the fortunes of his father during the civil wars. As they were for the most part men of family, they policed certain privileges, similar to those of the household troops in France, after whom they were modelled, and these privileges were continued long after the time when they ceased to be composed of the same class of men. It was, therefore, found necessary to reduce the privates, and to form a new corps, composed almost entirely of recruits under the old officers, and to place them nearly on the same footing with the roll of the cavalry; referring for them, however, the advantages arising out of a higher pay, and an exemption from floggings on the part of the privates, whose clothing is furnished by government. The life-guards claim the privilege, that their officers are not liable to be tried by any court-martial, unless the members are composed of their own regiments, or of officers of the other household troops. The first regiment of life-guards, consisting of very fine men, about 6 feet high at an average, was formed in 1768. The uniform is scarlet, faced with blue, and gold lace. The commissioned officers are a colonel, one lieutenant-colonel, one supernumerary lieutenant-colonel, two majors, five captains, six lieutenants, one adjutant and lieutenant, five cornets, one fergeon, and one veterinary surgeon. The non-commissioned officers consist of quarter-masters and corporals. The privates are about 150 in number. Their quarters are permanent at Knightsbridge barracks. The second regiment is on the same footing with the first, and of the same establishment. The average height of the men is 5 feet 11 ½ inches; the horses are from 16 to 18 hands high, of a black colour, with long tails. In this regiment, as well as the other, there are five troops; each troop consisting of one captain, one lieutenant, one cornet, one quarter-matter, three corporals, 49 privates, including a farrier, and one trumpeter. Each regiment has one kettle drummer. The officers usually ride bay-horses; the kettle drummers and trumpeters, grey. There are two "gold-flicks," one appertaining to each regiment: their duty is to attend alternately every month on his majesty. See Life-Guards.

A body of foot-guards was not regularly organized on the prefent plan till after the restoration. The regiment of General Monk, created duke of Albermarle, was, in compliment to him, retained on the establishment, when most of the other troops were disbanded. This regiment had been raised about ten years before the period alluded to, at Coldstream, in Scotland; and from this circumstance it assumed the name, which it has borne ever since. The year 1660 may thus be considered as the era of the formation of the foot-guards; and though other regiments were added, the Coldstream had the priority. The guards possess many peculiar honours and privileges: they have precedence of all others; their officers possess a higher rank in the army; and without expense to themselves, when on guard at St. James, they have a plentiful table kept for them by the public, and voted annually in the extraordinaries of the army. The king's perfon, the royal family, the Tower, and, in times of danger, the bank of England, are in a particular manner under their protection. Their uniforms are royal, with blue facings, and their pay superior to that of the marching regiments. See Foot-Guards.

The corps, denominated the royal regiment of horseguards, blue, commonly called Oxford blues, derives its appellation from the noble family of Oxford, who was its first colonel in 1661. This regiment has distinguished itself on a variety of occasions. The following circumstances are peculiar to this corps. It is the only regiment, denominated "horste," at present on the British establishment. The promotions, that of colonel excepted, are restricted to the regiment. The quarter-masters' commissions are signed by the king, so that they are properly termed commission-officers; whereas in all the other cavalry, or dragoon regiments, quarter-masters are only warrant-officers. The average height of the men is 5 feet 10 ½ inches. The uniform of the officers is blue, faced with scarlet, gold lace, and buff lining: of the privates, blue, with plain red hackets, very broad buff cross-belts, and gloves of the same colour. The troopers' horses are black, with long tails. The corps consists of nine troops; and to each troop belong four commissioned officers, five non-commissioned officers, and 34 privates: there are, besides, the colonel, one lieutenant-colonel, one major, an adjutant, a regimental fergeon and officer, and a veterinary surgeon. See Horse-Guards.

The establishment of a royal regiment of artillery took place early in the last century; the first colonel of the colonel having been filled, as it is, in the first year of the reign of George II. In a short time, the number of companies was augmented from four to eight. The uniform was blue, turned up with red; and waistcoats and breeches of the colour of the facings were then worn by the officers. The artillery take the right of foot on all parades, and like wise of dragoons, when dismounted. Each battalion consists of one colonel commandant, one major commanding, ten lieutenants-colonels, one major, ten lieutenants, ten captain-lieutenants, thirty lieutenants, one adjutant, one quarter-matter, one fergeon, and one officer, and one fergeon. The establishment of each company is 100 rank and file. The standard height of the men is 5 feet 9 inches, and upwards. The uniform of the officers is blue, faced with scarlet, gold epauletts, no lace, white waistcoat and breeches, boots, yellow breeches on a white buff shoulder-belt. The uniform of the privates is blue, with red cuffs and collar, no facings, yellow lace, and buttons impressed with the ordnance arms. The jockey wear furred gold lace. The arms of the officers and sergeants are yellow-leafed swords; of the corporals, bombardiers, and privates, carbine and bayonet. The horse artillery have swords and pistols. The officers ride in a regular gradation by seniority. See Artillery.

The first or royal regiment of foot claims a high degree of antiquity. It is undoubtedly the oldest regiment in the service. It is said to have been the body-guard of the Scottish kings, whence it has derived its name of the royal Scots, and to have been put upon the English establishment in 1643. The first colonel was nominated during the reign of Charles I.; but on the fatal issue of the civil wars to that monarch, this corps seems to have been disbanded. At the restoration of Charles II., this regiment was re-established. It consists of two battalions, both commanded by the same colonel; in every other respect they are considered as separate corps. The uniform of the officers is scarlet, faced with blue, gold lace embroidered; that of the private soldiers red, faced with blue and white lace.

The second, or queen's royal regiment of foot, was raised in the year 1661. The regiment being royal, the facings for the whole are blue; the lace for the privates white, with a blue stripe.

The third regiment of foot, called the "Buffs," was put upon the regular establishment of the army in the year 1665. It was denominated the "Buffs," from being the first whole accouterments were made of leather prepared from the buffalo, after the manner of hamsos. The waistcoats, breeches,
and facings of the coat, were afterwards directed to be made of a corresponding colour. When other regiments adhered to this part of their appointment, the third acquired the name of the "Old Buffs." This regiment has the exclusive privilege of marching through the city of London by beat of drum. Its uniform is red, with buff facings; buff waist-coats and breeches. The 31st regiment, which has the same uniform, is commonly called the "Young Buffs."

The fourth, or king's own regiment of foot, was raised in the year 1680, by Thomas earl of Plymouth. This regiment was the first that joined king William, on his landing at Torbay; on which occasion his majesty honoured it with the title of his own regiment; and directed it to bear in its colours the lion of England, which still continues the badge of the regiment, and is worn on the breast-plate, buttons, cap, and pouch. The uniform of the regiment, at the beginning of the last century, was red, faced with blue velvet, and large velvet cuffs, richly embroidered with gold. The present uniform is red, with plain blue facings, silver buttons and epaulet, white waistcoat and breeches. On the epaulet, buttons, and breast-plate, are the crown and garter, and round the latter "The King's own Infantry." In the centre is the lion of England, and under it the number 17 in small Roman figures.

The fifth regiment of foot was raised by James I., but it followed the fortunes of the prince of Orange. When the 4th, 5th, and 6th regiments were first raised, they were not placed upon the British establishment, but sent by James II. for the service of the states-general. On the abdication of that monarch, and the subsequent election of William, prince of Orange, they were numbered and taken into the line, according to the periods at which they landed from Holland. Thus the 4th, which had originally been raised after the 5th, arrived in England before it, and took precedence. The 5th, which had been levied before the 6th, returned at a later period than either, and was consequently placed according to that date. The 6th regiment has been augmented to two battalions, by drafts from the militia; its uniform golding green facings. The 24th, 54th, and 64th regiments are also faced with light green.

The sixth regiment of foot derives its origin from the seven years' war, in the course of which the United Provinces of Holland threw off their subjection to Spain. Its regular establishment did not take place until the year 1753; but, it had previously served under the three first princes of Orange. This was one of the three regiments intended, on their formation, to serve in Holland; and, therefore, it was paid by the Dutch republic. It came over to this country with king William, at the revolution in 1688, and was incorporated in our military establishment, being numbered as the 6th in the British line. Its uniform is deep yellow facings, white lace, with yellow and red frispes. The 9th, 10th, 11th, 12th, 13th, 14th, 15th, 16th, 20th, 25th, 26th, 28th, 29th, 30th, 31st, 32nd, 33rd, 34th, 35th, 36th, 38th, 44th, 46th, 57th, 58th, 62d, and 67th regiments have also yellow facings and white lace; and are distinguished from each other by the variations of the frispes, the tinge of the colour, &c.

The seventh regiment of foot, or "Royal Fusiliers," was raised, with nine others of infantry, and eight of cavalry, under James I., in the year 1685, three years before his abdication. As a fusilier regiment, the men wear caps, similar to those of the grenadiers, but somewhat shorter. In all other respects they are armed and appointed as the soldiers of other battalions. Three years after this, another regiment was raised, under the denomination of "Royal Welsh Fusiliers." This partiality for cap regiments is said to have been caused by the celebrity of the British grenadiers, who were easily distinguished by their caps. (By a regulation in 1800, all the regiments of the line, as well as the guards, are to wear a kind of caps.) The officers of these regiments never carried epaulettes, as the others did till the late change, but had fusils, like the officers of the flank companies throughout the army. The other regiments of fusiliers have second lieutenants, instead of ensigns. This regiment is peculiar in having none but first lieutenants, under the field-officers and captains. The uniform is royal blue facings, with white lace, and a blue stripe. The 8th, 18th, 21st, 23rd, 42d, and 60th regiments have also blue or royal facings, but different lace.

The first, or king's regiment of dragoon-guards, was raised and entered on the establishment on the 5th of June 1685. The establishment of this regiment, called, during its services in Germany in the course of the seven years' war, "Bland's dragoons," from the name of the officer who was then at the head of it, is ten troops, each consisting of one captain, one lieutenant, one cornet, one quarter-master, four sergeants, four corporals, one trumpeter, and seventy-one rank and file. The average height of the men is 5 feet 10 inches; of the horses, 15 hands 1 1/2 inch. The uniform of the officers is scarlet and gold lace, blue cuffs and collar; no facings on the ordinary uniform. The uniform of the troopers, red jacket, faced half-lappel, blue, white lace, buttons marked S. & C. The sergeant wears gold lace. The second, or queen's dragoon-guards, is one of the eight cavalry regiments raised in 1685, the second year after the accession of king James II. to the throne. Five of these remain on the English establishment, and three on the Irish: of the former three, five are distinguished as "Dragoon-guards," the other two as "Dragoons"; the first of which is denominated "the king's own regiment." The uniform of the officers red, faced with black velvet and silver lace; and that of the troopers red jacket, black collar and cuffs, royal lace, white buttons, marked S. & C. The sergeants wear silver lace. The third, or prince of Wales's dragoon-guards, is the last of the three regiments distinguished as dragoon-guards upon the British establishment. The uniform is scarlet, faced with white, and yellow buttons. The fourth, or royal Irish regiment of dragoon-guards, was raised, with seven others of the cavalry, in the year 1689, soon after James II. ascended the throne. It was originally called "the Prince of Wales's," or first regiment of horse; and, with the other three of horse upon the same establishment, it was, in the year 1758, put upon a new one, and called "Dragoon-guards," numbering on to seven; so that the fourth of horse, formerly so called, is now the seventh dragoon-guards. The uniform is royal, with silver lace. The fifth regiment of dragoon-guards, commonly called the "Green Horze," was originally the second of horse, and raised in England in the reign of king James I., in the month of July 1685. It was at that time put upon the regular British establishment. It went over with king William to Ireland in 1689, and remained more than 100 years upon the Irish establishment. It is now on the English establishment; and consists of nine troops, of the same strength with those of the fourth regiment of dragoon-guards; each troop consisting of one quarter-master, four sergeants, four corporals, one trumpeter, and seventy-one privates. The uniform of the regiment is green facings with gold lace for the officers, and yellow for the private men. The height of these men is in general from 5 feet 8 inches to 6 feet. The first, or royal regiment of dragoons, was raised for the service of Charles II. in 1685. Their badge is a horse-hoe, including 14 n., encircled with a wreath of laurels; the regiment consists of nine troops, of the usual number. The colour of the horses is black. The
second, or royal North British dragoons, called the "Scots Greys," were raised in Scotland during the reign of James II. The uniform is red, with gold lace, no facings, but blue collar and cuff. The horses are of an iron-grey colour, except those of the officers and trumpeters, which are of a light grey, approaching to white. The fifth, or royal Irish regiment of dragoons, was raised in or about the year 1688.

In consequence of the good behaviour of this regiment at the battle of Hohenfels, in August 1704, three additional troopers were put upon the establishment, making its strength to consist of nine troops. Again this regiment, affiliated by the Scots greys, distinguished itself at the battle of Ramilly in 1706; and both corps were distinguished from other cavalry regiments, by being permitted to wear grenadier caps.

The permanency of the nine troops was secured by an order, dated in 1753. At this time there was an insurrection of the rebels in the disaffected parts of Ireland, and this regiment was ordered to refit and supple it. In order to supply the loss it sustained in several conflicts with the rebels, its officers were instructed to receive eligible recruits. Many were enlisted, who, as the event afterwards proved, were rebel-partisans, who entered into a desperate plot for seizing the garrison at Lethamtown and massacring every officer and loyal soldier. The conspirators were seized, and suffered according to their deserts. The regiment, however, had the mortification to find it announced in the public papers, that several privates belonging to the fifth or royal Irish dragoons, had been found guilty by a general court-martial of joining the rebels. In consequence of this the regiment was, on the 10th of April following, disbanded by an order from his majesty, dated April 8th, 1759. See Grose's Mil. Anti. vol. ii. appendix.

REGIMENTAL Court-martial. See Court-Martial.

REGIMENTAL Staff. See Staff.

REGIMENTALS, the uniform clothing of the army, consisting of a hat, coat, waistcoat, breeches, flannel, stockings, shoes, gloves, and a sword, besides an ordinary small gun. See REGA, in Geography, a town of Golo, on the island of Corfu, in the department of Calvi; the canton of which contains 3013 inhabitants.

REGIO Assens, in Law, is a writ by which the king gives his royal assent to the election of a bishop.

REGIOMONTANUS, in Biography. See Muller.

REGIO, in Anatomy, denotes a division of the human body. Some anatomists have divided the body into three regions, or venters.

The upper region is that of the head, reaching as low as the first vertebra, and comprehending the animal organs, the brain, &c. See HEAD, &c.

The middle region is that of the thorax or breast, which Hippocrates calls the upper venter, and which receives from the clavicles to the diaphragm; in this are contained the vital parts, as the heart, lungs, &c. See HEART, LUNGS, &c.

The third, or lower region, is the abdomen or belly, &c. containing the natural parts, defined for digestion, purgation, and generation. See ABDOMEN.

REGIO, episcopal, epigraphic, and umbilical. See the adjectives.

REGIO, Regio, in Geography, a country, or particular division of the earth; or a tract of land inhabited by people of the same nation.

The modern astrologers divide the moon into several regions, or provinces, to each of which they give its proper name. See Moon.

REGIO, in Physiology. Authors divide the atmosphere into three regions, called the upper, middle, and lower regions. See ATMOSPHERE.

The lowest region is that in which we breathe, and is bounded by the reflection of the sun's rays, that is, by the height to which they rebound from the earth.

The middle region is that in which the clouds reside, where
meteors are formed, &c. extending from the extremity of the lowest to the tops of the highest mountains.

The upper region commences from the tops of the mountains, and reaches to the utmost limits of the atmosphere. In this region are perpetual, equable calmness, clearness, and serenity.

Region, Elementary. See Elementary.

Region, Ethereal, is used for the whole extent of the universe, including the orb of the fixed stars, &c.

Regions of the Sea. As some naturalists, in their descriptions of the subterraneous parts of the globe, distinguish the earth into three regions of different depths, in which different temperatures are observed; so in describing the sea, they allow it two regions; the one extending from the surface of the water, down to low as the rays of the sun can pierce, and extend their influence; and the other, from the lowest bounds of that to the bottom. It is easy to see that these regions rather regard quality than space, and that their boundaries are far from being regular, or equal in all places, and at all times. The places exposed to the hottest sunshine will have the largest upper region; those where the sun has least power will have the smallest; and the same part of the sea will have its upper region more or less deep, according to the season of the year. This upper region of the sea is always more or less hot; the lower region, except in some few particular places, is everywhere cold, and the water, where the upper region is large, is always remarkably still and quiet in the lower. Boyle of Coymall Qualities.

Region, Subterranean. The earth is not only divided on its surface into regions and countries, but philosophers, who have had occasion to discourse of its inner parts, have also divided them into three distinct regions, according to their different depths from the surface. The temperature of the subterraneous parts of the globe is distinguished according to the division of these regions, but is not so regular and precise as some have supposed. The first region of the earth is very variable, both as to bounds and temperature. The second region seems for the most part cold, in comparison of the other two; but in several places, which, by reason of their distance from the surface of the earth, it would be natural to call the middle region, the temperature of the air is very different at the same season of the year, which shews that it depends on something more than bare depth from the surface. The third region of the earth is universally observed to be warm, but by no means regularly or uniformly: the same depth in some places, giving only a moderate warmth, while in others it gives a very considerable heat.

Borrichius tells us of a certain abbe, fond of chemistry, and particularly curious in the matter of long digestions by regular heat, who found a way of making a furnace perpetually warm, by piercing the earth to a certain depth, and using the heat of this third region of it. His method was, to bore a hole with a pipe twenty feet deep, and pour into it ten or twelve pounds of quicksilver; this made its way into the earth, and through them in a body into the chambers of heat in this third region, where it boils, and gives that regular and digesting heat that no artificial fire could equal. But this is an alchemical Rory. Boyle of Coymall Qualities. Borrich. de Ortu Chim.
who presided over a kind of hospitals, and looked to the distribution of alms. There were also regional subdeacons, and regional notaries, as also regional bishops, &c.

A regio nary bishop was properly a missionary invested with an episcopal character; but without being attached to any particular see, that he might be at liberty to go to preach, and perform other functions of his ministry, with the consent of the Spirit of God and the wants of the people should call him.

REGIS, Peter-Sylvan, in Biography, a celebrated French philosopher, was born at Salvetat de Blanquefort, in the Agencois, in the year 1632. Having been instructed in clerical learning and the belles lettres, by the Jesuits, at Cahors, he entered himself a student of divinity at the university of that city, intending to qualify himself for the clerical profession. This, however, he abandoned, in order to devote himself to the study of the Cartesian philosophy, which at that time was taught with great success by Robaut. With this view he went to Toulouse in 1655, and read a course of lectures upon the principles of Descartes, and was attended by persons of all ranks and characters, who inflamed themselves in the number of his discip les. Among these were to be found the magistrates, clergy, and even the women of Toulouse, who affected to be the zealous converts to the new philosophy, in opposition to the old. To express their gratitude to the man who had been the instrument of diffusing this light over their city, the inhabitants granted him a pension; a circumstances which, it has been observed, corresponded more with the spirit and usages of ancient Greece, than of modern times. In 1680 he came to Paris, considering that as the most proper scene for the exhibition of his talents. Here he was extremely popular, and the friends to the Ariflotelian system began to be alarmed at his success, and complained against him to the archbishop of Paris, who prohibited him from continuing his lectures, and they were accordingly suspended. But after a short time, the prelate withdrew his interdict, and Regis devoted the remainder of his life to the propagation of the Cartesian philosophy, as well by his writings as his lectures. In 1699 he was admitted a member of the Academy of Sciences, but his infirmities prevented him from attending its meetings. He died in the year 1707, at the age of 75, highly esteemed by persons of the first distinction for talents and rank. He was author of a great number of works, of which the following may be mentioned: "A System of Philosophy, containing Logic, Metaphysics, and Morals," "An Answer to the Book of M. Huet, entitled "Cenfur" Philosopliic Cartelian," which is mentioned by Bayle as a model for every writer on the same side of the question; "An Answer to the Critical Reflections of Du Hamel on the System of Philosophy.""
of this act, before the registering of the memorial of the deed or conveyance, under which such subsequent purchaser or mortgagee shall claim; and the like as to memorials of wills not registered.

In 1735, a similar register of mortgages, &c. was legally enacted for the North Riding of the county of York; whence York and Middlesex are register counties. (2 & 3 Ann. cap. 4. 6 Ann. cap. 35. 7 Ann. cap. 20.) These registers do not extend to copyhold estates, leases at a rack-rent; or to any leases not exceeding 21 years, where the possession goes with the lease; nor to any chambers in the gift of courts.

Many have wished that the same regulation was extended to all the counties of England and Wales, but judge Blackstone observes, that, however plausible these provisions may appear in theory, it hath been doubted, by very competent judges, whether more disputes have not arisen in those counties, by the inattention and omission of parties, than prevented by the use of registers.

Register, more correctly Registrier, Registrator, is also used for the clerk, or keeper of a register, or register.

Of these we have several, denominated from the registers they keep; as register of the high court of delegation, register of the archdeacon court of Canterbury, register of the court of admiralty, register of the prerogative court, register of the province of Canterbury, register of the archdeaconry of Middlesex, &c. register of the faculty office, and register of the garter, who is always dean of Windsor, and deputy registrars.

There are also, in the court of chancery, the principal registrar, the lord chancellor's registrars, the registrars of the master of the rolls, entering registrars, and registrar of the affidavits.

The appellation of register or registrarius is also given to a notary. See Notary, and Notary, Public.

Register, City. See Town-Clerk.

Register of a parish church, is a book in which the yearly baptisms, marriages, and burials, of each parish, are orderly registered. See Marriage.

This practice was doubtless instituted by that great but unfortunate person, Thomas Cromwell, earl of Effey, anno 1538, while he was vicar-general to king Henry VIII.; and it was continued in the reigned of king Edward VI. and of queen Elizabeth.

These parish registrars are to be kept in a coffer, provided by the churchwardens, with three locks and keys, one of which is to remain with the minister, and the other two with the churchwardens severally, so that neither the minister without the two churchwardens, nor the churchwardens without the minister, shall at any time take that book out of the said coffer. These parish registrars are to be fabbricated by the minister and churchwardens; and the names of the persons shall be transmitted yearly to the bishop; and it has been enforced by canon 70, and by statute, &c.

By 26 Geo. II. c. 33. to make a false entry in a marriage register, to alter it when made, to forge or counterfeit such entry or a marriage licence, or to aid and abet such forgery, to utter the same as true knowing it to be counterfeit, or to destroy or procure the destruction of any register, in order to vacate any marriage, or subject any person to the penalties of this act; all these offences, knowingly and willfully committed, subject the party to the guilt of felony, without benefit of clergy.

By the 30 C. 11. c. 5. for burying in woollen, it is enacted, that the minister of every parish shall keep a register in a book to be provided at the charge of the parish, and make a true entry of all burials within his parish, and of all affidavits of persons being buried in woollen brought unto him according to the said act; and where no such affidavit shall be brought to him within the time hereinafter directed, he shall enter a memorial thereof in the said register, against the name of the party interred, and of the time when he notified the same to the churchwardens or overseers of the poor according to the said act.

An approved register of births, consisting of certificates signed by two persons who were present at the said births, and entered in a book signed by the registrar or secretary, is kept with great accuracy, and authenticated by a committee, for the benefit of Protestant dissenters and others. This book is deposited and carefully preserved at Dr. Williams's library, Red-cross Street, Cripplegate, to which any person may have access at the stated hours, under the direction of the secretary of the said library, whose attention to his office entitles him to public respect.

Register is also a title of a book, containing the forms of most of the writs, original and judicial, used in common law. This is called the register of writs, or registrum omnium brevium. This register, Coke on Littleton observes, is one of the most ancient books of the common law. And judge Blackstone observes concerning it, that it is the most ancient and highly venerable collection of legal forms, upon which Fitzherbert's Natura Brevium is a comment, and in which every man, who is injured, will be sure to find a method of relief, exactly adapted to his own case, as far as the compuls of a few lines, and yet without the omission of any material circumstance.

Register, in Antiquity, a book or table at the Capitol belonging to each particular regius, or ward, in which all fathers were obliged to enrol their sons, making oath, at the same time, that every son, so registered, was either born to them in lawful wedlock, or lawfully adopted. The adopted sons were registered in the festival Thargelia; the natural, upon the third day of the festival Apatrosis.

At what age children were thus registered is not agreed. Some are of opinion, that at every return of the Apatrosis it was customary to register all the children that had been born that year. Others affirm, that they were commonly three or four years old before they were registered.

There were two other feasons when young Athenians were enrolled in a public register; one, when they arrived at the age of eighteen years, and were admitted into the number of the ephebi, and was performed on the third day of the festival Apatrosis; and the other, before the festival Panathena, when those who were twenty years old were entered in a register, called δράκος, δρακον, δρακονικα, in which the names of all persons of that age, who were of age to succeed in the δρακον, or inheritance of their fathers, were entered. This was termed δρακονικα to be registered among the men: and the persons thus enrolled, became their own masters, and free from the government of their guardians. Potter's Arch. Græc. vol. iii. p. 45.

Registers of Estates, the accounts of particular things which belong to them, as those of rentals, valuations of fields, names, admeasurements, different portions of land, cottages, and other buildings distinct from the farms, and any other separative parts. In these registers the valuations are to be inserted in columns, as they arise from surveys or other ways, and afford the means of fixing the real values in re-letting the lands, or for other purposes.

Also, a general register of the timber trees which are growing on the several divisions of the estates, should always be kept; in which the number contained in each separate wood, grove, hedge-row, or any other part, must be entered,
regulated, with their kinds, and the admeasurement of each, for the use of the proprietor and wood managers.

A great many other forts of particulars regarding the
estates may likewise be usefully and conveniently put down in
these registers.

Register of Seamen. See Manning the Fleet.

Register Ships, or Ships of Register, in Commerce, were
vessels to which the king of Spain, or the council of the
Indies, granted permission to go and traffic in the ports of
Spanish America.

They were thus called, because the ships were to be re-
griffled before they set sail from Cadiz, which was the place
where they usually loaded for Buenos Ayres.

These vessels, by the tenor of the edicta or permit,
were not to exceed three hundred tons; but there sufficed
that good understanding between the merchants and the
information, that ships of five or six hundred tons
frequently passed unnoticed.

These register ships, which were first introduced in order
to furnish America with a regular and timely supply, and
thus to prevent a contraband trade with the English, French,
and Dutch islands, were fitted out, during the intervals be-
 tween the flated feasons, when the galleons and flotes failed,
by merchants in Seville or Cadiz, upon obtaining a licence
from the council of the Indies, for which they paid a very
high premium, and were destined for those ports where any
extraordinary demand was foreseen or expected. In pro-
portion as experience manifested the advantages of carrying
on trade in this mode, the number of register ships increased,
and at length, in the year 1748, the galleons, after having
been employed upwards of two centuries, were finally laid
aside. From that period there has been no intercourse with
Chili and Peru, but by single ships dispatched from time
to time, as occasion requires, and when the merchants ex-
pect a market will open. These sail round Cape Horn,
and convey directly to the ports in the South sea the pro-
ductions and manufactures of Europe, for which the people
settled in those countries were formerly obliged to repair to
Porto Bello or Panama.

But all the register ships destined for the South seas
were obliged to take their departure from Cadiz, and were
under a necessity of returning thither, this branch of the
American commerce, even in its new and improved form,
continued subject to the restraints of a species of monopoly,
and felt its pernicious effects.

The intercourse between Spain and her colonies has in
later times been much improved and facilitated. In the
year 1764, Charles III. appointed packet-boats to be dis-
patched on the first day of each month from Corunna to the
Havana or Porto Rico. From thence letters are con-
voyed in smaller vessels to Vera Cruz and Porto Bello,
and transmitted by post through the kingdom of Tierra
Firme, Granada, Peru, and New Spain. Packet-boats
also sail with the same regularity, once in two months, to
Rio de la Plata, for the accommodation of the provinces
to the east of the Andes.

With this new arrangement for facilitating intercourse
a scheme of extending commerce has been more immediately
connected. Each of the packet-boats, which are vessels of
some consider able burden, is allowed to take in a loading of
such commodities as are the product of Spain, and molt
in demand in the ports whither they are bound. In return
for these, they may bring home to Corunna an equal quan-
tity of American productions. This regulation may be
considered as the first relaxation of those rigid laws, which
confined the trade with the new world to a single port,
and the first attempt to admit the reit of the kingdom to
some share in it. This measure of relaxation was soon fol-
lowed by another more decisive. In the year 1765,
Charles III. laid open the trade to the windward isla-
das, Cuba, Hispaniola, Porto Rico, Margarita, and Trinidad,
to his subjects in every province of Spain. This ample
privilege was soon after extended to Louisiana, and to the
provinces of Yucatan and Campeachy. As soon as this
general liberty was permitted, it produced the most benefi-
cial effects: and it has been computed, that such a number
of ships was soon employed in the free trade, that the
amount of them far exceeded that of the galleons and flotes,
at the most flourishing era of their commerce. This ar-
angement extended its good effects through every province
of the kingdom; and by opening a new market for their
various productions and manufactures, encouraged and added
avidity to the industry of the farmer and artificer. Spain
has also permitted a free trade between the colonies them-
selves. In the year 1774, Charles III. published an edict,
granting to Peru, New Spain, Guatimala, and Granada,
the privilege of a free trade with each other. See Robert-
son's Hist. of America, vol. iii.

Register, among Letter Founders, is one of the inner
parts of the mould in which the printing types are cast. Its
use is to direct the joining of them justly together again,
after opening them to take out the new-call letter.

Register, in Printing, the diisposition of the forms of
the press, so that the lines and pages printed on one side of
the sheet meet exactly against those on the other; which
is done by means of two points in the greater or outward
typman.

Register, in Organ-building, is another word for a flop
in that instrument; but is in fact only a task pierced with
holes, corresponding with those in the found-board, which
by drawing out the flots opens the holes, and putting them
in flats them. By these flisters each flop speaks or is silent.
Register is figuratively used by musicians in speaking of a
voice, in which real and fallot notes are not well united.
Mr. Braham's high notes, for example, are said to be of a
different register from the low.

Registers, in Chemistry, are holes, or chinks, with flotes
in them, contrived in the sides of furnaces, to regu-
late the fire; i.e., to make the heat immediately more in-
tense, or remis, by opening them to let in the air, or
keeping them close to exclude it. See Fire-places and
Furnaces.

REGISTRY. Registry comprehends the office,
books, and rolls, in which the proceedings of chancery, or
any spiritual court, are registered or recorded.

REGISTRY of Shipping in Commerce. The registering
of ships appears to have been first introduced into this coun-
try by the Navigation Act, 12 Car. II. c. 18, § 10. By this
statute, however, foreign ships only, "British owned,"
were required to be registered. By Stat. 7 & 8 W. III.
c. 22, § 17, British or plantation built ships, British owned,
if intended to be employed in the plantation trade, and also
all "prize ships," were required to be registered; and in
consequence of a regulation at the admiralty, ships for
which Mediterranean passes were wanted, were also to be
registered. The provisions in the acts requiring registry
are founded upon the wifel policy, and are not left calculated
to prevent the commissipn of private fraud upon individuals,
but to advance the public policy of the state. By Stat.
26 Geo. III. c. 60. (lord Hawkesbury's act), no ship or
vessel foreign built (except such as have been condemned
as lawful prize in any court of admiralty), nor any ships or
vessels built or rebuilt upon any foreign made keel or
bottom, although owned by British subjects, and navigated
according
according to law, shall be entitled to the privileges of a British built ship, or of a ship owned by British subjects; and all the privileges and advantages allowed shall be confined to such ship only as are wholly of the built of Great Britain or Ireland, Guernsey, Jersey, and the Isle of Man, or some of the plantations in Asia, Africa, or America, now belonging, or which may hereafter belong to his majesty, except such foreign built vessels as before the 1st of May 1786 did truly and wholly belong to British subjects, navigated according to law, and duly registered, which shall continue to enjoy the privileges to which such ship or vessel is by law entitled; nor shall this act prevent any such vessel which may have been begun to be repaired or rebuilt before the 1st of May 1786 from being registered, provided it shall appear upon oath, to the satisfaction of the commissioners of the customs, that such vessel was stranded by the act of Providence, and was at the time of being stranded the sole property of some foreigner, or a drught of the admiralty; and if it shall appear that such vessel, from the damage received, was rendered unfit to proceed to sea without undergoing a thorough repair in this kingdom, and that she was necessarily sold for the benefit of the foreign owners, or under an order or commission from the court of admiralty, and that she was fairly and openly purchased by a British subject, and being the sole and entire property of such British subject, that she had been so much repaired, that two-thirds of her at least are of British built, she may be registered. f. 1.

No vessel shall be deemed British built, or enjoy the privileges belonging to British built vessels, which shall be rebuilt or repaired in any foreign port, if such repairs shall exceed 15s. for every ton, unless such repairs shall be rendered necessary by extraordinary damage, and absolutely necessary to enable her to perform the voyage, and to return in safety to some place or port within his majesty's dominions; and before such vessel shall be so repaired, the master shall report her state and condition upon oath to the British consul or other chief officer at the port where such repairs may be necessary, and cause the fame to be surveyed by two persons to be approved of by such consul or chief British officer, and shall deliver to such consul or officer, in writing, the particulars of the damage sustained, and verify upon oath the particulars and amount of the repairs, and that the same were become necessary in consequence of damage sustained during her voyage, to enable the same vessel to prosecute her intended voyage, and to return to some port within his majesty's dominions, which shall be certified under the hand and seal of the chief consul or other officer; or if no such consul, &c. shall be there resident, the survey shall be made by two persons to be approved of by two known British merchants residing at or near such port. And the master of such ship shall produce to such merchants vouchers of the particulars and amount of the repairs, and their certificate shall be of the fame effect as that of the British consul or chief officer. And the masters of vessels repaired in any foreign port shall make oath before the collector and comptroller, or other principal officer of the customs in the first port of arrival (if required so to do), describing the nature and amount of such repairs; and if such expense shall exceed 15s. per ton, and the master or commander of such ship shall neglect or refuse to deliver to such collector or comptroller, or other principal officer of the customs, the certificate by this act required to be produced, such vessels shall to all intents and purpofes be deemed foreign built. f. 2.

Ships above 15 tons British owned shall be registered in the manner hereinafter mentioned, and the persons claim-
admeasurement, the remainder will be the ship's extreme length, from which are to be deducted three inches for every foot of the load draught of water for the rake abaft, and also three-fifths of the ship's breadth for the rake forward; the remainder shall be esteemed the just length of the keel to find the tonnage; and the breadth shall be taken from outside to outside of the plank in the broadest part of the ship, either above or below the main-wales, exclusive of all manner of sheathing or doubling, that may be wrought upon the side of the ship; then multiplying the length of the keel for tonnage by the breadth to taken, and that product by half the breadth, and dividing by 944 the quotient shall be deemed the true contents of the tonnage. Nothing in this act to be construed to alter the manner of admeasuring the tonnage of any ship which has heretofore been practiced for the purpose of ascertaining the light duties, or any other duties or imposts payable according to the tonnage of any vessel. f. 14.

At the time of obtaining the certificate of registry, bonds shall be given to his majesty by the master, and such of the owners who shall attend, in the following penalties:

If a decked vessel, or from 15 to 50 tons, 100l.; 50 to 100 tons, 300l.; 100 to 200 tons, 500l.; 200 to 300 tons, 800l.; 300 and upwards, 1000l.

The condition of every bond given upon registry shall be, that such certificate shall not be folded, lent, or otherwise disposed of to any person or persons whomsoever, and that the same shall be solely used for the service of the ship or vessel for which it was granted; and that in case such vessel shall be taken by the enemy, burned or broken up, or otherwise prevented from returning to the port to which it belongs, the certificate, if preferred, shall be delivered up within one month after the arrival of the master in any port or place in his majesty's dominions, to the collector or comptroller of some port in Great Britain, or the Isle of Man, or of the British plantations, or to the governor, lieutenant-governor, or commander-in-chief for the time being, of the islands of Guernsey or Jersey; and that if any foreigner, or any person or persons for his use and benefit, shall purchase, or otherwise be entitled to the whole or any part or share of, or any interest in such vessel, and the same shall be within the limits of any port in Great Britain, Guernsey, Jersey, Man, or the British colonies, plantations, islands, or territories aforesaid, then in such cases the certificate of registry shall, within seven days after such purchase or transfer of property in such ship or vessel, be delivered up to the person or persons authorized by this act to make registry and grant certificates thereof at such port and place respectively; and if such ship or vessel shall be in any foreign port when such purchase or transfer shall take place, then that the same shall be delivered up to the British consul or other chief British officer resident at or near to such foreign port; or if such vessel shall be at sea, at the time of such transfer of interest or property, then the said certificate of registry shall be delivered up to the British consul or other chief British officer at the foreign port or place in or at which the master or other person having or taking the command of such ship or vessel shall first arrive after such purchase or transfer of property at sea, immediately after his arrival at such foreign port; but if such master aforesaid in the case above-mentioned shall not arrive at a foreign port, but shall arrive at some port of Great Britain, Guernsey, Jersey, Man, or his majesty's said colonies, plantations, islands, or territories, then the said certificate shall be delivered up in manner above-mentioned, within 14 days after the arrival of such ship or vessel, or of the person who had the command thereof, in any port of Guernsey, Jersey, Man, or any of his majesty's said colonies, plantations, islands, or territories. And if any past, called a Mediterranean pass, shall have been obtained and procured by any such ship or vessel, then and in such case the same shall be delivered up at the same time, and in like manner with the certificate of registry, to the person hereinbefore authorized to receive such certificate of registry; and such certificates so delivered up, shall be transmitted forthwith to the commissioners of the customs in England and Scotland respectively; and such Mediterranean passes shall also be transmitted to the admiralty of Great Britain, by the person or persons authorized to receive such certificate and passes, that the same may be cancelled. f. 15.

In case of any alteration of property in the same port by the sale of any share or shares in any ship or vessel after registering thereof, such sale or transfer of property shall always be acknowledged by indorsement in the certificate of registry, before two witnesses, in order to prove that the entire property in such vessel is vested in some of the subjects of Great Britain. In case any dispute should arise concerning the same, the above indorsement to be signed by the person transferring the property in such ship or vessel, or by some person legally authorized for that purpose, 7 & 8 W. III. c. 22. l. 21. 34 Geo. III. c. 68. l. 15, and by stat. 26 Geo. III. c. 62. l. 16.

In addition to the above indorsement there shall also be indorsed on the certificate of registry, before two witnesses, the town, place, parish, or wheresoever, where all persons to whom the property in any ship or vessel shall be transferred shall reside; or if such persons usually reside abroad, but in some British factory, then the name of such factory of which such persons are members; or if such persons reside in any foreign town or city, the name of such foreign town or city, and also the names of the house or copartnership in Great Britain or Ireland for or with whom such are agents or partners; and the person to whom the property of such ship or vessel shall be so transferred, or his agent, shall deliver a copy of such indorsement to the person authorized to make the registry, who is to cause an entry to be indorsed on the oath or affidavit upon which the original certificate of registry of such ship or vessel was obtained; and also to make a memorandum in the book of regishers, and forthwith give notice to the commissioners of the customs in England or Scotland, under whom they respectively act.

The certificate of registry of such vessel shall be recited in words at length in the bill or instrument of sale thereof, otherwise such bill of sale shall be utterly void. f. 17.

As often as the master or commander of any registered vessel shall be changed, the master or owner thereof shall deliver to the person authorized to make such registry at the port where such change shall take place, the certificate of registry belonging to such ship or vessel, who shall indorse and subscribe a memorandum of such change, and shall give notice to the proper officer of the port where such ship or vessel was last registered; who shall likewise make a memorandum of the same in the register book, and give notice to the commissioners of the customs in England and Scotland. f. 18.

No owner of any ship or vessel shall be permitted to give any other name thereto than that by which she was first registered. And all owners of registered vessels shall, within one month from the registry, paint in white or yellow letters, of a length not less than four inches, upon a black ground, on some conspicuous part of the stern (provided there shall be sufficient space, but if not, then in letters as large as such space will admit), the name by which such ship or vessel shall have been registered, and the port to which
which she belongs, and so keep and preserve the same.
And if such owner, or master or commander of such ship or
vessel shall wilfully alter, erate, or conceal, or permit the
name to be done, unless in the case of square rigged vessels
in time of war, or shall in any written or printed paper
describe such ship by any other name than that by which
she was first registered, or shall verbally describe such ship
or vessel by any other name to any officer of the revenue
in the due execution of his duty, such owner or commander
thereof shall forfeit the sum of 100l. f. 19.

By hat. 26 Geo. III. c. 60, all persons who shall ap-
ply for a certificate of registry in Great Britain, Guernsey,
Jersey, or the Ile of Man, for any ship which shall be built,
or whole building shall be completed after the 18 of
August 1786, shall produce to the person authorised to
grant such certificate a true account under the hand of the
builder of the name, of the proper denomination, the time
when, and the place where such ship or vessel was built, and
an exact account of the tonnage, together with the name
of the first purchaser; and also make oath before the
perfon authorized to grant such certificate, that the ship or
vessel for which such certificate is required is the same with
that so described by the builder. And every person apply-
ing for a like certificate in any of his majesty’s colonies,
plantations, or territories, shall, before such certificate is
granted, produce the like account, under the builder’s
hand, and take the like oath as is required to be pro-
duced and taken by persons applying in Great Britain.
f. 20, 21.

If any certificate of registry shall have been lost, a re-
gister and certificate de novo, in the form herein directed,
shall be granted for such vessel, according to 15 Geo. II.
c. 31; but in all such cases such security shall be given as
is directed in this act, and in lieu of the oath prescribed by
15 Geo. II. the like oath shall be taken and subscribed
hereinbefore directed, by the owner or owners of such ships
and vessels as are required to be registered by this act. f. 22,
23.

If any ship or vessel shall, after registry, be altered, either
in form or burthen, or in any manner whatsoever, such ship
or vessel shall be registered de novo as soon as the returns to
her port, or to any other port in which she may be regis-
tered by virtue of this act; on failure whereof such ship or
vessel shall be considered as a foreign vessel. f. 24.
The owners of all such ships as shall be condemned as
lawful prize, shall, upon registry thereof, before any certifi-
cate of registry shall be obtained, produce to the proper
officer of the customs a certificate of the condemnation of
such vessel, and also a true account in writing of all the
particulars contained in the certificate hereinbefore set forth,
to be made and subscribed by one or more skilful persons to
be appointed by the court to survey such ship or vessel; and
shall also make oath before the said officer, that such ship
or vessel is the same ship or vessel mentioned in the certifi-
cate. f. 25.

No ship condemned as prize shall be registered in the
islands of Guernsey, Jersey, or the Ile of Man, although
belonging to his majesty’s subjects resident in those islands;
but the name shall be registered either at Southampton,
Weymouth, Exeter, Plymouth, Falmouth, Liverpool, or
Whitehaven, by the collector and comptroller at such port respectively.
26 G. III. c. 60. f. 26.

In all cases where any ship or vessel taken and condemned
in any of his majesty’s colonies, plantations, or islands afo-
laid, shall be registered, and obtain a certificate, an exact
account shall be subjoined thereto of the sum for which
such ship or vessel shall have been sold, verified upon the
oath of the person applying for such certificate of registry.

f. 27.

All certificates, hereafter to be granted in pursuance of
this act, shall distinguish whether such ships or vessels be
of the built of Great Britain, Guernsey, Jersey, or the Ile
of Man, or of the colonies, plantations, islands, or terri-
tories aforesaid, or of any foreign country; and shall, if
British built, be entitled “Certificate of British plantation
registry,” and if foreign built, shall be entitled “Certificate
of foreign ship’s registry for the European trade, British
property,” as the case may be. f. 28.

No ship or vessel, directed by this act to be registered,
shall be permitted, after the first arrival at the port to which
she belongs, at the expiration of the notice by this act
directed, to clear outwards for foreign parts, or coastwise,
or to proceed to sea for the purpose of fishing on the coasts,
or for any other purpose, as a British ship or vessel, unless
the owners thereof shall have obtained a certificate; and in
case such ship or vessel depart from such port without being
registered, and without having obtained a certificate, every
ship or vessel, with all her guns, furniture, ammunition,
tackle, and apparel, shall be subject to forfeiture. f. 32.

If, after the expiration of the before-mentioned notice,
any ship or vessel (being square rigged) shall be found in
any port within 20 leagues by water from the port to which
she belongs, or if any vessel, not square rigged, be found
within any port other than that to which she belongs, with-
out having a certificate of registry hereinbefore directed,
it shall be lawful for the principal officer of such port, and
he is hereby required to detain until the master or com-
mander shall, if such ship or vessel be under 50 tons, give
security by bond in 50l. in manner hereinbefore directed; and
if the same shall exceed 50 and not exceed 100 tons, shall
give security by bond in 100l.; and if the same shall exceed
100 tons, then until the master or commander shall have one
security give bond in 200l, with condition that such master
or commander shall forthwith repair with her to the port to
which she belongs, and there cause her to be registered,
procure a certificate, and deliver to such officer such certifi-
cate within the time limited in the condition of such bond;
which time is to be fixed according to the diflance of the
vessel from the port to which she belongs, and the nature of
the voyage in which she may be engaged; and on failure of
producing such certificate, such bond shall be forfeited; but
if the certificate be produced within the time so limited, such
bond shall be void. And in case any square rigged vessel
shall be found in port, after the expiration of the aforesaid
notice, more than 20 leagues distant by water from the port
to which she belongs, or that the water at the entrance of
the port to which she belongs shall be so shallow as not to
admit her entrance, the master or commander shall, within
48 hours after his arrival at such port, make known his
arrival to the collector and comptroller of the customs, or
other principal officer of such port; and shall require such
collectors and comptroller to cause his ship or vessel to be sur-
veyed by the proper officer, who shall accordingly make a
perfect survey, and certify the several particulars thereof;
and such collector and comptroller shall immediately transmis
the said certificate of survey to the person authorized to
register ships and vessels at the port to which such vessel
belongs, who shall register such vessel, and grant certificate of
registry; and it shall be lawful for the collector and com-
ptroller, or other principal officer of the customs, in the port
where such ship or vessel shall be so found, to detain her
until a perfect and accurate survey, in the manner herein-
before directed, can be made.

The remaining sections of this act relate to penalties upon
the
the misconduct of officers, forging or altering certificates of registry, mode of recovering penalties, &c.

By 27 G. III. c. 19. f. 4, no oath taken for the sole purpose of acquiring the rights of a citizen or burgber in any foreign city or town in Europe, to be enjoyed during the time that such person taking such oath shall reside in such city or town, and for a limited time after such residence shall have expired, shall be deemed an oath of allegiance to a foreign state, nor inconformity with the form of the oath upon registry prescribed by 7 & 8 W. III.

Ships belonging to the East India company, or any other body corporate, to be registered upon the oath subscribed by the secretary of the said company or other body corporate, or by any other officer properly authorized.

No vessel whatsoever, not exceeding the burthen of 30 tons, and not having a whole or fixed deck, and being employed solely in the Newfoundland fisheries, or on the banks or shores of the provinces of Quebec, Nova Scotia, or New Brunswick, adjacent to the gulf of St. Lawrence, and to the north of Cape Canio, or in the islands within the same, or in trading coastwise within the said limits, shall be subject to be registered in pursuance of the said act. f. 7.

Ships built in Newfoundland, and those parts of the provinces of Quebec, Nova Scotia, and New Brunswick, adjacent to the gulf of St. Lawrence, and to the north of Cape Canio, or in the islands, within the said limits, on account of owners residing in his majesty's European dominions, shall be registered in the above places, upon the hubs or principal agents of the said ships taking the oath required; and such certificates shall be of the same effect as if granted upon the oath of the owners, until such time as they shall arrive in port in any of his majesty's European dominions, where they may be respectively registered upon the oath of the respective owners, but not longer. And whenever such ship shall arrive at any port in his majesty's European dominions, the certificates of registry, granted in pursuance of this act, shall be null and void, and shall be delivered up to be cancelled; and such ships are hereby required to be respectively registered de novo conformably to the requisitions of the preceding act. f. 9.

By 27 G. III. c. 19. f. 13, all ships not registered according to the directions and regulations of the said act, although such ships may be owned by his majesty's subjects, shall be held and deemed as alien ships, and shall in all cases be liable to the same penalties and forfeitures as alien ships are by law liable to in similar cases.

By 34 G. III. c. 43, foreign ships and vessels heretofore owned by subjects of the late French king, which in consequence of any capitulation may be put under his majesty's protection at the time of, or in consequence of the surrender of any foreign colony, may be registered as ships condemned as lawful prize, and shall become entitled to the privileges of British ships, under the regulations and restrictions hereafter mentioned. Provided always, that no ship shall be so registered but upon producing a certificate under the hand and seal of the person who commanded in chief, by sea or land, at the time when such foreign colony was surrendered (or in case of the death or departure of any such officer before such certificate shall have been so given), then upon a like certificate under the hand and seal of the person who shall command in chief, by sea or land, at such colony, testifying that such ship or vessel was put under the protection of his majesty at the said time; and upon oath, hereafter directed, being taken and subscribed before the person authorized to make such registry, by the owner of such ship, if the belong to one person only; or in case there shall be two joint owners, then by both of such joint owners, if both be resident within 20 miles of the place where such registry is required, or by one of such owners, if one or both of them shall be resident at a greater distance; or if the number of such owners shall exceed two, then by the greater part of them, if the greater number of them shall be resident within 20 miles, not in any case exceeding three of such owners, or by one of such owners, if all shall be resident at a greater distance. Provided that such registry shall, for the island of St. Domingo, be made at the port of Kingston in the island of Jamaica, and for any of the French Leeward islands, in the port of Roseau in the island of Dominica; and the said ports of Kingston and Roseau shall respectively, for the purpose of such registry, be deemed to be the port to which such ship belongs. f. 1.

His majesty, by the advice of his privy council, may at any time, on the arrival of any such ship in Great Britain, upon application made to him, authorize any such ship (without payment of any duty whatever for the said ship, or the same or other necessary tackle, apparel, and furniture thereof) to be registered, as in the case of a prize-ship, in any port of Great Britain. f. 4.

No person heretofore a subject of the late French king, being a white person, a mulatto, or free negro, shall be employed to navigate any vessel bound from such foreign colony, to any part of his majesty's dominions, or be conveyed as a passenger on board thereof, unless such person shall produce a certificate under the hand and seal of the person who commands in chief in such foreign colony, or at the place wherein such ship shall fail, testifying that such person has taken the oath of fidelity and allegiance to his majesty; and no negro-flave belonging to any person whatsoever, heretofore a subject of the late French king, shall be so conveyed or employed, but upon a certificate under the hand and seal of his master (which master shall have taken the oath of fidelity and allegiance as aforesaid), certifying the good character of such negro-flave, and testifying that his conduct has been such that he may be safely admitted into the ports of his majesty's dominions; which certificate shall be indorsed by the person who commands in chief his majesty's troops or vessels at the place from whence such ship shall fail, signifying that he has no reason to doubt of the truth thereof; upon pain that the master or commander of such ship shall forfeit 50l. for every person respectively employed or conveyed in such ship without having such certificate. f. 5.

By 34 G. III. c. 68, no goods, wares, or merchandizes whatever shall, from the expiration of six months after the conclusion of the present war, be imported into, or exported from, any port or place in Great Britain, or Guernsey, Jersey, Alderney, Sark, or Man, to any other port or place of the same, on board any ship or vessel which, by law, is or shall be required to be registered as a British ship or vessel, unless such ship or vessel shall be navigated by a master and three-fourths of all the mariners on board, of British subjects. Nor, from the expiration of six months from the conclusion of the present war, shall any ship or vessel, which by law is or shall be required to be registered as a British ship or vessel, be navigated but by a master and three-fourths of the mariners at least British subjects, except as hereafter provided. f. 1, 2, 3.

No goods, wares, or merchandizes whatever shall be carried from any port in Great Britain, or Guernsey, Jersey, Alderney, Sark, or Man, to any other port or place of the same, nor shall any ship be permitted to sail in ballast from or to any of the aforesaid ports, nor be employed in fishing on the said coasts, unless such ship shall be wholly and solely manned.
manned with and navigated by a master and mariners all British subjects. The commissioners of the customs may, however, by licence under their hands, authorize any such ship or vessel employed in fishing on the coast of Great Britain, or of the islands of Guernsey, Jersey, Alderney, Sark, or Man, to have on board any foreign mariners for the purpose of instructing the British mariners thereof in the art of fishing; such foreign mariners not exceeding one-fourth of the number of mariners on board such vessel, except in cases of sickness, death, desertion, or capture. f. 5.

By hat. 34 G. III. c. 68, no person shall hereafter be deemed to be qualified to be the master of a British ship, or to be a British sailor, seaman, or mariner, except the natural-born subjects of his majesty, or persons naturalized by any act of parliament, or made denizens by letters of denization; or except persons who have become his majesty's subjects by virtue of conquest or cession of some newly acquired country, and who shall have taken the oath of allegiance to his majesty, or the oath of fidelity required by the treaty of capitulation, by which such newly acquired country came into his majesty's possession, except as is hereinafter provided. f. 6.

But every foreign seaman serving on board any of his majesty's ships in time of war, for the space of three years, who shall also take the oath of allegiance, shall be entitled to be employed as a master of a British ship or vessel, or as a British mariner on board any British ship, upon delivering certificates from the captains under whom he served, of the time he shall have served, and of his faithful service and good behaviour, and a certificate of his having taken the oath of allegiance. f. 7.

No person who has taken an oath of allegiance to any foreign state shall be deemed qualified to be the master of a British ship or vessel, or a British sailor, unless such person shall have taken such oath of allegiance before he became so qualified; and any person who shall, after having become disqualified by taking such oath of allegiance, take the charge or command of any British ship or vessel, shall for every such offence forfeit one hundred pounds; and if such person shall engage to serve as a British seaman or mariner on board any such ship, he shall forfeit ten pounds, unless the owners shall show that such disqualifications were unknown to them or their agents at the time of engaging such master or sailor to serve on board such ship or vessel. Except in the navigation on the seas of America and the West Indies, any negroes belonging to his majesty's subjects, and in the seas to the eastward of the Cape of Good Hope, Laeufers and other natives of any of the countries to the eastward of the Cape of Good Hope, may be employed as British sailors, seamen, or mariners, in manner heretofore practiced. Provided nevertheless, that no negro belonging to any person who has become a subject of his majesty, in manner before described, in any of the islands or colonies late under the dominion of the French, shall be entitled to be employed in manner before mentioned as a British sailor, seaman, or mariner, unless all the conditions required by the 34th G. III. c. 42, shall have been complied with during the continuance of the said act.

By the 13th G. III. c. 3, his majesty in time of war may permit merchant ships to be navigated by foreigners, provided one-fourth of the crew be British subjects.

If any goods, wares, or merchandise whatever shall be imported or exported, or carried coallwise, contrary to the provisions of this act, or any of them, all such goods, wares, and merchandise, and also the ship or vessel, with all her guns, furniture, ammunition, tackle, and apparel, shall be forfeited; and if any ship shall fall in ballast, or shall fail to be employed in fishing along the coast in manner herein before mentioned, or, being required to be manned and navigated with a master and a certain proportion of British mariners, in manner herein before directed, shall not be manned and navigated accordingly, such ship or vessel, with all her guns, furniture, ammunition, tackle, and apparel, and all the goods, wares, and merchandise on board, shall be forfeited. f. 10.

All goods, wares, and merchandise, and all vessels, forfeited by this act, may be seized by the commander of any of his majesty's ships of war, or any commissioned, warrant, or petty officer specially appointed, or by any officer or officers of his majesty's customs or excise.

If any British ship shall be found at sea, having on board a greater number of foreign mariners than is allowed by this act, or any law in force or hereafter to be made, and the master of such vessel shall produce a certificate of the actual necessity of engaging such foreign mariners in some foreign port, by reason of the sickens or death, or desertion of the like number of British mariners, or of the same having been taken prisoners during his voyage, and that British mariners could not be engaged at such foreign port to supply their place, and that for the sake of navigation of such ship or vessel, it became necessary to engage, and employ such foreign mariners, or seamen, or mariners, or seamen, or mariners, belonging to his majesty's foreign port where the mariners are to engage, or, if there be no such confuls there, under the hands of two known British merchants at such foreign port, no seizures shall be made by the persons authorized under this act, nor shall such ships be molested or detained at sea; but such persons shall indemnify the certificate so produced, telling the production thereof, and when and where met with at sea, and that the number of foreign mariners correspond with the certificate of such British consuls, or such known British merchants, for the consideration and investigation of the commissioners of his majesty's customs in England and Scotland respectively.

By 34 G. III. c. 68, f. 14, no transfer, nor agreement for transfer, of the property in any ship or vessel, either in whole or in part, shall be made but by a bill of sale or instrument in writing, which shall contain a recital in words at length of the certificate of registry.

If a ship be at sea at the time when the transfer is made, so that an indorsement and certificate cannot be immediately made, the sale, or contract for sale, shall, notwithstanding, be made by some instrument in writing, and a copy thereof shall be delivered to the person authorized to make registry, who is to indorse an entry thereof on the oath or affidavit, make a memorandum in the book of regislers, and give notice to the commissioners of the customs as before directed; and within ten days after the ship returns to port, an indorsement shall be made on the certificate of registry, and a copy thereof delivered as before-mentioned; otherwise such sale shall, to all intents and purposes, be void. f. 16.

Where the owner of any ship shall, at the time of transferring the property in any ships, be abroad, so that an indorsement, &c. or such bill of sale, cannot be immediately made, the same may be done at any time within six months after such transfer, in which case, within ten days after the arrival of the owner or his agent in this kingdom, (if the ship be in any port thereof, and if not, within ten days after such ship's arrival), an indorsement on the certificate of registry shall be made, &c. as before directed. f. 17.

Masters of ships refusing to deliver up the certificate of registry to the proper person empowered to make registry, upon being required to do so by the owner or owners, or the major part of the owners, (if such master have not any property
property therein,) or by the other owner or owners, or major part thereof, (if such matter have any share therein,) and upon oath being made by such owner, owners, or major part thereof, before any justice of the peace near which such refusal shall be, such justice may grant his warrant to bring the matter before him; and if it shall appear that the said certificate is 

wisely detained, such matter shall pay one hundred pounds, and on failure of payment shall be committed to the common gaol, for not less than six months, nor more than twelve. f. 18.

Upon the justice's certifying the above 

wisely refusal of the matter of any vessel to deliver up the certificate to the person authorized to make registry, he shall register the said 

ship de novo, the terms and conditions of the law being complied with. f. 19.

When property in any ship or vessel belonging to any of his majesty's subjects shall be transferred by sale, and such vessel shall be required to be registered de novo, it shall not be done unless there be produced to the register, the bill or other instrument of sale. Provided always, that the commissioners of customs, and the governor, lieutenant-governor, or commander-in-chief for the time being of the islands of Guernsey or Jersey, or of any colony, plantation, island, or territory belonging to his majesty, may, upon due consideration of the particular circumstances of the case, give directions for the registering such vessel de novo, and granting a certificate of such registry, notwithstanding such bill or other instrument of sale shall not have been produced as aforesaid; and such registry shall be made, and such certificate thereof shall be accordingly granted, if all the other regulations required by the laws in force concerning the registry of ships de novo be complied with. f. 20.

If there shall be any alteration of property at the same port, and the owner shall be desirous of having the ship registered de novo, such ship may be so registered, provided all the rules, regulations, and conditions are complied with relative to vessels registered de novo. f. 21.

In case of any transfer of property in any ship whilst at sea, such ship shall proceed directly to the port for which the cargo then on board is defined, and shall fall from thence to the port of his majesty's dominions to which the belongs, or to any other port in which the cargo may be legally registered; and such ship may take on board in the port for which her original cargo was defined, or in any other port in the course of her voyage home, such cargo as may be legally carried to such port of his majesty's dominions where she may be so registered de novo. And if such transfer of property shall be made while such ship is in any foreign port, as soon as the master of such ship shall become acquainted therewith, such ship, after having delivered the cargo then on board at the port for which she is defined, shall fall thencefrom to the port to which the belongs, or to any other port in which the cargo may be legally registered; and may take on board at the port for which her original cargo was so defined, or at any other port in the course of her voyage home, such cargo as may be legally carried to such port of his majesty's dominions where she may be so registered de novo. And if such transfer of property shall be made while such ship is on a fishing voyage, as soon as the master of such ship shall become acquainted therewith, such ship, after having furnished such fishing voyage, without touching at any foreign port, except for the purpose of repairs or refreshments, or for delivering any part of her cargo, shall fall to the port of his majesty's dominions to which the belongs, or to any other port where the may be legally registered, and may take on board at the foreign port or ports last described, or at any other ports in the course of her voyage home, such cargo as may be legally carried to such port of his majesty's dominions; and every such ship as aforesaid shall be registered de novo, as soon as she returns to the port of his majesty's dominions to which the belongs, or to any such port in which she may be legally registered by virtue of the said act; on failure whereof such ship shall be deemed from thenceforth to be a foreign ship or vessel, and shall not again be registered, or be entitled to the privileges of a British ship or vessel, unless upon special representation of the circumstances of the case to the commissioners of customs, or to the governor, lieutenant-governor, or commander-in-chief for the time being of the islands of Guernsey or Jersey, or of any colony, plantation, island, or territory to his majesty belonging, as the case may be: provided nevertheless, that in no case the ship or vessel of which the property is so transferred, shall be entitled to the privileges of a British ship or vessel, unless the shall return to the port to which the belongs, or to such other port in which the may be registered de novo, within the period of twelve months after the date of such transfer of property, if such ship shall not be on a voyage to the east of the Cape of Good Hope, or to the west of cape Horn; or within two years, if the is on the above voyages at the time such transfer of property shall take place, except by the order of the said commissioners, governor, lieutenant-governor, or commander-in-chief respectively. f. 22. See Marine INSURANCE, and POLICY.

REGIUS Professors. King Henry VIII. founded five lectures in each of our universities: viz., of Divinity, Hebrew, Greek, Law, and Physic; the readers of which lectures are in the university statutes called regii professores.

REGIUS, in Medicine. See JAUNDICE.

REGLE de l'Oiseau, Fr., a rule for accompanying the octave ascending and descending in the base; giving to each note of the scale its appropriate harmony in every key. This rule, well known and practised in the 24 keys, major and minor, will enable students in thorough-bass to figure a base themselves, and to accompany modern music without figures.

It is disputed in France who was the inventor of this rule: Rameau and Roufaune assign it to Da Laire, M. Laborde to Campion. "This formula," says Roufaune, "was first published by Da Laire in 1700." If this date could be ascertained, it would remove all doubts concerning the author of the rule; as Campion's "Treatise of Accompaniment" is not pretended to have appeared till after 1705.

This rule ascertains what chords or harmony belong to every diatonic movement of the base, ascending and descending. See ACCOMPANIMENT, OF THOROUGH-BASE; where the base will be figured, and the chords written over it. We confine the infallibility of this rule to modern music, as no provision is made for 4ths and 5ths, which fo frequently occur in Corelli, Geminiani, and Handel. But these discords, and several other combinations, are considered in the articles COUNTERPOINT and ACCOMPANIMENT, OF THOROUGH-BASS; which see.

By this formula it will appear, that to the key-note there is always a common chord; to the 2d of the key, a 3; to the 3d of the key, a 6; to the 4th of the key, a 3; to the 5th of the key, a common chord. Thus far the chords are rigorously in one key; but in order to connect the 6th to the 5th, Rameau gives the chord of the 3 to the 6th, as in descending, which makes it the 3d of a new key; but then to recover the modulation into the original key, he gives 5 to the 7th or not. sonble of the key, and then ter-
REG

REGNANO, a town of Naples, in Capitanata; 16 miles from Manfredonia.

REGNANT QUEEN. See Queen.

REGNARD, John-Francis, in Biography, a French poet and writer of comedy, was born of a good family, at Paris, in 1647. His earliest passion was that for travelling, and he first made the tour of Italy. On his return, in an English ship, the vessel was taken by the Algerines, and the crew made slaves at Algiers. Regnard, by his skill in cookery, ingratiated himself with his master; he polished another art, which had nearly proved fatal to him. His perfom and manners recommended him to the attention of the ladies, whose advances he encouraged, and being discovered, the alternative was given him of being burnt to death or becoming a disciple of the Koran. He was, however, released from this difficulty by the interposition of the French conful, and the proper application of a considerable bribe. He gained his liberty, and returned to France, and in 1681 departed upon a new tour to the northern countries of Europe. After an absence of three years he came back to Paris, and settled quietly, with the view of cultivation his taste for literary pursuits. He composed a number of comedies for the French theatre, which were acted with success, and which, in the general opinion, placed him next to Molière in true comic honour. Gaisie is the predominant character of Regnard's comedies, which is sometimes maintained at the expense of morality. He excelled not less in the elevated or genteel comedy, than in the low, or familiar. His two best pieces are laid to be "Le Joueur," and "Le Legataire;" for describing, to the life, the scenes of the first, he was extremely qualified, being himself a lucky gaminet. He wrote eight comedies, some pieces for the Italian theatre, and an opera. He also published miscellaneous poems, containing faries, epistles, &c. In prose he gave a relation of his travels, of which the only part that excited much interest was his account of Lapland. Regnard died at the age of 62. His works have been printed collectively, of which the best edition is that of Paris, in 1790, in 4 vols. 8vo.

REGNAVADSOE, in Geography, a small island in the North sea, near the coast of Norway. N. lat. 60° 50'.

REGNI, in Ancient Geography, a name given to the ancient inhabitants of Surrern and Sufféct, and perhaps of part of Hampshire. They were seated E. of the Belge, and S. of the Atrebati. As these people possessed so large a tract of the sea-coast of this part of the island, it is very probable that they had come from the continent, and settled here not very long before the Roman invasion, perhaps at the same time with their neighbours the Belge. The Belge and the Regni had been near neighbours on the continent; the one having migrated from the country of the Suevians, now Soissons, and the other from the country of the Rhemi, now Reims. The Regni, like all the other Belge Britons, early submitted to the Roman power, and continued steady in their obedience, without engaging in any revolt. It is not known who was sovereign of the Regni when they submitted to the Romans, but soon after their submission, they were put under the government of Cogidunus, king of the Dobini. For this prince, who was then very young, had got so much into favour with the emperor Claudius, and his ministeris, that he was not only allowed to keep his own dominions, but he had several other neighbouring states put under his authority. It seems probable, from a famous inscription discovered at Chichester, that Cogidunus governed the Regni in quality of the emperor's lieutenant, or legatus Augusti; for in that inscription he is so styled. He continued a faithful and useful friend and ally to the Romans above 60 years, and thus he was so much endeared to them, that;
that, according to their custom in other countries, they permitted his polity to succeed him, perhaps for several generations. Although the Regni were very early and very obedient subjects of the Roman empire, yet as they were long after under the immediate government of British princes, few of the Romans seem to have settled among them. This is, without doubt, the reason that we meet with so few vestiges of those great and active people in those countries which were anciently inhabited by the Regni. Chichele was certainly a considerable place in the time of the Romans, and probably the capital of the Regni, which led the Romans to call it Regnum. However, Camden, Gale, Baxter, and others, are unanimous in fixing Regnum, the capital of the Regni, at Rugwood; but Mr. Horley has produced several reasons for supposing it to have been situated where Chicheley now stands. The Neamagus of Ptolemy, and the Noviomagus of the Itinerary, was a city of the Regni, and it is generally placed at Woodcote, near Croydon, in Surrey; though Mr. Baxter and some other antiquaries contend for Ravenham, in Kent. In the most perfect state of the Roman government in Britain, the country of the Regni made a part of the province called Flavia Caesariensis, and was governed by the president of that province.

REGNIER, Mathurin, in Biography, a French poet, was born at Chartres in 1572. He is said to have displeased, at a very early period, a great propensity to fatare, which his father in vain attempted to repress by chastisement. The exerise of his fatherly talents procured him patrons, among whom were the cardinal Francis de Joyeuse, and Philip de Bethune, both of whom he accompanied to Rome. By the interest of these great men he received considerable preferment in the church, but the dignity and gravity of the clerical character was no restraint upon his pleasures, and he died at the age of forty, worn out with licentious practices.

The works of Regnier confit of fatares, epistles, elegies, flanzas, odes, &c. of these his fatares are most esteem'd, and they were thought to make a kind of epoch in French poetry. The poems of Regnier have been frequently printed; the best editions are those of Rouen, 1729, and of London, 1734, with remarks.

REGNIER-DESMARAIS, Francis-Seraphin, a French author of considerable reputation, was born at Paris in 1632, of a family originally from Saintonge. Being the younger son of a numerous family, he had to depend solely upon his own exertions for making his way in the world, and he successively attached himself to several persons of rank, whom he accompanied in their travels. Making a proper use of his opportunities, he acquired a knowledge of the Italian and Spanish languages, and he became so much a master of the former, that when he attended the duke of Croqui on his embassy to Rome, in 1662, he wrote the official letters in Italian with so much purity, that they were not known to be the compositions of a foreigner. But he obtained a still greater triumph, by falling upon the academicians of Della Cruca one of his own odes for a newly discovered piece of Petrarch. In consequence of this he was elected, in 1667, a member of that celebrated academy. At the age of thirty-fix he took ecclesiastical orders, for the purpose of enjoying a priory given him by Lewis XIV., as a recompense for his public services, and in 1670 he was admitted a member of the French Academy, in the hope that he might become a contributor in the compilation of their dictionary. Soon after this, at the request of the Jefuits, he translated from the Spanish language a treatise "On Christian Perfection." In his capacity of academian, Regnier displayed so much activity and zeal, that on the death of Mezerai, in 1684, he was appointed to succeed him as secretary. When the dictionary was completed, the secretary by order of the Academy, drew up a preface, and an epistle dedicatory to the king; but, during his absence, other members, who were inspired with the desire of emulating him in this honour, procured a preference for certain of their own productions. This disappointment drew from Regnier some critical remarks upon the rival performances, tinged with that cavilling and disputatious spirit, to which it appears he so often gave way, that he obtained the title of the abbé Pertinax. He was so attached to his own opinion, that he could seldom be prevailed upon to give up his point, or to drop a dispute. Fontenelle, being once present at an academical discussion, in which Regnier was warmly engaged, exclaimed, "this is a dispute that might be prevented from ever ending, and therefore it ought to be ended immediately." Regnier obtained several benefices, and would probably have been promoted to the very highest dignity in the church, had he not been suspected of translating a scene in the "Pastor Fido," which seems to inculcate a licentious morality, and likewise suspected of writing a still more objectionable copy of verses. He was occasionally employed in public business. He died at Paris in 1713, at the age of 81. He had drawn up a great many of the most important articles in the dictionary of the French academy, and he published, as the result of his long study of the principles of the French language, his "Grammaire Franaçoise," in 2 vols. 12mo., which is considered as a very valuable performance. His other works in prose were "L'Histoire des Demeles de la France, avec la Cour de Rome, au Sujet de l'Affaires des Cordes." Translations of several of Cicero's pieces. In verse he gave an Italian version of the Odes of Anacreon, and miscellaneous poems in Latin, French, Italian, and Spanish. His French poems are varied, ingenious, and well turned, but they are allowed not to poffefs much fire or force. We have alluded to the abbé's unyielding disposition: but it must be added, that he was defervd of his kind with, infaxibly upright, and ferupulously veracious. The last quality, fays his biographer, he nobly expreffed, when, on being urged to violate the truth in favour of a man in power, and under the penalty of losing his friendship, he said, "I had rather quarrel with him than myself."
The term is now chiefly used, as it is described by flat. &c. and denotes one that buys corn, or other dead victuals, in any market, and sells then again, in the same market, or within four miles of the place.

Regrating is an offence against the public, and is liable, by the statute just cited, to the same penalty with engrossing and foretelling.

Regrator is also used for a person who furnishes up old moveables, to make them pas for new. See FRIPPERY.

Among masons, &c. to regrate is to take off the outer surface of an old hewn stone, with the hammer and rips, in order to whiten and make it look fresh again.

REGRESSION, or RETEGRADATION of curves, &c. See REGRADATION.

REGUNY, in Geography, a town of France, in the department of the Morbihan; five miles N.W. of Josselin.

REGULA, See RULE.

REGULUS, in Architecture. See REGLET.

REGULAR, Regularis, denotes the relation of any thing that is agreeable or conformable to the rules of art.

In this sense, the word stands opposed to irregular, or anomalous.

Thus we say, a regular proceeding, a regular building, regular poem, regular verb, &c.

Regular Figures, in Geometry, is a figure which is both equalateral and equangular; i.e. whose sides, and consequently its angles, are all equal.

The equilateral triangle and square are regular figures. All other regular figures, consisting of more than four sides, are called regular polygons.

Every regular figure may be inscribed in a circle; which see.

For the dimensions, properties, &c. of regular figures, see POLYGON.

Regular Body, called also Platonic body, is a solid terminated on all sides by regular and equal planes, and whose solid angles are all equal.

The regular bodies are five in number; viz. the cube, which consists of six equal squares; the tetrahedron, or regular triangular pyramid, having four equal triangular faces; the octahedron, having eight; the dodecahedron, having twelve pentagonal faces; and the icosahedron, having twenty triangular faces. See each under its proper article.

Bodies these five, there can be no other regular bodies in nature.

To measure the surface and solidity, &c. of the five regular bodies. — The solidity, &c. of the cube is found under the article CUBE. The tetrahedron being a pyramid, and the octahedron a double pyramid; and the icosahedron consisting of twenty triangular pyramids; and the dodecahedron of twelve quinquangular ones, whose bases are in the surface of the icosahedron and dodecahedron, and their vertices meeting in a centre; the solidities of these bodies are all found from what we have found under PYRAMID.

1. Their surface is had by finding the area of one of the planes, from the lines that bound it; and multiplying the area thus found by the number from which the body is denominated: e.g. for the tetrahedron, by 4; for the hexahedron, or cube, by 6; for the octahedron, by 8; for the dodecahedron, by 12; and for the icosahedron, by 20.

The product is the superficial area.

Of the superficial contents of any of the five Platonic bodies may be had by the following proportion; as 1 is to the square of the side of the given Platonic body,

\[
\frac{1}{3} \cdot 2.1816950 = \frac{1}{3} \cdot \frac{2.1816950}{(P/a)} = \frac{1}{3} \cdot \frac{2.1816950}{G} \geq \frac{1}{3} \cdot \frac{2.1816950}{J}
\]

2. The diameter of a sphere being given, to find the side of any of the Platonic bodies, that may be either inscribed in the sphere, or circumscribed about the sphere, or that is equal to the sphere.

As 1 is to the number in the following table, respecting the thing sought, so is the diameter of the given sphere to the side of the Platonic body sought.

<table>

</table>

3. The side of any of the five Platonic bodies being given, to find the diameter of the sphere, that may be inscribed in that body, or circumscribed about it, or that is equal to it. As the respective number, in the above table, under the title, inscribed, circumscribed, or equal, is to 1, so is the diameter of the given Platonic body to the diameter of its inscribed, circumscribed, or equal sphere, in solidity.

4. The side of any of the five Platonic bodies being given, to find the side of either of the Platonic bodies, which are equal in solidity to that of the given body. As the number under the title equal, against the given Platonic body, is to the number under the same title, against the body whose side is sought, so is the side of the given Platonic body to the side of the Platonic body sought.

5. To find the solid contents of any of the five Platonic bodies. As 1 is to the cube of the side of any of these bodies, so is 0.117813 to the solid content of a tetrahedron, 0.174043 to that of the octahedron, 1.000000 to that of the hexahedron, 2.1816950 to that of the icosahedron, and 7.6631189 to the solid content of the dodecahedron.

Hence we have the following rule:—multiply the tabular solidity by the cube of the side or linear edge, for the solid content. The demonstration of this rule, and that for the supercifices above given, is as follows:

The tabular numbers denote the surface and solidity of each body, when its side or edge is one; and, because, in similar bodies, the surfaces are as the squares of the linear edges, and the solidities as the cubes of the same, the truth of the rules is manifest.

If one of these bodies be required to be cut out of the sphere of any diameter, let \( dr \) (Plate XII. Geometry, fig. 9.) be the diameter of any sphere, and \( a b \), one-third of \( a b \), i.e. \( a b = b r \). Erect the perpendiculars \( a e, c f, \) and \( b g \); and draw \( d e, d f, e r, f r, \) and \( g r \); then will (1) \( r e \) be the side of the tetrahedron; (2) \( d f \), the side of the hexahedron; (3) \( d e \), the side of the octahedron; (4) and cutting \( d e \) in extreme and mean proportion in \( b, d b \) will be the side of the dodecahedron; (5) letting the diameter \( dr \) up perpendicular at \( r \), from the centre \( c \), to its top, draw the line \( e g \), cutting
cutting the circle in a, let fall the perpendicular g b; so is b r the side of the icosahedron.

Regular Curve. See Curve.
Regular Architecture, Fortification, &c. See Architecture, and Fortification.
Regular Attacks, in a siege, are those that are made in form, or by regular approaches. See Parallels.
Regular Battalion. See Bastion.
Regular Place. See Place.
Regular, in the Monastic Sense, denotes a person who has made the vows in some religious house. See Religious and Vow.

Under regulars are comprehended the whole body of monks, friars, and mendicants, &c.

The denomination of regulars, in this case, arises hence, that they are bound to observe the regular or rule of the order they are entered into. Hence,

Regular Priest is used for a priest who is in some religious order, in opposition to a secular priest, who lives in the world, or at large.

A cardinal is reputed both regular and secular, and is intitled to the privileges of both rates.

Regulars may be promoted to bishoprics and archbishoprics, as well as seculars; but their promotion secularizes them; the episcopal dignity dispensing them from the observation of the rule of which they had before made profession.

Regular Abbotts. See Abbot.
Regular Benefices, are such as can only be held by monks or religious; or at least, per cunctis profect, by a person desirous to embrace the monastic life. See Benefice.

It is a maxim in the Romish canon law, regularia regularibus, i.e. regular benefices are to be conferred on regular priests. The abbots that are chiefs of their respective orders are all regular, and can only be served by monks and cardinals. All benefices are professed to be secular, unless they be proved regular.

Anciently the regular benefices were almost all conferred by way of administration or curacy; the religious incumbents being always ad manum to their superiors, who displaced them at pleasure. Hence the common maxim among the canonists, omne beneficium regularum manus.

The benefices appropriated to regulars are abbeys, conventual priories, simple priories, and claustral offices. They may be conferred on seculars in commendam.

Regular Canons. See Canon.
Regular Places, are those within the boundary or incorporation of the convent; as the cloister, dormitory, chapter, and refectory. In opposition to those dedicated for guests, and for the necessaries of the house, which are reputed without the inclosure.

Regular Corporation. See Corporation.
REGULATION, a rule or order prescribed by a superior, for the uniform and orderly management of some branch of policy, justice, or the like.

Regulator of a watch, is a small spring belonging to the balance, serving to adjust the going, and to make it go either faster or slower.

Regulator of velocity, in Mechanics, is a contrivance for regulating or governing the motion of a mill, or other large machine, by means of which it will always be caused to preserve an equal and regular velocity in the motion of its parts, notwithstanding any accidental increase of the moving force, or decrease of the resistance that may occasionally arise. A regulator must be connected with some lever, or other parts of the machine, which commands the supply of whatever constitutes its moving force, as the shuttle of a water-wheel, the fall-cloth of a wind-mill, or valve of a steam-engine; and it should have the property of acting suddenly upon this lever, or other part, the instant any increase or decrease of velocity in the motion takes place, either to elevate or depress it, and thus regulate the supply in a degree proportioned to the quantity of alteration in the velocity; and it is by the sensibility and accuracy of the regulator in this respect that its perfection is estimated.

The regulator most commonly used is called a governor.

This consists of two or more pendulums suspended from joints, which are supported upon a vertical axis: this being caused to revolve by the machine, and the pendulums accompanying it, the balls will, by the centrifugal force, recede from the axis or centre a quantity proportioned to the velocity of the motion and length of the pendulum; then, on any acceleration of the motion, they recede still further from the axis, or vice versa, if the velocity diminishes. This motion is contrived to actuate the lever which regulates the velocity of the machine in a steam-engine: it is connected with the valve which admits the steam from the boiler to the cylinder, in a water-wheel with the shuttle, through which the water flows, or in a wind-mill with the mill-stones, or fall-cloths. See a farther description under Mill-work, Steam-engine, and Windmill.

The principle of the governor is the same with the circular or conical pendulum, of which Huygens has laid claim to the invention, as well as of the long pendulum for regulating clocks, who says he discovered it nearly at the same time as the other. The conical pendulum circulates seconds when of the same length with the common pendulum, which will vibrate only half seconds. To explain it, we must suppose a ball or weight to be suspended by a string or rod, so that the ball can describe in a horizontal circle by a motion of the rod round a vertical axis, with which the centre of suspension coincides. In this motion the rod of the pendulum will describe the surface of a cone, of which the point of suspension is the vertex, and the horizontal circle which the ball describes is the base: it is hence called the circular or conical pendulum. The ball has liberty to recede from, or approach to, the axis, by moving upon its centre of suspension, and hence the circle the ball describes will be enlarged or diminished; and it is this circumstance which gives it the property of circulating or performing a revolution always in the same space of time which a simple pendulum of four times the length would vibrate; for this takes place equally whether the ball is extended to describe a large circle, or retracted to rotate in a small one; though, it should be observed, that this is only true in the supposition that the pendulum-ball, in moving from the vertical axis upon its centre, will describe a parabola instead of a circle, in the same manner as the ball of a common pendulum is required to move in the arc of a cycloid instead of a circle, to cause all the vibrations, both long and short, to be performed in equal spaces of time. Mr. Martin has, in his Institutions, given a very complete explanation of the principle of this pendulum, by supposing an inverted parabola, with its axis placed in a vertical position; then supposing a bowl or vessel excavated by the revolution of this figure upon its axis a paraboloid will be formed. A heavy globe or ball being put in this bowl, may, by agitation of the vessel, be caused to perform a revolution in a horizontal circle within the vessel, and it will be found to circulate in the same period of time, whether it describes a small circle near the bottom of the vessel, or a large circle in its upper part, where the diameter is larger.
The governor or flying-ball is the regulator most generally used in machinery, although there are other means which, in particular instances, are preferable, from the circumstance of their possessing a greater power to operate upon the regulating part of the machine. One of these is called the water-regulator, consists of a pump, which, being worked by the machine, will raise water into a cistern, from which a constant stream flows off by a pipe and cock; a float is placed upon the surface of the water in the cistern, and this communicates with the steam-valve of the engine, or shuttle of the water-wheel. The operation of this regulator is easily explained, for the pump will raise a quantity of water exactly proportioned to the velocity of the machine, or the number of strokes it makes; whereas the stream which flows off by the cock is a constant quantity, and equal to that which the pump will supply when the machine moves with its intended velocity. When this is the case, the surface of water in the cistern will stand at the same height; but if the velocity is increased, the pump will raise more water into the cistern than the pipe and cock will carry off, and the surface rising, elevates the float, which, by its action to diminish the supply of power to the machine, will correct the acceleration which has taken place in its velocity. The opposite effect takes place if the velocity decreases, viz. that the supply to the cistern being diminished whilst the efflux is constant, the surface will sink, and the float descending, opens the valve or shuttle, and increases the supply of power to the machine until it regains the original velocity. The great advantage of this regulator is, that it can so readily be made to keep the machine steady at any velocity which may be required, and this by merely opening or closing the cock; thus, if it is opened to carry off a greater quantity, the surface will subside, and the float, by descending, opens a greater supply of power to the machine, and occasions it to move quicker; but this, though it raises more water by means of the pump, will not raise the surface of the water in the cistern to so great a height as it would at first, because the efflux is now equal to the increased supply.

In all cases this regulator will cause the machine to work at such a rate, as to make the pump raise the same quantity of water as the cock emits, and its rate may be ascertained before it is put to work; for if the quantity of water which the cock will discharge in a minute, or other given space of time, is known, and the dimensions of the pump; then it may easily be calculated what number of strokes per minute the pump must make to raise an equal quantity of water. The sensibility of this regulator will be increased by making the cistern of a small size, because then any deviation from the intended rate of working will cause the greater elevation or depression of the surface, and a greater action on the float; and, for the same purpose, it is best to make the cistern gradually diminish in area, so as to be smaller both towards the top and at the bottom, than at the place where the surface is expected to stand when the machine moves with the proper velocity. By this means it will rise or fall more rapidly, in consequence of the diminished area of the cistern, when the alteration of velocity is considerable, and a greater correction is required, than when the alteration is only trifling. It is necessary that the pump should raise a constant stream of water into the cistern, both in the ascent and descent of its bucket; to do this, two pumps, acting alternately, may be used, or by a very simple contrivance a single pump may be made to effect the same; thus, upon the rod of the pump a cylinder of wood is fixed, which is of such a diameter, that its area is equal to half the area of the pump-barrel, and its length being equal to the length thereof, its content will be equal to one-half of the barrel; this is fixed on such a part of the rod, that it will, by the rising and falling of the rod, be drawn up out of water as much as the rod and bucket moves; now, when the pump-bucket is drawn up, the rising of the cylinder above the surface of the water increases the capacity of the cistern one-half as much as the quantity of water which is thus drawn up into it, and the efflux of water by the cock being just equal to the other half, the surface will be stationary; and when the bucket descends, and no water is raised, the cylinder going down into the water diminishes the capacity of the cistern a quantity equal to the quantity of water which will flow off in the same time, and thus supplies the wants of water which flows off in the same time. A regulator of this kind may, in many cases, be formed from some part of the machine, without any additional apparatus; thus, the cold water-pump of a steam-engine will raise the necessary water into a cistern for the float to act in, and this float must be connected with the arm of the steam-valve. Also, in an engine for blowing a furnace, where it has a water-regulator (see Blowing), the rife of the water in the external cistern may regulate the motion of the engine, the whole machine being of the same kind with the regulator we have described.

A regulator would be applied with great advantage to a machine which is used in the Cotton Manufacture (see that article), for drawing a piece of cotton cloth regularly and slowly over a red-hot cylinder of iron by two rollers, from one of which it is wound to the other; now, if the men who turn these fluts and for a moment the cloth is burnt through, but by a regulator it might be lifted off the hot iron the instant the motion was so far diminished as to endanger the firing of it.

The water-regulator is rendered more powerful by suspending the cistern from the end of a lever, like a scale-beam, the opposite end of which has a counterpoise sufficient to balance the weight of the cistern when the water in it stands at the intended height; but if the water increases in the cistern from the causes above described, the box will descend, and the motion of the lever will act upon the machine to make the regulation the same as the motion of the float; on the other hand, when the water in the cistern diminishes, the counterpoise will draw it up and give motion to the lever. The water from the pump is introduced to the cistern by a spout, and all the other parts have the same construction as we have described.

It is a defect of both the regulators we have above described, that they do not operate upon the machine until the alteration of velocity has actually taken place, although they immediately correct it. It would be desirable to have others which would make the correction before the evil takes place; for instance, in a wind-mill, which is more subject to irregularity than any other machine, a large vane may be suspended by a heavy pendulum, and opposed to the wind; now the force of the latter, when blowing regularly, will cause the pendulum to incline a certain quantity from the perpendicular; but if the wind increases or diminishes, it will incline more or less, and this motion may be communicated to the shuttle which regulates the feed of corn, so as to give more or less to the flutes in proportion to the power of the wind for grinding it, thus adapting the resistance to the power; and if this should increase beyond all bounds, the same motion may be made to act upon the grip of the mill to check its acceleration effectually. In the same manner a water-wheel may have a float placed in the dam or head to act upon the shuttle whenever the surface thereof rises or falls above or below
REGULUS, Marcus Atilius, in Biography, a celebrated Roman general, was raised to the consulship the first time in the year 267 B.C., and, in conjunction with his colleague Libo, obtained the honour of a triumph on account of their successes over the Sarmatians, from whom they took their capital Brundusium. During the first Punic war the Romans elected Regulus consul, together with Lucius Manlius Vulso, B.C. 256, and gave them orders to carry their arms into Africa. They failed with a very powerful fleet, and in their voyage encountered a superior Carthaginian force, under Hanno and Hamilcar, which they totally defeated. After refitting in Sicily, and taking fresh troops aboard, the confuls failed for the African coast, where they took possession of the town of Clupea. They next advanced towards Carthage, which city was thrown into the utmost consternation by this unexpected invasion; and, after plundering the country almost to its gates, they returned to Clupea loaded with booty of all kinds. Very soon after this, orders arrived from Rome for the return of Manlius, leaving Regulus with part of the fleet and army to conduct the war in Africa. Regulus asked for his recall upon the following plea: he was poached of a farm of seven acres, from which his family derived their subsistence, and being informed that his servants were carrying off his flock, he begged that he might be allowed to save his family from starving. The plea was overruled, by an order that they should be maintained by the public during his absence upon the service of his country. He again advanced towards Carthage, crosseted the river Bagrada (in palling which, according to the Roman historians, he was encountered by a monstrous serpent), and laid siege to a town not far from the metropolis. Hamilcar attempted to relieve the place, but Regulus met him and gave him a very signal defeat. After this he took several towns, without any resistance. A revolt of the Numidians reduced the Carthaginians to still greater distress, so that it appears the enemy fought for peace. The terms, however, offered by Regulus were so unreasonable, that the senate of Carthage could not for a moment listen to them, and refused upon a vigorous prosecution of hostilities. During the interval of negotiation a body of Greek mercenaries arrived at Carthage, commanded by Xanthippus, a Spartan, by whom the Romans were completely defeated, with the loss of 30,000 men, besides 15,000 taken prisoners, among whom was Regulus himself, whom the Carthaginians brought in triumph into that city, which, but a few hours before, he had not only inflamed, but, in his own mind, devoted to destruction. Hitherto, says the historian, Regulus had appeared only as a Roman commander, and not one of the most conspicuous; the concluding scenes of his life are those which entitle him to rank among the first of Roman patriots. The Carthaginians behaved to their other prisoners humanely; but Regulus they treated with all the barbarity which they could devise; but, when the fortune of war appeared to turn against them, they began to use him with more lenity, in order that they might engage him to endeavour to obtain an accommodation. At their desire he went with their ambassadors to Rome, having first taken an oath that he would return to his prision, if the negotiation should not succeed. When he arrived at the gates of the city he refused to enter, being, as he said, a slave to the Carthaginians; and when his wife and children came out to meet him, he viewed them as strangers, and declined their careness. The senators assembled to give audience to the Carthaginian ambassadors, pressed him to take his seat among them, but he refused, till commanded by his masters to accept it. When he was called on for his opinion, he spoke strongly both against granting the Carthaginians peace, and exchanging himself and the other Roman captives for the prisoners of importance whom they had taken from that nation. Though convinced by his arguments, the senators were unwilling to send back a noble citizen, and a subterfuge was suggested to him by which he might be released from his oath, but he infantly rejected the base suggestion, and declared his resolution to return to Carthage in the face of the cruel punishment that he knew awaited him. Acting upon the idea that he was still a slave, he took no leave of his family, but, with an unmoved countenance, made his way in silence through the crowds of his admiring countrymen. The Carthaginians were told that their offers of peace were not only rejected at Rome, but chiefly through the means of Regulus, whom now they resolved to punish in the severest manner possible. For some days he was exposed to the rays of a meridian sun, and afterwards confined in a barrel, whose sides were every where filled with large iron spikes, till he died in the greatest agonies. His sufferings were heard of at Rome, and the senate permitted his widow to inflict whatever punishment she pleased on some of the most illustrious captives of Carthage, and she took a severe revenge, till at last the senate interpolated, and put a stop to the barbarity of her punishments. Regulus perished in the year B.C. 251. Univ. Hist.

Regulus, Petrus, King, in our Ancient Customs, is a term frequently used, as variously names, in the Saxon councils, for comes or count. Hence sub-regularus was also used for a vice-comes or vicount: though in many places the two feem used indifferently for the same dignitary. Thus in the archives of the cathedral of Worcester, Uthredus sometimes styles himself regularus, and sometimes sub-regularus, of the city of Worcester.

But in other places we find a distinction: "Offa, rex Merciorum; Uthredus, regularus; Aldredus, sub-regularus, &c."

Regulus, Konig, Germ., in Chemistry, denotes, in its most extensive sense, a metal in the proper metallic state. The term is now little used, though the chemists chiefly employed it as a diaphantine appellation in those cases where a metal and one of its ores happened to be called by the same name. Thus, the grey fulphuret of antimony was not known by the name of antimony long before it was suspected to contain a peculiar metal; when this discovery took place, the metal was called regularus of antimony, in order to distinguish it from the ore from which it was procured. For the fame reason, the metals arsenic and cobalt were denominated the regula of arsenic and cobalt.

Regulus of Antimony. See Antimony.
REGULUS, Martial, of Antimonia. See Antimonia.

REGULUS of Arsenic. See Arsenic.

REGULUS of Cobalt. See Cobalt.

REGULUS, in Astronomy, is a star of the first magnitude, in the constellation Leo; called also, from its situation, Cor Leonis, or the Lion's Heart; by the Arabs, Alhabar; and by the Chaldeans, Kallhelez, or Kallhelez; from an opinion of its influencing the affairs of the heavens; as is observed by Theon. See Leo.

REGULUS, in Ornithology, a species of Falco; which see.

—Allo, a species of Mactella; which see. See also Wren.

REGUSSE, in Geography, a town of France, in the department of the Var; 9 miles N.E. of Barjols.

REGYA, a river of Africa, which runs into the Mediterranean; 16 miles E. of Algiers.

REHABERE facias feifnam, quando vicecomes liberavit feifnam de magore parte, quam debet, in Lawa, a writ judicial; of which there is another of the same name and nature. (Reg. Jud. 13, 51, 54.) It lay when the sheriff in the Habere facias feifnam had delivered more than he ought.

REHABILITATION, REHABILITATIO, in the Civil and Canon Law, an action by which a prince or pope, by dispensation or letters patent, retestores a delinquent to the condition he was in before his delinquency. See DEGRADATION.

The king alone can rehabilitate an officer, noted, condemned, and degraded; or a gentleman who has derogated from his rank.

The pope alone pretends to rehabilitate, i.e. to render capable of benefices and orders, such as had fallen into heresy or other irregularities.

In Romish countries, an ecclesiastical who affils at the execution of a sentence of death, is to be rehabilitated by an abolution, called a fesus.

By the rehabilitation of a convict in the Code Napoleon, or French criminal jurisprudence, is understood his restoration to all the rights and privileges which he had forfeited by being subject to a painful or infamous punishment. He cannot demand it till five years have elapsed since the execution of his sentence, during the whole of which time he must have resided in the same arrondissement; or unless he has been domiciled during two complete years in the territory of the municipality to which the demand is addressed. It must also be supported by testimonials of his good conduct from the municipal authorities. The criminal court receives the demand, and pronounces on it at the end of three months: if their judgment be unfavourable, the application may be renewed at the end of five years, with the fame advantage; but if the party rehabilitated into socity should offend again, he becomes incapacitated for ever.

REHBURG, in Geography, a town of Weitphalia, in the principality of Calenberg; 18 miles W.N.W. of Hanover.

REHEARING, in the Court of Chancery, is a process to which either party, that thinks himself aggrieved, may have recourse, before the execution of a final decree. Every petition for a rehearing must be signed by two counsel of character, certifying that they apprehend the cause is proper to be reheard. And upon the rehearing, all the evidence taken in the cause, whether read before or not, is now admitted to be read; because it is the decree of the chancellor himself, who only now fits to hear reasons why it should not be enrolled and perfected; at which time, all omissions of either evidence or argument may be supplied. But after the decree is once signed by the chancellor, and enrolled, it cannot be reheard or rectified, except by bill of review, or by appeal to the house of lords.

REHEARSAL, in Music and the Drama, an essay or experiment of some composition, which is made in private, previous to the representation or performance of it in public; to habituate the actors or performers, and make them more ready and perfect in their parts.

REHOBOOTH, in Geography, a post-town of America, in Britton county, Massachusetts, on a branch of Providence river, a few miles from Providence, in Rhode island, 40 miles southwesterly from Bolton. It was called "Seconnet" by the Indians; incorporated in 1645, and contains 4866 inhabitants.

REHUT, a town of Hindoostan, in the circuit of Go- hub; 20 miles S.S.W. of Gwalior.

REI Domestica Domestica. See Domesticus.

REICH, in Geography, a town of Austria; 7 miles N.W. of Schwanenstadt.

REICHARDT, John Frederic, in Biography, chapellmister to Frederic II. king of Prussia, at Berlin, was born at Konigberg, in Prussia, in 1751, and studied under the organist of the principal church. Richter taught him the harpsichord, and formed his taste. He likewise practised the violin, and was powerful upon that instrument, particularly in double stops. With these talents he travelled in 1771, distinguishing himself in Upper and Lower Saxony, Drevden, Leipzig, Brunswick, Hamburgh, and Berlin; where he was appointed by the king, in 1775, chapellmister, in the station which Graun had formerly illustrated.

The first composition which he produced in his new office, was a prologue to Graun's opera of "Angelic a Medoro," which he set on occasion of a visit to the king of Prussia by the grand duke of Ruffia, in 1776; in which prologue he composed the famous air "Nell' error d'Atra Forea," for Mad. Mara.

In 1783 he went to Paris, and gave proofs of his abilities at the concert spirituel; and in 1784, he was present at the commemoration of Handel in London. He married the daughter of Francis Benda, born the fame year as himself, an excellent singer.

REICHELIA, in Botany, Schreb. Gen. 299. (Sagone; Audl. Guian. t. i. 1. 1. Jui. 134. Lamerac 111. 111. 1. 211.) Reduced by its author, on the suggestion of Swartz, to Hydroser; Schreb. 826. There have been two botanists of the name of Reichel; but Schreber, mott probably, had principally in view George Christian Reichel, professor of medicine at Leipzig, who published a dissertation on the Spiral Vessels of Plants, and died in 1771, at the age of 44.

REICHELSBERG, in Geography, a lordship of Germany, in the circle of Franconia, deriving its name from a mountain citadel, near the town of Aube, in the duchy of Wurzburg.

REICHELSBURG, a town of the duchy of Wurzburg; 20 miles S.E. of Wurzburg.

REICHELSDORF, a town of Bavaria, in the territory of Nuremberg; 7 miles S. of Nuremberg.

REICHELSEM, a town of the duchy of Wurzburg; 4 miles W. of Arnstein. Allo, a town of the principality of Nassau Weilburg, inhabited in the bishopric of Fulda; 50 miles S. of Marburg.

REICHELSWAND, a town of Bavaria, in the territory of Nuremberg; 3 miles E. of Laut.

REICHENAU, an island in the lake of Constance, about two miles long, and abounding with vines and other fruit
fruit trees, with a celebrated abbey, and the villages of Upper and Lower Zell.—Allo, a town of Bohemia, in the circle of Chrudim; 9 miles W.N.W. of Politzkza.—Allo, a town of Austria; 5 miles S.W. of Freystadt.—Allo, a town of Saxony, in the Vogtland, near Pawa.—Allo, a town of the Helvetic republic, at the union of the two branches of the Rhine; 6 miles S.W. of Coire.—Allo, a town of Bohemia, in the circle of Bechin; 6 miles E. of Rosenberge.—Allo, a town of Bohemia, called “New Reichenthan,” in the circle of Bechin; 8 miles E.S.E. of Pilgram.—Allo, a town of Prussia, in the province of Oberland; 8 miles S.E. of Ofterrood.—Allo, a town of Prussia, on the Oilla; 22 miles E.N.E. of Culin.

REICHENBACH, a town of Saxony, in the Vogtland, containing about 700 houses, two churches, and a Latin school. The inhabitants are chiefly clothiers, and dealers in cloth. Their method of dyeing is held in high estimation, the most beautiful scarlet in the whole electorate being made at this place; 10 miles S.W. of Zwickau. N. lat. 50° 31’. E. long. 12° 16’.—Allo, a town of Sileia, in the principality of Schweidnitz, containing two churches and an hospital. The town has some considerable manufactories of linen, canvas, and fustian; 9 miles N. of Schweidnitz. N. lat. 50° 35’. E. long. 16° 35’.—Allo, a town of France, in the department of the Sarre; 8 miles S. of Sautereck.—Allo, a town of Lusatia; 4 miles S.W. of Cmazem.—Allo, a town of Prussia, in the province of Oberland; 7 miles S.S.W. of Holland. —Allo, a town of Germany, in the county of Hennepke; 3 miles N. of Smalkalden.—Allo, a town of Germany, in the principality of Cumbach; 12 miles E.N.E. of Neufchatel. —Allo, a town of Germany, in the margraviate of Anspach; 2 miles N.W. of Schwabach.

REICHENBERG, a mountain of Swabia; 6 miles N.W. of Haffingen.—Allo, a town of Bohemia, in the circle of Boleslaw. Twenty thousand pieces of cloth are supposed to have been made in this town in one year; 25 miles N.N.E. of Jung-Buntzlau.—Allo, a town of Prussia, in the province of Ermeland; 3 miles S.W. of Halleberg.—Allo, a town and castle of Welfphalia, in the county of Catzenelnbogen; 5 miles E. of St. Goar.

REICHENBURG, a town of the duchy of Stiria; 12 miles S.S.E. of Cilery.

REICHENCK, a town of the duchy of Stiria; 5 miles E.S.E. of Cilery.

REICHENFELS, a town with a castle in Saxony, in the principality of Reußen; 8 miles N.W. of Greitz.—Allo, a town of the duchy of Carinthia; 24 miles N.E. of Clagenfurt.

REICHENHALL, a town of Bavaria, on the Salz, with a rich salt spring, the water of which is partly boiled here, and partly, by means of a large wheel 36 feet in diameter, thrown up to the higher parts of a lofty house, and thence conveyed by means of leaden pipes to the distance of 12 miles, over mountains, towards Traunstein, and there boiled, on account of the convenience of water, and also of exportation. An aqueduct of squared flints, two miles long and five feet broad, with an arched roof, was formed some centuries ago, for conveying water to turn the wheels and other engines, and to carry off any superfluous salt water. This aqueduct, after running to a depth of 12 fathoms under the town, and from thence under the gardens and fields, at last discharges its water in a strong torrent. The current of the water is so strong, that a boat with torches may fail from one end to the other in a quarter of an hour. In the aqueduct are five apertures in the form of towers, and through some of these a person may speak from the ram-
tars. "We fought," said some of them, "against Mr. Reid, when he came; and would have fought for him, when he went away."

The greater part of his residence at New Machar was devoted to the most intense study; and by way of amusement, he had recourse to gardening and botany, of which he was extremely fond, even in old age. In the year 1748 he published a paper in the Transactions of the Royal Society of London, entitled "An Essay on Quantity, occasioned by reading a Treatise, in which simple and compound Ratios are applied to Virtue and Merit." The treatise here referred to was Dr. Hutcheson's "An Inquiry into the Origin of our Ideas of Beauty and Virtue."

The professors of King's college, Aberdeen, in the year 1752, appointed Dr. Reid to be professor of philosophy: the choice originated wholly from the high opinion they were led to entertain of his talents and erudition. It is not known what particular plan he pursued in the course of his lectures; but his department comprehended mathematics, and physics, logic, and ethics. Soon after his removal to this situation, he projected, in conjunction with his friend, Dr. John Gregory, a literary society, which subsisted many years, and which, it is believed, had considerable effect in exciting and directing that spirit of philosophical research, which has since so particularly distinguished the north of Scotland. The writings of Reid, Gregory, Campbell, Beattie, and Gerard, vince the numerous advantages which the members derived from this institution, as they were in the habit of bringing such works as they intended for publication to the test of friendly criticism. Among the most original that of our author, published in 1764, entitled "An Inquiry into the Human Mind, on the Principles of Common Sense," intended to refute the philosophy of Locke and Hume, by denying the connection to which they supposed to subsist between the several phenomena, powers, and operations of the mind; and accounting for the foundation of all human knowledge on a system of instinctive principles. About the time when this "Inquiry" made its appearance, the author received from the college of Aberdeen the degree of doctor of divinity; and by the university of Glasgow he was invited to the professorship of moral philosophy. On the duties attached to this office he entered in 1764; and he was enabled, by means of a handsome income, to concentrate all his attention to his favourite pursuits, which had hitherto been frustrated by the miscellaneity of his academical engagements. The re-searches of Dr. Reid concerning the human mind were extended and methodized in a court, which employed five hours every week, during six months in every year. The fulness of these lectures was afterwards given to the world, in a more improved form, in the last of his publications. In the year 1773 appeared, in the form of an appendix to the third volume of Lord Kames's "Sketches of the History of Man," a brief account of Aristotle's logic, with remarks by Dr. Reid. In the year 1781 Dr. Reid withdrew from his public labours, but he was not inactive; his frequent works afford proof of the ardour with which he availed himself of his literary leisure. In 1785 he published his "Essays on the Intellectual Powers of Man," and in 1788, "On the Active Powers." These volumes complete the system of philosophy, begun in his "Inquiry" many years before.

Notwithstanding his advanced age, Dr. Reid continued to prosecute his studies with unabated ardour and activity. The modern improvements in chemistry attracted his particular notice, and he applied himself with his accustomed diligence to the study of its theories and nomenclature. He amused himself also, at times, in preparing for a philosophical society, to which he was a member, short essays on particular topics, which happened to interest his curiosity, and on which he thought he might derive or afford useful hints in the course of friendly discussion. His last essay appears to have been written in the 86th year of his age, and was read by the author to his associates but a short time previously to his death. In the month of September 1795, he was seized with a violent disorder, with which he for some time maintained a severe struggle; but which, together with some paralytic attacks, put an end to his useful life on the 7th of October, in the 87th year of his age. In point of bodily constitution, few men have been more indebted to nature than Dr. Reid. His form was vigorous and athletic, and his countenance was strongly expressive of deep and collected thought; but when enlightened by the face of a friend, what chiefly caught the attention was a look of good will and of kindness. The most prominent features of his character were intrepid and inflexible rectitude, a pure and devoted attachment to truth, and an entire command over his passions. In private life, no man ever maintained, more eminently or more uniformly, the dignity of philosophy; combining with the most amiable modesty and gentleness, the nobler spirit of independence. As a public teacher, he was distinguished by unwearying affability in inculcating principles, which he conceived to be of essential importance to human happiness. In his eloquence and mode of instruction, there was nothing peculiarly attractive. Such, however, were the simplicity and perspicuity of his style; such the gravity and authority of his character, that he was always listened to with profound respect, and, in his latter years, with a veneration, which age added to great wisdom always inspires. Stewart's Life of Reid.

REIDEN, in Geography, a town of Switzerland, in the canton of Lucerne; 18 miles N.N.W. of Lucerne.

REJECTIO, a word used by medical authors for the culling any thing up preternaturally by the mouth, whether it be by vomiting or by spatting.

REIFF, in Geography. See Riva.

REIFFERSHEID, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Prun. The place contains 31, and the canton 3,646 inhabitants, in 45 communes. Also, a town of France, in the department of the Rhone and Molshe, capital of a county in the archbishopric of Cologne; 42 miles W. of Coblenz. N. lat. 50° 33'. E. long. 56° 27'.

REFLING, a town of the duchy of Stiria, on the river Emn; 28 miles N.W. of Pruck.

REFITNTITZ, a town of Middle Carniola; 4 miles N. W. of Gottschee.

REIFENBERG, a town of Austria; 59 miles S.E. of Goritz.

REIGELSBURG, a lordship of the duchy of Wurzburg.

REIGNAC, a town of France, in the department of the Gironde; 9 miles N.E. of Blaye.

REIGNIER, a town of France, in the department of the Lyon, and chief place of a canton, in the district of Geneva. The place contains 126; and the canton 9,426 inhabitants, on a territory of 1024 kilometres, in 14 communes.

REIGNING WINDS, in Meteorology, are those winds which usually prevail in any particular coast or region, the knowledge of which is essentially necessary to every pilot, who is charged with the navigation in those seas.

REIKENES, in Geography, a cape on the S. coast of Iceland. N. lat. 63° 43'.

REIKEVIC,
REIKEVIG, a sea-port town of Iceland, consisting of about 60 or 70 houses, standing in two rows of nearly equal length, at right angles to each other, the high street being encumbered with rock. Among the rocks, which on every side surround the town, are scattered wretched hovels, a little raised above the level of the ground. The adjacent country much resembles the summit of some of the highest mountains in Scotland, being composed of fragments of rocks, and presenting only a few patches of alpine vegetation. Almost all the houses of Reikevig are of Norwegian construction, and inhabited by Danes. The women of this town are principally employed in the operation of drying fish. On the little island of Aker, near this town, are bred eider ducks in great numbers. About six miles to the south of Reikevig is an immense bed of lava, extending a length of 25 miles, and having its black and deformed surface broken into masses and fragments, which render it difficult and dangerous to traverse it, especially where quantities of the "tricholomum" conceal the hollow parts from view. The breadth of this remarkable current varies from two to ten miles; and its hideously shattered aspect is supposed to have resulted from the expansive force of elastic fluids which escaped during the cooling of the lava. Most of the produce of the Icelanders is brought to Reikevig; and the inhabitants of the interior of the country take back, in exchange for their tallow and skins, the dried heads of the cod-fish, and such fish as are injured by the rain and not fit for exportation. They form the principal article of their food, and are eaten raw, with the addition of butter, &c. Bishop Vidianus in this place has a library of 5 or 600 volumes. The author of the work now cited states the height of the region at about 5000 feet, and the population of Iceland at about 48,000 persons, who, from the rigour and instability of their climate, can never rely on their native produce even for the necessary articles of subsistence. The principal articles of export are dried fish, (especially cod of a superior quality), mutton, lamb, beef, butter, tallow, tallow-oil, coarse woollen cloth, the skins of sheep, lambs and foxes, eider-down and fathers; and their chief importations are timber, fishing tackle, various implements of tin, tobacco, bread, spirituous liquors, salt, linen, &c. A large proportion of their food consists of fish, butter, and various preparations of milk. Hooker's Journal of a Tour in Iceland in 1809.

REILLANE, a town of France, in the department of the Lower Alps; 7 miles S. of Forcalquier.

REIMBURSEMENT, in Commerce, the act of repaying or returning what monies a person has received, by way of advance, &c. or what another had disbursed or paid for him. A person who gives a bill of exchange in payment is to reimburse it, if it come to be protested, for want of being accepted or paid.

REIMBURSING is also used for paying the price a commodity costs its owner.

REIMS, or Rheims, in Geography, one of the most ancient and celebrated cities of France, and principal place of a district, in the department of the Marne, seated on the Velle. Before the revolution this city was the See of an archbishop, who was the first duke and peer of France, and always crowned the king. In this place was the abbey of the Benedicines of St. Remy, the noblest of that order in the kingdom of France; and on the altar of its church, under which St. Remigius was buried, was kept the holy viat, which, as tradition reports, was, in the year 496, at the baptism of Clovis by bishop Remigius, brought from heaven by a dove in deference to the prayer of that saint; the crowd obstructing his passage to the font with the usual oil. The university of Reims was founded in 1547, and in the following year authorized by the parliament of Paris. This city contains 50,205 inhabitants, in the three parts into which it is divided, and it has three corresponding cauons, the first containing 12,140, the second 10,100, and the third 10,140, in three, four, and five communes respectively, on a territory of 1778 square miles. Rheims carries on a considerable trade in wine, woolen and silk stuffs, and gingerbread. It has several remains of Roman antiquities, particularly the three gates of the city, which still bear the names of as many Pagan deities, viz. the Sun, Mars, and Ceres. It was taken by the English in the reign of Henry V. N. lat. 49° 15'. E. long. 4° 16'.

REIN, a town of the duchy of Sistria; 9 miles N.W. of Gratz.—Also, a town of the same duchy, on the river Save; 20 miles E. of Cilley.

REIN-DIER, in Zoology. See Cerius Taradus.

REINDORFF, in Geography, a town of Bavaria; 4 miles S.S.W. of Bamberg.

REINNECIUS, Reinier, in Biography, a learned German, who flourished in the 16th century, was a disciple of Melancthon, and taught the belles lettres in the universities of Frankfort and Helmstadt till his death, in 1595. He is known to the learned world by several works on history and genealogy, in which he was profoundly vered. His chief publications are, "Syntagma de Familis Monarchiarum trium priorum," 1574; "Familie Regnum Judaeorum;" "Chronicon Hierolymitanum;" "Historia Orientalis;" "Historia Judaica," three vols. folio; "Methodus Legendi Historian.

REINECK, in Geography, a town of France, in the department of the Rhine and Moselle, late capital of a burgrave, deriving its name from it, and situated between the duchy of Jules and elector of Cologne, on the borders of the Rhine; 14 miles N.N.W. of Coblenz.

REINEN. See REINE.

REINERTZ, a town of Silicia, in the comte of Glatz, on the borders of Bohemia; famous for its manufactures of beautiful cloth and plumps, and excellent paper, equal to the best in Holland; 11 miles W. of Glatz. N. lat. 50° 14'. E. long. 16° 10'.

REINFELDT, a town of Prussia, in the province of Pomerania; 12 miles S.W. of Dantzig.

REINFORCE, in Gunnery, is that part of a gun next to the breech, which is made stronger, to resist the force of the powder. There are generally two reinforcements in each piece, called the first and second reinforcement; the second is somewhat smaller than the first, upon the supposition that when the powder is inflamed and occupies a greater space, its force is diminished, which is very absurd. See CANNON.

REINFORCE Rings of a cannon, are flat mouldings like iron hoops, placed at the breech-end of the first and second reinforcement, projecting beyond the rest of the metal about one-fourth of an inch. See CANNON.

REINFORCEMENT, in War, a supply, or new provision of men, arms, ammunition, &c.

REINUS, in Geography, a town of Austria; 12 miles N.N.W. of Waidhausen.

REINHARTSBRUNN, a town of Germany, in the principality of Gottha; 10 miles S.S.W. of Gottha.

REINHARTZ, a town of Saxony; two miles W. of Schmildelberg.

REINHEIM, a town of the principality of Hesse Darmstadt; 5 miles S.E. of Darmstadt.

REINHOLD, ERASMUS, in Biography, an eminent German mathematician, was born at Salzfeld, in Thuringia, a province in Upper Saxony, in the year 1511. He was educated
educated at the university of Wittemberg, where his genius chiefly inclined him to the study of the mathematic, which he cultivated with great success. He afterwards became a professor of those sciences in the same university, and acquired very high reputation, not only by his lectures, but by the learned and useful writings which he communicated to the public. Of these, which are very numerous, we may mention "Theoria Nova Planetarum G. Purbachii," augmented and illustrated with diagrams and scholia. "Ptolemy's Almagest, with a Latin Version, and Scholia." In 1551 he published "Prutenica Tabulae Caelitum Motuam," which were several times reprinted. In carrying on this work, which cost seven years' labour, he was encouraged by the munificence of Albert, duke of Prussia. They were constructed by him from a comparison of the observations of Copernicus with those of Ptolemy and Hipparchus, and he has fully explained the use of them in a great number of precepts and canons, forming a complete introduction to practical astronomy. Reinhold also made many astronomical observations, but he never had any better instrument than a wooden quadrant. The result of these observations were shown to Tycho Brahe after the death of Reinhold, who expressed his surprize that so great and meritorious a cultivator of astronomical science was not furnished with better instruments. Reinhold died in 1553, when only in the 42d year of his age, pronouncing the following verse a short time before he expired.

"Vixi, et quem dederas cursum inihi, Chrilde, peregi."

He had a son of the same name, eminent as a mathematician and physician, who published a small work in the German language "On Subterranean Geometry," also a tract concerning the new star which appeared in Caffiopeia in 1572.

REINISCHDORF, in Geography, a town of Silefia, in the principality of Neisse; 5 miles N. of Neisse.

REINS, in Anatomy, the kidneys. See Kidney and Reno.

The word, according to Varro, is formed from the Greek, πραγμα, quasi rivi objecta locum ab in orintur.—The Greeks call the rein ραχις, from the verb ραχεω, to rain, snow, &c.

In the manage they say, a horse should have double reins; that is, he should have them a little more elevated on each side of the back-bone, than upon it; so that, passing your hand along it, you find it large, well-furnished, and double, by the hollow that goes all along the back-bone. The back should be firm and not hollow, or bending from the withers to the croup, but straight.

REINS, of a bridle, also denote two travs of leather meeting in the bridle-hand of the horseman, in order to make the bit bear, and keep the horse under subjection. See Bridle.

It is also a name given by the Duke of Newcastle to two travs or ropes of a caffelon, which he ordered to be made fast to the girths, or the pommel of the saddle, with intent that the rider should pull them with his hand, in order to bend and supple the neck of the horse.

REIN, Falde, is a lath of leather, paffed sometimes through the banquet, to bend the horse's neck, which is disapproved of by the Duke of Newcastle, because it shakes the curb, and makes the bit no more than a tarch that has no curb.

REINS, in Rural Economy, the long thongs or strips of leather, or other materials, by which horses or other animals are directed in carriages or teams. These reins are much used in some counties, as Norfolk and Suffolk, in directing the plough-teams, in order to save the expense of another person, the ploughman directing them in this way himself; the driver being by this means dispensed with.

REINS, Check, a term signifying the same thing as a fort of rein, and which is made ufe of in particular districts, in checking and directing the animals.

REINS, Whip, a term used to signify a fort of hempen rein, employed for directing the team in ploughing in some districts, so called in consequence of being ufed instead of whips.

REINS of a Vault. See Vault.

REINSBERG, or Rhinsberg, in Geography, a town of Brandenburg, in the Middle Mark; 10 miles N.N.E. of New Ruppin. N. lat. 53° 41'. E. long. 12° 58'.

REINSDORF, a town of Saxony, in the circle of Erzgebirg; two miles E.S.E. of Zwickau.

REINSPURG, a town of Bavaria, in the territory of Rothenburg; six miles S.S.W. of Rothenburg.

REINSTATING, the restoring of a person or thing to its former state or condition, from whence it had been disturb'd or displace'd. See Rehabilitation.

REINSTEIN, in Geography. See RENSTEIN.

REINSURANCE, or Re-Assurance, in Commerce, a contract by which a first insurer relieves himself from the risks which he has undertaken, and devolves them upon other under-writers, called re-insurers, or re-assurers. When a policy of insurance has been once signed, the under-writers are bound by the terms of it; nor can they be released from their contract without the consent of the insured. But if an under-writer repents of what he has done; if he be afraid to encounter the risk which he has engaged to run; or if he find that he has incautiously engaged himself to a greater amount than he may be able to discharge, he may shift it, or part of it, from himself to other insurers, by causing a re-insurance to be made on the same risk, upon the better terms in his power, and the new insurers will be responsible to him in case of loss, to the amount of the re-insurance. But in such case, the new insurers are responsible to the original under-writer only, and not to the original insured, who can have no remedy against him, in case of loss, even though the original insurer become insolvent; because there is no privity of contract between the original insured and the re-insurer. If, therefore, the original insurer fail, so that the original insured receive only a dividend, however small, the re-insurer can gain nothing by this, but must pay the full amount of the loss to the original insurer. Such is the law on this subject, in most of the commercial states of Europe. But in this country it was found, about the time when the statute 19 Geo. II. c. 17. was made, that this mode of insurance, though perfectly reasonable, when confined to its proper object, had been perverted from its original use, and was employed as a mode of speculating in the rise and fall of premiums; and the legislature foreseeing that it might be used as a colour for wager policies, and a means of evading the provisions of that act, declares (sect. 4.) "that it shall not be lawful to make re-insurance, unless the insurer shall be insolvent, become bankrupt, or die; in either of which cases, such insurer, his executors, administrators or assigns, may make re-insurance to the amount of the sum before by him insured; provided it be expressed in the policy to be a re-insurance." This clause, having no words to confine its operation to ships belonging to British subjects, like the first clause of the 3d restraining insurances, ifest or no inest, extends to re-insurances made in England in foreign ships, even when they are insured abroad. This has been so determined; though it is observable that the following case, in
which that question was made, was not the species of re-insurance above described, and to which only the statute refers, but a second insurance, effected on account of the original injured.

That was the case of an insurance made in London, on a French vessel, which had before been insured at Marseilles for the same sum, by an insurer there, who, at the time of sub-securing the second policy, was living and solvent, and who, in fact, afterwards paid the sum injured by him. Upon this case the court determined that the latter policy was void by the words of the act; for though the first clause of the act which prohibits insurances, ‘interest or no interest,’ is confined to insurances on British ships, yet the fourth section being general, and without any such restrictive clause, every re-insurance in this country, either by British subjects, or foreigners, on British or foreign ships, is declared void by the statute, unless the first insurer be insolvent, become bankrupt, or die.

There are two other kinds of re-insurance; the one where the insured infures the solvency of the insurers; the other, where he makes a new insurance, in consequence of the insolvency of an insurer during the continuance of the risk.

The insolvency of an insurer is permitted and practised in some foreign countries; but it seems never to have been in use among us; not, perhaps, as has been suppos’d, because the solvency of an under-writer is not an insurable interest, or that such an insurance would be deemed a wager; but, more probably, because the insolvency of an insurer seldom happens in England; besides, a double insurance would better answer the end propounded.

If France, if an insurer fall during the continuance of the risk, the insured may insist on the divolution of the contract, unless the creditors of the insolvent insurer, in order to entitle themselves to receive the premium, (which is rarely paid in that country till after the risk is ended,) will give security for the payment of the sum injured, in case of loss. At Marseilles, (for in France different practices prevail in different provinces,) the insured, in such case, sues the insolvent insurer, till he obtains a sentence, authorizing him to re-insure at the expense of the insolvent, which he may deduct from the stipulated premium, if it be not paid, and if this be insufficient, then out of the effects of the insolvent.

Double insurance is where the insured makes two insurances on the same risk, and the same interest; and it differs from a re-insurance in this, that it is made by the insured, in order that he may be entitled to receive a double satisfaction, in case of loss; whereas, a re-insurance is made by a former insurer, his executors or assignors, to protect himself and his estate from a risk to which they were liable by the first insurance. A re-insurance, except in the cases permitted by the statute Geo II. c. 37. § 4, is absolutely void; but a double insurance, though it be made with a view to a double satisfaction in case of loss, and is therefore in the nature of a wager, is not void by the law of England. The two policies are considered as making but one insurance. They are good to the extent of the value of the effects put in risk; but the insured shall not be permitted to recover a double satisfaction. He may sue the under-writers on both the policies, but he can only recover the real amount of his loss, to which all the under-writers shall contribute in proportion to their several subscriptions. And therefore, if he should content himself with suing only on one of the policies, the under-writers on that policy may recover a rateable contribution from those on the other.

In consequence of the determination of lord Mansfield, in 1763, it has been agreed to be the course of practice, that, upon a double insurance, though the insurer is not entitled to two satisfactions, yet, that in an action upon the first policy, he may recover the whole sum injured, and may leave the defendants thereto to recover a rateable satisfaction from the other insurers. Formerly, in the case of an over-insurance, that is, where, in a single policy, the sums subscribed amount to much more than the value of the effects injured, the first under-writers on the policy were held to be answerable to the extent of the loss, and the subsequent ones discharged. Although only a single satisfaction can be recovered on a double insurance by the same person, yet different persons may insure the same thing, and each recover the full value of the thing injured. To enable the defendant, in an action on a policy, to discover whether there be a double insurance, he may, by the authority of the statute Geo II. c. 37. § 6, call upon the plaintiff to declare in writing, what sums he has insured in the whole, and how much he has borrowed on bottomry or repondentia. Marshall’s Treatise on the Law of Insurance, vol. i. ch. 4. § 4.

REINTAL, in Geography, a town of Austria; four miles E.S.E. of Feldberg.

REINTEGRATION. See REINTEGRATION.

REJOINING FIRE, in Military Affairs, is used on obtaining a victory, or in celebrating some public festival: of this there are two sorts, viz. one by a volley, and the other by a running fire, from the right to the left of the battalion or line.

REJOINER, in Law, the defendant’s answer to the plaintiff’s replication.

The order of the court of chancery is thus; first, the defendant puts in an answer or plea to the plaintiff’s bill, which is sometimes also called an exception; the plaintiff’s answer to this is called a replication; and the defendant’s answer to that, a rejoinder.

The plaintiff may answer the rejoinder by a sur-rejoinder, upon which the defendant may rebut; and the plaintiff may answer him by a sur-rebutter; which pleads, replications, rejoinders, sur-rejoinders, rebutters, and sur-rebutters, answer to the exception, duplicatio, triplicatio, and quadruplicatio of the Roman laws. See Pleading.

REJOINTING, or REJOINTING, in Architecture, the filling up of joints of the stones in old buildings, &c. when worn hollow by the course of time, or by weather.

Rejointing is to be performed with the beet mortar, as that of lime and cement; sometimes also with plaiter; as in the joints of vaults, &c.

REIPOLTZHEIM, in Geography, a town of the duchy of Würzburg; three miles N.E. of Schwarzbach.

REIPOLTZKIRCHEN, a caille of France, in the department of Mont Tomerre, which gave name to a lordship, situated in the Hunrück; five miles E. of Lautereck.

REIS, RE, or RES, in Commerce. See Rees.

REISBACH, in Geography, a town of Lower Bavaria, in the Vils; 35 miles W. of Passau.

REISCH, a town of Moravia, in the circle of Iglau; 18 miles S. of Iglau.

REISCHSTADT, a town of Bohemia, in the circle of Boleflau; two miles N.W. of Nimes.

REIS-EFFENDI, in the Turkey Empire, one of the ten members of the divan, (which fee,) or council of the grand vishir, of which the vishir and mufiri are the preludents. The reis-effendi is a kind of secretary of flate, high chancellor of the empire, and minister for foreign affairs. He signs all the orders of the Porte, which do not directly concern the finances and the military operations; he treats with all the European ministers who are at Constantinople; in a word, every thing that concerns the foreign powers, and every
REISENDORF, a town of Silezia, in the principality of Neisse; four miles N. of Paltshau.
REISTEN, a town of the duchy of Warzburg; six miles N.N.E. of Arnstein.
REISTERSTOWN, a post-town of America, in Baltimore county, Maryland; ten miles S.E. of Wellminder.
REITERATED GRAFTING. See Grafting. REITERATING, in Printing. See Printing. REITERATION, the act of repeating a thing, or doing it a second time.

The church does not allow of the repetition of baptism. St. Gregory observes, that it is no repetition when there are wanting proofs of the thing's having been regularly done before.

REITLINGEN, in Geography. See Rethlingen. REITTERECK, a town of Striza; seven miles E. of Voihtburg.
REITTERS, an ancient title given the German cavalry. The word is originally High Dutch, and signifies a horseman, cavalier, or even knight.

REITZ, in Geography, a town of Portugal, in the province of Beira; three miles N. of Vifeu.
REKEK, a small island in the East Indian sea. S. lat. 1° 0' 33'. E. long. 138° 40'.
REL AS, in Fortification, a French term, the same with berme.

RELAND, ADRIAN, in Biography, an eminent orientalist and polite scholar, was born in the year 1676, at a village in North Holland. He was educated at Amsterdam, and made such progress in learning, that, having gone through the usual classical course when he was only eleven years old, he employed the next three years in making himself acquainted with the Hebrew, Syriac, Chaldee, and Arabic languages. At the age of fourteen he was sent to the university at Utrecht, and in three years was admitted to the degree of doctor in philosophy; and on this occasion he sustained a thesis "De Libertate Philosophandi." After a residence of six years at Utrecht he removed to Leyden, and was in a short time chosen by the earl of Portland as preceptor to his son. At the age of twenty-four, the university of Harderwyk nominated him to the chair of philosophy, but he did not remain long in that situation, for the university of Utrecht, on the recommendation of King William, invited him to the professorship of the Oriental languages and Jewish antiquities, which he accepted, and occupied with high reputation during the remainder of his life. He died at the age of 43, in the year 1719. Few writers have met with more general applause than Reland. His principal works, which are all extremely valuable, are; 1. "Palestina Monumentis veteribus illustrata," 2 vols. 4to. 2. "Dissertationes de nummis veterum Hebrorum." 3. "Antiquitates faecres veterum Hebrorum." 4. "Introductio ad Grammaticam Hebraeam." 5. "De Spolis Templi Hierofolymitani in Arcu Titiano Romae confpi- cibus." 6. "De Religione Muhamedica." Besides these he published many other things. In private life he was distinguished by his modesty, humanity, and learning, and carried on a correspondence with the most eminent scholars of his time. Moreri.

RELAPSE, in Medicine, the recurrence of a disease during the period of convalescence.

Relapses of all diseases, whether acute or chronic, are deemed more dangerous than the original attack, because the constitution, being already debilitated and reduced by the previous illness, is less capable of refuting the farther ravages of disease. This may be said to be true of all acute diseases,
diseases, such as fevers, dropgies, inflammations of the
lungs, liver, &c. Nevertheles, relapses of these disorders are
not always fatal; because, as the weaker constitution is
less capable of being excited to violent action, so these sec-
tond attacks are sometimes milder, and more easily influenced
by remedies. Relapses of chronic diseases, such as dropsy
or jaundice, are more unfavourable; because their recur-
rence implies that the internal disease, from which they ori-
ginate, is not removed, but has only been temporarily al-
viated.

RELATIO, Lat., Relation, Engl., in Music. Relative
sound is in general such as belong to two or more chords,
as in the key of C. The chords of A, F, G, and E, are
relative chords; as E, the 6th of A, is 3rd of C: in the chord
of F, C is the 5th; in the chords of G and E, each of
these sound is a part of the chord of C.

C major.

The relatives to A minor are obvious here.

In the modulation by rising and falling a 3d in the base,
two relative notes are in common with each chord. The
most agreeable relation of a minor key to a major, is in the
modulation from a minor key to the 3d above; as from A to
C, or D to F; the scales of both keys being the same in
defending. But falling a 3d in the base from a minor 3d to
a major, as from A to E, or from D to Bb, is still more
pleasing.

False relation is C♭ against C♮, or G♭ in the chord of
C♭. But even these false relations are allowed now, as
passing-notes of taste, though not in the body of the mor-
emony.

RELATION, Relation, in Philosophy, the mutual re-
spect of two things; or what each is with regard to the other.
The word is formed a referendo: relation consignifying this,
that one thing is referred to another; whence it is also called
respect, habitude, and comparison.
The idea of relation we acquire, when the mind so con-
siders any thing, that it doth, as it were, bring it to, and let
it by, another, and carry its view from the one to the other.
Hence the denominations given to things intimating this re-
spect, are called relatives; and the things so brought to-
tgether, are said to be related.
Thus, when I call Calus husband, or this wall a waller, I
intimate some other person or thing in both cases, with
which I compare him or it. Hence the wall is called by
the schoolmen the subject; the thing it exceeds in white-
ness, the term; and the whiteness, the foundation of the
relation.

Relation may be considered two ways; either in the part
of the mind referring one thing to another; in which sense
relation is only a mode or affection of the mind, by which
we make one thing to refer to or influence the mind
upon considering of two other ideas. So that relation, take
it as you will, is only in the mind, and has nothing to do
with the things themselves.

Any of our ideas, Mr. Locke observes, may be the
foundation of relation. Though where languages have
failed to give correlative names, the relation is not easily
taken notice of; as in concubine, which is a relative name, as
well as wife.

There is, in effect, no idea but is capable of an infinite
number of relations: thus, one single man may at once
furnish the relations of father, brother, son, husband,
friend, subject, general, European, Englishman, stranger,
master, servant, bigger, less, &c. to an almost infinite
number; he being capable of as many relations as there
have been occasions of comparing him to other things in any
manner of agreement or disagreement, or any respect what-
soever.

The ideas of relations are much clearer and more distinc-
tion than those of the things related; because the knowl-
edge one simple idea is oftentimes sufficient to give
the notion of a relation; but, to the knowing of any
substantial being, an accurate connection of several ideas
is necessary.

The perception we have of the relations between the various
ideas in which the mind acquiesces, makes what we call
judgment. Thus, when I judge that twice 2 make 4, or do
not make 5, I only perceive the equality between twice
2 and 4, and the inequality between twice 2 and 5.

The perception we have of the relations between the re-
lations of various things, constitutes what we call reason-
ing. Thus, when from this that 4 is a smaller number than 6,
and that twice 2 is equal to 4, I gather, that twice 2 is a
less number than 6; I only perceive the relation of the
numbers twice 2 and 4, and the relation of 4 and 6.

The ideas of cause and effect, we get from our observation
of the vicissitude of things, while we perceive some
qualities or substances begin to exist, and that they receive
their existence from the due application and operation of
other beings. That which produceth, is the cause; that
which is produced, is the effect.

Thus, fluidity in wax is the effect of a certain degree of
heat, which we observe to be constantly produced by the
application of such heat.

The denominations of things taken from time are, for
the most part, only relations. Thus, when it is said, that
queen Elizabeth lived sixty-nine, and reigned forty-five years,
no more is meant, than that the duration of her existence
is equal to sixty-nine, and of her government to forty-five,
animal revolutions of the sun; and so are all words anw-
sering to how long.

Young and old, and other words of time, that are
thought to stand for positive ideas, are indeed relative,
and intimate a relation to a certain length of duration, of which
we have the ideas in our minds. Thus, we call man young
or old, that had lived little or much of that time which men
usually attain to; and thus a man is called young at twenty,
but a horde old at the same period.

There are other ideas that are truly relative, which we
signify by names that are thought positive and absolute; such
as great and little, strong and weak. The things thus deno-
minated
Announced are referred to some standards, with which we compare them; thus, we call an apple great, which is bigger than the ordinary sort of those we have been used to; and a man weak, that has not so much strength or power to move as men usually have, or as others of his own size have.

Authors give various divisions of relations. The school philosophers commonly divide them into those of original, under which are comprehended the relations of cause and effect; those of negation, which are between opposite things; and those of affirmation, which are relations of agreement between whole and part, the sign and thing signified, the adjacent and subject. This division is founded upon this, that the mind can only compare things three ways; viz. by inferring, denying, and affirming.

Others divide relations into those of origination; those of agreement, e. gr. uniformity, parity, &c.; those of diversity; and those of orders, as priority, posteriority, &c.

Others divide them into predicable and transcendental. Under the first come those relations between things that belong to the same predicate, e. gr. between father and son. To the latter belong those which are more general than the predicaments, or are of different predicaments; as the relations of substance and accident; of cause and effect; and of Creator and creature.

Mr. Locke gives us a distribution of relations on a different principle. All simple ideas, he observes, in which are parts or degrees, afford an occasion of comparing the subjects in which they are to one another, in respect of those simple ideas; as whiter, sweeter, more, less, &c. These, depending on the equality and excess of the same simple idea, in several subjects, may be called proportional relations.

Another occasion of comparing things being taken from the circumstances of their origin, as father, son, brother, &c., these may be called natural relations.

Sometimes the foundation of considering things is some act, by which any one comes by a moral right, power, or obligation, to do something; such are general, captain, burgler; these are infinited and voluntary relations, and may be distinguished from the natural, in that they are alterable and separable from the persons to whom they sometimes belonged, though neither of the substantiates so related be destroyed. But natural relations are not alterable, but are as lasting as their subjects.

Another relation is the conformity or disafforestation of men's voluntary actions to a rule, to which they are referred, and by which they are judged of: these may be called moral relations.

It is this conformity or disafforestation of our actions to some law (by which good or evil is drawn on us from the will and power of the law-maker, and is what we call reward or punishment) that renders our actions morally good or evil.

Of these moral rules or laws there seem to be three sorts, with their different enforcements. First, the divine law; secondly, civil law; thirdly, the law of opinion or reputation. By their relation to the first, our actions are either sins or duties; to the second, criminal or innocent; to the third, virtues or vices. Locke's Essay, vol. i. chap. 25, 26, 33.

Relation, in Logic, is an accident of substantance, accounted one of the ten categories or predicaments.

Each substantance admits of an infinity of relations. Thus the same Peter confedered with regard to Henry, is in the relation of a master; with regard to John, in that of a tenant; with regard to Mary, in that of a husband, &c.

Again, with regard to one person, he is rich; with regard to another, poor; with regard to another, he is far, near, tall, short, a neighbour, stranger, learned, unlearned, good, bad, equal, &c. It is disputed among the school philosophers, whether or no the relation be a thing formally and really distinct from the foundation of the substantance.

Relation, Relation, in Rhetoric, is sometimes used to signify the same with recrimination; which see.

Relation is also used, in the School Theology, to denote certain of the divine perfections, called personal ones; because by these one Divine Person is referred to another, and distinguished from it.

Hence the schoolmen teach, that in God there is one nature, two proceedings, three persons, and four relations. These relations are paternal, filiation, active spiration, and passive spiration.

Relation, in Geometry, Arithmetic, &c., is the habitude, or respect of two quantities to one another, with regard to their magnitude. This we more usually called ratio or reason. See Ratio.

The equality or sameness of two such relations we call proportion; which see.

Relation, in Grammar, is the correspondence which words have to one another in construction; which see. See also Regimen and Syntax.

Faulty and irregular relations are the things chiefly to be guarded against in writing correctly; they make the sense obscure, and frequently equivocal. Thus: the orator was attended to with a coldness, which was the more remarkable, as the audience were under some emotion before he began. Here coldness being put indeterminately, the relative which can have no juitl and regular relation to it.

Relation is also frequently used for analogy, or what several things have in common. See Analogy.

In painting, architecture, &c., a certain relation of the several parts and members of the building, or picture, constitutes what we call symmetry; which see.

Relation, in Law, is where two things, as times, &c., are considered as if they were one; the thing subsequent being considered as taking effect, by relation, at the time preceding.

As if A deliver a writing to B, to be delivered to C, as the deed of A; the writing shall be deemed to be delivered to C, at the time when it was given to B, by relation.

When the execution of a thing is done, it hath relation to the thing executory, and makes all but one act to record, although performed at several times. (i Rep. 199.) Judgment shall have relation to the first day of the term, as if given on that very day, unless there is a memorandum to the contrary; as where there is a continuance till another day in the same term. (3 Salk. 212.) A verdict was given in a cause for a plaintiff, and there was a motion in arrest of judgment within four days; the court took time to advise, and in four days afterwards the plaintiff died: it was adjudged, that the favour of the court shall not prejudice the party, for the judgment ought to have been given after the first four days; and though it is given after the death of the party, it shall have relation to the time it ought to have been given. (1 Leon. 187.) Rule was had for judgment, and two days after the plaintiff died; yet the judgment was entered, because it shall have relation to the day when the rule was given, which was when the plaintiff was alive. (Poph. 132.) Judgment against an heir of the obligation of his ancestor shall have relation to the time of the writ first purchased; and from that time it will
will avoid all alienation made by the heir. (Cro. Car. 102.) If one be bail for a defendant, and before judgment he leaves his lands; they shall be liable to the bail, and judgment be given. 

By Stat. 39 Car. II. c. 3. § 16. writes of execution shall bind the property of goods taken in execution, only from the time of their delivery to the officer. Sale of goods of a bankrupt, by commissioners, shall have relation to the first act of bankruptcy; and be good, notwithstanding the bankrupt sells them afterwards. (Stat. Ja. I. c. 15.) If a man buys a cattle in a market, which are stolen and sold to him of the market, though the cattle are afterwards brought into the market, and the second bargain confirmed, and money paid, &c., this bargain will still be good; for it shall have relation to the beginning, which was unlawful. (Dyer 99.) Fines, being but common assurances, shall be guided by the indentures precedent; and the execution of them have relation to the original act. (Cro. Jac. 119.) Letters of admittance relate to the death of the intestate, and not to the time when they were granted. 

So bills in parliament by which the king affents on the last day of parliament shall relate and be of force from the first day thereof. Coke calls this fictio juris. RELATION, in MYST. See RELATIO. RELATIVE PROPOSITIONS, are such as include some relation and comparison. Thus, where the treasure is, there will be the heart. As much as thou hast, so much art thou worth, &c., are relative propositions. RELATIVE Gravity, levity, motion, necessity, place, space, time, velocity. See the several substantives. RELATIVE Terms, in LOGIC, are words which imply a relation, or a thing considered as compared to another. RELATIVE terms include a kind of opposition between them, yet so, as that the one cannot be without the other. Such are father and son, husband and wife, king and subject, &c. RELATIVE, in Grammar, is a word or term, which in the construction answers to some word foregoing, a word, the antecedent of which is the relative. All relatives are said to reciprocate, or mutually infer each other; and, therefore, they are often expressed by the genitive case. RELATIVE PRONOUN. See PRONOUN. RELATOR, in LAW, a rehearser, or teller, applied to an informer. See INFORMATION. RELAXATION, in LAW, is used for a relaxing. See RELEASE. In this sense, we say the relaxing of an attachment in the court of admiralty. The tenor of indulgence is a relaxation, or a diminution, of the pains of purgatory. RELAXATION, in Surgery, is a preternatural extension, or straining of a nerve, tendon, muscle, or the like; either through violence or weakness. Hernias are defects or relaxations of the intestines, &c. From the same cause arise defects or prolapses of the anus, &c. RELAY, a fresh equipage, horfe, &c., sent before, or appointed to be ready, for a traveller to change, to make the greater expedition; as in riding post. The term is borrowed from the French, relai, which signifies the same thing. In France, the general of the poits entitles himself superintendent of the relays. RELAY Horfe, in the ARTILLERY, are horfes that march with the artillery or baggage, and ready to relieve others, or to shift in going up a hill, or through bad roads, &c. RELAY, in Hunting, are fresh sets of dogs, or hores, or both, disposed here and there for redhounds, in cafe the game come that way, to be call off, or to mount the hunters in lieu of the former, which are fuppozed to want relife. RELAY, in TAPISTRY, is an opening left in a piece of tapestry, where the colours or figures are to be changed; because on those occasions, the workmen are changed; or else the places are left to be filled up, till the rest of the work is done. See TAPISTRY. RELEASE, RELAXATION, in LAW, denotes an instrument, by which shall, rights, titles, entries, actions, and other things, are sometimes extinguished and annulled, sometimes transferred, sometimes abridged, and even sometimes enlarged; and it is a species of conveyance which presupposes some other conveyance precedent, and serves to enlarge, confirm, alter, restrict, render, or transfer the interest, granted by such original conveyance. A relay is other in fact, in law. A release in fact, is that which the very words do expressly declare. A release in law, is that which acquits by way of consequence, or intentment of law. A release is the giving or discharging of a right of action, which a man hath claiming, or may claim, against another, or that which is his; or it is the conveyance of a man's interest or right which he hath to a thing, to another who hath possession of it, or some estate in it. (New Abr.) According to Coke releases are distinguished into express releases in deed, and those arising by operation of law; and are made of lands and tenements, goods and chattels; or of actions real, personal and mixed. (1 Inf. 264.) Releases of land may essere, or take effect, either, 1. By way of enlarging an estate, or enlarging PESTATE; as if there be tenant for life or years, remainder to another in fee, and he in remainder releases all his right to the particular tenant and his heirs, this gives him the estate in fee. (Litt. § 405.) But in this case the releefee must be in possession of some estate, for the release to work upon: for if there be a lessee for years, and, before he enters and is in possession, the lessor releases to him all his rights in the reversion, such release is void for want of possession in the releefee. (Litt. § 459.) But when it is said, that a release, which enures by enlargement, cannot work without a possession, it must be understood to mean, that an actual estate in possession is necessary, but that a "veiled interest" suffices for such a release to operate upon. By comparing this with the operation of a LEASE and RELEASE (which fee) it will be seen, that not only estates in possession, but estates in remainder and reversion, and all other incorporeal hereditaments, may be effectually granted and conveyed by lease and release; but it is an inaccuracy to say, that the releases are, in these cases, in actual possession of the hereditaments: the right expression is, that they are actually vested in him, by virtue of the lease in possession and the statute. 1 Inf. 270. (a) n. 4.

To make releases operate by enlargement, it is generally necessary, that the releefee, at the time the release is made, should be in actual possession of, or have a vested interest in, the lands intended to be released; that there should be a privity between him and the releefor; and that the possession of the releefee should be notorious. 2. By way of PASSING AN ESTATE, or MORT PESTATE: as when one or two co-parceners releafeth all her right to the other, this paffeth the fee-simple of the whole.
And in both these cases there must be a privity of estate between the realeffor and the releefee; that is, one of their estates must be so related to the other, as to make but one and the same estate in law.

5. Effext Common and right, Inft. 4. 169. An Ait. a specific releafe If releafe See A a Sid. Cor. as 787. Thunb. this certain matter this Co. privity A releafe Rol. releafe I 91. 2 689. a obligation, iny releafe, and 508. time, man that changes which the effection of his estates, and renders that lawful which before was tortious or wrongful. (Litt. §. 466.)

4. By way of extinguishment: as if my tenant for life makes a lease to A for life, remainder to B and his heirs, and I releafe to A; this extinguishes my right to the reversion, and shall enure to the advantage of B's remainder as well as of A's particular estate. (Litt. §. 470.) 5. By way of entry and feoffment: as if there be two joint defeffors, and the defeffor releases to one of them, he shall be forfeited; and shall keep out his former companion; which is the same in effect as if the defeffor had entered, and by that means put an end to the defeffion, and afterwards had enfeoffed one of the defeffors in fee. (1 Inft. 278.) And hereupon we may observe, that when a man has in himself the possession of lands, he must at the common law convey the freehold by seoffment and livery; which makes a notoriety in the country: but if a man has only a right or a future interest, he may convey that right or interest by a mere releas to him that is in possession of the land: for the occupancy of the releasee is a matter of sufficient notoriety already. Blackft. Com. book ii. See Lease and Releafe.

Littleton says, that the proper words of a releas are "remissiffe, relaxarife, and quietum clamaiffe," which have all the same significations. Lord Coke adds, "renuenciae, acquittacie, and sayes," and says, that there are other words which will amount to a releas; as, if the lessee grants to the lessee for life, that he shall be discharged of the rent; this is a good releas. (Litt. §. 445. 1 Inft. 264. Plowd. 140.) So a pardon, by act of parliament, of all debts and judgments, amounts to a releas of the debts: the word pardon including a releas. (1 Sid. 261.) An express releas must regularly be in writing and by deed, according to the common rule, "codem modo ortum, codem modo diffolitur," so that a duty arising by record must be discharged by matter of as high a nature: so of a bond or other deed. (Co. Litt. 264. 6. 1 Rol. Rep. 43. 2 Leon. 76. 213. 2 Rol. Aabr. 408. 2 Sand. 49. Morr. 573. pl. 787.) But a promise by words may, before breach, be discharged or released, by word of mouth only. (1 Sid. 177. 2 Sid. 78. Cro. Jac. 483. 620. See Cro. Car. 383. 1 Mod. 262. 2 Mod. 259. 1 Sid. 293.) A releas of a right in chattels cannot be without deed. (1 Leon. 283.) A covenant perpetual, as that the covenantor will not flee beyond a certain limitation of time, is an absolute releas. But if the covenant be, that he will not flee till such a time, this does not amount to a releas, nor is payable in bar as such, but the party hath remedy only on his covenantor. If two are jointly and severally bound in an obligation, and the obligee, by deed, covenants and agrees not to sue one of them; this is no releas, and he may notwithstanding sue the other. (Cro. Car. 551. 2 Salk. 575.) But if two are jointly and severally bound, a releas to one discharges the other. L. Raym. 420.

It seems agreed, that a will, though sealed and delivered, cannot amount to a releas; and, therefore, where in debt on an obligation, by the representative of a defeffor, a defendant pleaded, that the defeffor by his laft will in writing released to the defendant; this was adjudged ill, and that no advantage could be taken by plea. (1 Sid. 421.) But it hath been held in equity, that though a will cannot enure as a releas, yet provided it were expressed to be the intention of the defeffor that the debt should be discharged, the will would operate accordingly; and that, in such case, it would be plainly an absolute discharage of the debt, though the defeffor had survied the legatee. (1 P. Wm. 85. 2 Vern. 521.) If a debt is mentioned to be devised to the debtor, without words of release, or discharage of the debt, and the debtor die before the defeffor, this will not operate as a releas, but will be considered as a lasped legacy, and the debt will subtit. (2 Vern. 522.) A debt is only a right to recover the amount of the debt by way of action; and as an executor cannot maintain an action against himself, or against a co-executor, the defeffor, by appointing the debtor an executor of his will, discharges the action, and consequently discharages the debt. Still, however, when the creditor makes the debtor his executor, it is to be con- sidered merely as a specific bequest or legacy, devised to the debtor to pay the debt; and, therefore, like other legacies, it is not to be paid or retained till the debts are satisfied; and if there be not affets for the payment of the debts, the execute is answerable for it to the creditors. In this case, it is the same whether the executor accepts or refuses the executehip. On the other hand, if the debtor makes the creditor his executor, and the creditor accepts the executehip, if there be affets, he may retain his debt out of the affets against the creditors in equal degree with himself; but if there be not affets, he may sue the heir, when the heir is bound. (1 Inft. 264. b. n. See Executor)

Littleton says, that a releas of all demands is the best releas to him, to whom it is made; and Coke says, that the word "demand" is the largest word in law, except "claim," and that a releas of all demands discharges all sorts of actions, rights, and titles, conditions before or after, breach, executions, appeals, rents of all kinds, covenants, annuities, contracts, recognizances, latters, commons, &c. (Litt. §. 503. Co. Litt. 291.) A releas of all actions discharges a bond to pay money on a future day. But a releas of actions does not discharge a rent before the day of payment. (Co. Litt. 292.) By a releas of all manner of actions, all actions, as well criminal as real, personal and mixed, are released. Co. Litt. 287. See Jacob's Law Dict. by Tomlins.

RELEGATION, RELEGATION, a kind of exile or banishment, by which the obnoxious peron is commanded to retire to a certain place preferred, and to continue there till he be recalled.

Lord Coke calls relegation a banishment for a time only; Courton more adequately defines relegation a banishment to a certain place for a certain term.

In Rome, relegation was a lofty punishment than deportation, in that the relegated person did not thereby lose the rights of a Roman citizen, nor those of his family, as the authority of a father over his children, &c.

Siam, in the perfect florets, filaments five, very short; anthers combined into a tube. Pfl. in the perfect florets, germin oblong; style simple; stigmas two, reflexed; in the female ones, germin oblong, rather incurved; style simple; stigmas two, recurved. Peric. none, except the permanent unchanged calyx. Seeds, to all the florets alike, solitary, angular, with a membranous, many-cleft, short crown. *Recept. chaffy.*

M. L'Héritier distinguishes this genus from *Athanaia* by the presence of a radius; from *Ossietz* by the florets of that radius producing perfect seeds; and from *Leysera* by the want of a leafy seed-down. Gaertner remarks that his *Elopes*, adopted from his Joseph Banks's and Dr. Solander's papers, is nothing more than an *Athanaia*, furnished with a radius. A due attention to the winged florets chief fows teaches us to misinterpret this character, which is un

*Stevalia* is the generic or barrenness of the radiant florets capable of distinguishing natural genera, though Linnaeus has, unadvisedly, founded a distinction of orders, in the classification, upon those differences. We cannot but allude, therefore, to the opinion of Poiret, that the genus of *Relhania* is not naturally distinct from the Linnaean *Ossietze*, at least, which last name being already established, ought to have been retained. However striking the radiating, chaffy, shining inner scales of the calyx may be in a few species of *Ossietza*; approaches towards that character are found in the *Relhania*, as *genfiliola*, and still more in *palacea*. We are far from intending to do away the claims of our friend, Mr. Relhan, to botanical commemoration, even were that honour bestowed in general far less indiscriminately than it is. For the present, the *Relhania* of L'Héritier is received; and if that be at any time abolished, there ought to be one establised on more solid principles.

Willdenow has nineteen species of this supposed genus; all natives of the Cape of Good Hope, mostly of a shrubby bushy habit, green-house plants in England, where only one of them indeed appears to be cultivated. Their flowers are mostly corymbose, small, of a dull yellow, not remarkable for beauty. We select a few examples.

**R. squarrota**. Hook-leaved Relhania. Willd. n. 1. Ait. n. 1. (Athanaia squarrota; Linn. Sp. Pl. 1180. Amenc. Acad. v. 6. 98. Santolina squarrota; Linn. Ann. Acad. v. 4. 329.)—Leaves elliptical, pointed; recurved at the point. Sent to Kew by Mr. Mallow, in 1794. It flowers in the green-house in May and June. The whole *flores* is smooth, much branched. *Leaves* numerous, somewhat imbricated, about a quarter of an inch long, elliptical, obscurely single-ribbed beneath, entire, acute; strongly recurved, smooth, finely dotted on both sides. *Flores* solitary, on slender axillary flasks, three length the leaves. *Calyx* about half an inch long, very smooth, rather shining. This should seem a different plant from R. *squarrota* of Thunberg, who defines his "with terminal umbels," and has thus led Willdenow, contrary to the description of Linnaeus, to refer the species in question to the first section of the genus, "with aggregate flowers." It appears, by specimens in the Linnaean herbarium, that the flowers are sometimes so crowded about the ends of the branches, as to assume a corymbose appearance, though each flalk is really axillary. Such a specimen probably was described by Thunberg.

**R. genfiliola**. Broom-leaved Relhania. Willd. n. 2.
The abuses of that church in point of relics have been very flagrant. F. Mabillon, a Benedictine, complains of the great number of suspected relics exposed on altars: he owns, that were there to be a strict inquisition into the relics, vast numbers of impious ones would be found offered every where to the piety and devotion of the faithful; and adds, that bones are frequently consecrated, so far from belonging to saints, that, in all probability, they do not belong to Christians.

The catacombs are an inexhaustible fund of relics; yet it is still disputed who were the persons interred in them.

In the eleventh century, a method was introduced of trying supposed relics by fire. Those which did not consume in the fire were reputed genuine; the rest not.

It is an ancient custom, which still obtains, to preferve the saints in the altars on which masses is celebrated. To this purpose, a square hole is made in the middle of the altar, big enough to receive the hand; and in that is the relic deposited, being first wrapped in red silk, and inclosed in a leaden box.

The Romanists allege a considerable degree of antiquity in behalf of their relics. The Manichees, it seems, out of hatred to the faith, which they held an evil principle, are recorded as refusing to honour the relics of saints; which is esteemed a kind of proof, that the Catholics did it in the first ages.

Indeed, folly and superstition blended themselves with religion too early a period. Even the touching of linen cloths on relics, from an opinion of some extraordinary virtue derived from them, appears to be as ancient as the first ages; there being a hole made in the coffins of the thirty martyrs at Constance, expressly for this purpose.

This practice of honouring the relics of saints, on which the church of Rome, in succeeding ages, founded her superstitious and lucrative use of them, as objects of devotion, as a kind of charms or amulets, and as instruments of pretended miracles, seems to have originated in a very ancient custom, that prevailed among Christians, of alluming at the cemeteries or burying-places of the martyrs, for the purpose of commemorating them, and of performing divine worship. When the profession of Christianity obtained the protection of the civil government, under Constantine the Great, lately churches were erected over their sepulchres, and their names and memories were treated with every possible token of affection and respect. (See SAINTS.) In process of time, this reverence of the martyrs exceeded all reasonable bounds; and those prayers and religious services were thought to have a peculiar sanctity and virtue, which were performed over their tombs. Hence probably proceeded the practice, already mentioned, which obtained in the fourth century, of depositing relics of the saints and martyrs under the altars in all their churches. This practice, however, was then thought of such importance, that St. Ambrose would not consecrate a church, because it had no relics; and the council of Constance in Trullo ordained, that those altars should be demolished, under which there were found no relics. The rage of procuring relics for this and other purposes of a similar nature became so excessive, that, in 386, the emperor Theodosius the Great was obliged to pass a law, forbidding the people to dig up the bodies of the martyrs, and to traffic in their relics.

Such was the commencement of that respect for sacred relics, which, in after ages, was perverted into a formal worship of them, and became the occasion of innumerable proceedings, pilgrimages, and miracles, from which the church of Rome hath derived incredible advantage. Towards the close of the ninth century, it was not enough to reverence departed saints, and to confide in their intercessions and succours: it was not enough to clothe them with an imaginary power of healing diseases, working miracles, and delivering from all sorts of calamities and dangers; their bones, their clothes, the apparel and furniture they had pollied during their lives, the very ground which they had touched, or in which their putrefied carcases were laid, were treated with a lepidious veneration, and supposed to retain the marvellous virtue of healing all disorders both of body and mind, and of defending such as pollied them against all the assaults and devices of Satan. The confidence of this wretched notion was, that every one was eager to provide himself with these salutary remedies; for which purpose, great numbers undertook fatiguing and perilous voyages, and subjected themselves to all sorts of hardships; while others made use of this delusion, to accumulate their riches, and to impose upon the miserable multitude by the most impious and shockking inventions. As the demand for relics was prodigious and universal, the clergy employed all their dexterity to satisfy these demands, and were far from being nice in the methods they used for that end. The bodies of the saints were fought by fasting and prayer, infiltrated by the priest, in order to obtain a divine answer and an infallible direction; and this pretended direction never failed to accomplish their desires: the holy carcasse was always found, and that always in confquence, as they impiously gave out, of the fuggeftion and inspiration of God himself. Each discovery of this kind was attended with exquisite demonstrations of joy, and animated the zeal of these devout seekers to enrich the church with more and more with this new kind of treasure. Many travelled with this view into the Eastern provinces, and frequented the places which Christ and his disciples had honoured with their presence, that, with the bones and other sacred remains of the first heralds of the gospel, they might comfort desolate minds, calm trembling confidences, fave sinking flates, and defend their inhabitants from all sorts of calamities. Nor did these pious travellers return home empty; the craft, dexterity, and knavery of the Greeks found a rich prey in the stupid credulity of the Latin relic-hunters, and made a profitable commerce of this new devotion. The latter paid considerable sums for legs and arms, skulls and jaw-bones, (several of which were Papal, and none human,) and other things that were supposed to have belonged to the primitive worthies of the Christian church; and thus the Latin churches came to the possession of thofe celebrated relics of St. Mark, St. James, St. Bartholomew, Cyprian, Panta- lon, and others, which they faw at this day with fo much attention. But there were many, who, unable to procure for themselves thefe spiritual treasures by voyages and prayers, had recourse to violence and theft: for all sorts of means, and all sorts of attempts, in a caufe of this nature were confidered, when successful, as pious and acceptable to the Supreme Being.

Benediction from antiquity to which the Papists refer, in vindication of their worship of relics, of which the reader may form fome judgment from this article, Bellarmine appeals to Scripture in support of it, and cites the following passages, viz. Exod. xiii. 19. Deut. xxxiv. 6. 2 Kings, xiii. 21. 2 Kings, xxiii. 16, 17, 18. Hfiah, xi. 10. Matth. xi. 20, 21, 22. Aets, v. 12—15. Aets, xix. 11, 12. See Popery.

RELICS.
Relics are forbidden to be used or brought into England by several statutes; and justices of peace are empowered to search houses for Popish books and relics, which, when found, are to be defaced and burnt, &c. 3 Jac. I. cap. 26.

RELICT, RELICTA, in law. See Widow.

RELiCTA VERIFICATION, is when a defendant relinquishes his proof or plea, and thereupon judgment is entered for the plaintiff.

RELIEF, RELIEVUM, Lexavenam, a fine paid the chief lord, by a person at his coming to the inheritance of land held by military service.

This was said reliefe hereditatem caduam; and the money thus paid was called reliefenem, revelium, or relief. Relief is usually to the value of a year's rent or revenue.

The origin of the custom is thus: a feudatory or beneficial estate in land, being at first only granted for life, to the death of the vassal, it returned to the chief lord; and was hence called feudum caduam, or, d. fallen to the lord by the death of the tenant.

In course of time, these feudatory estates being converted into inheritances by the connivance and consent of the lord; when the possessor of such estate died, it was called hereditas caduca, or, d. an inheritance fallen to the lord, from whom it was to be recovered, by the heir's paying a certain sum of money. But this sum was arbitrary, and at the will of the lord; so that, if he pleased to demand an exorbitant relief, it was in effect to disinherit the heir.

The English ill brooked this confiscation of their newly-adopted policy; and, therefore, William the Conqueror by his laws (Cap. 22, 27.) aferained the relief, by directing (in imitation of the Danish heriots), that a certain quantity of arms and habiliments of war should be paid by the seigniory, barons, and vaillants respectively; and if the latter had no arms, they should pay 100s. William Rufus broke through this composition, and again demanded arbitrary uncertain reliefs, as due by the feudal laws; thereby in effect obliging every heir to new-purchase or redeem his land; but his brother, Henry I. by his charter, restored his father's law; and ordained that the relief to be paid should be according to the law so established, and not an arbitrary composition. But afterwards, when, by an ordinance in 27 Hen. III. called the Affixe of Arms, it was provided that every man's armour should defend to his own, for defence of the realm, and it thereby became impracticable to pay these acknowledgments in arms, according to the laws of the Conqueror, the composition was universally accepted of 100s. for every knight's fee; as we find it ever after established. (Glaw. 1. ix. c. 4. Lit. § 112.) But it must be remembered, that this relief was only then payable, if the heir at the death of his ancestor had attained his full age of twenty-one years.

Relief, Reasonable, called also lawful and ancient relief, is that enjoined by some law, or fixed by ancient custom; and which does not depend on the will of the lord.

Thus in a charter of King John, mentioned by Matthew Paris:—"Si quis comitum vel baronum nostrorum, vel altiorum tenementum de nobis in capite per servitium militare, mortuos suos, et cum decevitibus, hares suus, pleas et atatibus, et reliefibus debet, habet hereditatem suam per antiquum relevum." What this was, may be seen in the laws of William the Conqueror, &c. Bracton says this fine was called a relief, "quia hereditas, quae iacenit suæ antecessoris defuncto, relevatur in manu heredum, &c."

A relief is also paid in focage-tenure, or petit fejeanty; where a rent, or other thing, is paid by rendering as much as the rent or payment referred. But the manner of taking relief upon focage-tenure is very different from that upon tenure in chivalry. The relief on a knight's fee was 5l., or one-quarter of the supposéd value of the land; but a focage-relief is one year's rent or render, payable by the tenant to the lord, be the same either great or small (Litt. § 126.); and therefore, Bracton (l. 2. c. 37. § 8.) will not allow this to be so properly a relief, but "quædum praedatio loco relevi in recognitione domini." So, too, the statute 28 Edw. 1. c. 1. declares, that a free foman shall give no relief, but shall double his rent after the death of his ancestor, according to that which he hath used to pay his lord, and shall not be grieved above measure. Reliefs in knight-service were only payable, if the heir at the death of his ancestor was of full age; but in focage they were due even though the heir was under age, because the lord has no wardship over him. (Litt. § 127.) The statute 12 Car. II. refuses the reliefs incident to focage-tenures; and, therefore, whenever lands in fee-simple are holden by a rent, relief is still due of common right upon the death of a tenant. 3 Lev. 145.

By the custom of Normandy, relief is due for lands held in vilainage as well as in fee. By the custom of Paris, relief is not due upon inheritances in the direct line.

The quantity of the relief is very different; there are single reliefs, double reliefs, &c. The quality, too, is diverse: there are reliefs of property, paid by the heir; reliefs of bail, or storage, paid by the guardian for his minor, or by the husband for the fiefs of his wife, &c.; relief of horse and arms, &c.

By the laws of King Canutus, the relief of an earl, paid to the king, was eight war horses with their bridles and saddles, four cuirasses, four helmets, four swords, four hunting-horses, and a palfrey. The relief of a baron or thane was four horses, &c.

RELIEF, in Chantry, denotes an order sued out for the dissolving of contracts, and other acts, on account of their being unreasonable, prejudicial, grievous, or from some other nullity, either de jure, or de facto.

Minor or obtains relief against acts passed in their minority. Majors have relief in cases of enormous damage, deceit, violence, over-reaching, extravagant bargains, &c.

Among the Romans it is a rule, that the church obtains relief any time, and against all acts passed in its prejudice; no prescription prevailing against it.

RELIEF, Aid et. See Aid.

RELIEF of a Hart, among Hunters, is the place where the going to feed in the evening.

RELIEF, in Sculpture. See RELIEVO.

RELIEVE, in the Military Service. To relieve, is to take the post of another body. Hence, to relieve the guard, to relieve the trenches, &c. is to bring fresh men upon the guard, or to the trenches, and to send those to rest who have been upon duty before. They also say, relieve a station, which is generally done every two hours, by a corporal who attends the relief; relieve the fileman, &c. To relieve a place that is besieged, is to furnish it with a supply of men, provisions, ammunition, &c.

RELIEVER, in Artillery, is an iron ring fixed to a handle by means of a socket, so as to be at right angles to it. It serves to disengage the firr seeker of a gun, when any of the inshoots are retained in a hole, and cannot be got out otherwise.

RELIEVING TACKLES, in a Ship, are two strong tackles, used to prevent a ship from overturning on the careen, and to affl in bringing her upright after that operation is completed. The relieving tackles are furnished with
with two strong guys, or pendants, by which their efforts are communicated, under the ship's bottom, to the opposite side, where the ends of the guys are attached to the lower gun-ports. The other ends of the tackles are hooked to the thwart or pontoon, by which the vessel is clapped. Thus, if a ship is flit to be laid down on the larboard side, which is nearest the thwart, the relieving tackles are pulled under her bottom from the said thwart, and attached to the larboard side, by which they will restrain her from falling lower than is necessary, Falconer.

Relieving Tackle, is also a name given to the train tackles of a gun-carriage.

Relievo, or Relief, Imbossment, is applied to a figure which projects, or stands out prominent, from the ground or plane on which it is formed, whether that figure be cut with the chaff, moulded, or cast. There are three kinds of relievo; viz. alto, basso, and demi-relievo.

Relievo, Alto, haut reliefs, or high relievo, is when the figure is formed after nature, and projects as much as the life.

Relievo, Basso, bas reliefs, or low relievo, is when the work is but raised a little from its ground, as we see in medals, and in the frontispieces or buildings, particularly the histories, feafoons, foliages, and other ornaments in friezes. See Basso Relievo.

Relievo, Demi, is when one-half of the figure rises from the plane, i.e. when the body of a figure seems cut in two, and one-half is clapped on a ground. When in a basso relievo there are some parts that stand clear out, detached from the rest, the work is called a demi-basso.

Relievo, in Architecture, denotes the tally or projection of any ornament.

This, Davier observes, is always to be proportioned to the magnitude of the building it adorns, and the distance at which it is to be viewed.

If the work be inflate, and terminated on all sides, it is called a figure in relievo, or a round embossment. Such are statues, acroters, &c.

Relievo, in Painting, denotes the degree of force or boldness by which a figure forms, as a due distance, to stand out from the ground of the painting, as if really imbosmed.

The effect relievo depends much on the depth of the shadow, and the strength of the light; or on the light of the different colours bordering on one another; and particularly on the difference of the colour of the figure from that of the ground.

When the light is well chozen, to make the nearest parts of figures advance; and well diffused on the maffes, till diminishing insensibly, and terminating in a large specious shadow, brought off insensibly; the relievo is laid to be bold, and the claire obscure, well understood.

RELIGION, Religion, that worship or homage that is due to God, considered as Creator, Preserver, and, with Christians, as Redeemer of the world.

The foundation of all religion is, that there is a God; and that he requires some acknowledgment and service from his creatures.

Accordingly, religion, in the true meaning of the term, necessarily supposes and includes an intercourse between God and man; i.e. on the part of God discoveries and manifestations of himself and his perfections, and of his will with regard to the duties which he requires; and on the part of man, a capacity and readiness to receive and improve those discoveries, and to conform to all the significations of the divine will. For it is an undeniable principle, that whatsoever plainly appeareth to be the mind and will of God, whatever be the way in which we obtain the knowledge of it, we are indispensably obliged to observe. And as there are two ways by which God may be supposed to manifest himself and his will to mankind, viz. by his works and by his word, religion has been usually distributed into natural and revealed. These are not two kinds of religion, essentially different, much less contrary or contradictory to each other, because they both have God for their object, and proceed from him; nay, but rather altogether the same, and differing merely in the mode of their communication. Although all true revealed religion must be consistent with, and in no respect contrary to, the clear light of nature and reason, yet it may discover and reveal several things pertaining to truth and duty, which that light, if left to itself, could not have discovered at all, or not with sufficient clearness and certainty. These should not be opposed to one another; nor is the one of them designed to exclude the other.

Religion, Natural, has been taken in different acceptations. Some understand it by everything in religion, with regard to truth and duty, which, when once discovered, may be clearly shown to have a real foundation in the nature and relations of things, and which unprejudiced reason will approve, when fairly propounded, and set in a proper light. Accordingly some Christian philosophers and divines have comprehended under their scheme or system of natural religion, a considerable part of what is contained in the scripture revelation, e. g. the important truths and principles relating to the existence, the unity, and attributes of God, his governing providence and moral administration, the worship that is due to him, the law that is given to mankind; or the whole of moral duty in its just extent, as relating to God, our neighbours, and ourselves, the rewards and punishments of another state, and other articles nearly connected with these, and dependent upon them. Having taken great pains to shew, that all this is perfectly agreeable to sound reason, and founded in the nature of things, they have honoured the whole with the name of natural religion. None can hesitate to allow, that it is a real and great service to religion to shew, that the main principles and duties of it are what reason must approve; and there are unquestionably entitled to praise, who have undertaken to demonstrate this with great clearness and force of argument. But it does not follow that, because these things, when once clearly discovered, may be proved agreeable to reason, and to have a real foundation in the nature of things, reason alone, in the present state of mankind, if left to itself, without higher assistance, would merely, by its own force, have discovered all of them, with their genuine concomitants, and have applied them to their proper uses, for directing men in the true knowledge and practice of religion. Many things, says Mr. Locke, in his "Reasonable Christian," are taken for unquestionable truths, and easily demonstrable, without considering how long we might have been in doubt or ignorance respecting them, if revelation had been silent. Native and original truth is not so easily wrought out of the mine, as we who have it ready dug and fashioned to our hands, are apt to imagine. To the same purpose Dr. Clarke observes, (Difc. on Nat. and Rev. Religion,) that it is one thing to fee, that these rules of life, which are before-hand plainly and particularly laid before us, are perfectly agreeable to reason, and another thing to find out these rules merely by the light of reason, without their having been first otherwise made known. Accordingly some able and famous affectors of natural religion, or the law of nature, though they contend that it is founded in the nature of things,
things, and agreeable to right reason, derive the promulga-
tion of it from divine revelation. Hence it may be con-
cluded, that natural religion, or the Law of Nature (which
fee), is not so called, because it was originally discovered
by natural reason, but because, when once made known, it
is what the reason of mankind, duly exercised, approves, as
founded in truth and nature.

Natural religion, in the sense now explained, is very con-
venient with the supposition of an extraordinary divine reve-
lation, for the purpose of discovering and promulgating it
at first, and also of re-establishing and confirming it, when,
through the corruption of mankind, the important prin-
ciples and duties of it were sunk into such darknes, and so
confounded with pernicious errors, that an extraordinary
affurance was necessary to recover men to the right know-
ledge and practice of it.

Natural religion is understood by others in a sense which
is absolutely exclusive of all extraordinary revelation, and
in direct opposition to it. By natural religion, they mean
that religion which men discover by the sole exercise of their
natural faculties and powers, without any other or higher
assurance. These persons discern all pretences to extra-
ordinary revelation, as the effects of enthusiasm or imposture.
It is in this sense, that those who call themselves Deists (see
that article) understand natural religion, which they highly
extol as the only true religion, the only discovery of truth
and duty upon which we may safely depend; and which
comprehends the whole of what is necessary to be known
and done, in order to our obtaining the favour of God, and
attaining to true happiness. But those who take natural
religion in this sense entertain different opinions of the sub-
ject, and express their sentiments variously. The ablest ad-
vocates for natural religion, as opposed to revelation, main-
tain, that it is clear and obvious to the whole human race,
and that all men have a natural knowledge of it. They
argue, that since religion is equally the concern of all man-
kind, the wisdom and goodness of God require, that it
should be actually known to all. To this purpose is the
reasoning of lord Herbert, who alleges, that God hath
imprinted on the minds of all men innate ideas of the main
principles of religion and morality. Tindal also, and the
author of "Christiannity as old as the Creation," argue in a
similar manner: the former affirms, that this clear universal
light that shines into the minds of all men cannot be made
clear to any man by an external extraordinary revelation; with
the latter it is a kind of fundamental principle, that the law,
or religion, of nature was a perfect scheme of religion and
morality, fairly drawn on the mind and heart of every man,
in such a manner, that it is not possible for any man to mis-
take it: and he even affirms, that the most illiterate of the
human race have naturally and necessarily a clear and immediate
perception of the whole of religion and of their duty.
Hence it will be easily owned, that there is no need of an
extraordinary revelation to teach men what they naturally and necessarily know. This scheme, however plausible it may at first appear, and though it seems to exhibit a
beautiful representation of the dignity of our species, and of
the universal goodness of God to the human race, appears
to be altogether visionary, when brought to the test of fact
and experience: whilst it supposes, that religion, in its true
nature and just extent, is naturally known to all men, so
that they cannot mistake it, it contradicts the testimony of
the authentic history of mankind in all ages, which evinces
that they have mistaken religion in its important prin-
ciples and obligations.

Sensible of the inconveniences of this scheme, others, by
natural religion, understand not merely that which is na-
turally and necessarily known to all men, but that which
reason, duly exercised and improved, is able, by its own
natural force, to discover, without the assistance of any ex-
traordinary revelation. In order to form a just conception
of this theory, we might investigate the extent of the
powers and abilities of human reason in judging concerning
matters of religion, independently of all revelation: but
without entering on a speculation of this kind, the disqui-
ition of which would be more curious in the processes than
satisfactory in the result, we should recur to the surest and
plainest mode of judging, which is the examination of the
conclusions that may be deduced from fact and experience.
Let us then inquire, what hath human reason actually done
in this way, by its own force, without any extraordinary
assurance? The satisfactory answer to this inquiry cannot
be obtained from any fyltems formed by persons who have
lived in ages and countries which have enjoyed the light of
divine revelation; since in this case it may reasonably be
supposed, that they have borrowed light from revelation,
though they are not willing to acknowledge it, or may not
themselves be sensible of it. Systems, therefore, that have
been drawn up by our modern admirers of natural religion
in Christian countries, cannot be alleged in proof of the
force of unaided reason in matters of religion; and the
same may be said of those Pagan philosophers who have lived
after Christian times had made some progress in the world.
Nor can we fairly infer the sufficiency of the light of natu-
ral reason, without the aid of revelation, from the systems
of the ancient philosophers, lawgivers, and moralists, who
lived before the Christian revelation was published, unless
it can be shewn, that they themselves derived the religious
and moral principles which they taught, solely and entirely
from the researches and disquisitions of their own reason,
and disclaimed their having had any assurance, with regard
to those truths and principles, from tradition or divine in-
struction. And it is no hard matter to shew, by testimonies
from the most celebrated ancients, that this was not the case,
nor was it what they ascribed to themselves. It is well
known, that the most admired philosophers of Greece did
not pretend to set up merely on their own stocks, but tra-
vell ed into Egypt, and different parts of the East, for the
purpose of improving their knowledge by conversation with
the fages of those countries; who themselves professed to
devote their knowledge, not merely from the disqui-
sitions of their own reason, but from a higher source, from
very ancient traditions, to which, for the most part, they
affixed a divine original. After all it must be allowed,
that the most celebrated and fagacious of the ancient philo-
osophers made pathetical complaints of human darknes and
ignorance, and of the great difficulties they experienced in
searching after truth. Many of them were sensible of the
great need there was of divine instruction and assurance, for
enlightening and directing mankind in matters of religion
and their duty: so that no argument can be justly drawn
from the wise men and philosophers among the ancients, to
shew that the knowledge of what is usually called natural
religion, in its just extent, is wholly and originally owing to
the force of human reason, exclusive of all divine revelation.
And perhaps, says the excellent writer whose observations
we are now citing, it would not be easy to mention any na-
tions, among whom any true knowledge of religion has
been preferred, concerning which we can be assured, that
they never had any benefit from the light of divine revela-
tion; and that the principles of religious truth and duty,
which were to be found among them, were originally the
mere product of natural reason, without any higher assur-
bance. Several things may be observed among them, which

4 N 2
feem to be the remain of an ancient universal tradition, or primeval religion, derived from the remotest antiquity, and which, probably, had its original source in divine revelation, though in process of time it was greatly altered and corrupted. Leland's Advantage and Necessity of the Christian Revelation, vol. i. § 1.

RELIGION, Revealed, is commonly understood to be that knowledge of religion, which was originally communicated from God to men in a way of extraordinary revelation, for instructing them in important religious truth, and directing and engaging them to the practice of their duty. In a general sense, all truth, and the manifestation of it, may be said to come from God, even that which we discover in the ordinary use of those rational faculties which God hath given us. But revealed religion, as distinguished from that which is usually called natural, denotes that knowledge of religion which was originally communicated in an extraordinary and supernatural way. Leland, ubi supra. See Revelation.

The first kind of religion, above-mentioned, or natural religion, flows immediately from the relation between the creature and the Creator; the latter, or revealed religion, does not follow from such a relation, but is superadded from the mere will and pleasure of the Creator.

The first we ordinarily call morality, or ethics; because immediately conversant about the manners and duties of men towards one another; and towards themselves, considered as creatures of that Being. See Ethics, Morality, and Moral Philosophy.

The latter we call, by way of eminence, religion, as being the rule of our duty immediately to God himself.

The first supposes a God, a providence, and a future state, or rewards and punishments; the latter likewise supposes an immediate mission from God himself, attested by miracles, &c. See Christian Religion.

RELIGION is more particularly used for that special system of faith and worship, which obtains in a particular age, sect, or country, &c.

In this sense we say the Roman religion, the Reformed religion, the religion of the Greeks, the Mahometan religion, the Jewish religion, &c. See Judaism, Mahometanism, &c.

The Siamese hold the diversity of religions, i.e. the different manners of honouring God, to be pleasing to him; inasmuch as they have all the same object, and all tend to the same end, though by different means. Claude.

This sentiment of these idolaters is doubtfles more just than that of our zealots, who hold all but those of their own religion odious to God. The several sects in religion fee under their proper articles. See also Sect.

Of the religion of the ruling part of the world, you may find a lively description in a chorus in Seneca's Tragedy, at the end of the second act, beginning thus: "Verum est, an tumidos fabula decipi? umbrae corporibus vivere conditias, &c." This, according to Patin, is the religion of princes, and great men, of magistrates, moralic inhabitants, and even some physicians and philosophers. M. Du Maine, head of the leaguers in France, used to say, that princes have no religion till after they are turned of forty. "Cum numine nobis mors infrat, majora facit." Patin. Lekt. Choix. 106.

Under this article we are naturally led to discuss the subject of national religion, in its connection with religious establishments. It must appear, on the slightest reflection, that religion has a very considerable influence, not only on the disposition and character of individuals, but on the state of society in general. Accordingly legislators and rulers have often found it one of the most powerful instruments of civil policy; and the history of almost every country abounds with numerous instances of its being an excellent ally to the power of the civil magistrate, or the most dangerous rival.

By religion we mean that principle which influences men by the dread of evil or the hope of reward, from unknown and invisible causes: whether the good or the evil be expected to take place in this world or in another; and in this general sense of the term, it comprehends enthusiasm, superstition, and every other species of false religion as well as the true. It would lead us too far, if we attempted to trace the influence of this principle in the more barbarous or more civilized nations of antiquity. Enthusiasm and superstition have been more powerful and more efficacious on many occasions, which history records, than political wisdom in the cabinet, or martial skill and valor in the field. In some cases religion has concurred with the views of the civil magistrate; and in others, it has counteracted them in favor of the real interests of mankind. It is an observation of Mr. Hume's, that the precious sparks of liberty were kindled and preserved by the Puritans in England, and that it is to this fact, whole principles appear so frivolous, and whole habits so ridiculous, as he somewhat inquisitively describes them, that the English owe the whole freedom of their constitution. The aference, however, is too general. The capital advantage derived from Christianity in this western part of the world, is the total abolition of slavery, in consequence of its rousing men's ideas of the importance of the human species. It is a memorable fact, that after the introduction of Christianity into the Roman empire, every law which was made relating to slaves was in their favor, till at last all the subjects of the empire were reckoned equally free. Although, in later times, slavery has been revived and continued, for commercial purposes, in countries calling themselves Christian, we trull that laudable efforts, originating in the liberal sentiments and affections which Christianity inculcates, will be crowned with success, and gradually annihilate this nefarious kind of traffic in every nation of the globe. Christianity, indeed, is almost incompatible with absolute despotic power, both in foreign and private persons. The corruptions of Christianity, exemplified in the exorbitant power of the pope, and the superlition of the Popish worship, have been indirectly productive of considerable benefit. The union of the western churches under one supreme pontiff facilitated the intercourse of nations in barbarous ages; and the pomp of the Popish power contributed in no small degree towards preventing the fine arts from being totally lost in the barbarism of Europe, and to their subsequent revival, previously to that of literature and science in this western part of the world. Erroneous notions of religion, and the superlition blended with its purer principles, have been, however, the occasion of the most lamentable evils in the government of states. Beccaria says, in his "Essay on Crimes and Punishments," that more than 100,000 witches have been condemned to die by Christian tribunals. Falsc principles of religion have encouraged men to commit the most horrid crimes; and to inflict tortures both on themselves and others, which cannot be thought of without horror. The historical page of perfecition is stained with blood. But it is our present design to sketch out the benefits resulting from religion to civil society, rather than the evils which the perversion of its principles and genuine spirit have produced. It is natural to imagine, that the civil magistrate would take religion under his protection with a view to these benefits; nevertheless, it is much to be lamented that by erroneous notions of its nature and design, and a misapplication of its influence, it has been rendered the instrument
Religion.

If magistrates and rulers availed themselves of the affluence which religion affords for relieving the character and condition of the members of the community over which they preside; if they patronized and encouraged the principles and profession of it for the purpose of retraining the profligate and vicious, and of promoting a virtuous conduct with a view to the welfare and prosperity of the state; and if they made use of the mighty powers with which religion furnishes them merely for the purpose of maintaining order and peace in the community to which they belong; and of securing and advancing its true interests; there could be no reason for alarm or complaint. Religion and civil government might unite their efforts for such laudable purposes, and co-operate in promoting them, without any apprehension of danger; but lamentable experience has testified that too many instances of religion have been made subservient to ambition and worldly policy, inasmuch that many persons of just reflection and comprehensive views have dreaded the interference of civil governors in matters of religion. If, in some cases, they have done good, in others their interference has been pernicious, not only to religion, which has been thus corrupted and degraded, but to the civil community itself. Nevertheless the opinion, that it is necessary for the state to prescribe the principles, and to regulate the modes of religion, has been almost universally prevalent.

We are thus led briefly to discuss the subject of national establishments of religion; and that we may do this without prejudice and partiality, we shall state the arguments on both sides of the question, as much as possible in the language of those who oppose, and of those who defend them. Amongst those who have thought freely, and who have written as freely on this subject, we find some who contend against establishments in any degree whatever. They will not allow that religion should receive any support from the state, but insist that it ought to be left entirely to its own operation. There is naturally, they say, no more connection between civil government and religion, than between the former and any thing else that depends upon opinion; less than the business of philosophy or religion. Becanse these respect the present life, with which civil governors have to do; whereas religion respects the life to come, with which they have nothing to do. However, the conclusiveness of this kind of reasoning seems to be materially affected by our preliminary remarks. Religion, it is said, is a concern that lies out of the proper province of the civil magistrate. Its object is invisible: its principles and affections, which are the springs of moral and religious conduct, as well as its motives and actions, are not subject to the direction and control of secular counsel and power: its seat is the understanding and heart: nor is the external conduct, to which alone the cognizance of the civil magistrate extends, of any importance in a moral view, independently of the internal principles in which it originates, and by which it is guided and governed. Besides, it has been urged that civil rulers have no right to prescribe to the judgment in the province of religion, or to frame and enforce rules of moral conduct, for the observance or violation of which mankind are accountable only to God; nor are they competent or qualified for the exercise of such high powers. And if they cannot control the faculties of the mind, their influence on the profession and practice, and that outward conformity to modes and rites of a religious nature which they may enforce, without the consent of the judgment and concurrence of the will, are calculated to do much greater harm than good; and to add to the number of hypocrites or martyrs. As the civil magistrate cannot bestow the rewards, nor inflict the punishments, that are appropriate to religion; and as he cannot estimate the moral worth or demerit of his subjects, he cannot, without culpable presumption, assume, nor without intruding on the province of the supreme and almighty God, exercise the authority of a spiritual and final judge. Civil governors in general, such are their rank and station, the course of their education, and the habits of their lives, are less able than many others of lower condition, but of different views and connections, to decide concerning religious truth, or to determine who are qualified to advise and inflict them. Moreover, it has been observed, that neither magistrates nor their ecclesiastical advisers are warranted to establish a standard either of religious faith or moral conduct, to which all the members of a community are required to conform, and from which they are not allowed to deviate without incurring some loss or damage. Such a standard, let it be ever so liberally framed, or ever so mildly enforced, is not likely to be so comprehensive, as to include all the teachers and all the professors of religion, who are entitled to the protection of the state in which their lot is cast. Besides, if such a standard of faith and practice could be devised, those who object to religious establishments on the ground now stated, conceive, that their civil rulers have no right to establish and impose it; and thus to deprive persons, who cannot approve it, of worldly honours and benefits, to which they have naturally an equal claim with others of their fellow-subjects:—a claim, which they do not forfeit by the exercise of their own judgment in the province of religion. It has also been argued, that Christianity, far from countenancing, rather discourages every kind of religious establishment, that interferes with the right of private judgment. The language of the divine Author of our holy religion is, "Render to Cæsar the things that are Cæsar's, and to God the things that are God's;—Search the scriptures;—Call no man master on earth;—My kingdom is not of this world." And that of his apostles, "Let every man be fully persuaded in his own mind:—Judge ye what I say," &c. &c. The adversaries of establishments allege, that a national church, constituted by the civil magistrate, and governed by laws enacted by his authority, and the Christian church, founded on the doctrine of Christ and his apostles, are essentially distinct; and they say, that such a church, e.g. the church of England, is less exceptionable than many others, which claims and exercises, according to its 26th article, "power to decree rights and ceremonies, and authority in matters of faith," has, according to the true nature and constitution of the Christian church, no such power and authority: that it is inconsistent with the allegiance which Christians, as the subjects of Jesus Christ, owe to him, the only lawgiver and king in the church; who, as they say, hath expressly commanded that no power of this kind shall ever be claimed, or ever be yielded by any of his followers. In the prosecution of this mode of reasoning, they farther add, that if the church of England hath really this authority and right, the church of Rome had it before, and, as the elder and mother-church, ought to have been obeyed; and consequently the reformation, as it has been called, was a rebellion against superiors, a disobedience to the authority vested in the church, and ought, as such, to be denounced by returning to the church of Rome. They also argue, that this power to order the manner of God's worship, and to settle articles of faith, is not at all lodged in the bishops or clergy, who are the spiritual pastors and guides in the established church, but entirely in the king and parliament of those realms. So far were the bishops and clergy from having any concern in the first forming our present established church,
RELIGION.

or in ordering its rites and articles of faith, that it was done not only without, but in actual opposition to them. Hence they conclude, that the church of England is, in reality, a parliamentary church; that it is not, properly, an ally, as some have asserted, but a mere creature of the state. It depends entirely upon the acts and authority of parliament for its very essence and frame. The qualifications of its ministers, their power to officiate, the manner in which they are to administer the sacraments, are all limited and prescribed by authority of parliament; and this authority, which at first made, can alone alter and new-make it; can abolish, or add to its articles or rites, according to its pleasure, even though the whole body of bishops and clergy ever so much dislike or protest earnestly against it.

If it be asked, how came the civil magistrate to possess the authority which he exercises in the church of Christ? The objectors to establishments reply, that the subjection to higher powers, and obedience to magistrates, which the scriptures enjoin on Christians, relates only to civil, and not at all to religious matters, for this obvious reason, that the magistracy was at that time every where Pagan. They say, that Christianness is so far from enjoining, that it actually forbids obedience to civil governors in things of a religious nature. It commands us “to call no man upon earth father or master” (Matt. xxiii. 8, 9.), i.e. to acknowledge no authority or jurisdiction of any in matters of religion, but to remember, that “one, one only is our master” and lawgiver, even Christ, and that all Christians are brethren: and that, though “the princes of the Gentiles exercise dominion over them, and they who are great exercise authority upon them, yet it shall not,” says our Lord, “be so amongst you.” (Matt. xx. 25.) Chrift’s kingdom is not of this world, and of course he is the sole lawgiver, judge, and sovereign in religious matters. (See Matt. xxiii. 8, xxvii. 18, 19. 1 Cor. viii. 6. Ephes. i. 22.) In the church of Christ, it is said, all authority and jurisdiction are vested originally in him, and flow from him, nor can any one lawfully exercise them without a commiſion from him; but in the church of England, the king, or queen, is “supreme head,” poſſessing “all power to exerſice all manner of ecclesiasticall jurifdiſion, and archbishops, bishops, archdeacon, and other ecclesiasticall persons, have no manner of jurifdiſion ecclesiastical, but by and under the king’s majesty, who hath full power and authority to hear and determine all manner of causes ecclesiastical; and to reform and correct all vice, sin, errors, heresies, enormities, abuses whatsoever, which by any manner of spiritual authority or jurifdiſion, ought, or may be lawfully reformed.” (26 Hen. VIII. cap. 1. 37 Hen. VIII. cap. 17. 1 Eliz. cap. 1.) At the first establishment of this church under Henry VIII. and Edward VI. all the bishops took oaths of communion from the crown, for the exercising of their spiritual jurisdiction in these kingdoms, during the king’s pleurue only; “and in their commiſions acknowledge all forts of jurifdiſion, as well ecclesiastical as civil, to have flowed originally from the regal power, as from a supreme head, and a fountain and spring of all magiftracy within his own kingdom.” Burnet’s Hist. Reform. part ii. Col. p. 92.

Yea, even the power of ordination itself, which is reckoned a peculiar of the episcopal office, the first reformers and founders of this church derived from the king, and exercised only as by authority from him, and during his pleurue.

Thus Craunger, archbishop of Canterbury, Bonner, bishop of London, &c. took out commiſions from the crown, importing, that because the vicegerent (Cromwell, a lay perſon) could not perſonally attend the charge in all parts of the kingdom, the king authorizes the bishop, in his, (the king’s or perhaps the vicegerent’s) stead to ordain, within his dioces, such as he judged worthy of holy orders; to collate to benefices; to give indulgences; and to execute all other parts of the episcopal authority; and this during the king’s pleurue only.”

In confecution of this supremacy, the king or queen of this church hath power to communicate from, or to re-admit into it, independent of, yes, in direct opposition to, all its bishops and clergy. The king or queen revoke, if they please, any spiritual censures of the bishops or archbishops; yeas, can suspend, deprive, or even excommunicate, themselves; or can, by their proclamation only, without the least conſcience, humiliation, or satisfaction for their offence, pardon and re-allow excommunicated persons, the vile offenders, to the church’s bosom again.

Yea, further, they have power to forbid all preaching for a time; as did king Henry VIII. king Edward VI. queen Mary, and queen Elizabeth; to limit, instruct, and prescribe to the clergy what they shall, and what they shall not preach; as did queen Elizabeth, king James I. king Charles I. king William, &c. Finally, to the king or queen only does it pertain to declare what is hereby, and authoritatively to pronounce what doctrines and tenets are, and what are not, to be cenſured as such: nor have all the bishops and clergy, assembled in convocation, the least authority to cenſure any tenet as heretical, if the prince on the throne refufe his consent.

Accordingly, the objectors to religious establishments allege, that in Chrift’s church, himself is the only sovereign and head; he only hath power to decree ceremonies and rites, to fix terms of communion and authority in points of faith; nor hath any earthly prince power to make laws in his kingdom, which shall bind the conscience of his subjects; or soveraignly to dictate to his servants and ministers what they shall believe, and what they shall preach. Yea, his subjects are expressly commanded and charged to receive nothing as doctrine or parts of religion, which are only commandments of men.

But in the church of England there is another sovereign, lawgiver, supreme head, besides Jesus Christ; an authority which commands things which Christ never commanded, which teaches doctrines he never taught, which enjoins terms of communion, and rites of religious worship, which Chrift never enjoined. Hence they conclude, that these two churches are two distinct and quite different societies, framed after different models, consisting of different members, and governed by different officers, statutes, and laws. Whilft the objectors to established forms of worship esteem and reverence the great number of illustrious and excellent persons, both clergy and laity, of which the church of England can boast, they suggest, that the present established forms were drawn up when this kingdom just emerged out of Popish darkness; that in drawing them up special regard was had to the weakneſs of the people at that time, who could not be all at once entirely brought off from the old ceremonies and forms; and that there are several parts of our liturgy and ecclesiastical constitution, which even many of our bishops and clergy wish to see altered. Schemes have been proposed, and attempts have been made for omitting what is offensive, for correcting what is easily capable of amendment, and for accommodating the doctrine and forms of the established church, to the present advanced state of knowledge, and to the corresponding liberality of the modern professors of religion, both in and out of the church; but they have hitherto been unavailing: and it has been thought, that an exclusive establishment, appropriating to itself distinguished honours and benefits of a secular nature, and expelling those whom
whom it does not comprehend to privations, both of emolument and honour, has a tendency to discourage every effort for improving its constitution, and enlarging its boundaries. Some have also been of opinion that it restrains freedom of inquiry, embarrasses integrity, and too much disparages the uninstructed and uninformed to intolerance and persecution. From whom, it has been said, is a reform to be expected, but from those who have reason for withering every thing to continue in statu quo? The dignitaries of the church, whose emoluments induce them to rett satisfied, and the ruling magistrates of the state, who wish things to remain quiet, and the great body of the laity, connected in one way or other with ecclesiastical establishments, cannot be supposed to be very anxious about a change in the constitution of the church: nor will they be at a loss for plausible reasons for reftoring any material alteration. The church and the state are fo incorporated, that nothing but a revolution, as it has been said, in the latter, would cause any very important amendment in the former. Nevertheless, reformers have maintained, that if the liturgy, clergy, articles, canons, with all the ceremonies and rites of the established church, were entirely vanifhed from the land; if its immense revenues were applied to cace our heavy taxes, and for the payment of the public debts; and if preachers were paid only by voluntary contributions; the state would not fail to effential a loss and damage, that it could not thenceforward possibly admit. Would, say they, the British monarchy be overthrown; our courts of judicature be fhut up; the courts of law be ftopped; parliaments no more meet; commerce and trade ignite, because the national church was no more? On the contrary, however great the convulfion might be, the government, both civil and military, might remain the very fame. A timely reformation, however, would, as they imagine, prevent its total destruction, and contribute to its permanence and pro- perty.

Some notice should here be taken of the learned Warburton's famous argument in favour of an established church. The church, fays this prelate, has, by contract or alliance, reneged her supremacy in matters ecclesiastical, and her independency, to the state. In confequence of this, the state hath drawn up for her articles of faith, and forms of public worship, which it requires the church to fubcribe and use. This alliance is a mere phantom, created by the warm imitation of the paradoxical bishop, whole ingenuity and learning have not been sufficient to render it popular, even among the most zealous advocates of religious establishments. Neither our history nor our laws know any thing at all of it. The nature of our constitution utterly difowns it; and avows the church to be not an ally, but a Subject to the state. A nian alliance loposes independency in the powers between which it subsifts. But it is needles to enlarge on this topic.

Whilft it is allowed that religion has an influence on the conduct of men in this life, it is pleaded, on the other hand, that this beneficial influence of religion is promoted in all denominations of Christians, and as much in those which are reproached by the state as in those which are encouraged by it. It has been also said, that the Subject of religion is fo interesting to the generality of mankind, that if government did not interfere, the contention about it would be fo violent, that the public peace could not be preserved. To this argument in favour of establishments, it has been replied, that these contentions are much increafed by the favour shewn to one mode of religion, and the opprobrium which is confequently thrown on the rest; and that, where temporal interest is not concerned, mere opinions will not occasion any differences at which government need to be alarmed. Christianity was introduced and establihed, and subsisted for about three hundred years, without any favour or protection from the governing powers; and the example of America, in some provinces of which there is, strictly speaking, no establishment of religion, and in which numerous forms of religion are openly profefled, serves to shew, that the want of an establishment is attended with no danger to the state. It is farther objected, that the state, by undertaking the care of religion, the truth and utility of which will, under providence, ensure its permanence, has taken upon itself a great, dangerous, and unnecessary burden; and from its jealous of sectaries, often deprives itself of the services of some of its best and most amiable subjects; and at some times it has been induced to persecute and destroy them, because if they were left free, and even suffered to live, it was apprehended their principles might spread to the risk of the establishment. To the national establishment of our own country, the enlightened advocates of which abhor and discontinue intolerance and persecution, it has been objected, that it deprives the people of the choice of their own teachers and pastors; that it imposes subscription to creeds of doubtful evidence, and the observance of forms of questionable utility, on its own ministers; that it renders the support of them burdensome to those who avail themselves of their labours, and to others who derive no benefit from them; and that it excludes by obnoxious statutes a considerable class of loyal subjects from offices which they are competent to discharge, as well as emoluments and honours of which they have a right to participate. See Dissenters, Subscription, Test, and Tythes.

We now proceed to state the arguments that have been urged in favour of national establishments of religion; and we shall here avail ourselves of the reasoning of an excellent writer, who has done ample justice to the subject, and who, at the same time, has discussed it with a liberality and moderation, which have a tendency to reconcile those whose sentiments may be different from his own. "A religious establish- ment," he fays, "is no part of Christianity; it is only the means of inculcating it." It cannot be proved, that any form of church government has been laid down in the Christian religion, as it had been in the Jewish scriptures, with a view of fixing a constitution for succeeding ages; and which constitution, confequently, the disciples of Christ would, every where, and at all times, by the very law of their religion, be obliged to adopt. Certainly no command for this purpose was delivered by Christ himself; and though the apostles ordained bishops and prebyters among their first converts, and appointed also deacons and deaconesses, investing them with functions different from any that now subsift, such offices were at first erected in the Christian church, as the good order, the instruction, and the exigencies of the society at that time required, without any declared design of regulating the appointment, authority, or dissolution of Christian ministers under future circumstances. After this concession, our author founds the authority of a church establishment in its utility; and in judging of the comparative excellence of different establishments, he suggests, that the single view, under which we ought to consider any of them, is that of "a scheme of instruction," and the single end we ought to propose by them is, "the preservation and communication of religious knowledge." Every other idea, and every other end that have been mixed with this, as the making of the church an engine, or even an ally of the state; converting it into the means of strengthening, or of diffusing influence; or regarding it as a support of regal, in opposition to popular forms of government, have ferved only
RELIGION.

to debase the institution, and to introduce into it numerous corruptions and abuses. The notion, says our author, of a religious establishment comprehends three things, a clergy, or order of men excluded from other professions; to attend upon the offices of religion; a legal provision for the main- tenance of the clergy; and the confining of that provision to the teachers of a particular sect of Christians. Without these, there exists no national religion, or established church, according to the fence which these terms are usually made to convey. He, therefore, who would defend ecclesiastical establishments, must shew the separate utility of these three essential parts of their constitution. Under the first head he maintains, that the knowledge and profession of Christianity cannot be maintained in a country without a class of men set apart by public authority to the study and teaching of religion, and to the conducting of public worship; and that for these purposes they should be precluded from other employments; and that of course they ought to derive a main- tenance from their own. If they depended for this main- tenance upon the voluntary contributions of their hearers, he is of opinion, that few would ultimately contribute anything at all. To the consideration of the difficulty with which congregations would be established and upheld upon the voluntary plan, he adds, that of the condition of those who are to officiate in them. Preaching, he thinks, would in this case become a kind of begging; and the preacher, being at the mercy of his audience, would be obliged to adapt his doctrines, and alter his style and manner of preaching, to the pleasure of a capricious multitude; and to live in con- stant bondage to tyrannical and inconstant directors; which he could not do without a sacrifice of principle, and a depravation of character. Admitting these circumstances to be fairly rated, which perhaps an objector would reluctantly allow. Dr. Paley concludes, that a legal provision for the clergy, compulsory upon those who contribute to it, is expedient, and then proceeds to inquire, whether this provision should be confined to one sect of Christians, or extended indifferently to all. This question, it should be recollected, can never offer itself where the people are agreed in their religious opinions, and ought never to arise, where a system of doctrines and worship may be so framed as to comprehend their disapprobations, and which might satisfy all by uniting all in the articles of their common faith, and in a mode of divine worship that omits every subject of controversy or offence. Where such a comprehension is prac- ticable, the comprehending religion ought to be made that of the state. But where this comprehension is impracticable, and separate congregations and different sects must continue in the country, the question fairly recurs, whether, under such circumstances, the laws ought to establish one sect in preference to the rest; that is, whether they ought to confer the provision assigned to the maintenance of religion upon the teachers of one system of doctrines alone.

This question is intimately connected with, and in a great measure dependent upon, another; and that is, in what way, or by whom, ought the ministers of religion to be ap- pointed? In that species of patronage which subsists in this country, and which allows private individuals to nominate teachers of religion for districts and congregations, to which they are absolute strangers, some tend to be proposed to the persons nominated, in order to prevent that discordancy of religious opinions that might otherwise arise between the several teachers and their respective congregations. The requisition of subscription, or any other test by which the national religion is guarded, may be considered merely as a restriction upon the exercise of private patronage. Where- ever, therefore, this constitution of patronage is adopted, a national religion, or the legal preference of one particular religion to all others, must almost necessarily accompany it. If we suppose that the appointment of the minister of religion in every parish left to the choice of the parishioners, might not this choice be fairly exercised, without its being limited to the teachers of any particular sect? The effect, says our author, of such a liberty must be, that a Papist, or a Pref- byterian, a Methodi’st, a Moravian, or an Anabaptist, would succedevery gain possession of the pulpit, according as a ma- jority of the party happened at each election to prevail; and on every choice, it is apprehended, that violent conflicts would be renewed, and bitter animosities be sown.

If the state appoint the ministers of religion, this constitution will differ little from the establishment of a national religion: for the state would undoubtedly appoint only those whose religious opinions, or rather whose religious denomination, agree with its own; unless it be thought that religious liberty would derive any advantage from transferring the choice of the national religion from the legislature of the country to the magistrate who administers the executive go- vernment. The only plan which seems to render the legal maintenance of a clergy practicable, without the legal preference of one sect of Christians to another, is that of an ex- periment which has been attempted (and which is said to have succeeded) in some of the new states of North Ame- rica. The nature of the plan is thus described. A tax is levied upon the inhabitants for the general support of religion: the collector of the tax goes round with a register in his hand, in which are inserted, at the head of so many distinct columns, the names of the several religious sects that are professed in the country. The person who is called upon for the assessment, as soon as he has paid his quota, subscribes his name in which of the columns he pleases; and the amount of what is collected in each column is paid over to the minister of that denomination. In this scheme it is not left to the option of the subject, whether he will contribute, or how much he shall contribute, to the main- tenance of a Christian minister: it is only referred to his choice to determine by what sect his contribution shall be received. The above arrangement, says Paley, is un- doubtedly the best that has been proposed upon this principle; it bears the appearance of liberality and justice; and it may contain some solid advantages. But our author thinks that its inconveniences will be found to overbalance all its recommendations. It is fearfully compatible with the first requisite in an ecclesiastical establishment, which is the division of the country into parishes of a commodious ex- tent. If the parishes be small, and ministers of every deno- mination be stationed in each, which the plan seems to sup- pose, the expense of their maintenance will become too bur- densome a charge for the country to support. If, for reduc- ing the expense, the districts be enlarged, the place of assembling will, in some cases, be too far removed from the residence of the persons who ought to resort to it. Be- sides, if the pecuniary success of the different teachers of religion be made to depend upon the number and wealth of their respective followers, this would naturally generate sires and indecent jealousies amongst them, as well as pro- duce a polemical and profelyting spirit, founded in or mixed with views of private gain; which would both de- prone the principles of the clergy, and disunite the country with endless contentions.

If it be expedient, says our author, to establish a national religion, that is, one sect in preference to all others, some relation, by which the teacher of that sect may be distinguished from the teachers of different sects, appears to be an indis- pensable consequence. The existence of such an establish-
ment supposes it; the very notion of a national religion includes that of a test. But the necessity of a test has furnished to almost every church a pretence for extending, multiplying, and continuing such tests beyond what the occasion justified. For though some purposes of order and tranquillity may be answered by the establishment of creeds and confessions, yet they are at all times attended with serious inconveniences. They check inquiry; they violate liberty; they enflavour the confidences of the clergy, by holding out temptations to prevarication; and in course of time, they contradict the opinions of the church, whose doctrines they profess to contain; and they often perpetuate the proscription of sects and tenets, from which any danger has long ceased to be apprehended. Although tests and subscriptions may not be abolished, they should be made as easy and simple as possible. They should be adapted from time to time to the varying sentiments and circumstances of the church in which they are received; nor should they at any time advance one step farther than some subsisting necessity requires. Promises of conformity to the rites, liturgy, and offices of the church, if sufficient to prevent confusion in the celebration of divine worship, should be accepted in the place of stricter subscriptions. If any agreements, not to preach certain doctrines, nor to revive certain controversies, denominated articles of peace, would exclude indecent alterations amongst the national clergy, and also secure to the public teaching of religion as much of uniformity and quiet as is necessary to edification; then confessions of faith ought to be converted into articles of peace. In a word, it ought to be held, says Dr. Paley, a sufficient reason for relaxing the terms of subscription, or for dropping any or all of the articles to be subscribed, that no present necessity requires greater strictness.

It is a question that has been long agitated in the reformed churches of Christendom, whether a parity amongst the clergy, or a distinction of orders in the ministy, be more conducive to the general ends of the institution? Our author is inclined to the latter alternative, for reasons which he has stated.

In discussing the subject of a national establishment of religion, the right of the civil magistrate to interfere at all in matters of religion offers itself to consideration; and although this right may be acknowledged whilst he is employed solely in providing means of public instruction, it may be questioned whether he should inflict penalties, and impose restraints or incapacities on the account of religious dispositions. Our author, deducing the authority of civil government from the will of God, and inferring that will from public expediency alone, concludes that the jurisdiction of the magistrate is limited by no consideration but that of general utility; or that whatever be the subject demanding regulation, it is lawful for him to interfere, whenever his interference, in its general tendency, appears to be conducive to the common interest. Our author concludes, that there is nothing in the nature of religion, as such, which exempts it from the authority of the legislator, when the safety or welfare of the community requires his interposition. To the objection, that religion, pertaining to the interests of a life to come, lies beyond the province of the civil government, the office of which is confined to the affairs of this life, Dr. Paley replies, that when the laws intervene even in religion, they interfere only with temporals; their effects terminate, their power operates only upon those rights and interests, which concretely belong to their disposal. He proceeds to observe, probably without satisfying the objector, "that the acts of the legislator, the edicts of the prince, the sentence of the judge, cannot affect my salvation; nor do they, without the most absurd arrogance, pretend to any such power: but they may deprive me of liberty, property, and even of life itself, on account of my religion; and however I may complain of the injustice of the sentence, by which I am condemned, I cannot allege that the magistrate has transgressed the boundaries of his jurisdiction; because the property, the liberty, and the life of the subject, may be taken away by the authority of the laws, for any reason, which, in the judgment of the legislature, renders such a measure necessary to the common welfare. Moreover, as the precepts of religion may regulate all the offices of life, or may be so construed as to extend to all, the exemption of religion from the control of human laws might afford a plea, which would exclude civil government from every authority over the conduct of its subjects. Religious liberty is like civil liberty, not an immunity from restraint, but the being restrained by no law, but what in a greater degree conduces to the public welfare."

By way of qualifying this reasoning, which may be thought exceptional, Dr. Paley observes, that "still it is right to obey God rather than man."—"When human laws interfere their direction in matters of religion, by dictating, for example, the object or the mode of divine worship; by prohibiting the profession of some articles of faith, and by executing that of others; they are liable to clash with what private persons believe to be already settled by precepts of revelation, or to contradict what God himself, they think, hath declared to be true. In this case, on whichever side the mistake lies, or whatever plea the state may allege to justify its edict, the subject can have none to excuse his compliance. The same consideration also points out the distinction, as to the authority of the state between temporals and spirituals. The magistrate is not to be obeyed in temporals more than in spirituals, where repugnance is perceived between his commands, and any credited manifestations of the divine will; but such repugnancies are much less likely to arise in one case than in the other." The general proposition laid down by our author is as follows: "That it is lawful for the magistrate to interfere in the affairs of religion, whenever his interference appears to him conducive, by its general tendency, to the public happiness." To others this proposition will appear to be in many respects exceptional. The magistrate of course is to be the judge, what are the occasions in which he may interfere; and these occasions will occur whenever he pleases. Dr. Paley has therefore endeavoured to guard it against misapprehension and misapplication. Having stated, that it is the general tendency of the measure, or, in other words, the effects which would arise from the measure being generally adopted, that fixes upon it the character of rectitude or injustice, he then proceeds to inquire what is the degree and the sort of interference of secular laws in matters of religion, which are likely to be beneficial to the public happiness. In settling this point he premises two maxims; the first is, that any form of Christianity is better than no religion at all; and the second is, that of different systems of faith, that is the best which is the truest. From the first proposition it is inferred, that when the state enables its subjects to learn some form of Christianity by distributing teachers of a religious system throughout the country, and by providing for the maintenance of these teachers at the public expense; that is, when the laws establish a national religion, they exercise a power and interference, which are likely, in their general tendency, to promote the interest of mankind.

Vol. XXIX.
REL

But after the right of the magistrate to establish a particular religion has been, upon this principle, admitted; a doubt arises, whether the religion he ought to establish be that which he himself professes, or that which he observes to prevail among the majority of the people. Allowing it to be an equal chance, which of the two religions, that of the magistrate or that of the people, contains more of truth, it becomes a consideration of some importance, to which arrangement we may attach the greater efficacy; that of an order of men appointed to teach the people their own religion, or to convert them to another; and as in our author's opinion the advantage lies on the side of the former scheme, it becomes the duty of the magistrate, in the choice of the religion which he establishes, to consult the faith of the nation rather than his own. For our author's reasoning on other topics connected with a national establishment of religion, we refer to the articles Subscription, Test, and Toleration. He closes the discussion of the general subject with the following summary of his argument: the result of our examination of those general tendencies, by which every interference of civil government in matters of religion ought to be tried, is this: "That a comprehensive national religion, guarded by a few articles of peace, and conformity, together with a legal provision for the clergy of that religion; and with a complete toleration of all dissenters from the established church, without any other limitation or exception, than what arises from the conjunction of dangerous political dispositions with certain religious tenets, appears to be, not only the most just and liberal, but the wiser and safest system, which a state can adopt: inasmuch as it unites the several perfecutions, which a religious convention ought to aim at—liberty of conscience, with means of instruction; the progress of truth, with the peace of society; the right of private judgment, with the care of the public safety." Paley's Principles of Morals and Political Philosophy, vol. ii. ch. 10.

In most countries where religion is established, it is that of the majority of the people; and on this principle the writers in defence of ecclesiastical establishments vindicate them. But in a part of the united kingdom of Great Britain, viz. in Ireland, we have a remarkable exception to this rule. There the established religion is not that of the majority, but of a small minority of the people. Ever since the reformation the members of the church of England have kept possession of the tithes of the whole island, where they have long defrauded of bringing the people over to that religion for which they pay so dear.

In connection with the national establishment of religion we shall here remark, that in this country the care which government takes of religion extends itself to the benefit of education, confining the universities, which are supported by the national funds, to the education of the members of the church of England, and rigorously excluding all sectaries, either by requiring subscription to the thirty-nine articles at the time of matriculation, or of taking certain degrees, or obliging the students to attend the service of the established church, and to declare that they are bona fide members of it.

Among the offences against religion enumerated by judge Blackstone, and punishable by the laws of England, are apostacy and heresy, which see respectively; and also those which affect the established church. These latter are either positive or negative; positive by reviling its ordinances, or negative, by non-conformity to its worship. See Reviling, &c. Common Prayer, Non-conformists, Dissenters, Papists, and Popery. See also Blasphemy, Profaneness, Conjunction and Witchcraft, Religious Impostors, Sunday, False Prophecies, Drunkenness, Lewdness, and Simony.

Religion, again, is applied to a military order, consisting of knights who live under some certain rule, &c. In this sense we say, the religion of Malta, &c. See Malta.

Religion is sometimes also used for a convent. Thus, we say, there are religions of men, i.e. monks; religions of women, i.e. nuns.

Religion, The, used absolutely, denotes the Reformed in France. Thus, they say, d'Abalencourt and Dacier were of the religion. See Huguenots.

Religious, in a general sense, something that relates to religion.

We say, a religious life, religious society, &c. Churches and church-yards are religious places. A religious war is also called a crusade; which fee.

Religious is more particularly used for a person engaged by solemn vows to the monastic life; or a person that up in a monastery, to lead a life of devotion and austerity, under some rule or institution.

The male religious we popularly call monks and friars; the female, nuns and canonesses. See Canon, Monk, Nun, &c.

M. Nicole observes, that some domestic chagrin, and a certain pride, which leads people to abhor when they cannot make a figure to their mind, make as many religious as real piety. He adds, that a girl must often be made a religious for no other reason, but because she cannot be married answerable to her condition.

Great influence, however, may be attributed to enthusiasm and superstition, and to those mistaken notions of duty and of perfection of character, which have often originated in these fancies, and which have produced effect on human minds of a peculiar temperament and disposition. Whilfit no kind of argument can justify this retirement from the world, and total seclusion from the occupations and pleasures of social life, it would manifest a want of candour as well as ignorance of human nature indiscriminately to condemn all who have devoted themselves to such a kind of indolent and useless life.

A religious cannot make any will. By the council of Trent, a religious may reclaim his vows within five years.

Anciently the religious were all laymen, and it was even prohibited them to take up orders. In 1557, the parliament of Paris made a difficulty of receiving a bishop of Laon to the oath of a duke and peer, by reason of his being a religious; yet a religious, being promoted to a bishopric, is thenceforth secularized or dispensed from the observance of his rule.

In ancient deeds and conveyances of lands, we often find the selle restrained from giving or alienating it, viris religiosis, vel Judaeis, to religious, or to Jews; to the end the land might not fall into mortmain; which fee.

In a memorial directed by king John to his vicounts, they are ordered to proclaim through their respective counties, that nobody, as they love their bodies and cattle, injure the religious or clerks, either in word or deed, on penalty of being hanged up on the next oak. "Nulli, siclit dignitati corpora et catalla suas, malum faciant vel dicant viris religiosis vel cleris. Si quem inde attingere pellimus, ad proximam quercum eum fulsendi faciemus." 55

Religious Hovées, denote houfes set apart for religious purposes,
purposes, such as monasteries, churches, hospitals, and all other places where charity is extended to the relief of the poor and orphans, and for the use or exercise of religion. See "Notitia Monastica," or "A short History of the religious Houses in England and Wales," by Tanner, 8vo.; in which, according to the alphabetical order of counties, is accurately given a full account of the founders, the time of foundation, tutelar saints, the order, the value, and the dissolution; with reference to printed authors and MSS. which preserve any memoirs relating to each house; with a preface of the institution of religious orders. Cowel.

**Religious Impostors.** See Impostors.

**Religious Order.** See Order.

All military orders pretend likewise to be religious; as those of Malta, who make vows, &c. See Malta.

**Relinquishment,** in Law, is a forfeaking, abandoning, or giving over. It hath been adjudged, that a person may relinquish an ill demand in a declaration, &c. and have judgment for that which is well-demandd.

**Reliquia,** the remainder or debt, which a person finds himself debtor in, upon the balancing or liquidating an account.

Hence *reliquary,* the debarter of a reliquia; as also a person who only pays piece-meal.

The term reliquia is pure Latin.

**Reliquiæ,** Relics, in Antiquity, the ashes and bones of the dead, which remained after burning their bodies; and which they very religiously gathered, and put into urns, and afterwards deposited in tombs. See Relics.

**Reliquary,** a shrine or casket, in which the relics of a dead saint are kept.

**Relique.** See Relics.

**Reliquia,** in Natural History, a term used to express the fossil remains of certain subfactions found in different parts of the earth. In the article Petrifications we have given the Linnæan division of the fifth clafs of minerals, and a pretty full description of the eight genera into which it is divided. In this place we shall present our readers with a very brief view of Mr. Martin’s "Systena Reliquiorum." He considers the reignum fossilier, or fossilie kingdom, to be divided into five claffes, viz.:

1. Reliquia, or fossilie remains from animals or plants.  
2. Terra, earths.  
4. Inflammabilia, inflammable subfiances.  
5. Metalla, metallic subfances.

The reliquia he divides into two orders, viz. animal and vegetable remains; of the former he gives eight genera; of the latter only one genus, which are as follow:

**Order I. Reliquia Animalia.**

**Innata.**

**Genus I.**  
1. Mammodolithus, or remains of Mammalia.  
2. Ornitholithus, - - Birds.  
3. Amphibiolithus, - - Amphibia.  
4. Ichthyolithus, - - Fishes.  
5. Entolithus, - - Infuces.  
6. Helmintholithus, the parts of worms not fabricated.  

**Fabricata.**  
7. Conchylolithus, or remains of Teltacea.  
8. Erimatololithus, of fulciments, or fabricated supports of worms.

**Order II. Reliquia Vegetalia.**

9. Phytolithus, the remains of Plants.

Mr. Martin has given certain fundamental principles, on which he conceives the study of reliquia may be scientifically conducted: these are as follow.

1. All natural bodies without life found on or beneath the surface of the earth, and which are not susceptible of putrefaction, belong to the fossilie kingdom, and are either reliquia or minerals. Fossils are usually denominated "bodies delitute of an organic structure;" now though it be admitted that all fossils are, according to the common acceptation of the term, unorganized, they are not delitute of the structure which distinguishes an organized body. This being admitted, it follows that a line must be drawn between animal and vegetable matter recently buried in the earth, and which has acquired a genuine fossilie character. This line will depend perhaps on putrefaction, to which even organic subfances, after they have become fossilie, are no longer subject.

2. An organic structure, whether of a plant or animal, is the essence of an extraneous fossil or reliquium. By this alone it is charactarcised, or distinguished from a mineral.

3. It is the organic form alone which the arrangement of reliquia must be founded. Every system of natural bodies should assume for its basis but one principle, and this should be drawn from the most essential characteristics of the bodies under arrangement. It is on this account the form is pointed out as furnishing the only genuine principles, on which the classification of reliquia can be established.

4. The primary divisions of the arrangement, viz. orders, genera, &c. should agree with such natural divisions of plants and animals as are determinable by the form of the fossilie subjeclts.

5. The specific differences in reliquia depend on the specific differences of form in the original bodies. One species of plant or animal can give but one real or genuine species of extraneous fossil. For if the essence of the reliquium be an organic form, its other affections, arising from sublance, mode, and soil, are accidental, and cannot be used as specific denominations, which must always depend on something essential to the body which we wish to discriminate. Form, therefore, must furnish specific differences of reliquia, and it of course follows that there will be as many genuine species of reliquia, as there are genuine specific forms in the animal and vegetable prototypes or originals; and that the number of fossilie species are not increas’d by a separation of parts, or other accidental circumstances to which the original bodies may have been subjected during their change into fossils.

6. Specific distinctions of reliquia being founded only on the organic form, it follows, that their geological and mineralogical affections, with their modal diversities, merely characterize specimens.

7. The specific descriptions of reliquia are to be given according to the principles of botany and zoology. Thofe of the specimens, according to the principles of mineralogy and geology. The essential form of the reliquium must be distinguished from the accidental, that is, the form of the original body, from that which has arisen in the fossil from the mode of mineralization, the constituent sublance, and the soil of the specimen.

8. The nomenclature of reliquia should manifest the extent of the present state of knowledge with respect to the original bodies.

To what has been said, we shall add an account of our author’s "Delineations of Reliquia."

The leading parts in the definition of a reliquium are
RELQUIA.

the specific character or diagnosis, and the general description.

The specific character contains the marks that distinguish the species to which they belong, from all others in the same genus. Specific characters of reliquia should be so constructed as to distinguish permanent from temporary species; and those whole originals have not, as yet, been discovered. The specific character of the recent species of plants or animals frequently depends on parts often or constantly wanting in the fossil subject. When that is the case, another diagnosis must be given to distinguish the reliquium; that of the recent species being marked as a parenthesis. The generic and trivial names are prefixed to the specific character. And, generally, the name of the family, or subdivision of the genus to which the reliquium belongs: after which it is to be detailed in distinct classes. 1. The synonyms or names by which the species has been distinguished by authors, with references to the figures given of it. 2. The varieties of the species, with their synonyms. 3. The vernacular name. 4. The mode or rate at which the reliquium is found. 5. Its soil or geological situation. 6. Its geographic situation, and then the general description.

The description delineates in appropriate terms all the parts constituting the essential form of the reliquium, according to their number, figure, proportion, and situation: it must primarily refer to the original of the reliquium, as no just or perfect delineation of the species can be given until the nature of its prototype be ascertained. The terms employed in describing reliquia, which derive their form from the external parts of animals and plants, must be those used by zoologists and botanists of the Linnean school. But those which derive their form from the internal parts of organic bodies, are to be described in such terms as anatomists would use in distinguishing the same parts in the recent subjects.

As appendant parts to the general description of the reliquium must be given. 1. An enumeration of the specimens which exhibit the various accidental forms under which the species has been found. 2. An enumeration of the various substances which have been observed as constituting the reliquium and its matrix.

Having given this brief account of Mr. Martin's scientific delineations of reliquia, we shall present our readers with the fullness of two very interesting communications sent to the Royal Society since the printing of the article Petrifications. Of these, the first is "An Account of some Organic Remains found by Mr. Trimmer, near Brentford, in Middlesex."

"The specimens," says Mr. Trimmer, "have been collected from two fields, not contiguous to each other; therefore, to avoid confusion, I shall take each field separately, first describing the first as far as they have come within my knowledge, and afterwards I shall speak of the organic remains as they were respectively found in those fields. The first field is about half a mile north of the Thames at Kew bridge; its surface is about twenty-five feet above the Thames at low water. The fields here are, first, sandy loam from fix to seven feet, the lowest two feet slightly calcareous. Second, sandy gravel, a few inches only in thicknesses. Third, loam slightly calcareous, from one to five feet between this and the next field, peat frequently intermixed in small patches, of only a few yards wide, and a few inches thick. Fourth, gravel containing water; this field varies from two to ten feet in thickness, and is always the deepest in the places covered by peat; in these places the lower part of the field becomes an heterogeneous mass of clay, sand, and gravel, and frequently exhales a disagreeable muddy smell. Fifth, the main stratum of blue clay, which lies under this, extends under London and its vicinity; the average depth of this clay has been ascertained, by wells that have been dug through it, to be about two hundred feet under the surface of the more level lands, and proportionally deeper under the hills, as appears from lord Spencer's well at Wimbledon, which is five hundred and sixty-seven feet deep. This stratum, besides figured fossils, contains pyrites and many detached nodules; at the depth of twenty feet there is a regular stratum of these nodules, some of which are of very considerable size.

"In the first stratum, as far as my observation has extended, no remains of an organized body has ever been found, and as my search has not been very limited, I may venture to say it contains none. In the second stratum, shell-fossils, and the shells of river-fish, have been found, and a few bones of land animals, but of incredible size, and in such a mutilated state, that it cannot be ascertained to what classes they belong. In the third stratum, the horns and bones of the ox, and the horns, bones, and teeth of the deer, have been found, and also, as in the second stratum, shell-fossils, and the shells of river-fish. In the fourth stratum were found teeth and bones of both the African and Asiatic elephants, teeth of the hippopotamus, bones, horns, and teeth of the ox.

"A tuft of an elephant measured, as it lay on the ground, nine feet three inches, but, in attempting to remove it, it broke into small pieces. When this stratum dips into the clay, and becomes a mixed mass, as before stated, it is seldom without the remains of animals. In the fifth stratum, namely, the blue clay, the extraneous fossils are entirely marine, with the exception of some specimens of fruit and pieces of petrified wood, the latter of which may be considered as marine, because, when of sufficient size, they are always penetrated by teredines. The other fossils from this stratum are nautili, oysters, pinnæa marine, crabs, teeth and bones of fish, and a great variety of small marine shells; this stratum has been penetrated hitherto in this field only to the depth of thirty feet, throughout which the specimens found were differenced without any regularity.

"The second field is about one mile to the westward of the former, one mile north of the Thames, and a quarter of a mile to the eastward of the river Brent; its height above the Thames, at low water, is about forty feet. The strata are, first, sandy loam, eight or nine feet, in the lowest three feet of which it is slightly calcareous. Second, sand, becoming coarser towards the lowest part, and ending in sandy gravel from three to eight feet. Third, sandy loam evenly calcareous, having its upper surface nearly level, but gradually increasing in thickness from a feather-edge to nine feet. Below this are two strata of gravel and clay; as in the other field; but as these strata have been only occasionally penetrated in digging for water, nothing therefore is known with respect to them, but that they exist there.

"In the first stratum, as in the other field, no organic remains have been observed. In the second, but always within two feet of the third stratum, have been found the teeth and bones of the hippopotamus, the teeth and bones of the elephant, the horns, bones, and teeth of several species of deer, the horns, bones, and teeth of the ox, and the shells of river-fish.

"The remains of hippopotami are extremely abundant, that, in turning over an area of 120 yards in the present season, parts of six tusks have been found of this animal, besides a tooth and part of the horn of a deer, part of a tusk, and part of a grinder of an elephant, and the horns, with a small part of the skull, of an ox. One of these horns I had
an opportunity of measuring as it lay on the ground, and found it to be 43 feet in length, and five inches in diameter at the large end; it was found impracticable to remove it, otherwise than in fragments, which I have preferred, and have hopes of being able to put a considerable part of it together. The immense size of this horn is rendered more remarkable by another horn from the same spot, which measures but six inches in length. Though this horn is so extremely productive of the remains of animals, yet there are but few good cabinet specimens from it, owing, it is presumed, to their having been crushed at the time they were buried, and to the injury they have since received from moisture. It is necessary to remark, that the gravel-bones in this stratum do not appear to have been rounded in the usual way by attrition, and that the bones must have been deposited after the flesh was off, because, in no instance, have two bones been found together which were joined in the living animal; and further, that the bones are not in the least worn, as must have been the case had they been exposed to the wash of a sea-beach.

"In the third stratum, calcareous loam, have been found the horns, bones and teeth of the deer, the bones and teeth of the ox, together with mull-sheels, and the shells of river-fish.

"Brentford, in the neighbourhood of which are the fields I have mentioned, is situated on the north bank of the Thames, and is six miles west of London.

"The full of the Thames from Brentford to its mouth at the Nore, is estuinated at seven feet.""

The next communication is in relation to a fossil human skeleton, found imbedded in lime-stone lately brought from the island of Guadaloupe by the honourable Sir Alexander Cochrane, and presented by the admiralty to the British Museum. Of this highly curious specimen Mr. Konig has given an account that, to naturalists, will be regarded as highly important and interesting.

"On the history of the strata produced by the more recent catastrophes of the globe," says Mr. Konig, "most light has been thrown by the indurate deposits of the late Cuvier. Superlatively skilled in comparative anatomy, this gentleman has succeeded in determining the fossil bones of no less than 78 species, of which 49 are entirely unknown among the existing races of animals; about 12 are identical with known species, and the remainder strongly resemble existing species, although their identity has not been completely ascertained. From the multiplied observations which this naturalist has communicated in his numerous memoirs, we may gather that the viviparous quadrupeds appear at a much later period in the fossil strata than the oviparous; the latter being probably coeval with the fishes, whilst the former are found only in the earliest formations, in which, according to Brongniart and Cuvier's interesting discovery, marine beds are observed to alternate with those of fresh water, and which (in the neighbourhood of Paris) overlie the coarse shell lime-stone, which constitutes the last strata formed, as it would appear, by a long and quiet stay of the sea on our continent.

"All the circumstances under which the known depozitions of bones occur, both in alluvial beds and in the caverns and fissures of limestone, tend to prove, that the animals to which they belonged met their fate in the same places where they now lie buried. Hence, it may be considered as an axiom, that man, and other animals, whose bones are not found intermixed with them, did not co-exist in time and place. The same mode of reasoning would further justify us in the conclusion, that, if those catastrophes which overwhelmed a great proportion of the brute creation were general, as geognostic observations in various parts of the world render probable, the creation of man must have been posterior to that of those genera and species of mammals which perished by a general cataclysm, and whose bones are so thickly disseminated in the more recent formations of rocks.

"The human skeletons from Guadaloupe are called Galiby by the natives of that island; a name said to have been that of an ancient tribe of Caribis of Guiana, but which, according to a plausible conjecture, originated in the substiution of the letter i instead of r, in the word Caribbean. No mention is made of them by any author except General Ermouf, in a letter to M. Faujas St. Fond, inserted in vol. v. (1856) of the Annales du Muséum; and by M. Lavaiffe, in his Voyage a la Trinidad, &c., published in 1818. The former of these gentlemen writes, that, on that part of the windward side of the Grande-Terre, called La Moule, skeletons are found enveloped in what he terms "Maîles de mâtres-pères," which being very hard, and situated within the line of high water, could not be worked without great difficulty, but that he expected to succeed in causing some of these maîles to be detached, the measurements of which he states to be about eight feet by two and a half.

"The block brought home by Sir Alexander Cochrane exactly answered this account with regard to the maîles; in thickness it was about a foot and a half. It weighed nearly two tons; its shape was irregular, approaching to a flattened oval, with here and there some concavities, the largest of which, as it afterwards appeared, occupying the place where the thigh-bone had been situated, the lower part of which was therefore wanting. Except the few holes evidently made to assist in raising the block, the masons here declared, that there was no mark of a tool upon any part of it; and, indeed, the whole had very much the appearance of a huge nodule disengaged from a surrounding mass.

"The situation of the skeleton in the block was supra-axial, that its presence in the rock on the coast had probably been indicated by the projection of some of the more elevated parts of the left fore-arm.

"The skull is wanting; a circumstance which is the more to be regretted, as this characteristic part might possibly have thrown some light on the subject under consideration, or would, at least, have settled the question, whether the skeleton is that of a Carib, who used to give the frontal bone of the head a particular shape by compression, which had the effect of deforming the upper, and protruding the lower edge of the orbits, so as to make the direction of their opening nearly upwards, or horizontal, instead of vertical.

"The vertebrae of the neck were left with the head. The bones of the thorax bear all the marks of considerable concussion, and are completely dislocated. The seven true ribs of the left side, though their heads are not in connection with the vertebrae, are complete, but only three of the false ribs are observable. On the right side only fragments of these bones are seen; but the upper part of the seven true ribs of this side are found on the left, and might at first sight be taken for the termination of the left ribs. The right ribs must, therefore, have been violently broken, and carried over to the left side, where, if this mode of viewing the subject be correct, the femur must likewise lie concealed below the termination of the ribs. The small bone dependent above the upper ribs of the left side, appears to be the right clavicle. The right os humeri is lost; of the left nothing remains except the condyles in connection with the fore-arm, which is in the state of pronation; the radius of this side exists nearly in its full length, while of the ulna the lower part only remains, which is considerably pushed upwards. Of the two bones of the right fore-arm, the inferior termina-
tions are seen. Both the rows of the bones of the wrists are loll, but the whole metacarpus of the left hand is displayed, together with part of the bones of the fingers; the first joint of the fore-finger rolls on the upper ridge of the os pubis, the two others, detached from their metacarpal bones, are propelled downwards, and situated at the inner side of the femur, and below the foramen magnum ichii of this side. Vertebræ of three of the fingers of the right hand are likewise visible, considerably below the lower portion of the femur, and close to the upper extremity of the femur. The vertebrae may be traced along the whole length of the column, but are in no part of it well defined. Of the os facrum, the superior portion only is distinct: it is diftincted from the last vertebra and the ilium, and driven upwards. The left os ilium is nearly complete; but flattened, and one of the fragments depressed below the level of the rest: the os pubis, though well defined, are gradually left in the mafs of the bone. On the right side the os innominatum is completely flattened, and the fragments are funk; but towards the acetabula, part of its internal cellular structure is discernible.

"The thigh-bones and the bones of the leg of the right side are in good preservation, but being considerably turned outwards, the fibula lies buried in the bone, and is not seen. The lower part of the femur of this side is indicated only by a bony outline, and appears to have been divided by the compact lime-flone that fills the cavities both of the bones of the leg and thigh, and to the expansion of which these bones probably owe their present flattened condition. The lower end of the left thigh-bone appears to have been broken and lost in the operation of detaching the block; the two bones of the leg, however, on this side are nearly complete: the tibia was split almost the whole of its length a little below the external edge, and the siffure being filled up with lime-flone, now presents itself as a dark-coloured straight line. The portion of the bone which contained part of the bones of the tarsus and metatarsus unfortunately broken; but the separate fragments are preserved.

"The whole of the bones, when first laid bare, had a mouldering appearance, and the hard surrounding flone could not be detached, without frequently injuring their surface; but, after an exposure for some days to the air, they acquired a considerable degree of hardness. Sir H. Davy, who subjected a small portion of them to chemical analysis, found that they contained part of their animal matter, and all their phosphate of lime. Here follows an exact description of the rock, in which the foible skeloton is found. The attention of geologists being now directed towards this object, it may be expected that a scientific examination of the circumstances under which this lime-flone occurs, will not fail ere long to fix its age, and allign to it the place it is to occupy in the series of rocks. All our present information respecting the Grande Terce of Guadaloupe amounts to this, that it is a flat lime-flone country, derived principally from the detritus of zoophytes, with here and there linge hills (mornes) composed of shell lime-flone; while Guadaloupe, properly so called, separated from the upper part by a narrow channel of the sea, has no traces of lime-flone, and is entirely volcanic."

M. Lavailles, alluded to above as the only author who mentions the gallices, except general Ernouf, speaks of the bed of lime-flone which incloses them, as the most remarkable of the calcareous rocks in the Leeward islands. Mr. Konig, therefore, expected to find in his work an exact statement of its mode of occurring; but the only positive information he could collect from this author is, that the bed is a kilometre (nearly an English mile) in length, and that it is covered by the sea at high water. According to him, no trace of shells or organized bodies is discoverable in this rock; but in lieu of these, he was fortunate enough to meet with mortars, pebbles, hatchets, &c. of a basaltic or porphyritic rock, which, we are informed, were petrifled (petrifies). From this very vague account, we should not be induced to lay much stress upon the circumstance that the position of the skeletons is east-west, and that the spot must, therefore, have been a cemetery, which time and circumstances have transformed into a hard calcareous rock.

"I have to apologize for this long letter on a subject," concludes Mr. Konig, "which may turn out to be interesting only so far, as the human bones from Guadaloupe are unquestionably the only bones we are acquainted with that have ever been found imbedded in a hard flony mass, that does not appear to belong to common flatactic calcareous depositions. This circumstance admits of being easily ascertained by a close inspection of the locality, and I am perfectly of opinion, that a comparison of the nature of the different varieties of shell-fand, with which the neighbourhood of the Caribbean islands abounds, would alone be sufficient to remove many doubts relative to the origin of the bed in question. The sand from thence, which I had an opportunity of seeing, was unlike that of which the flone is composed."

RELL, Mouse, in Zoology, the English name of the white-bellicd moule, with a blackish back and long body. See Myxus and Glis.

RELLING, in Geography, a town of the duchy of Holstein; 2 miles S.E. of Pinnenberg.

RELLINGEN, a town of France, in the department of the Mofelle, and chief place of a canton, in the district of Thionville. The place contains 602, and the canton 9046 inhabitants, on a territory of 212½ kilometres, in 56 communes.

RELLINGHAUSEN, a town of Germany, lately belonging to the abbey of Corve; 16 miles N.N.E. of Dusseldorf.

RELLINGHUSEN, a town of the duchy of Holstein; 9 miles E. of Itzeboh.

REM, Information in, in Law. See Information.

REMAGEN, in Geography, a town of France, in the department of the Rhine and Mofelle, and chief place of a canton, in the district of Bonn. The place contains 790, and the canton 7801 inhabitants, in 37 communes.

REMAIGHIAN, a town of Persia, in the province of Laristan; 10 miles N.W. of Tarem.

REMAINDER, Remaigntia, in Law, an estate limited to take effect and be enjoyed after another estate is determined. As if a man feiled in lie-fimpole granteth lands to A for twenty years, and, after the determination of the said term, then to B and his heirs for ever; here A is tenant for years, remainder to B in fee. In the first place, an estate for years is created or carved out of the fee, and given to A; and the residue or remainder of it is given to B. But both these interests are in fact only one estate; the present term of years and the remainder afterwards, when added together, being equal only to one estate in fee. (Co. Litt. 143.) Thus, also, if land be granted to A for twenty years, and after the determination of the said term to B for life; and after the determination of B's estate for life, it being limited to C and his heirs for ever; this makes A tenant for years, remainder to B for life, remainder over to C in fee. In this case also, the first estate, and both the remainders, for life and in fee, are one estate only. Hence it is easy to infer, that no remainder can be limited after the grant of an estate in fee-simpole (Plowd. 29. Vaught.)
Vaugh. 269.) because this is the highest and largest estate that a subject is capable of enjoying; and he that is tenant in fee, hath in him the whole of the estate: a remainder, therefore, which is only a portion, or residuary part of the estate, cannot be reserved after the whole is dispised of.

The rules that are laid down by law to be observed in the creation of remainders, are as follow. 1. There must necessarily be some particular estate, precedent to the estate in remainder; which particular estate is said to support the remainder. (Co. Litt. 49. Plowd. 25.) 2. The remainder must commence or pass out of the grantor, at the time of the creation of the particular estate. (Litt. § 671. Plowd. 25.) as where there is an estate to A for life, with a remainder to B in fee; here B's remainder in fee passes from the grantor at the same time that feisin is delivered to A of his life-estate in possession. And it is this which induces the necessity at common law of livery of feisin being made on the particular estate, whenever a freehold remainder is created. (Litt. § 60. Co. Litt. 49.) 3. The remainder must vest in the grantee during the continuance of the particular estate, or to an estate that it determines. (Plowd. 1 Rep. 66.) As if A be tenant for life, remainder to B in tail: here B's remainder is vested in him, at the creation of the particular estate to A for life: or if A and B be tenants for their joint lives, remainder to the survivor in fee; here, though during their joint lives the remainder is vested in neither, yet on the death of either of them, the remainder vests instantly in the survivor; whence both these are good remainders. But if an estate be limited to A for life, remainder to the eldest son of B in tail, and A dies before B hath any son; here the remainder will be void, for it did not vest in any one during the continuance, nor at the determination, of the particular estate: and even supposing that B should afterwards have a son, he shall not take by this remainder; for, as it did not vest at or before the end of the particular estate, it never can vest at all, but is gone for ever. (1 Rep. 138.) Hence remainders are either voided or contingent. Voided remainders (or remainders executed, by which a present interest passes to the party, though to be enjoyed in futuro) are such where the estate is invariably fixed, to remain to a determinate person after the particular estate is spent. As if A be tenant for twenty years, remainder to B in fee; here B's is a voided remainder, which nothing can defeat or set aside. Contingent or executory remainders (by which no present interest passes) are where the estate in remainder is limited to take effect, either to a dubious and uncertain person, or upon a dubious or uncertain event; so that the particular estate may chance to be determined, and the remainder never take effect. (3 Rep. 20.) In the first case, if A be tenant for life, with remainder to B's eldest son (then unborn) in tail, this is a contingent remainder, because it is uncertain whether B will have a son or not; and if A dies before B's son is born, the remainder is absolutely gone; even though A leaves his wife big with child, and after his death a posthumous son is born. (Salk. 228. 4 Mod. 282.) But to remedy this hardship, it is enacted by statute 10 & 11 W. III. cap. 16, that posthumous children shall be capable of taking in remainder, in the same manner as if they had been born in their father's life-time; that is, the remainder is allowed to vest in them, while yet in their mother's womb. This species of contingent remainder, to a person not in being, must, however, be limited to some one, that may by common possibility, or potestas proponens, be in esse at or before the particular estate determines. (2 Rep. 51.) A remainder to a man's eldest son, who has none, is good; because by common possibility he may have one: but if it be limited in particular to his son John or Richard, it is bad, if he have no son of that name; for it is too remote a possibility, that he should not only have a son, but the son of a particular name. (5 Rep. 51.) A limitation of a remainder to a bastard before he is born, is not good (C箩. Eliz. 505.); for though the law allows the possibility of having bastards, it presumes it to be a very remote and improbable contingency. In the second case, where land is given to A for life, and in cale B survives him, then with remainder to B in fee; here B is a certain person, but the remainder to him is a contingent remainder, depending upon the uncertainty of his surviving A. During the joint lives of B and A, it is contingent; and if B dies first, it can never vest in his heirs, but is for ever gone; but if A dies first, the remainder to B becomes vested. Contingent remainders of either kind, if they amount to a freehold, cannot be limited on an estate for years, or any other particular estate, less than a freehold. Thus, if land be granted to A for ten years, with remainder in fee to the right heirs of B, this remainder is void (1 Rep. 150.); but if granted to A for life, with a like remainder, it is good. Contingent remainders may be defeated; by destroying or determining the particular estate upon which they depend, before the contingency happens, by which they become vested. 1 Rep. 66. 155.

In devises by last will and testament, remainders may be created in some measure contrary to the rules here laid down: though our lawyers will not allow such dispositions to be strictly remainders; but call them by another name, that of executory devises, or devises hereafter to be executed. Blackl. Com. book ii. chap. 11. § 3.

Spelman makes the difference between a remainder and a reversion to confit in this; that by a reversion, after the appointed term, the estate returns to the donor, or his heirs, as the proper fountain; whereas by remainder it goes to some third person or stranger.

Or, a remainder is an expectancy, created by act of the parties; whereas a reversion is created by act of law.

The limitations of personal goods and chattels, in remainder after a bequest for life, are permitted in last wills and testaments: so that if a man, either by deed or will, limits his books or furniture to A for life, with remainder over to B, this remainder is good. But where an estate-tail in things personal is given to the first or any subsequent possessor, it vests in him the total property, and no remainder over shall be permitted on such a limitation. 1 P. Wms. 290.

Glaville observes, that bishops and abbots, in regard their baronies are the king's alms, cannot give any part of them by way of remainder.

REMAI, in Geography, a town of Hindoostan; 18 miles N.W. of Agimere.

REMALAND, a town of France, in the department of the Orne, and chief place of a canton, in the district of Mortagne. The place contains 1703, and the canton 11,683 inhabitants, on a territory of 2042 kilometres, in 12 communes.

REMANCIATE, To, in Commerce, is to fell or return a commodity to him who first sold it.

REMANCIATION, REMANCIATION, among the Romans, a form of divorce observed in marriages that had been contracted by comission. This was done by delivering the wife into the husband's hands; so the marriage was dissolved
falved by the husband's re-delivering the wife into any per-
son's hands agreed upon between them.

REMAND, Fr. To, in Military Language, to send back; as when a soldier, who has been brought out of prison, or the guard-house, for the purpose of being examined or tried, is sent back, without any thing final occurring relative to his cafe.

REMANSO, in Geography, a town of South America, in the province of Cordova; 170 miles N. of Cordova.

RE-MARRYING, the repeating of a marriage; or the going through the solemnities of a second marriage.

Chandelline and unconvalical marriages are deemed null; and the parties are to be re-married in form; at least, it had always better be so to avoid disputes.

It was ancietly expressly forbid to re-marry in the first year of virginit. M. Boyle observes, that a person who does not re-marry, is answerable to the public for all the time lost in his virginit, or widowhood.

REMBANG, in Geography, a town on the N. coast of the island of Java, where the Dutch had a resident merchant. It yields fah and timber, and was the place where the small vessels of the company were built; 45 miles N.E. of Sar-marg.

REMERTUS, in Biography, the disciple, friend, and fellow labourer of Anfarius, styled the apostle of the north, was a native of Thurhol, in Flanders, in the monas-
tery of which, as well as in that of Corbev in Wettphalia, he officiated as school-ma7ier. He was one of the first promoters of Christianitv in Denmark, and in or about the year 860 he became bishop of Ribe. After the death of Anfarius, in 863, he was appointed to the archiepiscopate of Hamburg, which office he held till his death, in 888. He wrote, in conjunction with a friend, the life of Anfarius, which is inserted in the first volume of Langebeck's "Scriptores Rerum Danicarum." In this work Rembertus relates various facts, not elsewhere to be found, with regard to the state of Denmark at that period, but intermixed with fables. He collected extracts from Gregorius Magnus, whose works no longer exist, and he wrote many letters, one of which only is to be found in the second volume of Langebeck's collection. An account of Rembert's life and miracles is given in the same work. A Danish writer, quoted in the General Biography, to which we are indebted for this article, speaking of Rembert's labours, says, "here we have not so much the commencement of Danish literature, as the seeds of it. They were sown by the exertions of Ebbo, Wille-
had, Anfarius, and Rembert, but remained a long time, as it were, trodden down by the severer perfecutions to which the Christians were exposed from Gorm the old, and other kings; and retarded in their growth by the rudenesf and barbarism which formed the principal features in the charac-
ter of a people, who were fonder of roving about on the seas to rob and murder, and of feasting and drinking, than of reading and writing books. At length, however, the seeds which he had scattered took root, sprang up in the 11th century, and in the 12th and 13th produced abundance of fruit." Gen. Biog.

REMBERVILLERS, in Geography. See Rambervillers.

REMBRANDT, VAN RYN, in Biography, was born at a village near Leyden, in 1605. The real name of his family was Gerretz; but he acquired that of Van Ryn, from having resided in early life at a village upon the banks of the Rhine.

The little which this extraordinary artist owed to tuition was derived first from Zwabenburgh, then from Peter Laft-
man, and afterwards from Jacob P灶, from whose manner some are induced to think that Rembrandt drew his own in-
elination for powerful oppositions of light and shade; but whatever hints he may have obtained from others at the outset of his practice, they were soon lost in the effulgence of his brilliant career, and absorbed in the lustre of his own over-powering abilities.

He was first brought into notice by having taken a picture to the Hague, and offered it for sale to an able connois-
seur; who, confident of his merit, treated him with kind-
ness, and gave him a hundred florins for it. By this incident both himself and the public were made acquainted with his worth; and hence arose the reputation and success he afterwards enjoyed. Inceflant occupation soon crowded upon him, and many pupils applied for admission into his school, with each of whom he received 100 florins a year; and whole copies of his pictures he not unfrequently sold as or-
inals, after bestowing a short time upon them himself. By these means, aided by incessant industry, and the sale of etchings, which he produced with great facility, he also accummulated considerable wealth; his income, according to Sandrart, being, for a length of time, at least 2500 florins yearly.

His place of residence, during this successful display of his talents, was Amsterdam, where his peculiarities procured him the character of a humorist, whilst his abilities atmo-
sified and delighted his contemporaries, and he produced those works which still gratify succeeding ages.

The peculiarities of his mind are as much observable in the manner of producing his effects, as in the choice of the materials. The execution of his earlier works was in a style highly laboured, with great neatness, and patient comple-
tion of the figures; such is that of the picture of the wom-
an taken in adultery at Mr. Angerlein's. As he advanced in art, he took liberties with the pencil, wrought with all the broad fulness of the brush, and left the touch undis-
turbed; he even employed the fiek, the pallet-knife, or his fingers, accordingly as they were most capable of producing the effect he defired, when seen at a proper distance, difre-
garding the appearance of the work upon a closer inspec-
tion.

In his pictures is exhibited a total inattention to the taste of the antique; he is even said to have made it a subject of ridicule, and to have jocofely denominated a collection of old armour and rich dresses, which he had collected and em-
ployed to study and paint from, "his antiques." These he evidently used as his models, though frequently in most het-
erogeneous combination; but by an innate power of seizing the most striking effects produced by light and shade, super-
added to the most perfect mastery over the materials of the pallet, he always excided an interefl, either by originality or beauty.

It is not, however, the approval of his power in the tech-
nical part of the art, which can or ought to satisfy the ob-
server of the works of Rembrandt. Entering with the warmth of a poet into the nature of his subjects, he pro-
duced pictures which terrify with their sublimity, delight with their vivacity, or gratify us with the most perfect trans-
scripts of Nature, in her most varied aspects. Being himself polished of the full force of his subject, he impresses it strongly, and notwithstanding the frequent vulgarity, and even deformity of the agents he exhibits, he extends from us prais before we have time to consider the means by which we are stimulated to bellow it. To him every time and scene was alike easy of reprezentation; and all degrees of illumination, in form or quantity, he managed with the greatest perfection; no matter whether the scene arose from the breadth of the noon-day blaze, the dimes of twilight, the
the darknes of night, or the glimmerings of the lonely taper; whether the light were spread over an extended space and a multitude of figures, or confined to the interior of a room, and serving only to illumine the books or the figure of a fequestered philosopher.

He was certainly a genius of the first clafs, although the objects upon which he exercised his powers bore little or no proportional value when compared with those selected by the best Greek and Italian masters. His invention was abundantly fertile, but employed generally among low characters and materials, although the subject he treated might be, as it frequently was, of a facred or sublime quality. In designing the nude, he never appears to have had a thought of an elevated nature concerning form. Such as the model presented, he imitated with exactness, when he wished to be most perfect; but he sometimes seems to have sported with the idea of selection, by making figures demanding grace and beauty, such as Venus, Cupid, &c. till more vulgar, and in actions more disgusting, than those he drew of common life. The redemption of this vulgarity and meaness rels with the extreme force, depth, riches, brilliancy, and truth of his colouring, and the perfection with which he treated his chiaro-icuro; which conjointly fascinating the eye, and hold it in admiration, in spite of the deformities presented in design.

The power of Rembrandt in the art he practised was perfectly original, and its exercise quite unlike that of any other painter; being drawn from nature with the most faithful and discriminating eye, but with the most peculiar selection. Always powerfully and beautifully executed, but not unfrequently too artificial; and only agreeable because it is perfectly effective. All imitations of his style which are not well wrought, reduce it to manner, and only exhibit the artifice by which it is conducted.

To guess from the number and finch of his works, he must have painted with amazing facility. His style appears to have been that of using the ground as a half tint, and repeating the lights and darks till he had obtained the effect he fought for. His pencil, particularly in his earlier and more finished works, is remarkably delicate, yet full; and has never been exactly imitated; though some of his scholars, as Bohl and Eckhout, approached very near it: none of them, however, appear to have imbibed any large portion of his clear perception of natural effects, which so powerfully appeal to our sympathy in his scenes of twilight, of tempell, and the spirit-dimming gloom of night.

His pictures are jolyly and highly valued, and are rarely to be purchased; and then only at very high prices. We are possessed of many fine specimens of his talents, both in history and portraiture; and the gallery of the Louvre is rich in his smaller productions. At Florence also, and at Genoa, his name is esteemed, and his works preferred with due respect.

He lived to the age of sixty-eight, and died in 1674.

REMDA, in Geography, a town of Saxony, in the principality of Eilenach; 11 miles S.S.W. of Jena. N. lat. 50° 45'. E. long. 11° 16'.

REMEDIAL Part of a Law. See Law.

REMEDIAL Statutes, are those which are made to supply such defects, and abridge such superfluities, in the common law, as arise either from the general imperfection of all human laws, from change of time and circumstances, from the mistakes and unadvised determinations of unlearned judges, or from any other causes whatsoever. And this being done, either by enlarging the common law where it was too narrow and circumscribed, or by restraining it where it was too lax and luxuriant, hath occasioned another subordinate division of remedial acts of parliament into enlarging and restraining statutes. E. gr. In the case of treason, clipping the current coin of the kingdom was an offence not sufficiently guarded against by the common law; therefore it was thought expedient by statute 5 Eliz. exp. 11. to make it high treason, which it was not at the common law; so that this was an enlarging statute. At common law also spiritual corporations might leave out their citations for any term of years, till prevented by the statute 13 Eliz. exp. 10. This was, therefore, a restraining statute. Blackft. Com. book i.

REMEDIOS, in Geography, a town of South America, in the province of Popayan; 71 miles S. of Santa Fé de Antioquia.

REMEDIOS, or Nostra Segunda de los Remedios de Nuevo, a town of Mexico, in the province of Veragua; 90 miles W.N.W. of St. Yago. N. lat. 8° 44'. W. long. 82° 16'.

REMEDIOS, or Payufal, a town of Mexico, in the province of Yucatan, in lake Pue. N. lat. 17° 3'. W. long. 91° 46'.

REMEDIOS, a town of New Navarre; 120 miles S. of Cafa Grande.

REMEDY, in Law, is the action or means given by law for the recovery of a right.

REMEDY, Remedium, in Medicine, any physical agent by which a diseafe may be alleviated or cured.

Remedies are either general or topical; the former comprehending such as influence the actions of the whole frame, as blood-letting from any large vein, the cold-bath, and almost all those medicaments or drugs which are taken into the stomach; the latter including those which are applied to, or in the vicinity of, any particular part which is discafed; thus, among topical remedies, are blood-letting by leeches or cupping, blisters, fusses, cataplasms, ointments, plasters, &c.

The operation of remedies is rather a question of experience than of logical investigation. Some remedies, the number of which appears to be very limited, possess a specific power of curing certain diseafiles. There are, perhaps, not more than two medicines, however, that are fairly entitled to the appellation of specifics: these are mercury, which cures the venereal diseafes, and sulphur, which cures the itch. The bark of cinchona has, indeed, been deemed a specific for intermittent fevers; but it is not entitled to such a character: and the eau medicinale, which has recently been brought forward as a specific for the gout, appears to have lost much of its reputation. The pretended species daily advertised for many diseafiles by quacks, are mere impostions, being commonly disguised forms of the most active and dangerous medicines which are employed cautiously by the faculty; such as arsenic, corrosive sublimate, and other preparations of mercury; laudanum, hemlock, and other narcotics. Of the former species are Ward's auge-drop, and his white drop; of the latter, are Dalby's carminative, Godbold's balsam, and many others.

The danger resulting from the use of these nothums, arises from the indiscriminate administration of them in many diseafiles which have a similar name, but which vary much in different constitutions, and at different periods of life. Much injury is done by the constant sale of these pretended specifics, by the impression which it contributes to maintain, that each disease has its specific remedy; whereas no opinion can be farther from the truth. When it is considered that almost every disease, though similar in name, arises from several causes (which we have already illustrated when speaking of cough), it will be obvious that the same remedies must be applied, upon general principles, to diseafiles of different name, and different remedies to those which have the
fame appellation; and that, therefore, the cure of diseases is not to be effected by applying a certain remedy to a certain disease nominally the same, but only by first ascertaining the laws of the living body, and of its various organs, both in a state of health and of disease; in other words, the proper application of remedies can only be learned by much observation of diseases, after a previous study of the anatomy and physiology of the animal frame.

Remedies Appended. See Appendix.

Remedy for the Malaria of the Mint, in Coinage, denotes a certain allowance for deviation from the standard weight and fineness of coins. In some places the remedy is allowed in the weight, in others in the fineness; but mostly in both weight and fineness. It is considered generally as an allowance for the fallibility of workmanship; but in some foreign mints it is made a source of emolument: and when governments issue coins at a rate above their intrinsic value, the profit thus made is called "feignorage." Out of every fifteen pounds of gold coined at the mint in London (according to the account published by the learned Mr. Folkes, in his curious tables of English silver coins), some pieces are taken at random, and deposited in a strong box, called the pix: at certain intervals, sometimes of one year and sometimes of several years, the pix is opened at Westminster, in the presence of the lord chancellor, the lords commissioners of the treasury, and others; portions taken from the pieces of each coinage are melted together, and an assay made of the collective mags by a jury of the goldsmiths' company. At this trial the mint-master is held execuable, though the monies be either too bafe, or too light; provided the imperfection and deficiency together are less than the sixth part of a carat, which amounts to forty grains of fine gold on the pound of standard, or the one hundred and thirty-second part of the value. It is said that this remedy is contained within as narrow limits, as any workers can reasonably be supposed to make themselves answerable for. The remedy, for silver coins is two pennyweights in the pound. If the deficiency or excess of the coin should be more than this, either in the weight, or in the fineness, or in both together, the money must be recoined at the expense of the maker of the mint; and no allowance is made for remedy unless the error is suppos'd to have causally happened.

Remee, in Geography, a town of Bengal; 16 miles S. of Koonda.

Remembrance, is the idea of something formerly known recurs again to the mind, without the operation of a like object on the external sens. See Memory, Reminiscence, and Recollection.

Remembrancers of the Exchequer, are two officers, or clerks, therein, formerly called clerks of the remembrance. They are now distinguished by the apppellations of the king's remembrancer, and the lord treasurer's remembrancer. There is also another officer, called the remembrancer of first fruits. Their business is to put the lord treasurer and justices of the court in remembrance of such things as are to be called upon, and dealt in for the king's benefit.

Remembrancers, The King's, enters into his office all recognizances taken there before the barons, for any of the king's debts; for appearance; or for observing orders; and makes out processes against the collectors of customs, subsidies, excise, and other public payments, for their accounts. All informations upon penal statutes are entered in this office; and there all matters upon English bills in the exchequer-chamber remain. He makes the bills of composition upon penal laws; takes the statement of debts; has delivered into his office all manner of indentures, fines, and other evidences whatsoever that concern the affuring of any lands to the crown: he every year, in crating Annuaries, reads, in open court, the statute for election of sheriffs, and gives them the oath, and reads the oath of all the officers of the exchequer, where they are admitted.

Remembrancer, The Lord Treasurer's, is charged to make process against all sheriffs, escheators, receivers, and bailiffs, for their account; processes of fiend facias, extent for any debts due to the king, either in the pipe, or with the auditor; and processes for all such revenues as are due to the king, by reason of his tenures. He also makes record, by which it appears, whether sheriffs, or other accountants, pay their proffers due at Exeter and Michaelmas. He makes another record, whether sheriffs, or other accountants, keep their days of prefixion; all esteem or fines, issues, and amercements, set in any of the courts of Westminster, or at the affizis or seffions, are certificated into his office, and are by him delivered to the clerk of the exchequer to write process upon them, &c.

Remembrancer of the First Fruits, he who takes all compositions and bonds for first fruits and tenth; and makes processes against such as do not pay the same.

Remembrancer is also the title of an officer in the city of London, who is to attend the lord mayor on certain days, and whose business it is to remind his lordship of the half days, when he is to go abroad with the aldermen, &c. He is to attend daily at the parliament-houfe during the seffions, and to report to the lord mayor their transactons.

Remi, St., in Biography, archbishop of Rheims, who converted Clovis to Christianity, and baptized that monarch. He died about the year 535. There are some letters which pass under his name, but they are of a very doubtful authority. There was another saint of this name, or, as he is sometimes styled, Remigius, who was archbishop of Lyons, and presided in the council of Valens in 855. He was a steady supporter of the doctrine of St. Augulfine, on grace and predetermination, in several works that are now extant. He died in 875.

Remi, Joseph Honore, an advocate in the parliament of Paris, was born in 1738. At the age of eight he lost his sight, and it was believed irrecoverably, by the small-pox; but when he had attained the age of fourteen he was in the enjoyment of his eyes. He was author of a burlesque poem, entitled "Days," in opposition to Young's Night Thoughts; but his principal work is an eloq. on the chancellor de L'Hôpital, which was crowned by the French academy in 1777, and confused by the Sorbonne. He also wrote the elogies of Moliere, Colbert, and Fenelon, and furnished the articles relating to jurisprudence for the French Encyclopedia. He died in the year 1782.

Remi of Auxerre. See Remigius.

Remi, Order of St., or of the Holy Vial, an order of knighthood in France, which, according to the most approved historians of that kingdom, was instituted by Clovis, king of France, in the year 490. The reigning king of France is always sovereign of this order, and the knights companions are never more than four; nor is it ever conferred on any person but the barons, Terrier, Beletrre, Venetre, and Louverre, who file themselves baron knights of the Holy Vial, and are the bears of the canopy under which the vial is carried from the abbye of St. Remi to the cathedral of Rheims, for the inauguration of the kings of France at their coronations. The badge of this order, which is worn pendant to a black ribbon, is "a crois of gold, enamelled white, canted with four fleur-de-lis; on the crois,
cro's, a dove descending, dipping its beak into a vial held in a hand, all proper."

REMICH, in Geography, a town of France, in the department of the Forez, and chief place of a canton, in the district of Luxemburg, seated on the Moselle; 17 miles E. of Luxemburg. The place contains 1480, and the canton 10,885 inhabitants, on a territory of 230 kilometres, in 15 communes.

REMIGES, in Ornithology, denote the primary and secondary wing-feathers.

REMIGIO, Florentino, in Biography, a man of letters in Italy, was a native of Florence. He entered at an early period into the Dominican order, and was called to Rome by pope Pius V., to superintend an edition of the works of St. Thomas. He was himself a considerate author, and published "A Commentary on the whole Scriptures;" translations of "Aminarius Marcellinum;" "Cornelius Nepos;" and "Fazello's History of Sicily;" "Reflections on Guicciardini's History;" "Italian Poems;" and "A Translation in Verse of Ovid's Heroic Epistles," of which an elegant edition was printed at Paris in 1572. He died at Florence in 1580, about the age of 62. Moreri.

REMIGIUS. See Rem.

REMIGIUS of Auxerre, a learned French Benedictine monk in the ninth century, derived his surname from the abbey of St. Germain, at Auxerre, where he embraced the religious profession. He distinguished himself by his proficiency in profane and sacred literature, at a dark and barbarous period, and was placed at the head of the schools belonging to his monastery. About the year 882, he was called to Rheims by Foulques, the successor of Hincmar in that see, who gave him the direction of the literary learning which he had founded in his metropolitan city. Here he taught with great reputation for several years, after which he went to Paris, where he opened the first public school in that city, after the decline of learning which followed the ravages of the Normans. In the life of pope Formosus, by Platina, the name of Remigius of Auxerre is the only one that occurs of a perfom eminent for learning under that pontificate. He was author of "Commentarius in omnes Davidis Psalmodias," which was published at Cologne in 1536. It consists very much of the collected opinions and explanations of St. Ambrose, St. Augustine, and Cassiodorus, reduced into one main. — Another work of this author was entitled "Enarratio in psaltuores XI. minores Prophetae," published at Antwerp in the year 1545, with the "Commentaries" of Oecumenius upon the Acts of the Apostles, and their Epistles, and those of Arethas upon the book of Revelation; and "Expositio Mifue," deduced from the sentiments and authority of the fathers. Some critics have given, among the productions of Remigius, the "Commentary upon the Epistles of St. Paul," which by others has been ascribed to St. Remi, or Remigius, but which in truth are supposed to belong to Haymo, a German bishop, who flourished in the ninth century, and who was author of a long list of theological works. Such at least is the opinion of Du Pin, in opposition, indeed, to the authority of Mohlheim. Moreri.

Remigius left behind him "A Commentary on the Musical Treatise of Martianus Capella," which is still subsisting among the MSS. in the king of France's library, No. 5364. He acquired his science from Herc. Herc was the disciple of Rabanus, and Hayman of Halberstadt, who had converted with the Roman singers sent into France by pope Adrian.

REMI, in Geography, a town of France, in the department of the Ardennes; 7 miles W. of Charleville.

REMINISCENCE, REMINISCENTIA, is that power of the human mind, by which it recollects itself, or calls again to its remembrance such ideas or notions as it had really forgot: in which it differs from memory, which is a treasuring up of things in the mind, and keeping them there, without forgetting them.

Hence memory may be considered as a continual remembrance; and reminiscence as an interrupted memory.

How near akin the two faculties may seem, yet they are generally found separated; so that they who excel in one, are generally defective in the other.

The ancient Platonists were of opinion, that all learning and knowledge consisted in the reminiscence or recollection of notices which had been in the soul before its union with the body.

REMINISCERE, the second Sunday in Lent; anciently thus called from the first word of the introit of the mass said for that day, "Reminiscere miferationum tuarum."

REMIREA, in Botany, Aubl. Guian. 44. t. 16. Brown Prodr. Nov. Holl. v. t. 236. (See Rikwiha.) We are unacquainted with Mr. Brown's reasons for preferring the above name, whose origin does not appear, and which the classical Schreber rejected as barbarous.

REMIREMONT, in Geography, a town of France, and principal place of a district, in the department of the Vosges; 10 miles S.S.E. of Epinal. The town contains 3270, and the canton 14,916 inhabitants, on a territory of 235 kilometres, in 15 communes. N. lat. 48° 1' E. long. 6° 40'.

REMIS. — Recto quando dominus Remissi. See Recto.

REMISSAM, in Geography. See Remsa.

REMISSION, in Law, &c. denotes the pardon of a crime, or the giving up the punishment due to it.

REMISSION, in Medicine, is a dilutement, but does not go quite off, before it returns again; as is common in fevers which do not quite intermit. See Remittent.

REMISSION, Remissio, in Physics, the abatement of the power or efficacy of any quality. In opposition to the increase of the same, which is called intensity.

In all qualities capable of intensification and remission, the intention decreases as the squares of the distance from the centre of the radiating quality increase.

REMISSION, Remissio, in the Ancient Music, was used to signify the palliation of the voice from acute to grave, being opposite to intensification.

REMIT, in Commerce. To remit a sum of money, bill, or the like, is to send a sum of money, &c.

To remit is also used among bankers for what is accounted to be given a banker, or, as it were, discounted him, for his giving a bill of exchange.

To remit is also to give up part of one's due to a debtor; as, I would remit you a fourth of what you owe on condition of paying me the rest in hand.

REMITTANCE, in Commerce, the traffic or return of money from one place to another, by bills of exchange, orders, or the like.

A remittance is properly a bill of exchange, or the like, sent to a correspondent, and the content of it to be received by him, or some other person, on whom it is drawn. By means of these remittances, large sums of money are returned from one city to another, without danger, without carriage, &c.
In London it is easy to get remittances upon any city in the world; in the country it is more difficult.

Remittances, Book of. See Book.

Remittance is also used in speaking of the payment of a bill of exchange.

Remittance also denotes the due or fee allowed the banker or merchant, both on account of his trouble, and the different value of the species in the place where you pay the money, and where he remits it.

This remittance is more usually called change and exchange.

Remittance, in Medicine, implying also the word fever, is a fever which is characterized by a regular decrease and exacerbation of its symptoms every day, and differs from an intermittent, inasmuch as the symptoms never disappear altogether, and the exacerbation is neither begun by the complete rigors, nor terminated by the profuse sweat, which occur in the latter. The remittent fever, however, originates, in common with the intermittent, from the influence of marsh effluvia, but under particular circumstances, which will be stated immediately.

It is scarcely necessary to describe minutely the symptoms of the remittent fever after the ample detail which we have given of those of fever in general (see Fever); and it varies extremely in its character, according to the season, climate, and other circumstances under which it appears. In its milder forms, the remittent begins with chilliness, latitude, pains in the bones, headache, and a disordered condition of the stomach, loss of appetite, sickness, and even vomiting. At night the febrile symptoms run high; the heat and thirst are great, the tongue and mouth are parched, the pain of the head is violent, the patient is totally unable to sleep, and is continually tossing and tumbling about, and often becomes delirious. But generally in the morning, an imperfect sweat brings on a remission of all the symptoms. In the evening, the paroxysm returns, but is not preceded by any cold fit or shivering; yet it is commonly more feverish than the former. Next morning it remits as before; and these periodical changes recur daily, becoming, however, less marked, if the disease be neglected, until the fever insensibly assumes a continued form. The pulse is full and quick during the exacerbations, and continues during the remissions to indicate fever; but rigors seldom precede the fits at the first attack. Many patients discharge a bilious matter from their stomachs by vomiting, and all are disordered in that organ. In the more violent forms, which take place in hotter fevers and climates, the disease often seizes the patient at once with a burning and violent headache, with little or no sensible chills preceding it. The thirst and heat are intense, and acute pains in the back and all the limbs, with extreme latitude and inquietude, haras the patient, and nausea, vomiting, and pain of the stomach ensue. In some instances, indeed, the headache becomes suddenly and violently affected, that a violent delirium, alternating the appearance of insanity, seizes the patient without any previous indication, until the remission evinces the nature of the disease. Many of the sick become yellow, as if affected with jaundice. Indeed, the remittent fever assumes every degree of violence, from the autumnal bilious fever of temperate climates, to the most severe yellow fever of tropical countries.

The circumstances under which these varieties of form occur, have been amply ascertained by experience. The combination of marsh effluvia and great heat are necessary to the production of these fevers; and they are violent, nearly in proportion to the degree of the latter. In cold climates, and in cool fevers, as the spring, the miasmata excite but the common intermittent ague. But in the autumnal season, especially when the heat is considerable, and the quantity of miasmata great, as in the Low Countries, in particular years, the production of these fevers is very extensive; they become actually endemic, and affect especially those persons who are not accustomed to the climate. The experience of all our military expeditions to Holland and Flanders, in the autumnal season, affords fatal proof of this truth. (See the writings of Sir John Pringle, Dr. Home, &c. on the Diseases of the Army in the Campaigns of 1742–1748, inclusive. And the fever epidemic of Walcheren, at a more recent period, cannot be forgotten.) In these climates, the remittent usually commences at the close of summer, in a milder form, and gradually assumes a more violent and formidable character, as the heats of autumn advance. But if we extend our inquiries to the hotter regions of the globe, we find the disease under its most feverish and fatal forms. In the south of Europe, especially in Spain, and those parts of the Mediterranean coasts where miasmata are found, the autumnal remittent becomes a formidable malady in particular fevers; but we must proceed to the West Indies and America to discover the disease in its most terrific form; for although there may be a contagious fever, which puts on the yellow or bilious character, Dr. Bancroft appears to have demonstrated, satisfactorily, that the yellow fever, commonly called the yellow, is the feverish form of the endemic remittent of the hot fevers of hot climates. (See his able "Essay on the Diseases called Yellow Fever, &c." 1811.) He affirms, indeed, that all fevers, occurring in those countries in which the atmospheric heat riles, during certain fevers, to the 5th degree of Fahrenheit’s thermometer, have a tendency to assume that violent and dangerous appearance, which is usually considered as characteristic of the yellow fever.

The testimony of all experienced medical observers concurs in proving the origin of remittent fevers from the influence of miasmata. Thus, among the historians of disease, as it occurs among seamen in warm climates, Drs. Lind, Blane, Hunter, and others, have demonstrated the exclusive attacks of these fevers to be among those men who have gone on shore, in swampy grounds, for water, &c.; and especially among those who spend the night on shore. Many instances are recorded, in which all the men employed have been feazed with fevers, while the rest of the ship’s company have remained in health. (See Dr. Lind, on the Diseases incidental to Europeans in Hot Climates, p. 27, 221, &c. 5th edit. Dr. Blane, on the Diseases of Seamen, p. 92, and 392.) Again, Sir John Pringle, in his valuable work on the diseases of the army, has not only stated many facts which occurred under his own observation, but has added many corroboration from the writings of ancient physicians and historians, in corroboration of the evidence that these fevers have, every where, and at all times, originated in hot fevers, in circumstances where miasmata existed. (Part 3. chap. iv. sect. 3.) In times, indeed, not very remote, when the want of proper means of carrying off the filth and refuse of large towns by proper drains, and scavengers were not employed, and when the materials for the production of miasmata were accumulated even in the streets, the remittent and intermittent fevers were epidemic, in favourable feasons, for the generation of the miasmata, and the source of considerable fatality. Thus, even in London, Dr. Short remarks that, early in the seventeenth century, “one of forty of the whole that died of fevers, died of agues.” (See his New Observations, &c. on Bills of Mortality, p. 203.) And Burnet, in his History of the Reformation, says, that in the last year of Queen Mary’s reign, they “rag’d like a plague.” At a later period, we have
have the testimony of Sydenham and Morton, in proof of the great prevalence of remittents in London; and Morton affirms that they were extremely destructive for several years before the great plague, viz. from 1638 to 1664. He states that Oliver Cromwell died of an attack of remittent fever in the former of these years, and that he lost his own father, who was himself an experienced physician, from the same disease, which had gone through his whole family. (Morton, Pyrologia, appendix, ad Exerc. ii.) "The result of the whole, therefore, is," to use the words of Sir John Pringle, "wherever the greatest causes of moisture and putrefaction in the air exist, there also will be seen the greatest number and the worst kinds of the remitting and intermitting fevers. This truth is farther confirmed by the negative evidence, that these fevers have ceased to exist where marshes have been drained, where towns have become clean, and when armies have moved to dry situations, and when the heats of particular feasons have ceased, or failed to occur. What the nature of these maladies is, the investigations of philosophers have not yet taught us. Dr. Bancroft has entered at great length, and with great ability, into this question, relating it from a large collection of important evidence. He details a number of interesting facts, which seem to lead satisfactorily to the conclusion, that the mere exhalations from putrefying animal matter, however offensive to the senses, are never productive of fevers. The same inference has been deduced, not less satisfactorily, by Dr. Chilhorn, in a very elaborate and able dissertation upon this topic, published in the Edinburgh Medical and Surgical Journal for October, 1816, vol. vi. p. 389. However contrary to the general opinion, this doctrine, that mere putrefaction is not the cause of contagion and fever, appears, indeed, by these writers, to be established. The experiment, in fact, has been tried on a large scale in France, in the case of the prodigious exhalations made in the church-yard of St. Etloi, at Dunkirk, in 1783, and in that of the fants Innocents at Paris, in 1786. In the latter case, nearly 26,000 bodies were taken up, in every stage of putrefaction, and a considerable part of the work was carried on during the greatest heats of summer, rendering the whole city offensive; yet no fever was occasioned by this immense mass of corruption. (See M. Thouret's Memoir in the Journal de Physique, for 1791, p. 253; and the Annales de Chirurgie, vol. vi.) The good health of nightmen, of persons living in defecting-rooms, of those employed in the manufacture near Bath of a kind of permaceti, from putrefying fish of all descriptions, and many other striking facts, detailed by the two authors just quoted, constitute a strong evidence in proof of the absence of infection from mere putrefaction.

Dr. Bancroft next proceeds to prove, by another ample collection of facts and testimonies, that it is not the mere aqueus vapour that constitutes the morbid quality of marsh-maladies. The principal proofs that mere moisture is incapable of producing these fevers, are, that sailors at sea for many months are generally very healthy; that no man of men are more uniformly so than the Newfoundland fishermen, who are usually employed in the dampest hogs for several months together; that while persons living on shore on unwholesome islands, as at Walcheren, are speedily attacked with fevers, those who remain on ship-board, at a little distance from land, entirely escape them; and that the occurrence of these fevers has been frequently prevented by laying swampy ground under water, under which circumstances the moisture of the atmosphere must be highly augmented.

Considering, then, that the mineral part of the soil is not vaporizable in any natural heat, and that animal substances in a state of putrefaction are incapable of producing fever, as well as the mere aqueous vapour, Dr. Bancroft was disposed to conclude, that the morbid exhalations in question arise wholly from the mutual decomposition of vegetable matters and water; and that those swampy grounds are most likely to emit them, which contain the largest proportion of such matters, and in which the decomposition is most rapid and complete. This conclusion, he is of opinion, is confirmed by the facts that the exhalations from macerated hemp and flax are well known in Italy to produce fevers, and that those arising from heaps of decaying indigo, in the East and West Indies, have produced the same effects. See his Essay on Yellow Fever, above quoted.

Of the Treatment of Remittent Fevers.—As the violence of the symptoms, and consequently the actual character of these diseases, vary materially in different seasons, climates, and circumstances, under which they occur; no uniform rule of treatment can be pursued for their cure. The same remedies, indeed, which at one period of the same fever are beneficial, are hurtful if resorted to at another. This observation, however, is applicable to all febrile diseases, and cannot be too often inculcated; since not only empiricism, but the routine of too many of the professions, tends to the approbation of some leading remedy, whenever the name of a particular fever is mentioned; with lome it is barks, with others antimony, and with others mercury; the indiscriminate use of any of which must be necessarily productive of injury.

In the more violent forms of the disease, which are common in hot climates, and in which the attack is marked by a sudden and violent affection of the head, with a hard, full, and strong pulse, indicating, with other symptoms, an inflammatory affection of the brain, perhaps the only remedy which is capable of arresting the disease, is speedy and free blood-letting. In the most violent forms of all, this evacuation should be resorted to very early, as within the first twenty-four hours, or the mischief will have advanced beyond the reach of this remedy. In milder cases, a moderate bleeding from the temporal artery or jugular vein, or even from the arm, within the first day or two, will often remove the danger and severity of the fever. The repetition and extent of the bleedings must be determined by a consideration of the violence of the symptoms, the duration of the disease, and the vigour of the patient. The notion that these fevers of hot climates are of a putrid nature, because they speedily run on to symptoms of debility, or putrefaction, as they have been called, appears to be altogether erroneous; and it is now generally admitted, that the only effectual mode of preventing these symptoms, is by arresting the violent inflammatory excitement in the beginning of which they are the immediate effect.

The next most effectual remedy, if resorted to also sufficiently early, is purgation. The purgatives administered should be such as in bulk and quality are not calculated to offend the stomach, which is usually in an irritable state; calomel, with jalap, answers the purpose well; and it is in all probability by its purgative quality alone, that mercury has been found beneficial in these fevers. The efficacy of mercurial purgatives, indeed, seems to have been fully established by the recent experience of our naval and military practitioners, in every quarter of the globe; while the mercurial practice, which had for its object the excitation of faulution, is shown by Dr. Bancroft, from the testimony of Dr. Rush and others, its advocates, to have been by no means successful.

This early excitement is also considerably alleviated by the application of cold in every mode. Almost all the modern
modern writers bear their testimony to the important auxiliary operation of the cold and tepid affusion; although they admit that, alone, its effects are not sufficiently powerful or permanent to be depended upon. Cooling of the patient is to be promoted by every means; by the free use of cold aqueous drinks, by frequent walking, by the full admission of freth air, and by the use of few and light coverings on the bed.

These remedies should be actively employed, and repeated on the return of or non-cessation of the symptoms of excitement. For as an intelligent physician has remarked, "the great object is the removal of the local affection of the brain, or other organ, and the prevention of a complete remission of the febrile symptoms, as the best possible time, by which the dangerous symptoms of the latter stages are prevented, or greatly mitigated, and a perfect and rapid recovery insured." (See Dr. Burnett's Account of the Bilious Remittent Fever in the Mediterranean, p. 22. Lond. 1814.)

This object is rather impeded, than assisted, by the administration of emetics and sudorifics; and altogether defeated by the use of bark, cordials, or stimulants of any kind, whether in the way of food or medicine. With respect to emetics, they are objectionable in all stages of the disease; for they not only fail in removing nausea, but actually increase that distressing symptom; their operation aggravates the affection of the head, of which the nausea appears to be symptomatic; and as the tendency of the disease is to augment irritability of the stomach, which often becomes extreme and distressing in the latter stages, so they contribute to aggravate this and other dangerous symptoms. Sudorifics are also to be condemned; for, in the first place, they are unnecessary, because a natural perspiration will readily ensue, as soon as the excess of heat above the standard of health has been removed, which can be accomplished with certainty by the proper application of cold water to the surface of the body; and, in the next place, the sudorifics which are used are apt to irritate the irritability of the stomach; and if they fail to excite a diaphoretes, they excite the heat and the determination to the head, and tend to lengthen the paroxysm. With regard to the bark and cordials, they are invariably injurious in the first stage of the fever. When a distinct remission has taken place, some writers recommend the immediate administration of cinchona; but even these admit that "if it be given when there is a parched skin, a hard pulse, a dry tongue, great heat and pain at the stomach, or delirium, it will generally be found to increase and prolong these symptoms." (See Bancroft, loc. cit. p. 76.) On the whole, however, the late experience in the Mediterranean led to the rejection of the use of barks, while any febrile symptoms whatever remained. "Under its use," says Dr. Burnett, "mortality has been great, relapses frequent, and (as in the cases of the Temeraire and Invincible) dysentery attacked nearly all the patients who had fever in a fever form; nor was there an infallible, as far as I could learn, that, when given during a supposed remission of the symptoms, it prevented a return of the paroxysm. Too often it has been given with wine at the commencement of this disease, when the tongue has soon put on a brown, dry, and furred appearance; the anxiety, delirium, and irritability of the stomach have been much increased; the whole train of nervous symptoms soon became formidable, reftling every means of alleviation, till death has put a period to the sufferings of the patient."

loc. cit. p. 34.

If anything were wanting to corroborate the foregoing deductions from experience, in favour of the antiphlogistic and evacuant plan of treatment, in the commencement of remittent fevers, the detail of the appearances observed on defilection, after the death of patients in these fevers, would amply support them, by the proofs which it affords of the inflammatory condition of various organs of the body in these fatal cases. In different instances, investigated by Dr. Burnett and his colleagues in the Mediterranean, the vessels of the brain were generally distended, and in many cases completely gorged, with blood; the membranes of that organ were considerably inflamed, often presenting what that writer calls a "blood-shot appearance," and depopositions of coagulable lymph were seen among the convolutions: there were occasionally also adhesions, and the vesicles were often distended with a fluid, sometimes limpid, sometimes yellow. Appearances of high inflammation presented themselves in the cavity of the chest, affecting the lungs, pericardium, and diaphragm; and there were connected with depopositions of lymph and effusions of serum. In the abdomen, the liver was generally found enlarged, and sometimes exhibiting marks of inflammation; the stomach distended with air, more or less inflamed, and containing a dark coloured matter; and the intestines in a similar condition, with frequent intus-susception.

These appearances, which are in fact the effect of the continuance of the febrile actions in the organs in question, sufficiently prove that the first stage is the time when active remedies, of an anti-inflammatory power, can be chiefly expected to produce a very decided removal of the disease. When the fever is a little more advanced, the principal object of the practitioner is to diminish the violence of any local affection that may be severe. Thus, if head-ache remains, with flushed countenance, suffusion of the eyes, and a firm pulse, a small bleeding from the temporal artery (the pulse being at the same time carefully examined) may be employed with advantage; a blister, applied to the head at this time, is also manifestly beneficial, and daily evacuations of the bowels should be procured by gentle laxatives, such as castor oil, or glysters, the powerful cathartics being now laid aside. Irritability of the stomach, which is often distressing at this period, is relieved by the effuviating draught, and by the application of leeches, or of a large blister over the pit of the stomach. A degree of fever sometimes supervenes, which is often removed by a blister applied to the neck or forehead, or by the application of leeches to the temples. If there is any obvious affection of the abdominal visera, which should be carefully inquired into, blisters, and, above all, the warm bath, should be resorted to, as well as copious emollient glysters.

If, however, from want of the means of relief, or from the violence of the disease, it has advanced to that stage, in which the yellow suffusion of the skin appears, and various nervous symptoms, subfulus, tremors, &c. come on, with increased uneasiness about the stomach, hiccup, or vomiting of a dark matter, resembling coffee grounds, with ichurias, and a sinking or intermission of the pulse, little more can be done than to look on, and endeavour to obtinate symptoms as they occur. "Singultus," to borrow again the words of Dr. Burnett, "is dangerous, and commonly a most harrowing symptom at this time; it will often be relieved by camphorated julep, to which may be added opium and leeches. If the pulse quicken, the stimuli must be increased; and under these circumstances, I have found the carbuncle of ammonia, with aromatic confection, of singular benefit. But while we endeavour to reforest the circulation, are we not to induce that state of expectancy which; and as the pulse rises, the stimuli should be decreased. Constant attention must still be paid to the daily evacuation of the bowels; but at a period, when the excitability of the sys-
tem is nearly destroyed, powerful cathartics will be attended with the most delectious consequences: gylciter are particularly serviceable at this time. As the disease advances, the secretions are at times voided involuntarily: in a few I have observed a retention of urine, and in these last cafes the catheter should be used; but as a general symptom, there is oftener a deficiency in the secretion of that fluid. Frequently in this state, the stomach rejects every thing. We may now safely indulge the patient moderately with any thing to which his fancy leads him. Bottled porter, wine, and brandy and water, have been found beneficial. But no remedy can be relied on with any degree of certainty: whatever calms the irritability of the stomach, and moderately supports the excitability of the system, is useful. A few spoonsful of arrow-root or fage, with wine and fpike, given occasionally, will often be retained by the patient, and greatly at this period affift the cure." Burnett, loc. cit. p. 29.

During the state of convalescence at every period, whether from a complete remission being procured early, or from a gradual ceafation of the disease, extreme caution is necessary in regard to preventing repletion: in the former cafe, it is apt to induce a relapse; and in the latter, it will retard the cure. During the whole progress of recovery, attention should be paid to the regularity of the bowels. Some light tonic, as an infusion of quaffia, gentian, or cinchona, with an aromatic or sulphuric acid, may be administered. When the yellow fuffufion of the skin has been great, a protracted convalescence is commonly the consequence; and is often attended with irregular affections of the bowels, and symptoms of indigestion. In these cafes, small doses of the mercurial pill, with an occasional gentele purgative of caflor oil or rhuarbarb, are very beneficial. It is almost exclusively, indeed, in these protracted cafes, where a morbid affection of the liver, brain, or some other vifera, has been the refult of the uninterrupted violence of the firft flage of the fever, and especially when there is reason to fuppofe that affusion had taken place within the cranium, that mercury, in small doses, is of any actual utility. Small doses of calomel, or of the pilula hydrgyri, fhould be admiffed until some fenfible, but fitful, effect be produced on the falivary fystem; after which the disease often ceafes of itself, or is readily removed by the ufe of the Peruvian bark. See Burnett on the Bifous Remitter in the Mediterranean; Bancroft on the Yellow Fever; and Irvine on the Difeafes of Sicily. See also Fever, Tellow, and Mifia.

Remittent Fever of Children, the febris infantium remittentis of Dr. Butter, which is a very common affection of children, when the abdominal organs are deranged, has already been defcribed at length, under the head of Infants, § 5. Febris Difjafes of; which fee.

Remitter, in Law. Where a man has two titles to land, and is feized by the latter; and, that proving defeftive, he is remitted or relented to the former more ancient title; this is called a remitter, from the Latin, remittere, to find back.

If land defended to him that had right to it before, he shall be remitted to his better title, if he pleafe. 1 Inpl. 347. 6. Litt. § 659.

Remitter is claffed (with retainer) by judge Blackstone, among thofe remedies for private wrongs, which are effected by the mere operation of law, and is thus defcribed: remitter is where he, who hath the true property or jus proprietor in lands, but is out of poaffession thereof, and hath no right to enter, without recovering poaffession in an action, hath afterwards the freehold cafl upon him by some subfequent, and of course defeftive title: in this cafe, he is remitted, or fent back, by operation of law, to his ancicnt and more certain title. (Litt. § 659.) The right of entry, which he hath gained by a bad title, fhall be ipso fafio annexed to his own inherent good one; and his defeftive title fhall be utterly defeated and annulled, by the infinitaneous act of law, without his participation or consent. (Co. Litt. 358. Cro. Jac. 489.) As if A difficile B, that is, turns him out of poaffession, and dies leaving a fon C; hereby the exfand defines to C, the fon of A, and B is barred from entering thereon till he proves his right in an action: now, if afterwards C, the heir of the defclitore, makes a faf from life to D, with remainder to B the difficile for life, and D dies; hereby the remainder accrues to B, the difficile; who thus gaining a new freehold by virtue of the remainder, which is a bad title, is by act of law remitted, or in of his former and furer eflate. (Finch. L. 194. Litt. § 683.) For he hath hereby gained a new right of poaffition, to which the law immediately annexes his ancient right of property.

If the fubfquent eflate, or right of poaffession, be gained by a man's own act or content, as by immediate purfue of full age, he fhall not be remitted. For the taking fuch subfquent eflate was his own folly, and fhall be looked upon as a waifer of his prior right. (Co. Litt. 348. 350.) Therefore it is to be obferv'd, that to every remitter there are regularly three accidents; an ancient right, and a new defeftive eflate of freehold, uninting in one and the fame perfon; which defeftive eflate must be caft upon the tenant, not gained by his own act or folly. The reafon given by Littleton (§ 661.), why this remedy, which operates fliently and by the mere act of law, was allowed, is somewhat fimilar to that given under the article Retainer; because otherwife he who hath right would be depraved of all remedy. For as he himfelf is the perfon in poaffifion of the freehold, there is no other perfon againft whom he can bring an action, to eflate his prior right. And for this caufe the law doth adjudge him in by remitter; that is, in fuch plight as if he had lawfully recovered the fame land by fuit. Nor, as lord Bacon observes (Elæm. c. 9.), the benignity of the law is fuch, as when, to preferve the principles and grounds of law, it deprives a man of his remedy without his own fault, it will rather put him in a better degree and condition than in a worse. Nam quad remedio deftitutus, ipso re vult; fes culpa abfil. But there fhall be no remitter to a right, for which the party has no remedy by action (Co. Litt. 349.); as if the infue in tail he barred by the fine or warranty of his anceilor, and the freehold is afterwards cast upon him; he fhall not be remitted to his eflate tail. (Moor. 115. 1 Ann. 286.) For the operation of the remitter is exaftly the fame, after the union of the two rights, as that of a real action would have been before it. As, therefore, the infue in tail could not by any action have recovered his ancient eflate, he fhall not recover it by remitter.

The determination of the law, according to the doctrine of remitter above flated, might feme superfluous to an holy obfverver; who perhaps would imagine, that since the tenant hath now both the right and alfo the poaffession, it little ignifies by what means fuch poaffession fhall be faid to be gained. But the wisdom of our ancient law determined nothing in vain. As the tenant's poaffession was gained by a defeftive title, it was liable to be overturned by fiewing that defect in a writ of entry; and then he must have been driven to his writ of right, to recover his jult inheritance: which would have been doubly hard, because, during the time he was himself tenant, he could not eflate his prior title by any poaffiliary action. The law, therefore, remits him to his prior title, or puts him in the fame condition as
if he had recovered the land by writ of entry. Without the remitter, he would have had just, et fidelis, separatia; a good right, but a bad possession; now, by the remitter, he hath the most perfect of all titles, juris et fidelis _conditio._ Blacklt. Com. h. in.

REMLINGEN, in Geography, a town of Germany, in the county of Wertheim; 9 miles E. of Wertheim.

REMNEY, or REMPEY, a river of Wales, which rises in Brecknockshire, and, after separating the counties of Monmouth and Glamorgan, falls into the mouth of the Severn, a little below Cardiff.

REMOLADE, in the Manage. See Charge.

REMOLIAN, in Geography, a town of France, in the department of the Higher Alps, on the Durance; 15 miles S.W. of Embrun.

REMON, a township of Upper Canada, on the St. Lawrence; N. lat. 42° 50'.

REMONSTRANCE, an expostulation, or humble supplication, addressed to the king, or other superior, to befriend him to reflect on the inconveniences, or ill consequences of some order, edict, or the like.

REMONSTRANCE is also used for an expostulatory counsel or advice; or a gentle and humble reproof, made either in general or particular, to apprize or correct some fault.

REMONSTRANTS, REMONSTRANTS, a title given to the Arminians, by reason of the _remonstrance_ they made, in 1610, to the states of Holland, against the synod of Dort, in which they were condemned.

Episcopius and Grotius were at the head of the Remonstrants. And as the patrons of Calvinism presented an address in opposition to their remonstrance, which they called their counter-remonstrance, they received, in consequence of this, the name of "Counter-remonstrants."

REMONTER, Fr. in Muse, to new-firing an instrument.

REMONTOIR, or REMontoir, in Horology, is a species of escapement, in which a secondary spring frequently wound up, or a small secondary weight frequently raised, by means of the maintaining power of a watch or clock, is subordinated to the maintaining power itself, for the purpose of urging the balance or pendulum, at short intervals, by more equable impulses than can be constantly effected by the maintaining power alone, as varied by different degrees of friction in the train. When treating of ESCAPEMENTS in general, under their appropriate head, we described three only out of the four chafles, and referred the fourth clas, denominated Remontoir, till we arrived at our present article.

The first remontoir was invented and made by a German artist in 1600, according to Berthoud; but Huygens, who applied one to his marine clock, described it first in his "Horologium Oscillatorium," page 17, and, in conjunction with his cycloidal checks, it promised to be a great improvement in his machine; but, as no compensation had at that time been applied to the pendulum, and, as a pendulum is not calculated for a portable machine, particularly on the sea, the utility of the contrivance remained to be proved by subsequent artists. The contrivance under our consideration was a small weight, suspended by an endless well-made metallic chain, that was coiled round the crown-wheel of the escapement, and wound up a small space, at every vibration of a half seconds pendulum, by the next wheel, which took its motion from the maintaining power, through the medium of the train, as is usual in common clocks; a ratchet and click, however, were a requisite appendage, to act in the way that the endless cord was applied, in winding up the maintaining power without stopping the motion of the works; such as we have already described in the fifth section of our article

CLOCK-WORK. One half of the weight of the remontoir actuated the escapement wheel during its small fall, and the other half was supported by the wheel that as often raised it again to its original height, while both parts of the folded chain were sustained by the fall weight. Liedenitz and Dr. Hook also claimed the originality of a similar invention, but do not appear to have put it in practice, as Sully afterwards did.

Mr. Harrison and Mr. Mudge successively applied remontoir springs, instead of suspended weights, to the escapements of their time-pieces; but, as we have described their article _Chronometer_ with sufficient minuteness, it is not necessary to repeat here what we have there detailed of their constructions.

Mr. Cumming and Mr. Nichollion, on the contrary, had recourse again to weights instead of springs in their astronomical clocks; but as these weights did not act during the whole period of the vibration, we have already described them in another class, in the 21st and 30th sections of our _Escapements._

After Huygens and Sully, who left no plan of their mechanism behind them for the advantage of future workmen, who had not access to the original machines, Gaudron contrived a remontoir, which performed its office very well, but which was applied in a wrong place, so as not to produce the desired effect of equalizing the impulses given to the regulator; for, instead of being applied to either the balance or balance-wheel, it was made to actuate the wheel preceding the minute-wheel; and, therefore, permitted the irregular friction of a considerable portion of the train to affect the motions of the balance, which fault was avoided in the construction of Harrison's and Mudge's time-keepers: the former of which had its secondary spring wound up eight times in every minute, and the latter had its two remontoir-springs alternately coiled at every corresponding oscillation.

Haley's.—In the year 1796, Mr. Charles Haley of Wigmore-street, Cavendish-square, London, watch-maker, took out a patent for his invention of a new remontoir spring for a marine time-piece, or chronometer; the specification of which is contained in the 6th volume of the Repertory of Arts and Manufactures. Figs. 1 and 2, of Plate XLI. of Horology, exhibit, the first a perspective view, and the second a plan of Mr. Haley's remontoir escapement, as originally drawn; and we propose to retain the fame letters of reference as are inserted in the original description. The utility of the invention is stated to consist of its property of communicating an invariable force to the balance, which it does 150 times in the minute, in a train of 9000 beats in the hour. The same letters of reference apply to both figures, and indicate the corresponding parts, which will mutually illustrate each other. A B is the potance plate, and T the balance, the pivots of which, P, X, turn in the cock C and potance D; above the balance T is fixed a pendulum spring S, in the usual way; on the axis of the verge, below the balance, are placed two small iron collets I and K, by friction, having each a ruby pallet projecting a little way beyond their surfaces. I is called the discharging pallet, and K the impelled one; which pallets, together with the pendulum spring, all vibrate with the balance, whenever it is put in motion. E is the balance-wheel of the usual form, moving just clear of the potance plate, and having its pivots supported by the cocks F and G. W V is the axis of the remontoir, which the inventor calls the _removing spring;_ and the three axes, or arbors, are here called, stand in the straight line in the direction A B. Below the remontoir spring the round steel pallet M is fixed, so as
REMONTOIR.

pull to escape touching the ends of the balance-wheel’s teeth in its resting position, and the notch cut in this pallet is to receive the impulse of any tooth of the said wheel that may, at any time, act against it, in passing the line A B. Just above this large pallet is fixed, by friction, another smaller pallet N, of steel, in the form of a small-piece, and having inserted into it, near the centre of motion, and at right angles, a small ruby pallet, which points directly to the radial end of the notch cut in the large pallet M. A small collet, twisted fast to the axis of the remontoir, just above this small-pallet, receives the lower end of the spring R, while the upper end is made fast to a piece in the cock H, near W, in a manner similar to that by which the pendulum-spring is fixed. On the arbor of the remontoir, and under the plate A B, is twisted on a pallet I, which may be called the remontoir’s impelling pallet, because it gives motion to the balance by impaling the pallet K, which the author also called the impelling pallet; but as, we have named it, more properly the impelled pallet, because it receives the impulse which pallet I imparts. From this detail of the pallets it is obvious, that whenever the balance-wheel impels the large pallet M, the remontoir-spring R, the small-pallet N, together with its small ruby pallet and impelling pallet I, must have a contemporaneous motion, and will describe each its respective circle round the common arbor W V.

In fig. 2, a is a detent-spring, fixed by a screw and steady pin to the upper face of the potence plate, and pointing directly to the axis of the verge, which it nearly approaches. Its shape and mode of being fixed will be better understood from an inspection of fig. 3, which gives a side view of it, and from which it will be seen that it is placed high enough above the plate, to come in the way of the discharging pallet I, in each revolution of the latter. Upon the side of the said detent-spring a, next to the balance-wheel, a second, but very slender spring is pinned, so that its projecting end extends that of the detent-spring, and comes nearer to the balance verge than that of the detent, as represented at m, in fig. 3. To the detent-spring is made fast a small ruby pallet r, seen also in fig. 3. The cock f is screwed to the potence, and the hole at j is tapped to receive the screw f, the head of which, being turned towards the centre of the small, forms a banking for the detent-spring a, when stricken by the small-pallet. This screw f, r, is removed from its due place in the drawing, to avoid confusion; and for a reason which will presently appear, this double spring a may be called the remontoir-detent. On another side of the balance-wheel a second detent-spring d is fixed, pointing towards the centre of the remontoir axis, and forming nearly a right angle with the former detent: this second detent is adjusted by the screw y. The shape and situation of this second detent, which may be called the locking detent of the balance-wheel, is better seen in fig. 4, where its sapphire pallet s may be distinguished, against which the tooth 3 of the wheel is supposed to be resting in fig. 2. The situation of this pallet s, as adjusted by the screw y, determines the relieving-places of the tooth 1 and 2, while they are equally free from the edge of the pallet M. The locking detent d is likewise made fast by a screw to the upper face of the potence plate; and the screw f, placed in the cock e, but out of its place in the figure, forms a banking to the sapphire pallet s, while the screw g, in a smaller cock, limits the excursion of the detent-spring d itself.

Having described the various pieces of mechanism that compose this remontoir escapement, we will now proceed to explain its mode of acting. First, let us suppose all the parts at rest with the wheel locked by the pallet s last described, but that the wheel is ready to move in the direc-

Vol. XXIX.
pended by pallet L, before the pallet K of the balance returned to its place to receive it. Mr. Hardy, however, has lately contrived a species of locking that is quite certain, as well as safe, which we shall presently have occasion to describe.

Breguet's.—We have not been able to ascertain the exact date of the French watch-maker Breguet's invention of a remontoir escapement, but as Berthoud has placed it after Haley's in his "Histoire de la Méthode du Temps," we must conclude that it is of more recent origin. The mechanism is so complex, that the description given in the French work is divided into three parts, which plan we propose to follow. Figs. 5. and 6. of Plate XLI. of Horology, will suffice to explain the different parts of Breguet's remontoir; fig. 5. being a plan of the whole, and fig. 6. exhibiting a perspective view of such parts as could not be well understood without such representation.

The first portion of the mechanism consists of two wheels of unequal numbers of teeth, with their planes in contact, and revolving on one common arbor concentrically, namely, the wheel B B', and the wheel D, the first having many teeth and a larger diameter, and the second having few, for a reason which will appear hereafter: these wheels are actuated by a pinion g, connected with the train, and having just so many leaves as there are teeth in the large wheel B B', contained in the space between two contiguous teeth of the small wheel D; on the arbor of this pinion, near the pivot, is inserted a fly with unequal arms, represented by the letters g b, in both figures, the longer arm of which, g b, is armed with a piece of steel of peculiar shape, seen in fig. 6. A spring-detent r F, made fast to the cock at r, lies at right angles to the fly, when in a state of rest, and has a ruby pallet V at about one-third of its length from its interior end, which stops the fly by opposing its end b near a, and consequently prevents the train from urging the double wheel, so long as no force unlocks the pallet from the end of the fly; but if any impulse happen to bend the detent in a direction towards the pinion g, then the ruby pallet slips through a notch made in the fleet part of the fly, and the fly makes an entire revolution, while the pinion revolves and urges the large wheel the space of as many teeth as the pinion contains; that is, a space corresponding to the distance between two contiguous large teeth in the small wheel, which wheel also moves the same quantity, before the fly is again opposed and stops.

The second portion consists of the following parts; a spring G, curved at the interior, or moveable end, serves at the same time for a remontoir-spring, and also for a pallet to give the impulse to the balance; it has consequently a heel-piece n, by which it is urged into a state of tension by the small wheel D, at every revolution of the fly, and also a ruby pallet m, with a locking notch cut in it; a H, made fast at a, is a detent-spring, placed nearly at right angles to the spring G, and having a slender spring N made fast to its fids; this detent-spring carries a small ruby p, which locks into the notch of the piece m in the spring G, when this is in a state of tension. Another ruby, inserted into the extreme end of the detent a H at s, is so placed, that the slender spring N can move from right to left without impediment, but when urged in an opposite direction against the ruby s, it takes the large or detent-spring along with it, and unlocks the remontoir-spring G, by removing the small ruby p from the notch of m. The detent-spring H has at its extreme end a claw, against which the ruby m falls when this detent escapes back from a tooth of wheel D; and this claw has a pin in it, against which the slender spring N rests; again, at the extreme end of the slender spring N are fixed two parallel chamfered plates, so contrived, that any prejuive made on the upper slope, or inclined edge, will depress the spring, but a similar prejuive made on the under slope will elevate it again, the downward prejuive being employed to disengage the ruby m from the claw, and the contrary.

The third portion consists of the pieces or pallets K and b, borne by the superior end of the verge of the balance, and fixed at a quarter of a circle from each other. When the oscillation of the balance is from right to left, or in the direction from a to K, the unlocking pallet piece K, in its motion, bends the slender spring, and passes over it, but as the pallet b is placed above the plane of the wheel B B', and under the spring H, this oscillation from right to left is performed in freedom, except that the slender spring N requires to be a little bent out of the way; but when the oscillation is made from left to right, the pin at H profiles this slender spring against the ruby s, the spring H then gives way, and bending, allows the ruby p to escape from the notch at m, and the spring G, being unlocked, is at liberty to perform its office, which we now proceed to describe.

The action of these three portions of the mechanism may be thus explained: at the instant that the ruby p, in the detent a H, is disengaged from the notch at m in the remontoir-spring G, the pallet b of the balance is found pointing towards the common centre of the wheels, and ready to receive an impulse from the extreme end q of the curved part of the remontoir-spring G, which end now gives its stroke to the balance through the medium of pallet b; immediately after which stroke, the same end q proceeds till it falls on the end F of the fly's detent, to which it now gives a pulley, and remains quiet; this pulse unlocks the fly, as has been before explained, and an entire revolution is immediately performed by it, while its pinion g, now at liberty to advance, urges on the double wheel, till another tooth in the small wheel, catching the heel-piece n of the remontoir-spring, puts this spring again into a state of tension; and the ruby p, falling into the notch of m, locks it as before, the balance in the interim completing its oscillations: and in this manner the operation is repeated.

De Lanson's.—In the year 1801, the Adelphi Society for the encouragement of Arts, &c., rewarded Mr. John de Lanson with thirty guineas for his invention of a new remontoir watch escapement, which comes next under our notice. Figs. 1. and 2. of Plate XLI. of Horology, are a plan and section of this escapement, as given by the inventor in the Society's Transactions for the year above-mentioned. In both these figures, A is the escapement wheel; B, the lever-pallet on an arbor with fine pivots, which has, at its lower end, the remontoir spiral spring C, fixed with a collar and fluid in the usual way; D is the pallet of the verge, having a roller turning in small pivots, for the lever-pallet to act against without friction; E are the pallets for discharging the locking, with a roller between, containing a small notch; F is the arm of the locking pallets, continued at the other end beyond the centre of motion, to preserve the equipoise, and having flutings and screws for adjustment of the banking; a and b are the locking pallets, being portion of circles fastened on an arbor, turning on fine pivots at the mid-way between the pallets; G is the triple fork, at the end of the arm of the locking pallets. In fig. 2, tooth 1. of the wheel having caught the interior end of the lever-pallet B, has urged it forwards and wound up the remontoir-spring, and the instant that the verge pallet D comes nearly in contact with the remote end of the lever-pallet, the discharging pallet E, taking one prong of the fork, removes the arm F, thereby relieving the tooth 3 from the convex part of the claw a, that locks the wheels. The
The wheel now advances a little way, just enough to allow the interior end of the lever-pallet to pass back again, as urged by the spiral spring, while the remote end of the said lever gives an impulse to the balance, through the pallet D; the tooth 4 is then locked on the concave side of the locking claw b, and the interior end of the lever-pallet partly supports the following tooth; in this situation the oscillation is finished, and on the return of the balance, pallet E, striking the prong of the fork in a contrary direction, again unlocks the wheel from claw b, while the force of this wheel is partly suspended by the end of the lever-pallet; being now at liberty, the wheel proceeds to wind up the remontoir-spring again, till another tooth falls on the claw a, now brought inwards, when the operation is completed, and the pendulum of the inner end of the lever pallet against its contiguous tooth again revives the claw a from a part of the profile of the wheel, and thereby renders the unlocking as easy as before, when claw b was unlocked. This escapement appears to us an improvement on Howley’s, both as to its simplicity and safety of locking, and the inventor proposes a still further simplification, by substituting a straight remontoir-spring for the spiral one, particularly in time-pieces intended to remain in a stationary situation, where the weight of the spring would form no objection; but it does not appear that such construction was ever adopted. The simplicity of the locking of the remontoir-spring by the wheel itself, where this spring and the maintaining power mutually re-act, requires, as might be foreseen, an unusually strong maintaining power, which is, perhaps, one of the greatest objections to this mode of applying the remontoir; unless, indeed, what was remarked by the Society’s Committee be true, that the balance must vibrate in a large arc before the piece will continue to perform.

Maffey’s.—Mr. Edward Massy, of Hanley, in Staffordshire, received a reward of fifty guineas from the Adelphi Society, in the year 1803, for his invention of two different clock escapements, one of which we have already described, under our article Escapement; being without a verge; and the other we shall make the subject of our present fection. Fig. 3. of Plate XLII. represents so much of Maffey’s remontoir escapement as is sufficient to explain all the essential parts; in which A is the swinging-wheel; B, C, are two detached pallets, moving on separate arbor, at opposite sides of the swinging-wheel; B is seen urged by the remontoir-spring E, by the aid of a tail-piece fixed on the arbor of pallet B, which receives the action; and the other pallet must be conceived to have a similar spring and tail-piece, which cannot easily be represented in the drawing; F is the verge bearing two arms without pallets, which press under the pins of the detached pallets, and raise them alternately, at each vibration of the pendulum, from the teeth of the swinging-wheel, which had been previously impelled by the maintaining power, and K is the pendulum suspended in the usual way, and having a crutch to communicate its force to the verge at the moment of withdrawing the pallets. All, therefore, that the pendulum has to do, is, to disengage the pallets from the teeth of the swinging-wheel that locks against the inclined planes of the pallets; for the remontoir-spring then opposes the acient of the pendulum, and aids its descent, by means of the connection between the pins of the pallets and the arms of the verge, which must, from the nature of the construction, continue in contact during a large portion of each excursion of the pendulum. It is not stated in the author’s account (Trans. Adel. Soc. vol. xxii.) at what part of the arc of vibration the pendulum unlocks either of the pallets, but it seems to us capable of being made to effect this office at its point of greatest velocity, if it does not do that as now constructed. An attention to this particular is of utmost importance in any escapement, since the natural law of gravity is the least debarked, when any force is given, or taken away, when the pendulum is at the lowest point of its arc, for the velocity it has at that point determines the height to which the ball shall rise; but any addition or diminution of the pendulum’s momentum, beginning at any other point of the arc, either adds to, or diminishes the natural length of the vibration, and injures the isochronism. Besides, a spring commencing both its accelerating and retarding influence at the point of the pendulum’s greatest velocity, acts, not only by a law commensurate with the law of gravity, but their various forces, thus exerted, are contemporary, and, therefore, act together as one; a consideration which never should be lost sight of in the construction of an escapement of any denomination. The principal advantages that the author seems to insist on in this escapement, are, that the friction is diminished at the acting parts of the pallets, the impulse being given by a direct push, without, or with very little, sliding motion; and that a certain regular momentum is kept up in the pendulum, independently of any variation which may occur in the wheel-work, or in the acting part of the pallets during the short time of unlocking; but, what is the principal object of such a contrivance, he has not noticed, perhaps not considered, how this certain regular momentum is, or ought to be, modified.—Indeed, in speaking of his other escapement without arbors, he says, that one of its advantages over this is, that during a part of the vibration the pendulum is disengaged; from which remark, it should seem, that he thinks the constant action of this remontoir-spring, however modified, an objection to be avoided.

Antis.—In vol. xxiii. of the Transactions of the Society last mentioned, it is stated, that Mr. John Antis of Fulneck, near Leeds, sent this Society a model of a new clock escapement in 1805, with a corresponding description, for which a reward was voted him of twenty guineas. The model is deposited in the room at the Adelphi appropriated for the reception of models, but as the description is not published in the Transactions of the Society, nor an engraving of the model, we must infer, that the contrivance either is not new, or is not of such importance as to merit the particular notice that has been given by them to the inventors of like contrivances, who both preceded and followed him. Indeed, in the letters of Mr. Antis to the Society, published with their account of the rewards, it seems that two escapements were sent them, one a detached one, and the other, one that “would equalise the power of the impulse,” which must, therefore, have been of the remontoir description; but he confides that these contrivances by him “may have been practised before.” With respect to the latter escapement, he remarks, what is worthy of being recollected by clock-makers in general, that, by its means “a spring-clock will be as perfect as one which goes by weight, and more so if the latter has no remontoir.” Should any of our readers have a wish to see and examine Mr. Antis’ productions, which, he acknowledges, are done in a rough manner, and under disadvantageous circumstances, but which may not be the less ingenious on that account, there will be no difficulty in gaining admission to the model room, where the original work is preferred with a view to public inspection, provided the applicant be properly introduced.

Mendham’s.—It frequently happens that considerable
improvements are made in mechanical contrivances, by men whose principal employment has no connection with the art to the improvement of which they contribute; this was probably the case with Mr. Antis, and is confidedly so with Mr. Mendham, who was rewarded with the silver medal of the Adelphi Society, in the year 1807, (see vol. xxvii.) for a remontoir escapement for a chronometer, which next offers itself for our description. Figs. 4, 5, and 6, of Plate XI. II. are copied from the plate given by Mr. Mendham, fig. 4, being a section of the whole escapement, fig. 5, a plan of the wheel and locking pallet, and fig. 6, a detached view of the pallets and their common arbor. The letters a a, in fig. 4, are the two plates of the framework that contain the works; b is the balance, nearly of the usual shape and size; c is the pallet that acts with the wheel, and d its arbor; e is the locking single spring; and f is the unlocking pallet in the form of a pin, attached to e, and seen better in fig. 6. At the lower end of arbor d is placed g, the remontoir-sprung, that gives force both to the small pallet f, and also to the perpendicular pin b, that forms a part of the pallet e. The arbor d does not ascend above the upper plate of the frame, but the pin b does, and the plate being formed, as we suppose, like a rim, b is permitted to move in the vacant space within the rim, and sufficiently high to fall in the way of the finer pin b, inserted into and under the balance. The balance i has its verge immediately over the upper pivot of arbor d, point to point nearly, so that the motions of the balance-pin i, and of the pin b, that impels it, may be concentric. The cock k supports the upper pivot of the verge, and also holds the outer end of the balance or pendulum-spring. The action of these parts may be thus explained: before motion is given to the balance, we must conceive its pin i to be in contact, or nearly in contact with the pin b of the pallet e, and it must be remembered, that the wheel rolls on the pallet during the vibration of the balance: suppose now that the remontoir-sprung g is in the act of being wound up by the balance-wheel, as actuated by the train; and that the pin i of the moving balance has kept in contact with the impelling pin b, borne by the arbor of the remontoir, it is evident, that the force of the remontoir-sprung is here opposed to the momentum of the balance and at last stops it, thereby forming a banking of an unlimited extent; but the tooth of the wheel in contact with pallet e, at the point of shortest radius, affords to oppose or wind up the said spring during a space of one-fifth of a circle, till the tooth has paled and the wheel is locked; on the return of the balance the remontoir-spring exerts all its force on the balance, but without a jerk, the pins i and b being already in contact, till it comes to the flop; the balance then maintains its motion, and the small pallet f having unlocked the wheel by forcing out the detent, the next tooth of the wheel falls on the pallet e, and waits the return of the balance, when the same operation is repeated.

Mr. Ramlay of Ilkington was consulted on the merits of this escapement, and, on considering its properties, he gave a written report to this effect; that the impulse is here given to the balance without friction, exactly as in Mudge's chronometer; and that the remontoir is wound up by the maintaining power in a familiar way, except that the shape of Mudge's tooth limited the quantity of tension of the spring, which here depends on the amount of the maintaining power; but that this escapement, having but one remontoir-spring, is more simple than Mudge's, and allows an unlimited arc of vibration, which advantages compensate the foregoing disadvantage in the shape of the tooth; and lastly, that it is superior to the detached escapement, inasmuch as that it gives the impulse without friction.

G. Prior's.—The silver medal and twenty-five guineas were voted to Mr. George Prior, junior, of Otley, in Yorkshire, in the year 1809, by the Adelphi Society (vol. xxvii.) for his invention of a new clock escapement, in which an impelling (not however called a remontoir) spring acts, or proffes to actuate, the pendulum at each alternate vibration. The account, particularly of the action, as printed in the society's Transactions, seems to us so extraordinary, that we beg leave to transcribe it verbatim, in order to make some remarks on it, that may enable the reader to judge of the escapement's peculiar qualities, or at least of the manner in which they are described. Fig. 7. of Plate XI. II. already referred to, contains enough of the escapement to answer the purpose of the description in question, and therefore we will omit the references to fig. 1. in the original plate, and attend to its fig. 2. only. "Fig. (7) is a back view, which is supposed to be taken from behind the clock; a represents the axis of the swing-wheel, or leaf wheel of the train of the clock; b d is the swing-wheel fixed upon it, having thirty serrated teeth; it is turned round, in the direction from b to d, by the maintaining power of the clock; g is a spring-dent, which locks against one of the teeth of the swing-wheel, and this prevents its running down by the action of the maintaining power; k is another spring-dent, which is called the impelling spring; when left at liberty, it unlocks the former, by pulling against the end of the small arc e, fastened to the detent g, and thus removing the end of the dent which obstructed the wheel's motion; l is the rod of the pendulum, suspended by a cock foreward to the back plate of the clock; a small piece of brass, k, projects at right angles from the impelling spring b, so as to intercept the pendulum rod in its vibration, and at this place a small tooth is put through the pendulum-rod l, the point of which moves the impelling spring back: a small pin is fixed to the frame, in a line between the point of suspension of the pendulum, and the centre of the swing-wheel, against which the impelling spring stops when at liberty."

"Supposing the pendulum to be vibrating backwards and forwards, and the wheel locked as in the figure, the pendulum swinging from m to n, the impelling spring b follows by its elaticity, until the pendulum l arrives at its perpendicular (or lowest point of its arc); at this period the impelling spring comes to rest against the end of the arc e, which it pushes back, so as to release the tooth of the wheel from the detent-spring g; the wheel now moves round a very small space before it meets the end of the impelling spring b, and is stopped thereby; in the mean time the pendulum continues its motion the extent of its vibration towards s, when it returns, and arriving at the perpendicular, it meets the impelling spring b, and carries it along with it, until the tooth of the wheel which rests against it escapes from the end of it, and another tooth of the wheel comes to rest against the spring-dent g. The succeeding vibration of the pendulum repeats the same operation." This is the whole account, from which the reader is induced to believe that the pendulum, and impelling spring b, acts and reacts on each other ad infinitum, without any aid from the maintaining power through the medium of the wheel, which is never allowed to raise, or otherwise to move the impelling (or remontoir) pallet, in order that it may, in its turn, impel the pendulum by its acquired force. Again, it is said, the impelling spring unlocks the dent g when it arrives at the perpendicular, or nearly, if not quite, at the point of its quiescence, where it has no force, and from that point, not the
the wheel, but the pendulum unbinds it into a state of tension, to refuse its operation; that is, the pendulum raises the spring, that the spring may drive the pendulum back again; and thus the vibrations are maintained without the aid, and consequently without the necessity, of either a maintaining power or train; and what is equally extraordinary, the impelling spring locks the wheel by its reflexion near the perpendicular line (within the space of one tooth), where it has almost the smallest force, or nearly the same small force that it has when it unlocks the detent. According to this account, even supposing the action of the wheel on the remontoir pallet to be omitted, the pendulum is under the influence of the impelling pallet during nearly the whole of one excursion, and free from it in the other. The model, however, is said to be preferred in the society's room, and will explain itself.

G. Prior's improved.—Mr. George Prior, jun., again presents an improved remontoir escapement for a clock to the society we have repeatedly had occasion to name in this article, in the year 1811 (vol. xxix.), and again receives a reward at their hands, of twenty guineas, for his improvement. The description given of this escapement, and of its action, is sufficiently clear, and the alteration made in the construction is in many respects an improvement, though we shall take occasion to shew, in our remarks on it, that it is still liable to objections. In the plate last referred to, fig. 8, contains the original fig. 1, which will explain the account with sufficient precision. “The flying-wheel A,” says the author, “has thirty teeth cut in its periphery, and is constantly urged forwards by the maintaining power; C, D, are two spring-dets, catching the teeth of the wheel alternately; these are, at the proper intervals, unlocked by the parts marked 2 and 3 upon the pendulum-rod H, intercepting small pins a, b, projecting from the dets, as it vibrates towards the one or the other; E is the renovating or remontoir-spring, fixed to the same line, F, as the desets, it is wound up by the highest tooth of the wheel, its position, when unwound, being shown by the perpendicular dotted line. This being the case, suppose a tooth of the wheel caught by the detent D, which prevents the wheel from moving any farther, and keeps the renovating spring from escapine off the point of the tooth; in this position the pendulum is quite detached from the wheel; now if the pendulum be caused to vibrate towards G, the part of it marked 2 comes against the pin b, projecting from the renovating spring E, and pushes this spring from the point of the wheel's tooth; on vibrating a little further, it removes the detent D, which detained the wheel, by the part 3 striking the pin a, which projects from the detent; the maintaining power of the clock makes the wheel, thus unlocked, to advance, until it is detained by a tooth resting upon the end of the detent C, on the opposite side; by this means the renovating spring will be clear of the tooth of the wheel as it returns with the pendulum, and gives it an impulse by its pin b striking against the part 2 of the pendulum, until the spring comes to the position shown by the dotted line, in which position it is unwound, and re-sets against a pin fixed in the cross-bar of the plate; the pendulum continues vibrating towards I, nearly to the extent of its vibration, when the part 1 meets the pin in the detent C, and removes it from the wheel and unlocks it; the maintaining power now carries it forward, pushing the renovating spring E before it, until another tooth is caught by the detent D, which detains the wheel in the position first described.” Agreeably to this description, the pendulum is opposed in its ascent, and accelerated in its descent, in one of its excursions from the centre, or perpendicular line, by both the impelling spring E, and detent D, after it is unlocked, though not the whole distance; but is alternately accelerated and retarded in the other excursion by the detent C alone, and only after the unlocking; these unequal checks, given at different parts of the arc of vibration, we apprehend, are no means favourable to the natural isochronism of the pendulum.

Hardy's.—Mr. Hardy, chronometer-maker, of Copeplace, Clerkenwell, London, whose ingenious improvements in clock and watch-making have placed him high in public estimation, on contemplating Mr. C. Haley's failure in the locking of his remontoir detent, contrived a remedy which fully answers its purpose, and which, on that account, merits our particular notice.

Fig. 7. of Plate XI. of Horology, represents the plan of Hardy's new remontoir escapement, which, though it appears to differ considerably in construction from Haley's, yet resembles it so much in its action, as well as principle, that we will put the same letters of reference to the same corresponding parts, in order that the reader who has perused our description of Haley's remontoir with attention, may the more clearly comprehend our description of Hardy's, and perceive in what the improvements consist. As in Haley's construction, T T represents the balance, or rather the place of the balance not seen; E the escapement, or balance-wheel; P the pivot of the verge; S the balance-spring, supfended as usual; K the impelled pallet; I the unlocking pallet of the remontoir; N the remontoir detent, or locking pallet, on the same axis with a, the arm of the flender or unlocking spring, which lies parallel with it; c the cock, taking the pivot of the remontoir detent's arbor, and also the upper end of its spiral spring; e the head of the banking ferew, and its fluid; f the cock that takes the pivot of the remontoir, or cylindrical spring at W, and also one end of the said spring, represented by the small circle at R; L is the impelling lever or pallet, for giving motion to the pallet K of the balance; M is a lever, instead of the notch in Haley's large circular pallet, by means of which the wheel winds up the spring R of the remontoir; O is a lever, in place of the small ruby unlocking pallet of Haley, fixed to the main; d is the spring-detent of the wheel, and i its ruby, or sapphire pallet, on which the wheel is locked, and g being the banking ferew and its fluid, and y the place where it is fixed by a screw on the plate; and lastly, the fectorial piece Q, in which the improvement chiefly consists, is the addition introduced for rendering the locking of the remontoir-spring, when wound up, both certain and secure. The acting faces of the pallets s, M, K, N, and of the circular portion of Q, are of ruby, or other precious stones nicely polished, and are properly shaped for their respective offices. From this description of the mechanism before us, it will be perceived that the double spring e, and the detent with a claw pallet at N, are both fast to the arbor of the spiral spring, which gently presses the detent at all times down upon the fectorial piece Q, thereby preventing its being thrown back from its position for locking, as was the case with Haley's remontoir detent. It will also be seen that the arbor W, of the remontoir-spring R, has the said fectorial piece, the impelling lever I, the lever M impelled by the wheel, and the discharging lever O, all fast to it at different heights, the two first being above, and the two last below, so that when one of these four pieces is moved out of its first situation by any external force, they all move together, as do also the remontoir detent N and its spring a on their common arbor, and as do likewise the pallets K and I on the verge of the balance. These particulars being understood, and that levers in Hardy's construction are used
of for pallets in several instances, we may proceed to ex-
plain the action of the different parts, and to show how they
produce the defired effects of producing equable impulses
on the balance at all times, and of effecting certain and
secure locking of the remontoir-spring. In the figure
before us, tooth I of the wheel has just proceeded far enough,
by the action of the main-spring and train, to wind up the
remontoir-spring, and its detent N, urged by its own spiral
spring against the curved face of the sectorial piece, after
sliding smoothly along it, has locked it: that is, by opposing
it at right angles, prevents its return, which would take
place when the wheel leaves the arm M, or, which is the
same thing, when the remontoir-spring, on the same arbor
with this arm, is wound up. The balance is now supposed
to have commenced its motion, carrying the pallets K and I
outwards from the wheel, but the small pallet I has not
yet arrived at the slender spring of the remontoir-detent,
though it is approaching it; the slender spring, however,
soon yields to the outward impulse of this small pallet,
without disturbing its arm or the detent N, therefore the
remontoir-spring remains locked: at the return of the bal-
ance, which takes place when its spring is wound up, the
said little pallet I displaces not only the slender spring but its
arm also, which lies next towards the wheel, the one not
being liable to move in this inward direction without the
other; the consequence is, that the detent N is now lifted
by its connection with the arm of the slender spring, and at
that instant the remontoir-spring, being wound up, and at
liberty to act, throws back the sectorial piece Q nearly its
whole breadth, but not quite, for the claw of the detent in
question rests on the curve of the sector during the motion
we have described, till the unlocking lever Q strikes the
end of the single detent-spring d, and forces the ruby pallet
i out of the wheel, which wheel instantaneously resumes its
motion from the train, and meeting with lever M winds up
the remontoir-spring a second time; in the mean time the
impelling lever L has given its impulse to the pallet or lever
K, and consequently to the balance, which thus had its
momentum increased; and on its returning vibration ex-
actly the same process is repeated. Thus the force of the
maintaining power is expended in winding up at each alter-
nate oscillation the remontoir-spring, which spring, so re-
forced, impels the balance in its turn by quantities of force
that are always the same, whatever may be the irregularities
of the force transmitted through the train that winds up the
remontoir-spring; therefore, properly speaking, the
remontoir-spring is the maintaining power that restores, at
each alternate oscillation, the loss of momentum that the
balance has experienced from the resistance of the air, and
friction of the parts in action. This escapement is, notwith-
standing, of the detached kind, feeling the balance performs
the greatest part of its oscillations without any connection
of even the auxiliary force derived at intervals from the
remontoir-spring; and a chronometer of this construction,
made by Hardy for his royal highness the duke of Suffolk,
answers the maker's most sanguine expectation, and will
probably become a model for other makers when its merit
is proved, and made public. The same artifit has made sev-
eral experiments on the same principle, with this differ-
ce, that the remontoir-spring is retained by the lever roll-
ing on the tooth of the wheel, in place of being locked by
the sectorial piece, as is the one before us.

Besides the preceding escapement, Hardy invented one
for the astronomical clock he made for the Royal Obser-
vatory at Greenwich, which at first sight appears to refem-
ble Maffey's and Prior's improved one, with spring pallets,
but on close examination we discovered that it has the fol-
loving desirable properties peculiar to itself: i.e., it gives
the impulse not only from remontoir-springs, but strikes and
locks the two separate detents alternately, at the instant
when the pendulum has the greatest velocity; and, 2dly, the
accelerating and retarding power imparted to the pendulum
co-ordinates with the force of gravity, thereby deranging
the natural law of gravity as little as possible. We feel not
at liberty to enter more minutely into the description of this
escapement, because we understand its inventor propo-
ses giving an account of his machine himself, to be read before
the Royal Society, as constituting the companion to Trought-
on's transit circles, already described by the astronomer
royal. We have permission, however, to subjoin the rate of
the clock in question for three quarters of a year, as taken
at the Royal Observatory, which will afford the bell proof of
its pretensions to public notice. We have further to add, that
the inventor has applied the same principle of movement to a
chronometer of a large size, in which the balance has two
metallic rods to adjust it for temperature, in place of the
metal being fluxed on the rim of the balance, as is common.
See Compensation.

Trial of Mr. Hardy's clock at the Royal Observatory
at Greenwich in the year 1811.

From the above stated authentic document it appears, that
for the nine months of trial, and in opposite extremes of
temperature, the daily rate never varied quite four-tenths of
a second; and when the quantity of mercury proper for the
compensation of the pendulum is exactly ascertained, it may
be expected that the performance will be still more accurate;
seeing that the deviation in the rate depends evidently on
the change of temperature, and not on the escapement.

REMOIRA, in Natural History, the fucking-fish; a little
fish, resembling a herring, called by the Greeks echeneis,
famous for sticking to the fides of ships. It belongs to
the genus of echeneis and clafs of tbarcei in the Linnean
sytem.

Its caracters, according to Artedi and Linnæus, are
these: the branchiofege membrane on each fide contains
about ten bones; the head is thick, depreffed, naked, and
marked on the upper fide with tranferve rougie ftrize; the
body is oblong, round, and naked, but somewhat com-
prefed; the back-fin is oblong, and placed very far toward
the tail; its under jaw is longer than its upper; it has
a great number of teeth in both jaws; the colour of its body
is hoary, and it has seven fins; two pectoral ones, two ven-
tral ones placed farther from the fnot then the pectoral
ones, one at the anus, one on the back, and one at the tail;
the ftrize of the head are from eighteen to twenty-four in
number, they are rough and tranferve, but are divided as it
were into two feries by a middle longitudinal line. By
means of these ftrize or ridges the fih can fix itfelf to any
animal
animal or other substance, and has often been found adhering
 to the sides of ships and the bodies of sharks, &c.

Linnæus enumerates two species of the echeneis; the remora
and neudracus: the former has a forked tail, and eighteen 
finz on the head; the latter has an entire tail, which is longer 
than that of the former, twenty-four finz, a larger body, and 
shorter fins. They are both inhabitants of the Indian ocean. 
The remora is much talked of by the ancients, who, as we find from Pliny, lib. ix. cap. 25. 
lib. xxxi. cap. 31. unanimously believed it had the force 
 to stop a vessel in full sail, or a whale in swimming; and hence 
 called it remora, a remorando. (See Linnæus’s Hill, de Animal. 
lib. ii. cap. 17. Plutarch. Sympo. lib. ii.) But Mr. 
Catesby observes, that even several or those fishes together 
can do no more than shells or corals, and other foulheads of 
the same bulk, which make a ship sail somewhat the slower. 
And in the same manner only they may be some slight hindrance 
to a whale. The author last mentioned affirms he has 
taken five of them off the body of a shark. Vide Phil. 

Remora, among Surgeons, is also an instrument used for 
setting broken bones.

Remora Mutia, in Natural History, a name given by 
some to the genus of shells called concha veneras, and 
porcelanae. See Porcelain Shell.

Remotion, Recolte, in Rhetorick, the same with 
what is otherwise called metalas.

Removal of the Poor. See Poor.

Removalle, in Geography, a town of France, in 
the department of the Voiges; 5 miles E. of Neufchateau.

Removing Obstructions to Tillage, the means of removing 
stones and any other substances that may be in the way of 
the plough.

The operations which are to be performed in these 
tensions are of several different kinds, as the removing of various 
forts and stones of stony matters, both from above and 
below the surface of the lands; the eradicating and destroying 
different kinds of woody materials of the trees, root, and 
plant forts, the taking away of the superabundant wetnesses; 
the destruction of many aquatic vegetables, and some others.

See Land, Stone, Tillage, and Wood.

Remoulin, in the Mango, is used to denote a flat 
upon a horse’s forehead.

Remouline, in Geography, a town of France, in 
the department of the Gard, and chief place of a canton, 
in the district of Uzes; 7 miles S.E. of Uzes. The place 
contains 895, and the canton 4758 inhabitants, on a territo-
ry of 135 kilometres, in 8 communes.

Remount, in War. To remount the cavalry, or dragozs, 
is to furnish them with fresh horses, in lieu of such 
as have been killed or disabled in the service.

Remphan, in Antiquity, the Egyptian name for the 
planet Saturn. Some think that remphan was the moon, 
others Mercury and Mars, and others the sun. See 
Chieu.

Remple, in Heraldry, something filled up. The term 
is chiefly used to denote, that the chief is quite filled up 
with a square piece of another colour, leaving only a bor-
dure of the proper colour of the chief about the said piece.

Remporetty, in Geography, a town of Hindoo-
stan; 30 miles N. E. of Travancore.

Rems, a river of Wurtzberg, which runs into the 
Neckar, 4 miles N.W. of Waiblingen.

Remsa, or Remssam, a town of Saxony, in the 
lordship of Schonburg; 2 miles N.N.E. of Glashau.

Remscheidt, a town of the duchy of Berg; 2 
miles S.W. of Lennep.

Remsen, a township of America, in Oacida county, 
New York. E. of Layden and adjoinig it.

Remungol, a town of France, in the department 
of the Morbihan; 7 miles S. of Pontivy.

Remuria, among the Romans, a festival instituted in 
 honour of Remus by his brother Romulus. See Remuria.

Remuzal, in Geography, a town of France, in the 
department of the Drome, and chief place of a canton, in 
the district of Nyons; 6 miles N.E. of Nyons. The place 
contains 514, and the canton 3724 inhabitants, on a territo-
ry of 2724 kilometres, in 17 communes.

Remy, a town of France, in the department of the 
Oise; 6 miles N. of Clermont.

Ren, a town of Russia, in the government of Nov-
gerod; 16 miles S.E. of Uiltuzana.

Renaison, a town of France, in the department of the 
Rhone and Loire; 6 miles W. of Roanne.

Renai, a town of France, in the department of the 
Scheldt, and chief place of a canton, in the district of 
Audenaarde. The place contains 9499, and the canton 
14,683 inhabitants, on a territory of 70 kilometres, in 6 
 communes.

Renalis, Renal, in Anatomy, an epithet applied to 
the parts belonging to the kidney; as to the artery and vein 
of the organ, also called renalgent, of which the former comes 
from the aorta, the latter joins the inferior vena cava; see 
Artery and Vein: to the plexus of nerves derived principally 
from the ganglia of the great sympathetic; see Nerve: 
and to the small bodies placed above the kidneys, 
called the renal capsides. See also Kidney.

Renalise Lapsis, in Natural History, the name given 
by many authors to a sort of fideinichitum, or crutlated 
ferrigenous body of that kind, containing a nucleus of a 
different matter from that of the crutis. It is found about 
Prague, and in some other places, lying near the surface in 
kratas of a yellow clay. Its usual bigness is that of a ripe 
peach, and its crutis are of a dusky ferrigenous brown 
colour: and its internal nucleus of a pale yellowish-green, com-
posed of a marly earth, and usually of a kidney-like 
shape, whence its name.

Renassau, in Geography, a town of Hindooftan, in 
Dowlatabad; 114 miles N.W. of Hyderabad. N. lat. 19° 
30’. E. long. 79° 10’.

Renathia, a town of Alpine Turkey, in Caram- 
 mania; 10 miles S.W. of Satalia.

Renau d’Eliagaray, Bernard, in Biography, a dif-
tinguished engineer and naval architect, was born in the 
province of Bearn, in the year 1652. He was at an early age 
instructed in the mathematical sciences, and was observed 
ot to read a great deal, but to think most profoundly, and 
as he advanced in years, he was capable of thinking upon 
the most abstruse subjects, as well in the middle of company, 
as in the closet. One of the first books that attracted his 
attention was Malebranche’s “Recherche de la Veritez,” 
and, it is said, it made such an impression upon him, that 
nothing could efficace it through the whole of life. It gave 
him a full conviction of the truths of religion, and preferred 
his morals pure and uncorrupted. In 1679 he was placed 
with the count de Vermamdois, admiral of France, as his 
instructor in naval affairs. When, by the royal command, 
conferences were held to determine upon a plan for bring-
ing to perfection the construction of vessels, Renau was 
called upon for his opinion; and at length the syslems of 
Du Quefhe and that of Renau were alone left for con-
ideration, and to the honour of Renau, then young and 
amost unknown, his plan was adopted, and he himself was 
felt to Breit and the other parts to put it in execution.

In
In 1688, the Algeciras having declared war against France, Renan proposed the bombardment of Algeciras, for which purpose he conceived the idea of bomb-vessels, which were as yet unknown. This was at first regarded as visionary; but reliance being placed on his talents, he was permitted to make the trial, and he brought five of these vessels before the town, where, under the command of Du Quehen, the bombardment was executed with complete success. In 1684 he was employed, as engineer, at the bombardment of Genoa; from this place he went to join Vauban, who was fortifying the frontiers of Flanders and Germany, and he contracted an intimate friendship with that great man. In 1688 he accompanied Vauban to the siege of Philippsburg, and afterwards conducted, or was present, at some other sieges; yet in the midst of these active services he found leisure to attend to his studies, and published in 1698 his 'Theorie de la Manoeuvre des Vaiffaux'; some of the propositions in this work were contested by the celebrated Huygens. In this same year he endeavoured to prove, by argument, that the navy of France might be rendered capable of making head against that of England and Holland united, and his observation produced such an effect upon the government, that an order was made to change all the 50 and 60-gun vessels, on the rocks, into ships of a higher rate. About the same time he invented a new series of naval evolutions, signals, and orders of battle. His merits were well understood by the government, who rewarded him with a pension, and considerable rank in the service. He was now sent to Breit for the purpose of instructing the naval officers in his newly invented evolutions, &c. He met with an opposition, which is not uncommon in endeavouring to change old established customs. Of his opponents, two of the most distinguished were put under arrest and broke, though he did his utmost to prevent the punishment being carried to that extremity. He afterwards served under Vauban at the siege of Namur, from thence he repaired to St. Malo after the battle of La Hogue, to have the relics of the French fleet which had taken shelter there. Having constructed a vessel of 54 guns upon his own plan, Renan put to sea with the view of intercepting two rich English East Indiamen, one of which he captured after a desperate engagement. Among the booty were some packets of diamonds, which he thought of too great value to be claimed by himself, though the naval customs would have justified him in it, and he carried them to the king, who accepted the prize, and remunerated the captor with an annuity. When Philip V. succeeded to the crown of Spain, he sent to his grandfather, Lewis XIV., to requell that he might have Renan to direct his engineers in fortifying his most important towns. He found means to render the crown of Spain the most important services, and was, in 1704, employed in the siege of Gibraltar, which, it has been affirmed by the French biographer, was about to surrender, when it was relieved by the English fleet. To the disgrace of the court of Spain, whose interests he had effectually promoted, and in whose cause he had expended his own property, he was suffered to return to France with a single pilote in his pocket, though his Catholic majesty had given him the title of lieutenant-general of the armies of Spain. The high reputation which Renan had acquired as an engineer, caused the grand master of Malta to requell that he might be sent to that island on an alarm of an invasion, which was readily granted. Soon after this Lewis XIV. died, and the duke of Orleans succeeded to the regency, who appointed Renan to be counsellor of the marine council, and grand-croix of St. Louis. He died of a dropy in 1719, and his death was, like that of La Trappe, in ardent aspirations after another life; "What a difference," he exclaimed, "from one moment to the following! I am going to pass in an instant from the thick dark night to perfect light." He had been twenty years an honorary member of the Academy of Sciences, and was among the first after that clafs was instituted. RENAUDOT, Eusebius, a learned writer on the ecclesiastical history and antiquities of the Eastern church, was born at Paris in 1646. He was educated at the Jesuits' college, and entered the congregation of the oratory when he was about 19 years of age, though he had no intention of entering into holy orders; or to the taking any ecclesiastical degree. He was particularly attached to the study of the oriental languages, in the knowledge of which he far excelled almost all his contemporaries; and he applied with success to the study of so many other tongues, that he was sufficiently master of seventeen different languages, to be able to speak the greater number of them with facility. He became well known at court, where his genius, his talents, and his politeness, made him much esteemed and admired. Here he was noticed by M. Colbert, who was desirous of establishing printing-presses for the oriental languages at Paris, and consulted Renaudot upon the subject, as a person who might ably contribute to render such an establishment useful to the state as well as the church. To engage his affiance, he promised him the reversion of the post of keeper of the king's library; but the munster died before the place became vacant. He received a similar promise from the archbishop of Rheims, and was again disappointed. He was, however, employed by the king in various confidential concerns of great importance relating to the affairs of Rome, England, Spain, &c. So much was his time occupied by these engagements, that he almost entirely discontinued his favourite studies. In the year 1689 he was received into the French Academy, and in 1692 into the Academy of Inscriptions and Belles Lettres. He found a patron in the cardinal de Noailles, archbishop of Paris, whom he accompanied to Rome in the year 1700, and into the conclave which elected Clement XI. to the papal dignity. While he remained in that city, the collections of the Vatican furnished him with new matter relating to the oriental churches, and revived an intention, which he had long before encouraged, of preparing for publication some pieces which serve to illustrate their history and opinions. In this design he was assisted by the new pope, who persuaded him to remain in Rome several months after the departure of cardinal de Noailles. His holiness would gladly have conferred upon him some valuable benefits, but he refused to accept of any thing beyond a small privy. The abbe Renandot afterwards went to Florence, where he met with most flattering reception from the grand duke, who alligned him apartments in his own palace, loaded him with presents, and on his departure directed that he should be conveyed on board one of his own vessels to Marseille. At Florence, likewise, he was made a member of the Academy de la Crufla. Soon after his return from France, he was rouzed by an attack upon father Nicole's "Perpetuity of the Faith of the Catholick Church respecting the Euchari- st," and in 1708 he published "A Defense of the Perpetuity of the Faith Against the Calunious, &c." He afterwards entered more fully into the subject which he defended, and displayed all his moderation and ingenuity in endeavouring to shew the conformity between the doctrine of the Greeks, and all the oriental Christians, with that of the Latin church. What he wrote upon the subject extended to two vols. 4to., which were published in 1711 and 1713, by way of
of supplement to father Nicol’s work. During the re-
gency of the duke of Orleans he made frequent efforts to
obtain his encouragement in the plan for establishing print-
ing-presets for the oriental tongues, and was promised, but
never obtained effectual support. The latter years of his
life he spent in completing numerous very learned and im-
portant publications, among which may be mentioned,
"Hispania Patriarchezum Alexandrinorum Jacobitarnus;"
"Liturgianum Orientalium Collectio," in 2 vols., accom-
panied with very learned diffusions; "Ancient Accounts
of India and China, by two Mahometan Travellers in the
9th Century, translated from the Arabic." Renudot died
in the year 1729, at the age of 74 years, greatly regretted
by the literati of that age, to whom he was a communicative
and most agreeable companion, and lamented by the poor,
who, in whose relief he had dedicated a large portion of his
income.

RENAY, or RONSE, in Geography, a town of France,
in the department of the Jemappe, with a magnificent
chateau; 7 miles S. of Oudenarde.

RENCHEN, a town of the duchy of Baden; 4 miles
N.N.W. of Oberkirch.—Alfo, a river of Baden, which
rises in the Ortau, and runs into the Rhine, 10 miles N.
of Oberkirch.

REN COUNTY, formed from the French, rencontre,
meetings, in the Military Art, the encounter of two little
bodies or parties of forces.

In which sene, encounter is used in opposition to a
pitched battle.

REN COUNTER, in single combats, is used by way of con-
tradiction to duel.

When two persons fall out, and fight on the spot, with-
out having premised the combat, it is called a ren-
counter.

REN COUNTER, or RENC O N T R E, in Heraldry, is
applied to animals when they flew the head in front, with
both eyes, &c., or when the face stands right forward, as
if they came to meet the person before them.

Indeed, in deer, this is called mafacre; and, in the lep-
opard, it is the natural situation. He bears bafe, in ren-
counter, a golden fleecce.

RENDE, in Geography, a town of Naples, in Calabria
Citara; 5 miles N.N.W. of Cofenza.

RENDER, in Law, a term used in keying a fine.
A fine with render, is that by which something is rendered
back again by the cognizee to the cognizer.

The lawyers also lay, there are certain things in a manor,
which lie in render, i.e. which may be taken by the lord,
or his officers, when they pleaephy, without the tenant’s
leave; and others which lie in render, that is, must be rendered
or answered by the tenant, as rents, reliefs, heriot, and
other services. See PRENDER.

Some service conflits in seigneur, some in render.

RENDERING, in Building. See PAVING.

RENDERING, in Sea Language, is generally understood to
be the effect of yielding or giving way, without resistance,
to the efforts of some mechanical power. It is usually
expressed of a complicated tackle, laniard or lailing, when
the effect of the power applied is communicated with facility
to all the parts, without being interrupted in its passage.
It is therefore used in contradiction to jamming.

RENDEŽOUS, or REN D V OUS, a place appointed to
meet in, at a certain day and hour.

The word is French, and is found fo commodities, that
most nations use it in its purity, for want of a word of
equal import in their respective languages.

Thus, in a military sense, the rendezvous is the place ap-
pointed by the general, where all the troops that compose
the army are to meet at the appointed time, in case of an
alarm; and the regiments have their particular rendezvous,
called their quarters of assembly.

In a naval sense, it denotes the port or place of deftna-
tion, where the several ships of a fleet, or squadron, are
appointed to rejoin the whole, in case of separation, oc-
nasioned by tempestuous weather, or other unforeseen accident.

RENDEŽVOUS Bay, in Geography, a bay on the S. coast
of Antigua, W. of Falmouth harbour.

RENDEŽVOUS ISLANDS, an island, or rock, in the southern
Indian ocean, discovered in 1773 by M. de Kerqulent, near
the N. coast of Kerguelen’s land, and called by captain
Cook “Bligh’s Night-cap.”

RENDEŽVOUS KEY, a small island in the bay of Honduras;
near the coast of Mexico. N. lat. 16° 59’. W. long. 88°
40’.

RENS, in a Ship, are the same as the seams between
her planks.

RENDSBERG, in Geography, a town of Germany, in
the duchy of Holstein, seated on a canal which communi-
cates with the Baltic, on the borders of Sleewick, suppos,
ed to be one of the strongest towns in the Danisf dominions,
and generally well garrisoned. The number of inhabitants
is about 3600; 15 miles W. of Kiel. N. lat. 54° 22’. E.:
9° 22’.

RÊNÉ, a town of France, in the department of the
Sarthe; 15 miles N. of Le Mans.

RÉNÈMAI, in Botany, a new genus of Mr. Brown’s, has lately received that name from him, in just commemoration of Paul Rénémais, or Renaulinse, a phy-
cician at Blois, who published, in 1611, a thin quarto vol-
ume at Paris, entitled Specimen etzorai Plantarum, with
exprefTive, but fift, and not neatly finifhed, engravings in
copper, in which each plant is distinguished by an ap-
propriate Greek name, mostly of the author’s invention.
Mr. Brown observs, that this author was the first who paid
attention to the differences in the number, situation, and pro-
portion of the flammis. Linnaeus, in his own copy of the
work, has exprefTed a well-founded surprize, at its being
never quoted by the Baulins. Plumer was the author of the
first Reneæna, now funk in the Linnaean Tilledlæüa.
Linnaeus, or his son, dedicated a monandrous genus, in the
Supplementum Plantarum, to the memory of this meri-
toribian botanist; but it proved not difficult from a more
generally-received genus, of the same date, Alpinia. We with
the present Renæmais may be found sufficiently different
from Silyrinchium, to which its species were originally rel-
v. 1. addend. (Silyrinchium; ibid. 304.)—Chafs and order,
Monadphila Triandra. Nat. Ord. Enfites, Lin. Irideæ,

Eff. Qu., Calyx none. Petals fix, regular; three inner
ones largest, contracted at the base. Style one. Stigma
three, thread-shaped, inovulate, acute. Capsule inferior,
obovate, of three cells. Seeds angular.

The species are herbaceous, smooth, inhabitants of woods.
Roots fibrous, sometimes tuberous. Leaves gristy, lax,
ribbed. Stem roundish, sometimes divided. Flowers in al-
ternate umbellate bunces, with short permanent fleas.
Corolla regular, white, spreading, soon falling off; the
outer petals generally greenish at the back; the inner often
furnished with claws. Filaments either combined below, or
divided; their upper part spreading. Capsule membranous.
Seeds in two rows, black.

1. R. paniculata. Panicled Renæmais. Brown n. 1.—Stem
panicled. Leaves ribbed; roughish at the edge. Outer
4 petals
petals linear-lanceolate; inner scarcely twice as large, obovate-oblong. Filaments united half way up.—Gathered by Mr. Brown, near Port Jackson, New South Wales. The leaves are all from ten to eighteen inches long, and for the most part rough-edged.

2. *R. grandiflora*. Large-flowered *Renaclibia*. Brown, under the former.—Stem panicled. Leaves ribbed; roughish at the edge. Inner petals four times as large as the outer. Filaments united half way up.—Gathered by the Rt. Hon. Sir Joseph Banks, in New Zealand. Akin to the former, but differing in the proportion of its inner petals, which are four or five times the size of the outer.

3. *R. pulchella*. Elegant Small *Renaclibia*. Brown n. 2.—Stem nearly simple. Leaves with smooth edges. Outer petals oval-oblong; inner obovate, with short claws. Filaments distinct.—Gathered by Mr. Brown near Port Jackson. The leaves are only three or four inches long.

**RENEE DE FRANCE**, in *Biography*, duchess of Ferrara, born at Blois in 1510, was daughter of Lewis XII. and Anne of Brittany. She was allied, when very young, to Charles of Austria, afterwards emperor, and some years after was sought in marriage by Henry VIII. of England, but neither of these matches took place, and Francis I. gave her to Hercules II. of Este, duke of Ferrara. This princeess is celebrated for her talents: she had a great capacity, and an inatifiable thirst for knowledge, and her studies were not limited to history, the languages, and mathematics, but embraced various other topics, especially astrology and theology. The religious controversies of the time greatly interested her, and she became zealously attached to the tenets of the reformers; her court at Ferrara became the refuge of all who were suspected of heresy; and her conduct gave so much offence to the court of France, that Henry II. sent a doctor to the duke with the following instructions: “If the duchesses perfet in her errors, she must be separated from all conversation; her children must be taken from her, and all her domestics who are suspected of heresy, and who are to be prosecuted; with regard to the princess herself, the king refers to the prudence of her husband to proceed against her as he shall judge proper, avoiding, nevertheless, what might occasion too much scandal.” After the death of the duke, in the year 1559, this princess returned to France, and resided at her castle of Montargis. In the religious wars the duke of Guise fummoned her to deliver up some partizans who had taken shelter with her, she replied, “I will never deliver up those who look to me for protection; and if you attack the castle, I will be the first to appear in the breach, to see if you will have the audacity to kill a king’s daughter.” She was, however, at length obliged, much against her will, to send away 460 persons, to whom she had afforded an asylum. She parted with them in tears, after providing for the expenses of their journey. At the massacre of St. Bartholomew she was the means of saving the lives of a great number of Protestants. Her four children were taken successively from her, and brought into France, to be educated in the principles of the Catholic church. She died at Montargis, in the year 1575.

Moreri.

**RENAGADO REEF**, in *Geography*, a rocky shoal in the bay of Honduras, near the coast of Mexico. N. lat. 16° 16’. W. long. 88° 30’.

**RENATEGAE**, Renegade, a person who has apostatized, or renounced the Christian faith, to embrace some other religion, particularly Mahometsim.

They are the renegades who prove the most barbarous to the Christians when they fall into their hands. The renegade is thus called, *quaefi re-negat Christiun*.—Hoveden men-

tions this in the year 1192, under the name of *renier*, from the French, *re nier, to deny again*.

**RENDLE**, in *Geography*, a river of France, which runs into the Seine near Rouen.

**RENDLING CURD**, in *Rural Economy*, a term used provincially to signify the broken curd in cheese-making. See CHEESE and DRAINING.

**RENES**, in *Anatomy*, the Latin name for the kidneys. See Kidney.

**RENEX Succenturii**, the two small bodies, of which one is placed above each kidney. The literal translation of the expression, *reavor kidnies*, seems to indicate a notion, entirely unwarranted by our knowledge of their organization and functions, that they might supply the place of the kidneys if they failed in their office. These bodies are also called *capulare renale* or *atrabilare*, and glandula suprarenale. They are described in the article Kidney.

**RENESBONA**, in *Geography*, a river of America, which runs into lake Erie, N. lat. 41° 47’. W. long. 81° 55’.

**RENETTE**, in the *Meneger*, is an instrument of polished flesh, with which they found a prick in a horse’s foot.

**RENEWING OF LEAVES AND LIVES**. See *REVIVER*, *ANNITY*, *POLITICAL ARITHMETIC*, &c.

**RENFORCER**, Fr., in *Muse*, to reinforce, to pass from soft to loud, from loud to very loud, not all at once, but by degrees, swelling and augmenting the sound, whether a single note fullanted, or a series of notes, till the order to reinforce the note or passage is fulfilled, and then return to the common degree of force.

**RENFREW**, in *Geography*, a royal borough-town in the county of Renfrew, Scotland, is situated near the south bank of the river Clyde, at the distance of six miles from Glasgow, and 49 miles W. by S. from Edinburgh. Though much inferior in magnitude and population to Paisley, it is the head-town, or capital of the county. This distinction it derives from its superior claims to antiquity, and from the circumstance of its being incorporated under a royal charter, originally granted by king Robert II., who had a palace in the immediate vicinity. In virtue of that deed it is governed by a provost, two baillies, and sixteen councillors. In former times it sent one representative to the parliament of Scotland, and is now a contributory royal borough with Rutherglen in returning a member to the British legislature. About 200 years ago the Clyde passed close to the town, but the river afterwards deserted its ancient course, which has been converted into a canal communicating with its present channel. By this canal vessels of 200 tons burthen are enabled to reach the town in spring tides; but notwithstanding the advantage of that conveyance, the trade of Renfrew is very inconsiderable; owing, as Mr. Forryth justly remarks, “to the pernicious effects of borough politics, in withdrawing men from industrious habits and pursuits.” A small manufacture of thread, and some soap and candle works, on a confined scale, constitute the chief support of the town; but many of the lower orders are likewise employed in weaving for the manufacturers of Paisley and Glasgow. With respect to buildings, Renfrew consists chiefly of one principal street, about half a mile in length, with several lanes diverging from it. The houses are wholly constructed of stone, but are extremely irregular as to size, form, and position. The public buildings are the church, which is parochial, the town-hall, and a grammar-school. The lat is under the patronage of the town-council, and is at present conducted with much ability. There is no regular market held here, but provisions of all kinds may always be obtained at a reasonable price. The fairs
fairs take place on the third Tuesday in May and July, the 29th of September, and the first Friday in December. A general post-office is established at Renfrew. The revenue of the corporation exceeds 500l. per annum, arising from the rents of lands, customs, a salmon fishery on the Clyde, and the profits of a public ferry over that river. This ferry is perhaps the object most worthy of notice of any connected with the town. There is a ferry-houfe on each side of the river, the property of the corporation; and a ferry-boat constructed in so convenient a manner, that a carriage, with a pair of horses harnaffed, can be ferried over and delivered by one man in five minutes. This is accomplished by fixing, on both banks of the river, a rope which runs upon rollers at each end of the boat, and being pulled by the boatman puts it in motion. Renfrew, as the thire town, is the place where all county meetings are assembled, and where the county quarter sessions of the peace are held.

Renfrew parish extends between three and four miles in every direction. The whole is level, inclosed, and in a high state of cultivation. The soil is a rich loam, and the climate is peculiarly healthy, though subject to occasional heavy rains. The burgh lands consist of about a hundred acres. This parish is intersected by the great road between Glasgow and Greenock. Ecclesiastically, it is within the prebifhury of Paisley, and the fynod of Glasgow and Ayr. According to the parliamentary returns of 1811, the number of its houses is estimated at 344, and its inhabitants amount to 2305. Beauties of Scotland, 8vo. vol. iii. Carlile's Topographical Dictionary of Scotland, 4to. 1813.

RENFREWSHIRE, a county in the south-western division of the kingdom of Scotland, is bounded on the east by Lanarkshire, on the west, north, and north-east by the river Clyde, and on the south-west by the hills of Ayshire. This county is of fair extent, and of irregular shape; and contains, according to the parliamentary returns of 1811, 8409 houses, and a population of 92,596 persons. In general, and especially along the northern parts of it, the surface of the ground is level; but there are nevertheless several ridges of hills within its boundaries, some of which, upon the borders of Ayshire, are of considerable elevation. The hills of Balagieh and of Dunware rise to the height of 1000 feet above the level of the sea; and the isolated hill, called the Craig of Neilston, to 820. This hill is covered with fine graps to its very summit. Those adjoining to Ayshire, however, are bleak and barren, but command very fine views. On the south and west sides, the fertile vale of Cunningham, which feems at a distance to be wholly covered with wood, stretches itself to the shore of the Clyde; while on the north and north-east are beheld the level parts of Renfrew and the city of Glasgow, with the lofty Ben-Lomond towering above the clouds, in the back ground.

The rivers and lakes of this county are not of very considerable confluence in relation to themselves, but by the industry of the inhabitants on their banks, they have been rendered of great importance and utility to society. Unlike the romantic waters of Ayshire, adorned with wood and interesting interest by the vestiges of ancient magnificence which they every where display, the streams of this district are made subservient to the purposes of human industry. If they underflow from a height, it is not to add to the charms of the surrounding scenery, but to give motion to extensive machinery, inclosed within immense piles of building, where hundreds of mortals toil in the service of luxury, or form the materials which are to furnish clothing to distant nations. Here, if a stream spreads abroad its waters, it is not to embellish a park, but to afford convenience to a bleach-field, or to serve a reservoir for the mills in case of drought. In proportion as Glasgow is approached, every thing assumes an aspect of activity, of enterprise, of arts, and of industry. The principal streams are the White-Cart, the Black-Cart, and the Grif, which fall into the Clyde below Inchman bridge. The White-Cart, which generally receives, by way of eminence, the Cart, runs in a direction from south-east to north-west, nearly parallel with the Clyde. It takes its rise in the moors of East Kilbride, Lanarkshire, and is particularly celebrated in ancient record for its fine large pearls. These, however, have long disappeared; but the river becomes a source of more certain and beneficial wealth by its utility to the manufacturing interests of the county. Above Paisley, which stands upon its banks, it winds its way through a variety of small hills capable of cultivation to their summits; sometimes disappearing altogether, and again spreading its waters abroad into the plain. Below the town it is navigable for small vessels, and is thus beneficial to commerce and trade by facilitating the conveyance of goods. The Black-Cart rises out of Castle-Semple loch, in the parish of Lochwinnoch. From that beautiful lake it descends northward, and receives in its course the waters of the Grif. This last stream has its source in the elevated territory above Largs, which looks down upon the angle formed by the frith of Clyde. After its union with the Black-Cart, these conjoined rivers flow into the White-Cart at Inchman bridge. The lakes in the county, besides those of Castle-Semple above mentioned, are Queen-side loch, in Lochwinnoch parish, two lochs in Neilston parish, and various other smaller ones, all of them appropriated to useful purposes. The mineralogy of this county, though not so important as that of some others in Scotland, is nevertheless deserving of attention. In the parishes of Eaglesham and Kilbrachan, the mineral called the oofand stone is frequently found. This remarkable stone is of various colours, and when newly quarried, is so soft that it may be cut with a chisel; but afterwards becomes much harder. It breaks in all directions with unequal and harsh surfaces, readily absorbs water, and if recently heated, the absorption is attended with a hissing noise. Acids do not attack it, nor is it rent or melted by a strong heat. Hence it is much used for paving pavements, furnaces, &c. When burnt, it assumes a darkish colour, and lores three per cent. of its weight, but afterwards regains by its aborption. Some of it is considerably porous, and almost fenitivirited, in which case, when struck, it emits a clear and strong found. It is found in large masses in the form of rocks, having the intervening spaces filled with siliceous or calcareous spar, and occasionally with zeolite, flenites, and barytes. This last mentioned substance is found in abundance at Balagieh hill in the parish of Eaglesham, where are likewise two very noted mineral springs. But the chief field of minerals in Renfrewshire is that in the vicinity of Paisley, which extends on the one side into the parish of Kilbrachan, and on the other towards Glasgow. That part of it which is most singular is the coal at Quarrel-town, which is undoubtedly one of the most extraordinary mases of that mineral hitherto discovered in the British dominions. Its thickenes, measured at right angles, is fifty feet; and it consists of five layers or strata in contact with each other. In confluence of its enormous depth, it is wrought in different floors, in the mode practised in great open quarries. It is difficult to form a just conception of the manner in which this singular mass of coal lies. In a field of fifteen acres, it is found to dip in various directions. At least, conceiving a nearly circular area of these contents, the coal, from the north, the eft, and four quarters of that circle, dips pretty uniformly towards the centre. This, however,
however, is in some measure interrupted by several hitches, at one of which the masts of coal is suddenly thrown up about fifty feet, at another above thirty. These hitches interrupt not only the direction, but the degree of the dip. On one side of the northern hitch, it is about one foot in three; on the other side, only one in six. Some years ago, this bed of coal having been discovered, the farmers gave way and the ground fung, leaving the surface in a very rugged state. The difficulties thus produced, however, have been surmounted, and this mineral treasure refurred to all its utility. The other coal-mines in the county of Renfrew, are those of Hawkhead, Cathcart, and Kilbarchan. The first has been wrought above two hundred years. In the fame neighbourhood, lime is quarried in great quantities, also in Cathcart parish. Iron-lonc accompanies all the coal strata, but is more particularly abundant along the shores of the Clyde.

On the agriculture of Renfrewshire, it will be unecessary to offer many remarks. Almost every portion of the county is inclosed and cultivated, but grass lands are far more predominant than arable fields. This arises from the great demand which exists for the products of the dairy, the garden, and the fold, in consequence of the vicinity of trading and manufacturing towns, and the vast importation of grain which takes place from other parts of the country, or from abroad. Here the farmers are more facile than to object to a free commerce in that article; because there do not enven the inhabitants of less populous districts, who find no better employment for their lands than that of encouraging them by endless crops of grain. One would imagine that the practice in this district alone ought to decide the principle of the corn laws. Here, free importation, so far from injuring the farmer, augments the value of the soil in every respect, simply by incurring the ratio of population. The lands here differ according to their vicinity to the Clyde, or in the lower part of the county, according to their proximity to the waters of the Cart. In the parishes of East-Wood and the abbey of Paisley, the lands are beautifully interspersed with small rising hills, although the soil is generally of a thin clay. Here the farmers keep one half of their grounds in grass, which they consider as the most important crop. In the upper district of the county, which comprehends the parishes of Mearns, Eggleston, Neilston, Lochwinnoch, Kilbarchan, Erkined, and Kilmalcolm, the lands are peculiarly adapted for salturing sheep, but none of them are fo bloated, excepting some inclosures about gentlemen's farms, and a few parks in Neilston parish. The parishes of Mearns is perhaps unequalled in Scotland for numerous small hills. The farmers here make large quantities of butter. The cows are small, of a brown and white colour, and are chiefly of the Ayshire breed. Twelve of them afford, during the summer months, about sixty English gallons of milk daily.

Towards the northern part of the county, in Kilmalcolm parish, the enclosures are generally formed of fles loaded up to the height of four feet. The rotation of crops is three successive crops of oats, and six years of palingage. Farm servants are usually unmarried, and live in the farmers' houses. The horss are of the best kind, and drawn in a single horse cart, from 17 cwt. to a ton. Farms throughout the whole county are on a small scale; few of them exceed seventy acres.

Renfrewshire contains one borough-town, Renfrew, and three large manufacturing and commercial towns; viz. Paisley, Greenock, and Port-Glasgow, all of which are noticed under their respective names. Here are likewise several populous and thriving villages, such as Pollockshaws, Bridge of Johnstone, and Lochwinnoch, which are chiefly inhabited by weavers, who derive employment from the manufactories of Glasgow and Paisley. The principal manufactured products are thread, silk-gauze, and different kinds of cotton goods.

Various remains of antiquity are still visible in this county. At Paisley was a celebrated abbey for monks of the order of Cluny, the ruins of which are much admired. Here is also an old chapel, in the early pointed style, which is noted as the burial place of Margery Bruce, and several of the earls of Abercorn. In the parishes of Kilbarchan, near Callie-Semple, is one of those monitory mazes of whin- flone, believed to be a Druidical altar. It is twelve feet in height, and fifty-seven feet in circumference; and is known by the name of Clochdredoritlone, a corruption of the Gaelic, Cloch-a-Druig, the Druid's flone. It is composed of the same fort of whinflone of which the neighbouring hills are formed, and has probably been hewn from an elevated rock to the eastward, on which is a farm-houfe, called Clocho dredrig; but by what mechanism it was conveyed cannot, in the present state of the mechanical arts, be exactly determined. It rolls upon a narrow base; but the lower part of it has been covered with stones gathered from the landscape. At some distance square large grey flones have been formed to have been part of a faced circle surrounding the altar. The parish of Cathcart is noted for being the scene of the battle of Langside, the field contested by the unfortunate queen Mary, to regain her mother's crown. The place where the action was fought is an eminence rising rapidly on the north and west sides, and defended very gradually on the south and west sides. On the summit is a small elliptical intrenchment, commonly called queen Mary's camp; but which is undoubtedly of much higher antiquity, and probably of Roman origin. On an hill opposite to Langside, is the old castle of Cathcart, near which queen Mary stood during the battle, and witnessed the defeature of her friends, and the annihilation of her hopes. On the other side of this range of hills is another ancient castle, now in ruins, which belonged to the ancestors of the great reformer Knox; and at a short distance from it, on an elevated rock, may be seen one of those green artificial hills, usually called moats. It is of a square form, the moats facing the four cardinal points; the westward rolls on the precipitous edge of the steep rock; and the remaining sides are defended by a deep trench, cut out of the fold stone. Each side of this mount measures sixty feet in length at the base, and nineteen at the summit; and is twenty-one feet high. The top appears to have been a hollow square, surrounded by a parapet, with an entrance on the easterly side. No fewer than five other artificial mounts can be seen from the one described; also a Roman encampment near Paisley, distant about five miles. On the top of Barhill are the remains of a rude encampment, which occupies the summit of a precipice, formed of a perpendicular rock of a bafaltic appearance, which defends it on the north; and on the south it has a parapet of loose flones. The tradition in the neighbourhood is, that it was an encampment of the celebrated Sir William Wallace. The pinnacle of rock is shewn where they say Wallace fell while he enticed the English forces into a bog at the bottom of the rock, where they were all destroyed; but no historian confirms this statement. In an island of Callie-Semple loch is still to be seen the Pall or Peel, an old castle, to which the lairds of Semple were accustomed to retreat in times of unusual danger. In the lake, canoes hollowed out of single trees, like those of the Indians, have been occasionally discovered. Lower down the country the ruins of the castle of Newark chiefly claim attention. It stands on the eastern point of the bay, on which the town and harbour of Port-Glasgow is situated.
situated. When entire it consisted of a square court, with a tower at one angle, which is by far more ancient than any other portion of the building. When, or by whom it was erected, is unknown: this castle was long the property of the Dennetiouos of that ilk, and afterwards came into the possession of the family of Maxwell. In this county is a variety of objects bearing the name of the renowned and patriotic Wallace, who was a native of the village of Elderslie, in the neighbourhood of the town of Falkley. See Wallace.

The only other objects of antiquarian interest we shall mention, are four communion cups, still preserved in Kilmailton parish, and which were used by John Knox in administering the sacrament of our Lord's supper. They appear to have been originally candlesticks; and it was perhaps only from the necessity of the times that they were converted to this pious purpose. They are of the purest silver; and, whether from the affection of ideas, or their actual fashion, have a very antique and venerable appearance. Beauties of Scotland, vol. iii. 1866.

RENGAH, a town of Sweden, in Welf Bothnia; 30 miles N.N.W. of Umea.

RENGO, a town of Sweden, in the province of Vastmanland; 8 miles S.S.W. of Vasthallus.

RENI, Guido, in Biography, the principal painter of the Caracci school, was born at Bologna in 1574. At an early age he became the disciple of Denis Calvart, a Fleming of great reputation, but afterwards studied under the Caracci, preferring the style of Ludovico to that of Annibal, because there appeared more of grandeur and of grace in his compositions than in those of the others.

When he left the Caracci, he went to Rome; and with a mind intent upon forming a style of art for himself, studied the works of Raphael, with which he seemed enraptured; but the vigour and force with which the recent works of Caravaggio were conducted attracted him, and for a while he attempted to follow it. Happily he was diverted from it by an observation of Annibal Caracci; viz. that the best mode of rivalling the renown of Caravaggio might perhaps arise from a different mode of art, by contrasting his calm and lamp-like effects with a broader and more ample light; and for his vulgar forms, and obscure outline, substituting clearness in the parts and forms, built upon the pure models of antiquity. This remark, made in person by Caracci, operated powerfully on the mind of his skilful pupil, and induced him to try its truth. He immediately devoted himself to the study of what was graceful and agreeable in form, colour, and effect; and his successes are testified by numberless beautiful productions, of which we possess many in England; and France is still more rich in them.

His composition is not, however, so free from affectation as the nature of the subjects he chose demanded; the very attempt to make them graceful, too frequently militated against its object, and he subordinated the grace of the theatre to that of form. In his female heads and proportions, his model was the antique; and the character and features of the daughter of Niobe is discernible in most of them. He dreaded them with becoming elegance, and executed the different parts with great freedom and truth of pencil; not unfrequently, however, in a tone of colour too light, or too leaden for flesh; with a greenish hue which rather characterizes the hand of death, or the coldness of marble, than the glowing warmth of life, and the flexible softness of nature.

His disposition of draperies was elegant; judiciously applied to the filling up of voids in the grouping of limbs, or figures, and was wrought with the greatest freedom; yet infallibly with almost minute attention to the foldings. There he arranged in a grand style, but they not unfrequently exhibit the flany which he bestowed upon them; and appear to arise rather from the necessities of art, than the actions of the figures. The execution of his pictures is of the most free and agreeable kind: manifesting a perfect understanding of nature; the touch being light, full, and delicate; and though they are infallibly very highly, yet there remains no appearance of labour. In expression, he sometimes attained the greatest perfection; as in the head of our Saviour in the Louvre, and of which the president Wett has a very fine duplicate; but, in general, it was rather the grace and airifice of the theatre which guided him; and his figures appear to act more than to feel. Such was the respect paid to his abilities, that he was crowned with honour and riches; but it is lamentable to add, that one vice, in which he indulged after he had passed the meridian of life, viz. gaming, robbed him of both, and reduced him to poverty and disgrace; from which he was not able to free himself during the remainder of his life, which continued till he had attained the age of 67.

In the gallery of the Louvre there are between 30 and 40 of the works of Guido, large and small, and in his various manners; and as he there comes in immediate competition with his masters, connoisseurs have an excellent opportunity of judging of his comparative merit. We have also a great many of his called pictures in England, but they are scattered about in various collections.

RENI, in Geography, a town of European Turkey, in Beffariah, on the Danube; 40 miles W. of Iffmail. N. lat. 45° 23'. E. long. 28° 44'.

RENNOLME POLIUM, in Botany, a kidney-shaped leaf. See LEAF.

RENTENCY, RESEXENTIAL, or RESEISUS, among Philosophers, that force in solid bodies, by which they reful the impulfe of other bodies; or re-act as much as they are acted on.

RENY, in Rural Economy, a term provincially signifying tall or high, when applied to animals, &c.

RENNEBAUK, in Geography, a river of America, in the province of Maine, which runs into the Atlantic. N. lat. 42° 26'. W. long. 76° 43'.

RENEBO, a town of Norway, in the province of Drontheim; 36 miles S. of Drontheim.

RENNEL'S SOUND, a bay of the North Pacific ocean, on the W. coast of Queen Charlotte's island. N. lat. 52° 28'. W. long. 137°.

RENNERSDORF, a town of Slieflia, in the principality of Neiffe; 8 miles E. of Neiffe.

RENNES, a city of France, and chief city of the department of the Ille and Vilaine; and, before the revolution, the see of a bishop, and capital of Bretagne; situated on the Vilaine, by which it is divided into two parts. It is large and populous, containing eight parish churches, besides the cathedral and several convents. The four parts which it comprehends are denominated the north-east, south-east, south-west, and north-west. The first contains 5950 inhabitants, and its canton 13,147, on a territory of 124 square kilometres, in 7 communes; the second contains 5253 inhabitants, and its canton 12,664, on a territory of 572 square kilometres, in 4 communes; the third contains 3081 inhabitants, and its canton 12,254, on a territory of 142 square kilometres, in 9 communes; and the fourth part contains 11,620 inhabitants, and its canton 14,532, on a territory of 371 square kilometres, in 3 communes. N. lat. 48° 7'. W. long. 1° 36'.

RENET,
RENNET, in Rural Economy, a term applied to the coagulum for making cheese. It is prepared from the bag, maw, or stomach, of the young calf, by a sort of salt pickle. It is of vast advantage in the art of cheese-making to have good sweet rennet, the particular mode of managing which may be seen under the heads Cheese, Dairy, and Dairying.

The preparation is formed in different modes, in different cheese districts, in the different parts of the kingdom; but mostly either in the manner of a solution, or that of a dry skin. As there is, however, much variation in the quality or strength of the different skins, it is probably the best method to reduce them into the state of a solution; as, by that means, the necessary quantity, in every case, may be the skin acertained.

In some places, it is found the most certain practice to prepare the whole of the dried maw skins, which are required for a lecanon, at one time, by pickling and steeping them in different separate quantities of pure spring water and salt, in an open vessel, or vellums, mixing the different infusions together, and then panning them through a fine linen sieve, afterwards adding rather more salt to the whole than can be retained in the state of solution, as shown by the appearance of some at the bottom of the vessel. The extraneous vegetable matter, that comes to the surface, is continually to be removed as it riseth, and fresh portions of salt occasionally supplied, as they may be wanted. In this state it is ready for use, about four ounces being sufficient for a large cheese.

In other parts, the maw skins are simply well salted, and steeped in salt pickle for some length of time; then well dried, by being spread out by means of small pieces of sticks; in which state they are made use of, by cutting pieces from the top and bottom parts of them, about the size of a half-crown for a middling-sized cheese, as those parts are in general the strongest.

And the following method of preparing rennet is practised in the northern parts of the island, and described as the most approved method in the Report on Agriculture for Argyleshire. Take the maw skin of a calf, which has fed entirely upon milk; after it is cold, wash it gently in water, fill it nearly with salt, and place it on a layer of salt in the bottom of an earthen mug. One or two more, with salt between, and a good deal above them, may be put in the same mug: and kept in a cool place, with a slate on the top, for six or eight months, or till cheese-making time next year. The skins are then taken out, and the brine allowed to drain from them; after which they are distilled on small hoops or splinters, put crois-wise within them, till they dry. Put the skins then in an open vessel, with three pints of pure spring water for each skin. Let them stand twenty-four hours; after which take them out, and infuse them other twenty-four hours in other water, but not more than a third of the former quantity. Mix these two infusions together, pas them through a fine linen sieve, and give them salt till the water is more than saturated, and some remain undiluted at the bottom. Rather less than a gill will serve for thirty-eight pounds of cheese. It is remarked, that, instead of two infusions, some use only one, giving four English pints of the skin, and direct the water to be first boiled, and mixed with salt into brine that will swim an egg, and then to let the heat go off till it is like-warm, before the skin is put in twenty-four hours to steep.

It was formerly the practice to mix different kinds of aromatic herbs with the rennet; but the custom is much laid aside at present. The manner of doing it is this: when the maw skin is well prepared, two quarts of soft, pure water should be mixed with salt, in which should be put sweet briar, rose-leaves, and flowers, cinnamon, mace, cloves, and in short, almost every sort of spice and aromatic that can be procured. Boil them gently till the liquor is reduced to three pints, taking care it be not smoked. Strain it clear from the skins, and, when milk-warm, pour it into the maw; a lemon may then be fixed into it, and remain a day or two, after which it should be strained, and put in a bottle well corked, and it will keep good for a year or more. A small quantity will turn the milk, and give the cheese a pleasing flavour.

RENO, in Geography, a town of the island of Corrica; 3 miles N.E. of Vico.

RENO, a river of Italy, which rises a little to the N. of Pilosia, and runs into the Po, 4 miles above Ferrara. Reno, a department of Italy, so named from the above-mentioned river. It consists of part of the Bolognese, and contains 109,500 inhabitants, who elect 15 deputies. The capital is Bologna.

RENOGRUND, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 59', E. long. 23° 3'.

RENOVATOR, in Horology, is a watch that has the property of renewing the power of its main-spring, or of winding itself up, by periodic jerks that it receives from the human body in motion. Recordon of Charing-Crofs, London, took out a patent for this contrivance some years ago, which is more ingenious than useful; for, while it profites to keep the watch going, without the usual winding up, so long as the watch is worn in the pocket, it foregoes the more useful property of the fusee, and renders the maintaining power very unequal at different times of the day. And should the watch remain suspended, or laid down in a state of rest, for more than 24 hours, it will cease to perform; so that instead of being a watch that will go without winding, it requires to be wound many hundreds times in the day, by small successive quantities, before it will continue, perform throughout the night. We have been favoured by the inventor with a copy of so much of the specification as will suffice to give our readers an idea of the mechanism, and of its mode of action; both which we have examined, and found corresponding with the specification. Others have varied the construction; but the original, we conceive, will be deemed sufficient for us to particularize, which we will do by a reference to figs. 1, 2, and 3, in Plate XLIII. of Horology, which are copied from the inventor's drawing. Exact Copy of the Specification, No. 1.—** Letter H represents a weight of filler, or other metal, which is in equilibrium in the position it is viewed, being held down by a spiral spring fixed to its arbor, as described by fig. 3. In wearing the watch, or by any external motion that lifts the watch up, it loses its state of rest; and by its vis-inertice (matter) overcoming the strength of the spring, it yields to the laws of gravity, and falls upon the lower spring, marked ee. When the watch, by the motion of the body, defends, the spring ee, and the afteraid spiral spring, are left at liberty to exert themselves, and return the weight upwards, till it touches the other spring ee; and thus, by the motion of the body, is this weight alternately thrown up and down, which turning the ratchet-wheel, marked C in fig. 2, which is fixed on the arbor of the weight just below the spiral spring, gathers a few teeth every motion in the wheel P, and being prevented from returning by the click M, carries forward the wheel with a pinion of to, marked E, which turns the wheel B; which having a pinion of 12 at G, takes into and turns a wheel under the barrel A, which is fixed on the barrel arbor, and by that means is the spring wound up.

The
The upper part of the barrel arbor, marked \( b \), has a tooth, which gains a tooth in the wheel, \( a \), every revolution; and that brings the pin \( c \) nearer to the centre, which, when it arrives in a certain position, raises the piece \( K \) (fig. 1.), of which the centre, \( D \), (not seen in the figure) is conicul, in order that when the said pin \( c \) comes near it, it raises it with ease, and forces it into the holes, marked \( M, N, N \), in the weight marked \( H \) (fig. 1.), which efficaciously drops its motion, and prevents the ill consequences of over-winding.

A is a cock that carries the pivot of the barre's axis.

I is a cock that carries the pivot of the wheel \( H \).

The patent was obtained in July 1780; and part 2d of the specification contains drawings, and a plan for applying the same principle to the fusee; but we do not understand that it has yet been made to answer.

RENKETH, in Geography, a town of Germany, in the county of Henneberg; 3 miles s. of Schleusingen.

RENS, Rens, or Rees, a town of France, in the department of the Rhine and Mofelle; near which, in the Rhine, is a remarkable monument of antiquity, called the "Koenigskuh," or "Thornus regalis," consisting of a round vault, built of free-stone, and resting upon nine stone pillars, one of which stands in the middle. This vault is 80 feet in circumference, furnished above with seven feats, agreeable to the number of electors at that town. The ascent to it is by stairs of stone, consisting of 26 steps, and it has two strong doors. On this regal chair the electors formerly held previous consultations for some time, concerning the election of a king and emperor; and when that election could not be performed at Frankfort, it was done at this place; and here we have also transacted the notification and elevation of the elected personages, and also the consultations of the electors concerning the weighty matters of the empire, as well as a solemn confirmation of their privileges on the part of the emperors. Here also was established, in the year 1338, the electoral league. Maximilian I. is thought to have been the last emperor who was brought hither; 5 miles s. of Coblenz. N. lat. 50° 19'. E. long. 7° 5'.

RENS, a lake of Prussia, in the palatinate of Culm; 10 miles N.N.E. of Culm.

RENSSLEREAU, or RENSSLEREAU, a township of Albany county, New York, bounded S. by Columbia county, and W. by Hudson river. In this township, opposite to the city of Albany, is an medicinal spring, combining most of the valuable properties of the celebrated waters of Saratoga.

RENT, RENT, in Law, a profit, such as a sum of money, or other consideration, inflowing yearly out of lands or tenements, alienated on that condition.

The word rent, or render, reditus, signifies a compensation, or return; it being in the nature of an acknowledgment given for the possession of some corporeal inheritance. Co. Lit. 144.

It is thus called from the corrupt Latin, rendita, for redita, of reditus; because, as Fleta tells us, retiro, et gustantis redit.

The original of rents is to be sought for in the constitution of the ancient feuds, which were of a military nature, and in the hands of military persons; however, the feudatories, being under frequent incapacities of cultivating and maintaining their own lands, soon found it necessary to commit part of them to inferior tenants, obliging them to such returns in service, corn, cattle, or money, as might enable the chief feudatories to attend their military duties without distraction; which returns, or reditus, were the original of rents.

Under the pure feudal system, this reditus, return, or rent, consisted, in chivalry, principally of military services; in villegage, of the most servile offices; and in soeage, it usually consists of money, though it may fall consist of services, or of any other certain profit.

Rent is regularly due and payable upon the land from whence it is levied, if no particular place is mentioned in the reservation (Co. Lit. 201.) but, in case of the king, the payment must be either to his officers at the exchequer, or to his receiver in the country. (4 Rep. 73.) And strictly the rent is demandable, and payable before the time of the day in which it is reserved; though some have thought it not absolutely due till midnight. 1 Saund. 287.

The usual remedy for non-payment of rent is diftrict; however, by the common law, diftricts were incident to every rent-service, and by particular reservation to rent-charges also, but not to rent-charge, till the statute 4 Geo. II. c. 28 extended the same remedy to all rents alike. Moreover, by this statute it is enacted, that every landlord, who hath, by his lease, a right of re-entry in case of non-payment of rent, when half a year's rent is due, and no sufficient diftrict is to be had, may serve a declaration in ejectment on his tenant, or fix the same upon some notorious part of the premises, which shall be valid, without any formal re-entry or previous demand of rent. And a recovery in such ejectment shall be final and conclusive, both in law and equity, unless the rent, and all costs, be paid or tendered within six calendar months afterwards. Other remedies are action of debt, an affile of mort d'ancieter or novel difleen, the writ de confectutinibus et servituis, which compels a specific payment of the rent, the writ of callavit, and the writ of right for disclaimer.

For an account of the rental of England and Wales, see Political Economy.

The lawyers ordinarily reckon three sorts of rents, viz. rent-service, rent-charge, and rent-fees.

Rent-service, is where a man holds lands of his lord by fealty, and certain rent; or by fealty-service, and certain rent; or that which a man, making a lease of lands to another for term of years, releveth to be yearly paid for them.

Rent-service is so called, because it hath some corporal service incident to it, as at the least fealty, or the feudal oath of fidelity. (Co. Lit. 142.) For, if a tenant holds his land by fealty, and 10s. rent; or by service, and 12d. rent; or by the service of ploughing the lord's land, and 5s. rent; these pecuniary rents, being connected with personal service, are therefore called rent-service. And for these, in case they be behind, or in arrear, at the day appointed, the lord may distrain of common right, without requiring any special power of disfetf; provided he hath in himself the revocation, or future eftate of the lands and tenements, after the lease or particular eftate of the lessee or grantor is expired. Lit. § 215.

Rent-Charge, is where a man makes over his eftate to another by deed indented, either in fee, or fee-tail, or for term of life; yet refers to himself, by the fame indenture, a sum of money yearly to be paid to him, with a clause of ditreff.
dilatory for non-payment: so called, because, in this manner, the land is charged with dilatory for the payment of it. Co. Litt. 143.

Rent Sec, or Dry-Rent, or Burthen-Rent, is that which a man, making over his estate by a deed indented, reserved yearly to be paid to him, without any clause of dilatory mentioned in the indenture. There are also other species of rents, which are reducible to these three.

Rents of Affize, are the certain established rents of the freeholders, and ancient copyholders of a manor; thus called, because affixed and certain, in opposition to reditus nobilis.

Those of the freeholders are often called chief rents, reditus capitales, and both sorts are indifferently denominated quit rents, because by them the tenant goes quit and free of all other services. When these payments were reserved in silver or white money, they were anciently called obit rents, or blanch-farms, reditus alb, in contradistinction to rents, referred in work, grained, or better money, which were called reditus nigro, or black-mail. 2 Hals. 19.

Rent, Fee-farm, is a rent-charge arising out of an estate in fee; or of at least one-fourth of the value of the lands at the time of its reservation. (Co. Litt. 143.) Rack-rent is only a rent of the full value of the tenement, or near it. For a grant of lands, referring to considerable a rent, is indeed only letting lands to farm in fee-simple, instead of the usual method for life, or years.

These are the general divisions of rent; but the difference between them (in respect to the remedy for recovering them) is now totally abolished; and all persons may have the like remedy by dilatory for rents-fee, rents of affize, and chief-rents, as in case of rents reserved upon lease. Stat. 4 Geo. II. c. 28.

Rents Reticulate, are reckoned among the fee-farm rents to be held by the form. 22 Car. 11., being such rents or tenths as were anciently payable to the crown from the lands of abbeys and other religious houses; which lands, upon the dissolution of abbeys, being demised to others, the said rents were still reserved, and made payable to the crown.

Rents, affize, chambery, chief, gold, pearly, rack, quit, and white, are the several adjectives.

Rent, in Agriculture, the price paid for lands as farms by the tenants of the proprietors. The rents of lands are so extremely various, according to the nature of the soil, situation, markets, the state of the fences, buildings, and other conveniences, the ease of obtaining manures, and many other circumstances, as to be almost incapable of having any general specific prices affixed to them. They were formerly, especially in the northern parts of the island, paid in produce and personal services; but at present, according to Mr. Donaldson, over the greatest part of the island, they are paid in money, and at two periods or terms in the year. In England, Michaelmas and Lady-day are the customary terms of payment; the first payment commences six months after entry to the possession of the farm. But that in Scotland, the ordinary terms are Martinmas and Whitmas; or Whitmas and Christmas, the tenant being allowed twelve months' credit of the first half of the rent in the one case, and in the other eighteen. And he observes, that this difference in the terms of the payment of rents is material in the purchase of landed property, being in general nearly one year's purchase in favour of England. And it is farther stated, that it was the custom of former times, in various parts of Great Britain, for the tenants to pay what was called fore-hand rents, that is, paying the half, and in some cases, the whole year's rent immediately on entering to the farm, and before any benefit was derived from the possession of it. This practice is, however, now generally diffused, although still kept up in some parts of Staffordshire and Pethshire, in some degree. And we believe that it still prevails in some places in Ireland. It is likewise added, that letting lands for a term of years at the former rent, but making the farmer pay a considerable farm in ready money by way of fine, was also a very common custom; but is now chiefly confined to the crown and church lands in England. This mode was evidently attended with bad consequences. By draining the tenant of all, or greatest part of his ready money, he was prevented from improving his farm. Leases of lands are considered in law as heritable property; therefore, in the event of the demise of the tenant, soon after having completed a transference of this nature, his eldest son succeeded to the lease, and the widow and other children were of course, in many instances, reduced to poverty: all that was left to them being their proportion of the stock on this farm, and often thereby the heir was rendered incapable of keeping possession of the farm. In a word, in nine cases out of ten, it was robbing the tenant of the well-earned reward of his industry, during the existence of the former lease, and depriving him of the means of turning his new acquisition to the best account; without giving any solid advantage in return for it.

It is remarked also, that along the greatest part of the east coast of Scotland, which is the principal corn country in the kingdom, a considerable proportion of the rent of almost every farm is paid in grain and oatmeal. These articles being left fluctuating in their value than money, this appears the most equitable mode in which the rents of corn farms can be paid. It may indeed affect the farmer's interest when any sudden and unexpected rise takes place in the price of grain; but if a judgment can be given from experience, it will be found this very seldom happens. On the contrary, for the last twenty years, with only two exceptions, 1783 and 1795, the price of grain, owing to the operation of the corn laws, has been extremely moderate, while every other production of a farm has been doubled in value, and in many cases tripled. Since these periods, the price of this article has, however, risen, and continued high. The public are often essentially benefited by so great a proportion of the rents being paid in this way. Many of the proprietors have granaries erected on their estates, where, in times of plenty, they store the grain and meal which they receive from their tenants. And every person, who is in any degree acquainted with the agricultural exports and imports which take place between some districts in Scotland and others, must, he thinks, know that the supplies afforded on many occasions from these stores have been the means of preventing scarcity, and an unreasonable advance in the price of these articles in the large manufacturing towns and other populous places. In Egl. Lothian, according to the agricultural report of that district, it has been suggested by some proprietors, that one half of the rent should only be paid in money, the other in kind; and affixed as a reason, that the profit or loss arising from any material, as the rye or fall in the price of grain, would, in that way, be equally divided between the landlord and tenant. This is a mode probably founded on equity and justice. And it is further stated, by the first writer, that in the most northern parts of Scotland, the rents are, to a certain extent, paid in personal services. The tenants are bound to plough and harrow a certain portion of the landlord's farm, to reap, carry home, thresh, dress, and mill a certain quantity of the crop. They are also bound to pay poultry, eggs, butter, cheese, sheep, swine, linen
REN'T.

Linen yarn, fish, &c.; in a word, they are more the flaves of the landlord than their own masters.

These are shameful feudal practices, which the proprietors of such lands should remove as soon as possible, as without it their interests must suffer greatly from the lands remaining without improvement. Besides, it is a species of bondage highly disgraceful to civilized society. The able author of the Agricultural Report of the county of Argyle in Scotland, thinks that all services, whether paid to the master or to any under him, should be entirely abolished; and all rents formed into one sum of money, including public burdens, such as millers' lifts, schoolmasters' tallow, road money, &c. Thus, says he, the tenant would have always a clear view of the amount of his rent, and have time and trouble, and perhaps expense, by having to lettle with one only instead of many. His time is precious, and should never be thrown away without necessity.

In regard to the parliamentary and parochial taxes, they may be laid to be paid, the first writer says, by the tenants over the greatest part of both kingdoms; and many leaves contain a clause, he observes, binding the tenants to pay, not only all the taxes that are imposed, but also all that may be imposed. But, he thinks, that it appears absurd that the proprietors, whose interest it is to attend to the increase or decrease of all such taxes as more immediately concern their property, should devolve the payment of those taxes on their tenants. They must know, that whoever pays them in the first instance, to them the lands are of less value, in consequence of such taxes having been imposed. They ought also, he thinks, to consider that their interest might be the means of keeping the most extravagant of them, such as the tithes and poor's rates, within more reasonable bounds, than it is to be suspected the utmost exertions of the tenants can be able to effect. And that, further, proprietors could ascertain the value of their property with more minute exactness, were they, on the one hand, to receive from their tenants the full rents which their lands are worth, and, on the other, pay all taxes to which they are subjected. The interest of agriculture, and the ease and comfort of the farmers, would at the same time, he thinks, be essentially promoted, were they relieved from these taxing exactions and compositions with which they are so frequently molested, particularly in this part of the kingdom.

And he further, in respect to the general price of renting lands, that when it is considered how many circumstances operate in determining the rent of land, and how much these frequently vary in the same parish or lordship, it will be found impossible to form any correct idea in regard to the rents payable by the acre for the various kinds of soil over the whole island. Any conjecture that may be formed (for the subject admits, he says, no more) must be vague and incorrect. It is supposed, that the remarkable change that has taken place in the situation of the kingdom and the manners of the people, by the abolition of the feudal system, the increase of commerce, manufactures, and agricultural improvements, with the immense additional quantity of paper-money introduced within these few years into circulation, have had the effect of enhancing both the value and rent of lands. While these flourish, and paper-money supports its nominal value, lands in property or lease must necessarily, he thinks, continue to advance. But that, should any droves accident interrupt the former, or deprive the value alluded to the latter, the recent great advance in the rent of lands, in various parts of the island, would render such calamities more universal in their effects, and of course of more serious consequence to the country.

The rent of land is kept up by a great variety of local causes, as the particular nature of the farms, their extents, the goodneds of the roads and markets, the convenience of canals and other forts of water carriage, and many other circumstances of a similar nature. In dairy and grazed districts, as well as some others, rents are kept up by the particular modes of occupation, in many instances. Many little advantages are connected with the former; while the latter has not any heavy expences to contend with. Small farms are confidantly higher rented than those of the larger kind. Convenient carriage and large markets are always favourable to rents. Local convenience has invariably great influence in raising the rent of land. In short, it has been suggested by an able writer, that every fort of improvement in agriculture, as well as manufactures, has a tendency to advance the rent of land; and that, if, to the practical excellence of the former, improvements in the latter should be added, with a more extended commerce, rents may be raised to an extraordinary degree. While the contrary of these matters is calculated to reduce the quantity of wealth, and, of course, to lower the rent of land; consequently rents rise and falls with the prosperity or declining state of the agriculture, the manufactures, and the commerce of the country, the former of which is only to be preferred by peace.

But though the rents of land have been greatly increased within these few late years, it is probable that they must feel the effects of the want of taxation and other charges which bear so hard upon agriculture at present.

But the ascertaining of the rents of lands in the different districts of the kingdom is a point of considerable importance both in a political and agricultural view, as by such means the produce of them may be better and more certainly calculated.

Mr. Smith, in his valuable Agricultural Survey of Argyllshire, states, that the quality of the soil is there extremely different; so that such valuations as have been lately made, differ, sometimes on the same farm, from 25 to 157. the acre of arable ground. The pasture, too, being partly green hill, but mostly heath, differs no less in its quality than the arable land. Some of it is valued below 40. and some above 45. the acre. In the neighbourhood of Campbeltown, a few spots of arable land let from 25 to 37. the acre. But this price may be said to be put not altogether upon the land, but partly upon the accommodation. But what proportion the rent of a farm should bear to its produce, depends so much on soil, climate, situation, and other circumstances, that no general rule can, he thinks, be laid down on the subject. In regard to arable lands more particularly, it is a common, though perhaps not a just remark, that one-third of the produce should go for rent, one-third for expense and management, and one-third for the farmer's profit, interest, &c.

But Mr. Middleton remarks, that the method practised by some gentlemen, of estimating the produce of land by trebling the rent, is very fallacious: three times the rent is not by any means equal to the value of the produce of a farm. But the general rule is this, that the farmer is under the old exploded course of fallow, wheat, oats, in the scanty produce of common fields, and when taxes and the expenses of living were at one-half of the present amount, it was not very distant from the truth. But under the more improved course of husbandry on land, at and under twenty shillings an acre, the produce is now, he thinks, more generally worth from five to seven times the rent.

In the North Riding of Yorkshire, as stated in the report of that district, the average rent of farms of pretty good soil is from 15s. to 21s. per acre, in which there may be land rated
RENT.

at from 5s. to 35s. per acre, so that the average value of a farm will vary according to its proportion of good and bad land. Some farms of the latter kind may be let as low as 5s. per acre, and some let cheaper at 30s.; so great is the inequality of the soil, that nothing accurate on this head can be stated. Near large towns, land for convenience in small parcels, and in the aggregate to no great amount, is let at 3d. or 4d. per acre.

But in the western districts of that county, as about Skipton and Settle, the lands found to let as high as 40s. and 50s. the acre; while from the best information in the corn part of the county at the same time, 20s. and 30s. were considered as a high rent, and in many places it was still much lower.

In Shropshire, the rents of lands, where the roads are bad, and the grounds little improved, are from 8s. to 12s. the statute acre, and in more favourable districts and situations, from 15s. to 20s. the farm together. But near towns, the price is much higher, as from 2l. to 6l. the acre.

And in Norfolk, according to Mr. Young, in the light land district, as marked in the Survey, the average price of letting is 6s. the acre; the various loams at 16s.; the better lands at 12s.; the rich loams 26s. and the marl land clays 28s. In Suffolk the several soils are stated to be rented as below, the whole county included, sheep-walk, waste commons, &c. which are very large deductions from the rate of the cultivated lands:

<table>
<thead>
<tr>
<th>Soil Type</th>
<th>Rate (s. d.)</th>

<td>10 0</td>
</tr>
<tr>
<td>Western district of ditto</td>
<td>5 0</td>
</tr>
<tr>
<td>Fens</td>
<td>2 6</td>
</tr>
</tbody>
</table>

But in all the districts, with the exception of the fen, there are tracts that are let at 20s. to 25s. and even higher, especially meadows.

In the county of Essex, the average rent of good landed farms may be stated at about 20s. or 25s. the acre. They have lately increased very much in some places.

In Suffolk, good land is rented at from 20s. to 30s. the acre, but there is a great deal let at much lower rents.

Land has risen much of late years in many parts of the country.

In the county of Oxford, the rent of land is very various. The red land lets on the average at 30s., the miscellaneous loams at 25s.; the Brome-lands at 20s., and the Childer at 16s. the acre. There are, however, large portions of land let at still lower rents in different parts.

In Cheshire, the land averages full 30s. the acre in rent as farms; and in Lancashire, the rent of land is equally as high, if not higher.

In the very south-western district of Cornwall, the rents of land fluctuate very greatly, as from 5s. to 50s. the acre in farms properly so named. The circumstances affecting rents here, besides the quality of the soil, and the aspect or situation, are the vicinity to sea land, and to market towns. There are instances of land letting very high in particular situations, as at 13l. the acre about Penzance. And in the same parishes the rents of land sometimes vary from 8l. to 52l.; nay, even on the same farm, not exceeding 150 acres, some parts are worth 50s., and others not 5s. the acre.

The neighbourhood of towns and large markets, as well as of extensive manufactories, has, in all cases, a tendency to raise the rent of land, whether as farms or otherwise, in every part of the kingdom.

In all parts of Scotland, even in the Highlands, the rise of rents has been gradual and progressive for many years, and in some places they have been more than doubled within these last twenty-five or thirty years.

It has been stated by Mr. Collingsworth, of Daventry, in the fourth volume of Communications to the Board of Agriculture, that in respect to the principle of increasing rents, where liberty is given to break up old gras or pature lands that are under lease, that he has known, within this five years past, a double rent given for leave to plough up and old pature for croping for three years; and that consequently it appears to him that a statement of the expenses and profits upon arable and pature lands should be severally made out, to ascertain by how much the balance of profit of the one exceeds that of the other. He therefore states them, upon a probable calculation, in the following manner:

Table of Expenses.
Rent.

Produce.

By this means the rent that can be afforded to be given may be ascertained with tolerable correctness in many instances of farming. See Grass Land.

The author of the Argyleshire Agricultural Survey, after remarking that there is very little arable land in that county but which is capable of higher cultivation, besides the great quantity of waste ground that may be improved in almost every farm, says, that the land is therefore capable of being made to yield a much higher rent when better cultivated; though not a great deal of it, as is generally thought, can bear much more, in the present stage of improvement, than what is laid on already, unless it be under a different management, which in sheep lands might be by the introduction of better woolled breeds, and in arable lands by adopting a better system of husbandry.

It is conceived, that the idea of high rents being a spur to improvement and exertion, is a common, and, to a certain extent, a just maxim. No doubt there may be some who, if they had the land for nothing, would be ruined by their indolence. But the more common cafe is, that when a tenant fees that all his exertions will not do, he becomes dispirited and desperate, and allows himself to be carried along by the stream which he cannot stem. The land suffers, the tenant fails, the farm gets a bad name, and the rent must be lowered. Thus the landlord, as well as the tenant, suffers, by raising the rent higher or lower than the improvement of the land will bear. But he adds, that a substantial tenant is generally cautious of engaging to pay a rent that is exorbitant. He fees the successes of those who invest their money in other branches of business; and he follows their example, if he has not the prospect of a farm's yielding him full interest for his money, and an adequate return for his diligence and labour. Whereas he who has learnt to lose, is often the most forward to offer, and the landlord is often tempted to accept the offer, without considering that a capital is necessary for paying the rent, and improving the land. Instances of ruin to the tenant, and loss to the landlord, from too high rents, are not unfrequent, especially on some of the smaller estates. Most of the farmers till hard, live poorly; and for one who has a trifle for his pains, perhaps two give their pains for nothing. Many who have old leaves obtained before the late rise in land, and in its produce, took place, are very well, as are also many of those who have sheep flocks; as their possessions are managed with less expense, and the value of some of them was not well known till they were tried under the sheep system. But even bad bargains.
bargains are become good by the late rise on every article of produce; and most of those who have leases are at present at their ease.

It is concluded that the occupiers of land, whether in paffurage or tillage, ought certainly to be able, like labourers or tradefmen, to live by their occupation, and to support their families by their daily care and labour. The interest of money invested in their stock, with the proper allowance for fear, wear, and rick, they should be able to fave as a provision for their families, and for old age; as the money so invested would give this return, it laid out on interefl, without any trouble whatever. It cannot be confidered as any part of the produce of the ground; and therefore no part of it ought, in equity, to enter into the payment of the rent; and yet not one in ten, perhaps, is able to fave it; nor do they commonly advert that so much ought to be faved in justice. They are generally satisfied if they can keep their stock undiminifhed; fo that the bufinefs, in general, returns much less to those engaged in it than almoft any other. A happy predilection in favour of the occupation in which they were brought up, is, he thinks, what induces fo many to follow it. Perhaps it may be also faid, that there is implanted in the human mind, for wife purpofes, a certain innate difpofition, or inclination, which leads it to delight in rural occupations.

These remarks should be well attended to by the pro prietors of farms, as their advantages, as well as that of their tenants, may be greatly promoted by such means.

In regard to the receiving of rents where they are of different kinds, as for cottages, titles, in the form of compositions, chief rents, quit rents, and fome other forts, besides those of the farm kind, they require fome attention and method, fuch as the fixing of diftant times in the fame, or different days, for the reception of each, when on a large scale, fo that the exact times of attendance for each may be known to thofe who have anything to fettle. So far as farm rents are concerned, the fixing of proper periods for receiving them is of great importance, though the matter has hitherto been little attended to, there being often no fixed time known to the holders, until Signified by the precept of the receiver. And that is, in many cases, liable to alteration. This is very inconvenient to the farmers in many inftances, as they muft either sell their corn and live-stock to great disadvantage, many times, before it was neceffary, and have large fums of money lying ufefully by them, or meet the receiver, perhaps, with only part of the rent. The propriety and neceffity of having certain exact times for receiving rents are therefore evident, and, of course, the most fuitable times for these are to be ascertained, as whatever enables the holders of land to turn their produce to the molt advantage, increases the prosperity of the farms, and ultimately benefits the proprietor.

In this country it is faid, by the authour of the work on Landed Property, farm rents moftly become due at Ladyday and Michaelmas. But the proper times of paying them depend on the marketable produce of the land, and the feafon of the year at which it goes, and can be fettled in the markets. The holders of farms should never be forced to improper regulations in these repects, or be fuffered to withhold the payment of their rents when they have obtained the money for their produce.

Upon corn farms, which are numerous in moft parts of this country, Michaelmas is the molt improper time in the whole year to call upon tenants for their rents. It is at the clofe or height of harvest, as the situation may be, when their pockets are drained by extra expensive labour, and when the grain cannot be threfhed out to replenih them; alfo when much of the off-going live-stock is not ready for the market.

In the county of Norfolk the above writer paid great attention to this matter, and found that there, the latter end of February, or beginning of the fucceeding month, was the molt proper feafon for Michaelmas farm rents to be paid; and the month of June for thofe of Ladyday. And, by correct examinations, thofe molt proper in other places may be found, keeping the above principles constantly in view. Farmers fhould never be obliged to do any thing improper in the di{pofal of their articles at unfuitable feafons or markets, or to raise money in any improper ways; nor be led into fpeculations with money while it lies idly by them.

The bell feafons having been ascertained, the exact periods are to be fixed on, from the particular nature of the farms, the cultums of the districts in refpect to fairs and the dealers in different forts of produce, which may generally be readily managed without much difficulty.

Rent Accounts, fuch as are kept on estates, whether of farms, cottages, chief rents, or any other forts of annual payments, by the managers. They fhould be clear and comprehensive, containing every thing of importance about them, as their different circumftances may direct.

The management of the farms, in rent accounts, whether yearly or half yearly, muft be the fame as in the receiving rentals, as they appear on the general map; and as they naturally lie on the face of the estate, according to the ideas of the writer of the work on Landed Property. See Map of Estates.

The parishes, or manors, lying wholly or partially within the estate, are to be first geographically arranged, and then the farms on the same principles, they lie within the respective parishes. In this way it is conftantly the fame, and has the advantage of not being liable to be disturbed by changes of any fort, which affords much facility and convenience in all such accounts on many occasions.

Rent Charges, the fixed payments to which an estate or farm is fubject to, fuch as chief rents, quit rents, annuities, endowments, schoolmasters' falarics, charitable donations, &c.

Rent Days, the particular days or times when the rents of estates or farms become due. They fhould, in all cafes, be exactly and properly fixed as to feafon and other circumftances. See Rent.

Rent-Roll, a general fatement of the gros annual income of an estate, or receiverhip, whether it arises from farms, woods, lands, quarries, cottages, or any other fimilar things; or from tithes, quit rents, or any other fort of rents, &c.

In farming rent-rolls, this fort of general view of income is beft arranged, according to the writer of the work on Landed Property, in columns, as being the molt plain and perpicious; and for a fchedule of farms, the following heads are proper. First, the numerals identifying the feveral farms in the general map. Secondly, the names of the farms. Thirdly, the contents or admeafurement of each. Fourthly, the names of the prefent holders. Fifthly, the amount of the efling rents. Sixthly, the amount of the outgoing, if any payable by the proprietor. And, feventhly, the expirations of the terms, if any. The farms fhould be arranged according to their circumftances.

In the receiving of rentals, they are the particulars. These are few where the rents are regularly paid, the farms under proper management, and the holders pay the taxes and repairs. But it may be neceffary to fee in the receiver, at one view, the name of the farm, and the name of the holder, as well as the amount of his half year's rent.
And where arrears are suffered, and, of course, accounts created, more particulars are necessary, such as the name of the farm and the tenant, his arrear at the last payment, his half year’s rent, and any other charge that may be against him, as well as any allowance which is to be made to him, and the net sum that is receivable—a blank being left for the sum received, and another for the arrear left. These things should be done in the manner of the belt accountants, the arrangements being made in the same way as the rent-roll with an alphabetical index.

REN, in Geography, a lake of Albania, near Scutari.

RENTA, in Geography, a lake of Albania, near Scutari.

RENTAL, a roll in which the rents of a manor are written and let down, and by which the lord’s bailiff collects the rent; it distinguishes the lands and tenements, and the names of the tenants, the several rents arising, and for what time, usually a year. See Rent-Roll.

RENTER WARDEN, an officer in most of the companies of London, whose business is to receive the rents or profits belonging to the company.

RENTERBACH, in Geography, a river of Saxony, which runs into the Elbe near Witttenberg.

RENTERIA, a town of Spain, in Guipuzcoa; three miles S.E. of St. Sebastian.

RENTERING, Fine-drawing, in the Manufactories, the sewing of two pieces of cloth, edge to edge, without doubling them; so as that the seam scarcely appears at all; hence it is called fine-drawing.

The word is formed from the French, rentraire, which signifies the same thing; and which Menage, after Salmatisus, derives from the Latin, retabere, of re, in, and rabere, by reason the seam is drawn out of sight, and covered.

Serge, &c. are to be fewed: cloths fine-drawn. The author of one of the Lect. Edif. et Cur. speaking of the great dexterity of the fine-drawers in the East Indies, affures us, that if you tear a piece of fine muslin, and give it one of them to mend, it shall be impossible for you to discover the place where it is rejoined, even though you had made a mark to know it by.

The dexterity of our own fine-drawers, though inferior to that above-mentioned, is nevertheless such, as puts them in a condition to defraud the king, by sewing a head or slide of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so as to pass the whole, as of a piece; and by that means avoid the duties, penalties, &c. The trick was first discovered in France by M. Savary, author of the Diction de Commerce.

To render, in Tapestry, is to work new warp into a piece of tapestry damaged, eaten by the rats, &c. and on this warp to re-forest the ancient pattern, or design. The warp is to be of woollen, not linen. Among the titles of the French tapestry-makers, is included that of renters.

Fine-drawing is particularly used for a rent, or hole, happening in the dressing or preparing of a piece of cloth, artfully fowed up or mended with silk.

All finedrawings are reputed defects or blemishes; and ought to be allowed for in the price of the piece. Hence, M. Savary establishes it as a rule, which is certainly founded on natural equity, that every manufacturer mark the fine-drawings of his cloth with a piece of packthread tied to the lid; to direct the draper to the spot; that the draper apprise the tailor, or other person to whom he sells it, of the fame, that he may not come to damage in the cutting; there being instances of drapers condemned to take back their cloth, when cut to pieces, for omitting to mention the fine-drawings, and other flaws.

On this occasion, M. Savary extols the procedure of an English merchant, who, finding a piece of cloth damaged in one spot, to his correspondent at Paris, put a piece of gold in the damaged place, to make up the damage. But as this example is perhaps the only one of its kind, that author recommends it to the merchant, or draper, to unfold all the pieces entirely, as they come to him; to discover the fine-drawings, and other flaws; in order to make the clothier accountable for them.

RENTERSHAUSEN, in Geography, a town of the duchy of Wurzburg; 7 miles E. of Lauringen.

RENTOWN, a town of Scotland, in Dumbartonshire, for its manufactures; 5 miles W. of Dumbarton.

RENTRÉ, Fr. in Music, a return to the subject of a musical composition, after a pause, or some excursus or deviation from the theme; or in a fugue, an imitation of some particular passage or design.

RENTY, in Geography, a town of France, in the department of the Ais de Calais, on the Aa; 9 miles S.S.W. of St. Omer.

RENTZ, a town of the Island of Rugen; 11 miles S.S.W. of Bergen.

RENUENTES, in Anatomy, a pair of muscles of the head, thus called as being antagonists to the annutees; and serving to throw the head backward, with an air of refusal.

From their situation they are also called rectus capitis, major et minor.

RENVERSE, Fr. in Music. With respect to intervals inverted, this term is opposed to direct. (See Direct.) With respect to chords, it is opposed to fundamental; which see.

RENVERSE, inverted, in Heraldry, is when any thing is set with the head downward, or contrary to its natural way of standing: thus, a chevron renverse is a chevron with the point downwards.

The same term they also use when a beast is laid on its back.

RENVERSED VOLTE. See VOLTE.

RVERSEMENT, Fr. in Music, an inversion in the order of sounds which compose the chords, and in the parts which constitute the harmony: which is done by substituting, by octaves, treble notes for the base, and base notes for the treble. It is certain that every common chord has a fundamental and natural order pointed out by the harmonics of a single string, a great bell, or organ pipe. (See Harmonics, and Resonance.) But the circumstances of the counterfeits, the true, expression, selection of notes for melody, variety, approximation of the harmony, frequently oblige a composer to change this order, by inverting the chords, and consequently the disposition of the parts. As any three things may be arranged in fix different ways, and four things in twenty-four ways, it seems at first as if a common chord was susceptible of six changes, and an accompanied discord of twenty-four; as the one is composed of three sounds, and the other of four; and that the inversion only consists in the transposition of octaves. But it must be remembered, that in harmony a change in the upper parts is not regarded as an inversion, provided the base or fundamental found remains the lowest. Thus, these two orders of founds, C G S, or G S C, are not regarded as inversions of the harmony. And in the chord of the 7th no change in the upper parts constitutes an inversion.

As long as the fundamental found is the lowest part, the order is direct. But when this order is changed, or the fundamental found is given by transposition to one of the upper parts, the harmony is inverted. In whatever part a discord is prepared, it must be resolved by the same part;
a sharp 7th must ascend, a flat 7th must descend; false relations must be avoided. This is the key to the chief mysteries of composition. Binding notes in conjunction in the treble and base must be differently treated: in the 9th the chord is direct; in the 2d it is inverted, the discord being in the bass.

Upon the organ, and other keyed-instruments, inversions are necessarily made for the convenience of the hand, in giving different faces to the same chord. See Face.

RÉVERSING. See Reversing.

RENUKA, or RENUCA, in Mythology. See Runeka.

RENUCA, Renunciation, the act of renouncing, abdicating, or relinquishing any right, real or pretended. The act of relinquishing a right, &c.

Renunciations are sometimes expres, as by contracts, &c.; sometimes tacit, as by contrary acts. To renounce an inheritance, a community, &c. is to pass a solemn act before a notary, or public officer, by which a person declares he will not intermeddle in an inheritance, or profit in a company; but surrenders his part, and quits all pretensions.

RENVOI, Fr. in Music, a reference to a strain, or part of a strain that is to be repeated; either implied by dots in the spaces of the staff, or by an $\,$, dotted, which is the initial of signo, ital. a sign. See Repeat.

RENWÉZ, in Geography, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Mézières; 7 miles N.W. of Mézières. The place contains 1202, and the canton 6061 inhabitants, on a territory of 140 kilometres, in 16 communes.

REOLLE, L. a town of France, and principal place of a district, in the department of the Gironde. N. lat. 44° 35'. E. long. 0° 2'.

REORDERING, Reordination, the act of conforming orders on the already ordained.

The ceremony of ordination impresses what the divines call an indelible character; and cannot, therefore, be repeated: yet is reordination practiced in England, with regard to the dissenting ministers, who conform to the church; the bishops pretending that they alone have a right to confer holy orders, and that every priest or minister, who does not receive them at their hands, has no lawful or regular vocation.

This has formerly proved a great obstacle to the re-union of those ministers to the church of England; many of whom, otherwise disposed to conform, have scrupled to be reordered; insomuch as re-ordination implies their former vocation to be null; that they had administered the sacraments without any right thereto; and that all their ministerial acts were invalid.

In the 11th century, the crime of simony having been very flagrant, many people fell into the error to believe, that theimoniacal bishops could not ordain validly, and those who had received orders at their hands should be reordered. The people of this opinion made a party of themselves, and were distinguished by the title of "Reordinantes."

REORTHE, L. in Geography, a town of France, in the department of the Vendée; 13 miles W. of Châtaigneray.

REPAIR a Statue, To, or other piece of sculpture, is to touch up a statue, &c. (cast in a mould) with a chip, graver, or other instrument, to finish the places which have not come well off.

To Repair a Coffin, figure, or the like, they clear off the harp, and what is redundant in the joints and projections. See Statue.

To Repair a Medal, is to retouch it; so as, from rust and defaced as it was, to render it clean, neat, and perfect. In order to this, they take off the rust with a graver, touch up the letters, polish the ground, and raise and restore the figures which before were sometimes scarcely seen. When the figures are eroded or broken, they fit a piece of cement on the spot; and on this cut with a graver so dexterously, that the figures appear entire, and well kept; yet nothing spoils medals so much as repairing them. See Medal.

To Repair a Ship, is to amend any injuries, or supply any deficiencies, which a ship may have received by age, battle, tempestuous weather, &c. The repair is necessarily greater or smaller in proportion to the loss or damage the vessel has sustained. Accordingly a suitable number of the timbers, beams, or planks, or a sufficient part of either are removed, and new pieces fixed in their places. The whole is completed by burning, caulking, and painting the body with a new composition of clay.

REPAIRERS, artificers who chase figures and beauty word-hilts, &c.

REPAIRING, in Building, &c. See Reparation, and Restoration.

The repairing of large walls, doors, ceilings, coverings, &c. belongs to the proprietor or landlord: the tenant is only charged with small repairs, as glafs windows, locks, &c. by the French called locative repairs.

REPAIRS, in Hunting, are the haunts and places which the hare runs to.

REPAIRS of Farm Buildings, in Rural Economy, the necessary means of putting and keeping them in proper order. This properly belongs to different sorts of workmen, as masons, carpenters, &c. It is a bad practice to let buildings of this nature fall much into decay, as by such neglect a great deal of expense is frequently incurred that might otherwise have been avoided. See Farm-Buildings.

REPADUM Folioum, in Botany, a leaf whose outline is undulating, without the surface, or substance, being otherwise than even. See Leaf, where, for nephyoides, read nymphaeoid.

REPARANDIS Pontibus. See Pontibus.

REPARATION, Repartatio, the act of repairing, re-establishing, retrieving, or mending a building, or other work, damaged, or gone to decay.

The enemy repaired the breach as soon as it was made. The establishment of turnpikes is for repairing of the roads. An ecclesiastical patron is by ancient custom obliged to repair the choir or chancel of a church, and the parishioners the nave.

REPARATIONE Facienda, in Law, is a writ which lies in divers cafes, e. gr. where there are tenants in common, or joint tenants of a house, &c. which is fallen to decay, and the one being willing to repair it, the other two will not; in this case, the party willing shall have this writ against the other two.

REPARO, in Geography, a small island near the coast of Brasil. S. lat. 29° 23'.

REPART, in the Mange, is to put a horse on, or make him part a second time.

REPARTEE. See Repartie.

REPARTITION, Repartitio, a dividing or sharing a thing a second time.

REPARTY, or Repartee, a ready, smart reply; especially in matters of wit, humour, or raillery.

The word in the original French, repartie, has the same signification.

Wicquefort observes, that there is a great difference between
between a free, sprightly repartee, and an offensive farceum: which see.

REPA ST, REPASTUM, a meal or refection, taken at a flat rate hour.

In old law-books repast is particularly used for a meal's meat given to servile tenants, while at work for their lord. The French call their meal repas; the Latinus, poffus; the Italians and Spaniards, pofbo.

In antiquity the repasts were frequently sacrifices; for which reason we find them often prepared by kings themselves.

REPEALING, in Law, the revoking or annulling of a statute, deed, or the like. See Abrogation, Revocation, &c.

No act of parliament shall be repealed in the same session it was made in. A deed or will may be repealed for a part, and stand good for the rest.

Brook uses the word refellance in the same sense.

REPEAT, in Music, a character shewing that what was last played or sung must be repeated, or gone over again.

The repeat serves instead of writing the same thing twice over. There are two kinds of repeats; the great and the small.

The great repeat is only a double bar, dotted on each side; or two parallel lines drawn perpendicular across the staff; with dots on either hand. See its form under Characters of Music.

This mark shews, that the preceding strain is to be repeated; that is, if it be near the beginning of the piece, all hitherto sung or played is to be repeated; or, if towards the end of a piece, all from such another mark.

In gavots, we usually find the repeat at about the third part of a piece; in minuets, borees, courants, &c. towards the end.

Some make this a rule, that if there be dots on each side the bar, they direct to a repetition both of the preceding and the following strain; if there be only dots on the side, then only the strain on that side is to be repeated.

The small repeat, is where only some of the last measures of a strain are to be repeated: this is denoted by a character over the place where the repetition begins (see Characters in Music), and continues to the end of the strain.

When the song ends with a repetition of the first strain, or part of it, instead of a repeat, they write the word du cape, i.e. from the beginning.

REPEATING Circle, an instrument used in Navigation, Astronomy, and Surveying. This instrument derives its name from the property it has of giving the average of several repeated measurements of an angle, made round the whole circle, so as to diminish the errors of division and of excentricity; which is a very useful property, where the art of dividing is not brought to that perfection which it is in England.

When the lunar method of determining the longitude, by the help of improved tables of the moon's motion, was proposed to be put in practice, Mayer offered a construction of the circle, by which, by repeating the measure of a lunar distance, repeated to increase the accuracy with which such distance could be measured; and after him, Borda went a step farther towards the attainment of the desired object, both whose contrivances we have described under our article Circle.

These instruments, like Hadley's octants, measured the angles by reflection, and were consequently used at sea; but the principle of repetition is not confined to reflecting instruments: and Borda contrived, or contrived the construction of, a repeating circle, which will measure either vertical or horizontal angles without reflection, with a degree of accuracy that has placed it high in the estimation of the French, among whom accurate dividing is yet a defideratum. This instrument we have also described, and likewise Troughton's improvement on it, in the article already referred to.

But the repeating principle was extended by Joseph de Mendoza Rios in the reflecting circle, so as to measure both backwards and forwards, and to give double results by means of a moveable or flying circle, which we have likewise described under the article Circle, together with our observations on the peculiarities of its construction. It remains, therefore, that we now describe a recent construction of reflecting and repeating circle, contrived by professor Hafler of Philadelphia, who is a native of Switzerland, and who has resided several months in London, for the purpose of collecting superior astronomical and surveying instruments, at the expense of the American government. The object of this ingenious foreigner was to unite the repeating principle of Borda, with the firm construction of Troughton's reflecting circle, so that his new instrument might be free from the objections of the repeating circles that preceded it, arising from shallow centre-work, and clamping after the contacts were made in an observation; and in the construction which he has adopted, by the aid of Troughton, he has rendered his instrument free from those objections, and given it every advantage which its original contriver contemplated: we cannot, however, admit, that in practice it is superior in accuracy, and certainly not in simplicity, to Troughton's reflecting circle, which we have before described, as giving the average of six readings at two operations, in inverted positions, at the different sides of zero on the fixed circle. The union of Borda's and Troughton's constructions is thus effected by Hafler; the circular border of Troughton's instrument is made moveable round the centre, like his three armed verniers, and is grasped like his, while a pair of opposite verniers move round the same centre, above the plane of the moveable flying circle, having a clamping apparatus for flow motion at one of the two opposite verniers, so that the pair of verniers may be made to revolve with or without the graduated flying circle; another pair of verniers, similar to the former, and having also a clamping apparatus for flow motion, are made fast to the frame, and have the extreme ends of their connecting diametrical bar united by a graduated semicircle, that lies under the flying circle, and is hid thereby when the graduated face of the circle is uppermost; the use of this semicircle, is to receive a pair of sliding pieces of brass that act as stops to the indices, when they are properly placed at the rough angle, to the right and left of zero on the flying circle, by a previous operation; so that, when the bar of the verniers one of in contact with either of these stops, it is known, even in the dark, that the place where a contact is to be made is nearly ascertained, and the vernier-bar may be made fast, for the screw of flow motion to be brought into action to complete the contact. The principle on which the measurement is effected is this: the revolving verniers move forward from zero of the graduated circle, when the stops are previously let to the rough angle, till the index or vernier-bar touches the stop to the left, when the graduated face is uppermost, and is clamped to the fixed verniers; the clamping apparatus then fixes the verniers, and the tangent-screw completes the contact; the two revolving verniers might now give the angle, by two readings, but the repeating principle has not yet been introduced, and consequently no advantage is yet derived from this first observation, over a common circle with a double vernier; the fixed verniers are in the next place unclamped, but as they have no motion, the flying circle and revolving verniers are brought back to the right together, across the point zero,
till the vernier-bar touches the second flop, and during this motion, the revolving verniers have moved backwards just double the rough distance with the attached circle, that they did forwards before without it; consequently the fixed verniers will now read the same angle at the right of zero, that the revolving verniers did on the left, when the clamping was again made and the contact completed; but still this is only a second mode of reading a single measure of the angle, and nearly all that is yet gained in accuracy, is the examination of the index error, and that of the dark glas, if used; these errors having been alternately positive and negative, if any existing. These two measures, separately read, are equivalent to Borda's croffed observation, as he calls it, because the motion of the vernier-bar crofes the point zero in his fixed circle: here it is presumed that the two objects, that include the angle, are equally luminous; but if not, it will be necessary to invert the face of the instrument before each second, fourth, fifth, &c. contact, and then the motions will all be forward, or from right to left, which otherwise would be alternate: the second reading, however, may be omitted; the revolving verniers, being unclamped, must be moved again to the first flop in the original position, where, the contact being complete, they will give a double measure if examined; but the readings are yet omitted: the fixed verniers are now unclamped, the instrument again inverted, and the contact completed, when these verniers, if examined, will also give double measures; and thus triple and quadruple measures must be had successively at both the revolving and fixed verniers, or even more, if the circle has not been paffed over by each pair of verniers, before the readings are required to be examined, and then the average of all the measures by the fixed verniers, added to an average of all the measures by the revolving verniers, will afford the means of getting an average of the whole number of measures.

From this description of Hafsler's mode of applying the repeating principle, it will be obvious to the reader, that the diametrical bars of the two pair of verniers must not be contiguous to each other, when the glasfs called the horizon-glafs and index-glafs are parallel; and accordingly we find, on examining an instrument of this construction, that these bars crofs one another at right angles before the operations begin; but as there is but one zero in the circle, one pair of the verniers must necessarily begin at 90°, when the other pair begins at 0°; consequently ninety degrees must be deducted from the sum of the measures of this pair before their average is taken: otherwise, if neither pair of the verniers begin at zero, the two numbers from which they respectively come must both be deducted before the averages are taken, in which case it will be of no importance at what part of the flying circle the operations begin. Should the reader find any difficulty in comprehending this description of Hafsler's repeating circle, without a reference to a drawing, we recommend that he refer to our account of reflecting circles, described under the article CIRCLE, where he will find the account of the two separate instruments of which this forms an union; and at the same time will see how it differs from Mendoza's, which gives double results.

By way of illuftrating the use of Hafsler's repeating circle, we will suppose that force known liar is to the cell or well of the moon, and that the longitude of the place of observation is required from an actual measurement of the distance of the said liar from the moon's limb, when compared with its computed distance as given for a certain hour on the fame evening at Greenwich, in the Nautical Almanac: we will suppose the glasfs of the circle adjusted, and the small telescope ferewed into its socket, and so adjusted both for distinct vision, and comparative brightnes of both objects, that the liar can be brought to touch the moon's limb, and have a teable contact; in this place, hold the plane of the circle in such an inclined position that it may pass through both objects, and get the liar into the field of view, while the revolving verniers are at zero, and the fixed ones clamped at 90°; in the next place, move the revolving verniers with an equable motion, and let the eye follow the liar, or rather the image of it, till it comes to the edge of the moon, which it may be made to approach by a proper motion of the body; then clamp the index there till the flop is put on the semicircle very nearly to touch the edge of the index, where it must remain; the second flop must alfo be put to the fame division on the semicircle at the other side of its zero, provided this zero be co-incident with the zero of the circle; or, which is the fame thing, the distance between the flops must be somewhat more than double the angle to be measured; the contact may now be completed by the tangent-fcrew; let the fixed verniers be unclamped, and the releafe circle and revolving verniers be made to recede together till the second flop gives them a check, there they must be clamped and the circle inverted, when the liar will again be seen nearly in contact, which must now be made entirely to by the screw of flow motion; in the next place the moveable verniers, being first unclamped, must be carried again to the first flop and clamped, to make the contact as before, after the inversion of the circle has again taken place; and in this manner the revolving verniers must be moved to the first flop, and the verniers and circle together to the second flop, before each inversion and contact, till five, six, seven, or more alternate operations have been gone through, and the whole circle has been travell'd over, which may always be known from the position of the flops. The exact times must be noted at the beginning and end of these operations, which by an expert observer will be gone through in a few minutes, and the mean time will be had of the moment correfponding to the mean of the repeated observations: at these times the affiliants must alfo take each their two altitudes. Say now that the flops were required to be nearly at 40° at each side of zero of the semicircle, or that the diftance between them was 60°, within a few minutes over, and that there were nine observations thus made with the revolving verniers, and eight with the fixed ones, which numbers fuppofe the firft and laft measures to be taken with the fame pair of verniers, or with the fame face of the circle uppermost; say also, that the final readings by this pair of verniers were respectively 1° 10' 20", and 181° 10' 0", or rather 368° 10' 20", and 541° 10' 0", because these verniers completed the entire circle; then if we diminish the latter reading by 180°, its diftance before the other, we shall have 361° 10' 20", and the average of the pair of opposite verniers will be 308° 10' 10", which quantity divided by 9, the number of measures taken by them, will give a quotient of 40° 8' 8":9. For the average of the diftance, resulting from the operation of the revolving verniers alone; again, let the final readings of the fixed verniers be respectively 50° 57' 30", and 234° 57' 30", but if we increase the first reading by 360°, we shall have 410° 57' 20", which must be diminished by 90°, because it farterd from this number, and the remainder will be the correct reading, namely 320° 57' 20"; also 230° 57' 30" increased by 360° is 590° 57' 30", and this number diminished by 90°, as before, and then by 180°, the diftance which it precedes its fellow-verniers, will be 320° 57' 30", and consequently the average of the two final readings of the fixed verniers will be 320° 57' 25", which sum divided by 8, the number of repeated.
Sir Isaac Newton computes, that the attractive force of the rays of light is above 10000000000000 times as strong as the force of gravity on the surface of the earth: hence arises that inconceivable velocity with which light (if it consist of real particles) must move, to reach from the sun to our earth in seven minutes. For the rays emitted from the body of the sun by the vibrating motion of its parts are no sooner got without the sphere of attraction of the sun than they come within the action of the repelling power.

The catlectricity or springiness of bodies, or that property by which, after having its figure altered by an external force, they return to their former figure, follows from the repelling power. See Repulsion.

REPENTANCE, in Theology, is a change of sentiments followed by a change of conduct; or repentance denotes such a conviction of the evil and danger of a sinful course, as is sufficient to produce flame and sorrow in the review of it, and effectual revolutions of amendment. This definition expresses the sense of the two words μετανοια and μετανοια, which are commonly used by the evangelical writers to signify repentance.

REPENTIGNY, in Geography, a town of Canada, on the river St. Lawrence. N. lat. 45° 43'. W. long. 73° 15'.

REPERCUSSION, in Mechanic. See Reflection.

REPERSION, in Music. Iteration, a repetition of the same note or sound.

This often happens in the modulation, where the essential chords of each mode, or of the harmonical triads, are to be struck oftener than the rest; and of these three chords, the two extremes, i.e. the final and the predominant one, (which are properly the repercussion of each mode) oftener than the middle one.

REPERNDORF, in Geography, a town of the duchy of Wurzburg; 7 miles S.E. of Wurzburg.

REPERTORY, Repertorium, a place in which things are orderly disposed, so as to be easily found when wanted.

The indices of books are repertories, shewing where the matters sought for are treated of. Common-places are a kind of repertories, very useful to the learned.

Repertorium Anatomicum, denotes a large hall near an amphitheatre of dissections, where skeletons, both human and brutal, are ordered precedence. Such is the repertory in the French king’s garden at Paris.

REPENTEND, in Arithmetic, is used for that part of an indeterminate or infinite decimal fraction, which is continually repeated ad infinitum.

Thus, in the indeterminate decimal fraction 317.45316316316, &c. the figures 316 are called the repetend.

These repetends often arise in the reduction of vulgar fractions to decimals, thus $\frac{1}{3} = 0.3333, \text{ &c.} = \frac{1}{3}\times 33.333\overline{3}$.

Decimals of this kind are called repeating or circulating decimals, (which see,) on account of this continual repetition or circulation of the same figures. Infinite decimals are of two kinds, which may be distinguished by the general denominations of certain and uncertain. A general infinite decimal is such whose numerator runs into infinity by a continual repetition of one or more figures, as $\frac{1}{44} = 0.090909\ldots, \text{ &c.}$ Uncertain decimals are such, whose numerator goes on for ever without a confinable circulation of figures. The essential difference between these two kinds is this; that the certain infinite decimals have a determinate, finite, and certain value, in that there is a certain determinate vulgar fraction, which expresses the true and complete value of that infinite decimal, whereas the uncertain have no such finite and assignable value; and hence the reason of the names.
REP

Repitend, Single, is that where only one figure is repeated, as in o. 3 3, &c.

Repitend, Compound, is that where two or more figures are repeated, as in o. 09 09, &c. or in o. 142857 142857, &c.

Decimals with repetends may always be reduced to vulgar fractions; for either the repetend begins with the decimal, or not.

If the repetend begins with the first place of decimals, or if the decimal is a pure circulate, make it the numerator of a vulgar fraction, and make the denominator consist of as many 9's as the repetend has figures; or if there be cyphers between the point and repetend, with as many cyphers to the right hand of the denominator, then will this vulgar fraction be equal to the decimal.

Thus, if the repetend be single, as in o. 3 3 3, the vulgar fraction equal to it will be \( \frac{3}{9} = \frac{1}{3} \). So if the repetend be compound, as in o. 09 09, &c. the equivalent vulgar fraction will be \( \frac{09}{99} = \frac{3}{11} \).

And in like manner o. 142857 142857, &c. = \( \frac{142857}{999999} \) = \( \frac{1}{7} \).

The reason is obvious from this consideration, that the decimal o. 3 3 3, &c. = \( \frac{3}{9} + \frac{3}{9^2} + \frac{3}{9^3} + \&c. \), the sum of which will be equal to \( \frac{1}{3} \) divided by \( 1 + \frac{1}{9} = \frac{1}{8} \); and fo of the rest.

If the repetend does not begin with the first place of decimals, but at some place farther on towards the right, or if it be a mixed circulate, as in the decimal o. 8 3 3 3 3, &c. where the repetend does not begin till the second place of decimals, observe, that o. 8 3 3 3 3 + &c. = \( \frac{8}{9} + \frac{3}{9^2} + \frac{3}{9^3} + \&c. \). And \( \frac{8}{9} + \frac{3}{9^2} + \&c. = \frac{8}{7} \), as before; therefore the proposed decimal is \( \frac{8}{7} + \frac{3}{9^2} + \frac{3}{9^3} + \&c. = \frac{24}{30} + 1 \)

\( = \frac{24}{30} = \frac{4}{5} \).

Thus also if the decimal o. 2 27 27, &c. were proposed, we shall find it \( = \frac{2}{9} + \frac{27}{9^2} + \frac{27}{9^3} + \&c. \). And \( \frac{2}{9} + \frac{27}{9^2} + \&c. = \frac{2}{9} \), the decimal will be \( \frac{2}{9} + \frac{27}{9^2} + \frac{27}{9^3} + \&c. = \frac{22}{110} = \frac{1}{5} \).

The reason of which is obvious from what has been said.

It may, perhaps, be worth while to observe, that if the numerator of a vulgar fraction be unity, and the denominator any prime number, except 2 and 5, the decimal equal to the proposed fraction will always be a repetend, beginning at the first place of decimals; and this repetend must necessarily be a submultiple, or an aliquot part of a number expressed by as many nines as the repetend has figures; that is, if the repetend have fix figures, it will be a submultiple of 999999; if four figures, it will be a submultiple of 9999, &c. From whence it follows, that if any prime number be called \( p \), the series 9999, &c. produced as far as is necessary, will always be divisible by \( p \), and the quotient will be the repetend of the decimal fraction \( = \frac{1}{p} \). For the management of decimals of this kind, see Malcolm's Arithmetic, book v. chap. 4.

REPETITION, Repetito, the repeating of an action. See Reiteration.

Habits are acquired by the frequent repetition of actions. School-philosophers call the repetition of the same numerical effect, in another place, the repetition of that effect.

REPETITION. The French make use of this word for a rehearsal, which the Italians call a prova. " Rehearals (fays Rouffeau) are necessary for compositions that are to be performed in public, in order to prove whether the several parts are correctly copied, and for ascertaining the entrances and the exits of the several characters, as well as to see that they seize the spirit of their parts, and of the entire drama. Rehearals are likewise of use even to the composer himself, to enable him to judge of effects, and to make such changes as may seem necessary."" 

REPETITION, in Music, denotes a repetition or playing over again the same part of a composition, whether it be a whole strain, or part of a strain, or a double strain. The repetition is denoted by a character called a repeat; which is varied so as to express the various circumstances of the repetition.

REPETITION, Reply, is also used when, after a little silence, one part repeats or runs over the same notes, the same intervals, the same motions; in a word, the same song, which a first part had already gone over during the silence of this.

REPETITION, Reply, is also a doubling or trebling, &c. of an interval, or repetition of some concord or discord.

Thus, a fifteenth is a repetition of the octave, i.e. a double octave, or second octave.

REPETITION of Passages. See Rosalia.

REPETITION, in Rhetoric, is a figure by which the orator reinforcing the same words or phrases over again.

Of this there are two kinds. In the first, the word is repeated precisely in the same sense: as, Ob, Jerufalem, Jerufalem, who killeth the prophets, &c. My God, my God, why hast thou forsaken me?

Such repetitions have the same effect in discourse, with second strokes of the pencil in writing; they render the colours more strong and lively.

Sometimes the orator begins again and again with the same word, of which we have an instance in the beginning of Cicero's first oration against Catiline: "Nihilus nostrum praefidium palatium, nihil urbis vixitulis, nihil timor populi, nihil consenfus bavarum omnium, nihil hic magnifus haudini fanatus loci, nihil in usq velutique moveri? Where the word nihil so often reiterated gives an admirable force and vehemence to the discourse. Again, the same author: Quem fanatus damnatris, quem populus R. damnatris, quem omnium eftinuam damnatris, cum nos detentitus effris abfolvet? Again, Non faram, non patiam, non fume. The second kind of repetition, called repeating, place, (which see) is a repetition of the same word in the same phrase; but in such a manner, as that some new idea or character is added to the word in the second, which it had not in the first.

As, Corydon is always Corydon: E e illo Corydon Corydon fest tempore nobis; by which we signify, that Corydon is no ordinary person; and that nothing can dishonour him but the repetition of his own name: as if we should say, he is Corydon, that is enough. By the fame figure our Saviour speaks, when he says: Let your language be yes, yes; and no, no. See Recapitulation.

REPETITUM, or Vehitum Namium, in Law. See Namum.

REPHEM, or Reepham, in Geography, a market-town and parish in the hundred of Eynsford, and county of Norfolk, England, is situated at the distance of 13 miles N.W. by N. from Norwich, and 112 N.E. by N. from London. The charter for its market, which is held on Saturday weekly, was obtained by sir John de Vaux, in the fifth year of the reign of king Edward V. An annual fair, on the 29th of June, was granted at the same time. At one period this parish was remarkable for having three churches situated within one fenrical inclosure; e.g. Reepham, Whitwell, and Hackford; but only two of these are now standing.
The church of Reepham serves also for the village of Kerdelton, which belongs to the same lords. In this edifice was formerly a "famous image of the Virgin Mary," which, like the shrine of Diana at Ephesus, was productive of no small gains to its possessors; numerous pilgrimages having been made to it by persons of rank and influence. Here are several monuments to the memory of different branches of the Kerdelton family. One of them, placed against the north wall of the chancel, bears the figure of a knight templar in armour, with his hands and legs crooked. It has no inscription, but is traditionally said to have been raised in honour of Sir Falk de Kerdelton, who died in 1270. Blomefield's History, &c. of Norfolk. Beauties of England and Wales, vol. xi. by John Britton. F.S.A.

REPIN, a river of Poland, which runs into the Dnieper, near Kiev.

REMITZ, or Ropitz, a town of Saxony, in the margravate of Meißen; 2 miles N. of Torgau.

REPLANTING, in Gardening, the act of planting a second time. The gardeners used to dislant their tulips every year, and replant them. Lettuces must be displanted and replanted yearly, to make them head and knit. If strawberries, &c. be not displanted and replanted once in a few years, they degenerate.

REPLEADER, REPLICAIRE, in Law, is to plead over again what was once pleaded before.

If, by the misconduct or inadvertence of the pleaders, the issue be joined on a fact totally immaterial, or insufficient to determine the right, so that the court upon the finding cannot know for whom judgment ought to be given, the court will after verdict award a replacer, qui partes replicant; unless it appears from the whole record that nothing material can possibly be plead in any shape whatsoever, and then a replacer would be fruitless. (4 Dab. 301, 302.) And whenever a replacer is granted, the pleadings must begin de novo at that stage of them, whether it be the plea, replication, or rejoinder, &c. in which there appears to have been the first defect, or deviation, from the regular course. Raym. 453. Salk. 570.

REPLEGIANDO, in Homine, Writ to. See HOMINE.

REPLEGiare de Avoiris, a writ brought by one whole cattle are dislained, and put in a pound, by another; upon security given the sheriff to pursue, or answer the action at law against the dislainer.

REPLETION, in the Canon Law, is where the revenue of a benefice or benefices is sufficient to fill or occupy the whole right or title of the graduate who holds them. When there is a repletion, the party can demand no more by virtue of his degrees. In England, where benefices are not appropriated to degrees, repletion, strictly speaking, has no place.

In France, by the old constitution, 600,000 livres, or 437. fothering per annum, made a repletion, when the benefice was obtained otherwise than by a degree; and 300. per annum, when it was obtained by virtue of a degree.

REPLETION, in Medicine, sometimes signifies the general failure of the habit, which is called plebriasis; and sometimes the temporary overloading of the stomach with food and drink, which occasions particular attacks of disfave, such as a fit of apoplexy, or of the gout, or a diarrhoea.

REPLEVIN, PLEVIN, in Law, a remedy granted on a dislainer; being a re-delivery of the goods dislained to the first polleflor, on security or pledges given by him to try the right with the dislainer, and answer him in the course of law.

If a person dislay another's goods or cattle for rent, or damage seashore, &c. the owner, upon giving security to the sheriff, that he will prosecute his action against the party dislaining, and return the goods or cattle again, if the sheriff shall be adjudged good, may have a writ of replevin or replegiari faciat. See DISTRESS and REPLEVY, infra.

REPLEVISI{H}, is to let one to mainprise upon surety. See MAINPRIZE.

REPLEVY, REPLICAIRE, (from the Latin replegiari, to re-deliver to the owner upon pledges of surety,) is the bringing of a writ of replevin or replegiari faciat, issuing out of chancery, by him whose cattle or goods are dislained by another upon any cause; having first given security to the sheriff, that, on the delivery of the cattle or goods, he will prosecute the action against the person who made the dislais.

In the plat. 24, Henry VIII. we read of canes repligianti, or bona replicata, in a case between the abbate of St. Alban's and Geoffrey Childwise.

Goods may be repleved in two ways; viz. by writ, which is that used by the common law; and by plaint, which is that by statute law, for the more speedy having again the cattle and goods; and is brought in the sheriff's court.

Accordingly, the statute of Marlbridge (52 Hen.—III. cap. 21.) directs, that (without suing a writ out of chancery) the sheriff, immediately upon complaint made to him, shall proceed to replev in the goods. And, for the greater ease of the parties, it is further provided by statute 7 P. & M. cap. 12, that the sheriff shall make at least four deputies in each county, for the sole purpose of making replevins.

Upon application, therefore, either to the sheriff, or one of his paid deputies, security is to be given, in pursuance of the statute of Waltham. 2. 13 Edw. I. cap. 2. 1. That the party repleving will pursue his action against the dislainer; for which purpose he puts in plagias de profectando, or pledges to prosecute and, 2. That if the right be determined against him, he will return the dislais again; for which purpose he is also bound to find plagias de returno habendo. Besides these pledges, which are merely discretion ary in the sheriff, the statute 11 Geo. II. cap. 19, requires, that the officer, granting a replevin on a dislais for rent, shall take a bond with two sureties, in a sum of double the value of the goods dislained; which bond shall be given to the avowant or perfon making cognizance, on request made to the sheriff; and, if forfeited, may be fixed in the name of the assignee. The sheriff, on receiving such security, is immediately, by his officers, to cause the chattels taken in dislais to be restored into the possession of the party dislained upon; unless the dislainer claims a property in the goods so taken. If this be the case, the party repleving must lose out a writ de propriate profectando. But, if no claim of property be put in, or if (upon trial) the sheriff's inquest determines it against the dislainer, then the sheriff is to replev in the goods, if they be found within his county. When the goods are delivered back to the party repleving, he is then bound to bring the action of replevin, which may be prosecuted in the county court; but either party may remove it to the superior courts.

REPLICATION, REPLICAIRE, in Logic, the asuming or using the same term twice in the same proposition; otherwise called reduplic Vere.

Some philosophers use the phrase replatio mundi, replication of the world, for its conversion, or turning round. The human soul is said to be in a place replicativius, replication, when conceived to be all in the whole, and all in every part of it.

REPLICATION, in Law, is an exception of the second de-

T. 2
gree, made by the plaintiff to the plea or first answer of the defendant.

The replication is particularly that which the plaintiff replies to the defendant's answer in chancery; and which is either general or special. The special is grounded upon matters arising out of the defendant's answer, &c. The general is so called from the general words used in it. See REJOINER, and CONFESS and avoid.

REPLIQUE, Fr. in Mufc. This term, which implies an octave, has been, not very happily, rendered into English by replicheate, in the wretched translation of Racan's treatise; but though it has been generally adopted, it has never been properly naturalized to our language. Sir Francis Bacon has used the word recurrence for the same purpose, which is much more congenial with our idiom. There is necessarily a repetition of the same found, or its octave, in every composition of four parts.

REPlot, in Geography, one of the Quarken islands, in the gulf of Bothnia. N. lat. 63° 15'. E. long. 210° 7'.

REPOLON, in the Manege, is a demi-volte, the croupie in, cleft at five times. The Italians are extremely fond of this sort of manage. In making a demi-volte, they ride their horses short, so as to embrace or take in let's ground, and do not make way enough every time of the demi-volte.

REPOLOVSKOI, in Geography, a town of Ruffia, in the government of Tobolks, on the Irtilch; 171 miles N. of Tobolks.

REPONSE, Fr. in Mufc, the answer to a subject of fugue. The answer to a fugue, and the time when it is to be introduced, are difficulties in the art of regular fugue, concerning which contrapuntists are long doubtful. See FUGUE and COUNTER-SUBJECT.

REPORT, the relation made upon oath, by officers or persons appointed to visit, examine, state, or estimate any thing.

Damages, repairs, &c. are judged from the reports of experienced persons. Provvis for persons wounded are only granted on the reports of surgeons, &c.: in cases of rapes, a report of matrons is to be had.

Report, in Law, is a public relation, or bringing to memory, of cases judicially argued, debated, resolved, or adjudged, in any of the king's courts of justice, with the cause and reason of the same delivered by the judges. They are histories of the several cases, with a short summary of the proceedings, which are preferred at large in the record, the arguments on both sides, and the reasons the court gave for its judgment: taken down in short notes by persons present at the determination; these serve as indexes to, and also to explain, the records.

These reports, which in matters of consequence and nicety the judges direct to be searched, are extant in a regular series from the reign of king Edward II. inclusive; and from his time to that of Henry VIII. were taken by the prothonotaries, or chief serives of the court, at the expense of the crown, and published annually; whereas they are known under the denomination of the "Year-books." And it is much to be wished (says Judge Blackburne) that this beneficial custom had, under proper regulations, been continued to this day; for though King James I., at the instance of lord Bacon, appointed two reporters, with a hard- fome stipend, for this purpose, yet that wise institution was soon neglected; and from the reign of Henry VIII. to the present time, this talk has been executed by many private and contemporary hands; who sometimes through haste and inaccuracy, sometimes through mistake and want of skill, have published very crude and imperfect (perhaps contradictory) accounts of one and the same determination. Some of the most valuable ancient reports are those published by lord chief justice Coke, which are so highly esteemed, that they are generally cited without the author's name; and are filed \( \textit{ad initium} \), the reports. The reports of judge Coke are also cited in a particular manner, by the name of those princes in whose reigns the cases reported in his three volumes were determined, e. g. queen Elizabeth, king James, and Charles I., as well as by the number of each volume. Blackft. Com. book i. &c.

When the chancery, or any other court, refers the rating of some cause, or comparing an account, &c. to a matter in chancery, or other referere, his certificate therein is also called a report.

REPORTS, in Military Matters, are daily, weekly, and monthly reports of the state of the companies or regiments, relative to their being present or absent, on duty, sick, confined, &c.

General officers report to the commander-in-chief only. The commander-in-chief's guard reports to himself by one of his aide-de-camps. Reports of cavalry are given in to the general officers of cavalry; and reports of infantry to the general officers of infantry. On a march the field officer of the piquet reports to the general of the day who leads the column; and in camp to the next superior officer to himself. A provost martial gives in his return of prisoners, and reports to the general of the day.

Deputy judges advocate, acting in districts or garrison, &c. lend in the minutes of courts martial, and report to the judge advocate general, without going through any general officers. Regimental surgeons report to their commanding officers, and surgeons in districts, &c. to the medical board.

The life-guards report, through the Gold Stick, to the king direct, from whom they receive the parole.

The foote-guards report, through the field officer of the day, to the King direct.

All other troops belonging to the British service, the marines excepted, who report to the admiral, report through their several commanding officers, &c. to the adjutant-general and secretary at war, and to the commander-in-chief.

A special report is said to be made when the name of an officer is transmitted by his commander to the general of a district, independent of the regular returns; and some specific instance of misconduct is laid before him. It must be generally remembered, that every officer, on his arrival from abroad with a regiment or detachment of troops, must report himself to the governor or commanding officer of the place at which he arrives; and every officer who takes his pay from foreign service, must do the same previous to his departure.

The senior officer in each recruiting quarter reports weekly to the field officer of the district, the number and strength of the parties therein. The field officers commanding recruiting parties in districts, report to the inspector-general, to whom all returns and reports are to be transmitted by them, and not direct from the recruiting officers.

The various subordinate reports are those of a rear- guard, of a guard, of a quartermaster, of a main-guard and its dependencies, &c. &c.

In the column of remarks which must accompany each of these reports, it is necessary, for the peron who signs, to specify all casualties and extraordinary occurrences according to the particular nature of each report. The different hours at which the grand rounds, visiting rounds, and paroles are given, must likewise be put down.

REPORT, Pinion of. See PINION.

REPOS, Fr. in Mufc. a repose, or pause. It is the termi-
REPOSE, in Poetry, See Rest, Pause, 

REPOSE in Painting, is applied to certain mallees, or large figures in allegories of light and shade; which, being well conducted, prevent the solution of objects and figures; by engaging and taking up the eye so as it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groups gradually, and, as it were, to proceed from flage to flage.

REPOSE, in Military Language, is a phrase that applies to troops which are allowed to be stationary for any given period, during an active campaign, either through sickness, or from some other cause.

REPOSITION of the Forest (formed from re, and ponere to lay again), an act by which certain grounds, before made purblind are, upon a second view, laid to the forest again.

REPOSITION in Surgery, the reduction of a bone.

REPOSITORY, Depository, store-house or place where things are laid up and kept. In which sense we lay, the repository of the royal society, the royal repository at Woolwich, containing models of every sort of warlike stores, &c. See Museum.

REPOSITORY of Farm Manure, in Rural Economy, the place where it is put or laid up. See RECEPTACLE of Stoll Manure.

REPOSIO, in Geography, a small island near the coast of Brail; S. lat. 19° 36'.

REPPELE, a town of Hinder Pomerania; 7 miles W.S.W. of Zachau.

REPPIIN, a town of Brandenburg, in the New Mark, on the Eylan; six miles S.S.W. of Droffen, N. lat. 52° 25'. E. long. 15° 2'.

REPREHENSION, in Rhetoric. See PARRHESIA.

REPRESENTATION, Representation, in the Drama, the exhibition of a theatrical piece; including the scenes, machines, recitation, &c.

Sir Richard Steele's principle is, that the design of a play is not to be read but represented; so that it is on the stage, not in the press, it is to be judged of; and that the pit not the public, are the proper judges.

REPRESENTATION, in Insurance, is understood to mean a collateral statement, either by parol or in writing, of such facts or circumstances relating to the proposed adventure, and not included in the policy, as are necessary for the information of the insurer, to enable him to form a just estimate of the risk. Such representations are often the principal inducement to the contract, and afford the best ground upon which the premium can be calculated. A representation may be untrue, either wilfully and fraudulently; or inadvertently and innocently.

A wilful misrepresentation, or allegata falsa, in any fact or circumstance material to the risk, is a fraud that will always avoid the contract. As if an agent, knowing that a ship had failed from Jamaica for London on the 24th of November, effect an insurance on the voyage, and tell the underwriter that the ship failed in December; this is a fraud, and the policy is void.

And such misrepresentation to completely vitiate the policy, that the injured cannot recover upon it, even for a

lofs arising from a cause unconnected with the fact or circumstance misrepresented. As if the injured represent that the ship or goods insured are neutral property, when in fact they are enemy's property; he shall not recover even for a

lofs occasioned by shipwreck.

So it would be if the broker or agent were to affect that a ship or goods were neutral property, without knowing whether this was true or false, and they are, in fact, enemy's property: for, though it may not, perhaps, be equally criminal in foro conscientiae for a man to aver that to be true which he knows nothing of, as to aver that to be true which he knows to be false; still it is unquestionably a fraud, and in the case of an insurance, equally injurious to the underwriter; because he is induced by the deception, however occasioned, to compute the risk upon false principles. The same reasoning holds even in the case where the person himself making the representation believes it to be true.

But if he were only to say that he believes the ship to be neutral property, knowing nothing on the subject, and having no reason to believe the contrary; there, though the ship be not neutral, the representation will not avoid the policy; because the under-writer may infer himself of the grounds of this belief, before he enters into the contract; and if he neglect to do so, he takes upon himself the risk of its being unfounded.

For the same reason, if the word expected be used, this will not amount to a representation: as when a broker in getting insurances effected on several ships, belonging to the same owner, and speaking of them all, said, 'Which vessels are expected to leave the coast of Africa in November or December,' when, in fact, they had all failed in the May preceding; this does not amount to a representation, being only an expectation, the ground of which the under-writer might have enquired into.

There is a material difference between a representation and a warranty. A warranty, being a condition upon which the contract is to take effect, is always a part of the written policy, and must appear on the face of it: whereas a representation is only matter of collateral information or intelligence on the subject of the voyage insured, and makes no difference in the face of the policy. A warranty, being in nature of a condition precedent, must be frigidly and literally complied with, but it is sufficient if a representation be true in substance. A warranty, whether material to the risk or not, the injured takes his claim of indemnity upon the precise truth of it, if it be affirmative, or upon the exact performance of it, if executory; but it is sufficient if a representation be made without fraud, and be not false in any material point; or if it be falsefondly, though not literally, fulfilled. A false warranty avoids the policy, as being a breach of a condition upon which the contract is to take effect, and the insurer is not liable for any loss though it does not happen in consequence of the breach of the warranty. A false representation is no breach of the contract, but if material, avoids the policy on the ground of fraud, or at least because the insurer has been misled by it.

It has already been shown that a warranty must appear upon the face of the policy, and make a part of the written contract, and therefore a written paper, wrapped up in the policy, or even waivered to it, is only a representation. For the same reason, the written instructions for effecting the policy, unless inserted in it, cannot be deemed a warranty, but only a representation; for the under-writer, by not insisting on having these instructions inserted in the policy, shows that he is content to take them as a representation.
 But it behooves all agents and brokers concerned in the effecting of policies, to keep correct entries of these instructions, and indeed of all representations made to the under-writers; for the whole question between the insured and the under-writers often turns upon these instructions. Besides, they are answerable to the insured for the consequences of any representation made by them without authority, as well as for those of omitting to make such representations as they have been instructed to make.

By an extension of equitable relief in cases of fraud, it seems to be now settled that if a false representation be made to the first under-writer on the policy, in a material point, this shall be considered as a misrepresentation made to every under-writer, so as to infect the whole policy, otherwise it might be a contrivance to deceive many; for when a respectable under-writer stands first on the policy, the rest subscribe the policy without asking a question; and if the first under-writer be imposed upon, the rest are entrapped by the same fraud.

But the insurer must avail himself of this sort of objection in the first instance; for after a verdict has been obtained, the court will not set it aside upon an affidavit of the first under-writer, that a material misrepresentation had been made to him. The defendant, in such case, knows what has been represented to himself, and might have known what had been represented to the first under-writer; and he shall not be by till after a trial, in order to make the objection, if the verdict should be against him.

If the insured state his computation as fait, instead of the information on which he founds his computation, and it prove untrue, it is a misrepresentation; and if material, it will avoid the policy.

A misrepresentation in a material point equally vitiates the contract, whether it be the misrepresentation of the insured himself or of his agent, and whether it proceeded from fraud, mistake or negligence; for the insurer is thereby led into an error, and computes the risk upon false grounds.

As a representation is only matter of collateral information, it is sufficient if it be true in substance; and its not being being in the policy in the form of a warranty, is looked upon as a proof that the insurer does not require it to be strictly and literally true. Although the voyage be represented as being less than the voyage described in the policy, yet, if there be no fraud, and the voyage actually performed be within the policy, it will be protected by the policy. Even if a representation as to the course of the voyage be literally untrue, yet if it be made in conformity to an established usage of trade, and no person be deceived by it, and the voyage meant to be performed be within the policy, it will not avoid the contract.

Every representation respecting the rate of the ship, and the time of her sailing, is material; and therefore if it be stated that a ship was ready to sail on a certain day, when, in fact, she had failed the day before, this is both a misrepresentation and a concealment, and will avoid the policy.

Concealment, or "suppreffio veri," is nearly allied to misrepresentation, or "allegatio falsi," and consists in the fraudulent suppression of any fact or circumstance material to the risk; and this, like every other fraud, avoids the contract ab initio, upon principles of natural justice. But it is not merely on the ground of fraud that a concealment avoids the contract; for even a concealment which is only the effect of accident, negligence, inadvertence, or mistake, will be equally fatal to the contract, as if it were intentional and fraudulent. Whatever respects the rate of the ship, the time of her sailing, the nature of the employ in which she is to be engaged, &c. ought to be fully disclosed; and the keeping back of any part of this will be fatal to the contract.

In such case, the concealment is vitiated the policy that it will afford the insured no remedy, even for a los arising from a cause unconnected with the fact or circumstance concealed; for a concealment is to be considered, not with reference to the event but to its effect, at the time of making the contract. A well-founded suspicion of concealment will amount in the courts to proof of fraud. As it is in some cases necessary to state to the under-writers the nature of the service in which the ship is to be employed; if this be attended with any extraordinary danger, the concealment of it will avoid the policy. A material concealment is fatal, though the fact concealed was not disbelieved, because the broker thought it immaterial. Doubtful rumours respecting the safety of a ship which it is intended to insure "lost or not lost," ought to be faithfully disbelieved to every under-writer; and the withholding of such information will avoid the contract. The obligation of a strict observance of good faith is equally binding on both parties in all contracts; and in that of insurane, the under-writer, as well as the insured, is bound to disbelieve all circumstances within his knowledge affecting the risk. If, therefore, it should appear, that at the time when he underwrote the policy, he knew that the ship was arrived safe, the contract will be void as to him, and an action will lie against him to recover back the premium.

There are, however, many matters, which are open to both parties, and upon which they may both exercise their judgments, with regard to which they may be innocently silent. The insured need not divulge what the under-writer knows, or what he ought to know. The under-writer need not be told what lessens the risk agreed upon, and is understood to be comprised within the terms of the policy. He is bound to know every cause which may occasion natural perils, as the difficulty of the voyage, the variation of seasons, the probability of lightning, hurricanes, &c. He is also bound to know every cause which may occasion political perils, from the rupture of states, from war, and its various operations; and he is bound to know the probability of safety from the continuance and return of peace, from the imbecility of the enemy, the weaknesses of their counsels, or their want of strength. There are other circumstances which the under-writer ought to know; and, particularly, it is not necessary to communicate to him, that the ship is foreign built, though this enabled her to sail without convoy, and without a licence to do so, being within the exception in the stat. 38 Geo. III. c. 76. § 6; it being the business of the under-writer to obtain this information for himself. In cases of concealment, the question must always be, whether there was, under all the circumstances, at the time when the policy was underwritten, a full and fair statement, or a concealment; fraudulent, if designed; or, though not designed, varying materially the object of the policy, and changing the risk; understood to be run; and in both cases avoiding the contract. It is not necessary that there should be any previous representation as to the rate of the ship, that being covered by the implied warranty that she is sea-worthy. For a variety of other particular facts and documents, relating to the subject of representation and concealment, we refer to Marshall's Treatise on the Law of Insurance, vol. i. b. i. ch. 9 and 10. See Warranty.

REPRESENTATIVE, one that perforates, or supplies the place of another; and is invested with his right and authority.

The word representative is equivalent to procurator or proxy.
The commons are the people's representatives in parliament; which see.

There is this defect in the constitution of our parliament; that whereas all Englishmen who have considerable estates ought not to be taxed without their own consent in parliament, by themselves, or their representatives; copyholders, of whom some have a thousand pounds a-year, have no voice in the election of knights of the shire. See parliament.

Representative Character, in Political Economy, thus denominated by way of excellence, or in contradistinction to other kinds of representation, constitutes the ambassador, or minister of the first rank, who represents his master in his very person and dignity. It places him above all other ministers, who are not invested with the same character, and precludes their entering into competition with the ambassador. (See Embassador.) Envoyos are ministers of the second rank, and are not invested with the representative character, properly so called, or in the first degree. See Envoy.

Representative Power, in Metaphysics, a term introduced by Leibnitz, to signify that power of the human soul, by which it represents to itself the univerfe, according to the situation of the body in the universe.

Wolfius calls this power vis representationis, to denote its being an active power, or rather a force actually exercising itself. For he expressly says, 'quia vis conflict in volgus, est et actio.' And he thinks that from this principle of a vis representationis, every phenomenon of the human mind may be accounted for. See his Psycholog. Ration. art. 329.

But it may be premised, that many will find this principle too obscure to be admitted.

When it is said, that our ideas are representative of things without us, or of the universe; it may be asked in what sense this is to be understood? Do they represent it, 1. As a picture does its original? Or, 2. As an effect of a cause? Or, 3. As a sign represents the thing signified? The first opinion is exploded in part by Locke and the Cartesian, and totally by Dr. Berkeley, late bishop of Cloyne. The second is admitted by Hobbes, but denied by Leibnitz himself and the idealists. The third should seem to be the opinion of Leibnitz, but he is not sufficiently explicit.

Dr. Berkeley admits ideas to be signs, but according to him they are arbitrary signs, depending on the immediate will of the Deity; hence the visual language; and ideas only signify or suggest each other, and spirits; but not bodies, the existence of which is totally unknown.

REPRIVE, or REPRIVE, from reprendere, to take back, in Lat. a suspending or deferring the execution of the law upon the prisoner for the present time.

A reprieve is properly a warrant from the king, for suspending the execution of a person condemned.

This may be, 1st, ex arbitrio judicis, either before or after judgment; as, where the judge is not satisfied with the verdict, or the evidence is insufficient, or the indictment insufficient, or he is doubtful, whether the offence be within his cognizance; or sometimes, if it be a small felony, or any favourable circumstances appear in the criminal's character, in order to give room to apply to the crown for either an absolute or conditional pardon. These arbitraries reprieve may be granted or taken off by the judges of gaol-delivery, although their jurisdiction be final, and their commission expired; but this rather by common usage than by strict right. (2 Hal. P. C. 41.) Reprieves may also be ex necessitate legis, as where a woman is capitally convicted, and pleads her pregnancy; which is referred to a jury of matrons. Another case of regular reprieve is, if the offender become non compos between the judgment and the award of execution. See Lunatic.

REPRIMAND, a sharp authoritative reproof. Such a person was reprimanded in court by the bench, &c.

REPRIMAND, a military punishment at the head of a regiment, is sometimes ordered by a court-martial, and sometimes only in the presence of the officers of the corps; it is generally given by one of the field-officers, and usually in such terms as these: "Captain, or lieutenant A. B., you have been tried for ——, and are, by the sentence of a general court-martial, found guilty thereof, and sentenced to be reprimanded at the head of the regiment: the disagreeable talk of doing it is assigned to me: I therefore do hereby reprimand you, and hope, that it may prevent your falling again into the like error." Non-commission officers are sometimes, though not frequently, ordered to be reprimanded.

REPRISALS, or REPRIEVALS, Repriemad, in the Civil Law, a right which princes have to retake from their enemies such things as they unjustly detain from them; or other things equivalent to them.

The word is formed from the Italian repriemad, which signifies the same thing.

When a place is taken or held from a prince, he seizes another by way of reprisal. Sometimes he takes men of the opposite party, by right of reprisals.

The Romans called this clariatio; and the Greeks had something like it under the name of androlæphus.

Reprisals are used between nation and nation, to do justice to themselves, when they cannot otherwise obtain it.

If a nation has taken possession of what belongs to another; if it refuses to pay a debt, to repair an injury, or to make a just satisfaction; the other may seize what belongs to it, and apply it to its own advantage, till it has obtained what is due for interest and damage, or keep it as a pledge till full satisfaction has been made. The law of nations permits reprisals only upon a cause that is evidently just, as for a debt that is extremely clear. For he who forms a doubtful pretention, can at first demand only an equitable examination of his right. In the second place, he should, before he proceeds so far, have in vain demanded justice, or, at least, have the utmost reason to believe that it would be in vain for him to demand it. Then alone he may right himself. It would be too contrary to the peace, to the peace, and safety of nations, to their mutual commerce, and to the duties which bind them to each other, for any prince suddenly to apply to force, without knowing whether the other is disposed to do him justice, or to refuse it. It must be observed, in order perfectly to understand this article, that if, in a litigious affair, our adversary refuses the means of bringing the right to proof, or artfully eludes it; if he does not, with good faith, apply to pacific measures for terminating the difference; and, above all, if he is the first who begins acts of hostility, he renders the cause just, which was before doubtful: we may then make use of reprisals, or seize his effects, to oblige him to embrace the methods of reconciliation, which the law of nature prescribes. This is the last attempt before coming to an open war. As the wealth of the citizens forms a part of the total wealth of a nation, and between state and state, whatever is the property of the members is considered as belonging to the body, and is answerable for the debts of the body; it follows, that in reprisals they seize the goods of the subject, in the same manner as those of the state, or sovereign. Every thing that belongs to the nation is subject to reprisals, as soon as it can be seized, provided it be not a deposit trusted to the public faith. This deposit is found in our hands, only
only in consequence of that confidence which the proprietor has put in our good faith; and it ought to be respected, even in cases of open war. Thus it has been usual to behave in France, England, and elsewhere, with respect to the money which foreigners have placed in the public funds. He, however, who makes use of reprisals against a nation, on the goods of its members indiscriminately, cannot be taxed with feizing the wealth of an innocent person for the debt of another; for, in this case, the sovereign is to recompense those of his subjects on whom the reprisals fall: this is a debt of the state or nation, of which each citizen ought only to support his quota. It belongs only to sovereigns to use and order reprisals; in the manner now stated. This is a measure of too great consequence to be abandoned to private persons. In all civilized states, a subject who thinks himself injured by a foreign nation has recourse to his sovereign, in order to obtain the permission of making reprisals. This is what is called defining "letters of marque." See the next article.

We may use reprisals against a nation, not only for the actions of the sovereign, but also for those of his subjects. Accordingly the sovereign demands justice, or makes reprisals, not only for his own affairs, but also for those of his subjects, whom he ought to protect, and whose cause is that of the nation. But to grant reprisals against a nation, in favour of foreigners, is to let himself up as a judge between that nation and these foreigners, which no sovereign has a right to do.

As we may feize the things which belong to a nation, to oblige it to do justice, we may, for the same reason, arrest some of the citizens, and not release them till we have received entire satisfaction; the subjects thus detained being only regarded as a security to oblige a nation to do justice, if their sovereign is obstinate in refusing it. We cannot take away their lives, nor inflict any corporal pain upon them, for a refusal of which they are not guilty. But the sovereign may make use of force against those who refuse the execution of this right, and use as much as is necessary to humour their unjust resistance. In this case, the true and just welfare of the state is the grand rule: moderation is always laudable in itself; but the conductors of nations ought to exercise it only so far as it is consistent with the happiness and safety of their people. A sovereign, however, has no right to oppose force, or to make war against him, who, in such a case, by ordering the making of reprisals, only exercises his just right. Whenever a sovereign can, by the way of reprisals, procure a just recompense, or a proper satisfaction, he ought to make use of this method, which is less violent and less fatal than war. Those who run to arms, say the excellent Vattel, without necessity, are the scourges of the human race, barbarians, enemies to society, and rebels to the law of nature, or rather to the common father of mankind. There are cafes, however, in which reprisals would be justly condemned, even when a declaration of war would not be so; and these are precisely those in which nations may with justice take up arms. When it relates to differences, not an act of violence, or of an injury received, but of a contended right; after having in vain attempted ways of conciliation, or pacific means of obtaining justice, it is a declaration of war which ought to follow, and not pretended reprisals, which, in such a case, would only be real acts of hostility, without a declaration of war, and would be contrary to the public faith as well as to the mutual duties of nations.

There is one kind of retribution sometimes practiced in war, under the name of reprisals, which we must here mention. If a general of the enemy has, without any just reason, caused some prisoners to be hanged, a like number of his men, and of the same rank, will be hung up; signifying to him, that this retaliation will be continued for obliging him to observe the laws of war. It is a bad extremity thus to put a prisoner to death for his general's fault; and if this prisoner was before promised his life, reprisals cannot be made on him with any colour of justice. Yet as a prince, or his general, has a right of sacrificing the life of his enemies to his safety, and of his men, if he is engaged with an inhuman enemy, who frequently commits such enormities, he appears to have a right of refusing life to some of the prisoners he may take, and of treating them as his wreck. But Scipio's generosity is rather to be imitated. That great man, having reduced some Spanish princes, who had revolted against the Romans, declared to them, that on a breach of their faith, he would not call the innocent hostages to an account, but themselves; and that he would not revenge it on a disarmed enemy, but on those who should be found in arms. (Liv. i. 28.) Alexander the Great, having cause of complaint against Darius for some mal-practices, lent him word, that if he continued to make war in such a manner, he would pursue him to the utmost, and give no quarter. (Quint. Curt. i. iv. c. 11.) It is thus an enemy, violating the laws of war, is to be punished, and not by causing the penalty due to his crimes to fall on innocent victims. Vattel's Law of Nations, b. ii. ch. 18. b. iii. ch. 8.

Reprisals is also used for a letter or permission, which a prince sometimes gives a subject, upon a full cognizance of the cause; authorizing him to retake from the first persons he meets of the opposite party, as many effects as make an equivalent to what have been violently forced from him, and for which the opposite prince has refused to do him justice.

These permissions are also called letters of marque, or mart; and in the it. 27 Edw. III. law of marque; in regard a person denied justice in another man's territory, redresses himself by goods belonging to men of that territory. See Letters of Marque.

Reprisals is also used in the same sense with reciprocation.

Reprise, or Reprize, in the Commerce by Sta, a merchant-ship, which, having been taken by a corsair, privateer, or other enemy, is retaken or recovered by a vessel of the contrary party.

The word is French, and signifies a resumption or replacing.

When a vessel, thus retaken, has been twenty-four hours in the hands of the enemy, it is deemed a lawful prize. If the reprize has been made within twenty-four hours, the vessel is to be retold to the proprietor, with every thing in it, upon his allowing one-third to the vessel who made the reprize.

If the reprize has been abandoned by the enemy, either in a tempest, or from any other cause, before it has been led into any port, it is to be retold to the proprietor. See Recapture.

Reprise, in the Manege, is a lèfion repeated, or a manege recomenced. Thus we say, to give breath to a horse upon the four corners of the volue with only one reprize, that is, all with one breath.

Reprise, Fr., in Music. Every part of an air or strain that is to be repeated, without being written or printed twice over, is called by the French a reprize. There are various ways of marking repetitions in music: first by a double bar dotted; if on both sides, both parts or strains are
are to be repeated; if only one side of the double bar is dotted, that side only is to be repeated. This figura \textsuperscript{\text{3}}, and sometimes \textit{dis capto al figura \textsuperscript{\text{3}}}, imply a repetition of particular portions of a melody, as do, likewise, dots in the spaces of the staff. (See \textit{Renou} and \textit{Reference}.)

Grety, in his \textit{Mémoires}, says that the repeating of the first and second parts or strains of a movement is a barbarous custom.

\textbf{Repri\textecirc;es, in Law, are deductions, drawbacks, or duties, paid yearly out of a manor, or lands. Such are rent-charges, peni\textdoublespace;es, fees of lewards or bailiffs, &c. The manor of Doll yields \textit{40l. per annum, ultra repri\textecirc;as}, besides all repri\textecirc;es.}

\textbf{REPROBATION, Reprobatio, in Theology, a decree or resolve, which God has taken from all eternity to punish sinners, who shall die in impenitence. Reprobation stands in direct opposition to \textit{election}.}

Divines hold it a symptom of reprobation, when a sinner is hardened so as not to feel any farther remorse or mitigations of conscience.

The calu\textdoublespace;als distinguish two kinds of reprobation, positive and negative. Positive is that by which God is supposed to create men with a positive and absolute resolution to damn them eternally. This opinion of reprobation is countenanced by St. Aug\textdoublespace;ulline, and others of the fathers; and is strongly maintained by Calvin, and most of his followers. Something like it is also found in the thirty-nine articles of the church of England; but it is now generally exploded, as injurious to the justice of God. Negative or conditional reprobation is that by which God, though he creates all men with a sincere desire to save them, and furnishes them with the necessary means thereto, so that all may be saved, if they will; yet fees there are several who will not do it, with the aids he shall afford them, how powerful soever; and fees, at the same time, they would do it with certain other aids, which he fees, but will not give them. \textit{O altitudine! &c.}

By comparing one part of scripture with the other, says Dr. Doddridge in his \textit{\textcyrillic{C}}\textit{letures}, (Prop. 132, schol. 1.) there seems to be this remarkable difference between the predetermination to life and that to death (here called reprobation), that, in the former case, God determines by the influence of his grace to work such a change in the hearts of his elect, as that their salvation should be the whole be ascribed to him, and not unto themselves; whereas he determines to bring others into such circumstances, that though their ruin should in fact happen, yet they themselves should be the authors of it, and the blame lie as entirely upon themselves, as if it had not been so much as foreknown. (See Rom. ix. 22, 23; Matth. xxv. 34, 41.) But the opposers of this doctrine allege, that this kind of reasoning is an evasion and not a solution of the difficulty. This learned divine, advert\textdoublespace;ing to the objection, that the above-d\textdoublespace;ated doctrine tends to make the persons whom it concerns derelict, observers, that if it be granted, that sufficient afflictions are given to all, none will have reason to despair, nor will any have an excuse to plead before God, in con\textdoublespace;quence of his secret purposes, which will not be made a rule of his final judgment. If it be said, that nevertheless those who are not predestinated to life are left under a necessity of per\textdoublespace;iling, and an impossibility of salvation; it must be owned, that it is difficult to say, how the doctrine, as explained by some, can be freed from this objection; but that this consequence does not necessarily follow from it, according to his statement. See \textit{Election and Predestination}. See also \textit{Sublapsarian and Supralapsarian.}

\textbf{REPRODUCTION, in Physiology.} In speaking of the growth of organic bodies, we must notice their power of reproduction; that wonderful property of renewing parts that have been mutilated or entirely lost. This is one of the most important provisions of nature, inasmuch as it guards animals and plants against the multiplied dangers to which their bodies are exposed. Hence, when viewed in connection with the system of nutrition altogether, it forms one of those decisive and grand characters, which distinguish at once the machines that proceed from the hand of the Creator, from all, even the most ingenious and boastful, productions of human skill. The difference is recognized at the first glance; the distance is immeasurable.

The springs and wheels of mechanical instruments have no power of repairing themselves, when they are bent, broken, worn, or spoiled; but such a faculty is enjoyed in various degrees by every animal and by every plant.

At different periods of the year, several organized beings lose, by a spontaneous and natural process, certain parts of their body, which are subsequently renewed. Examples of this occur in the fall of the flag's horns; in the molting of birds; in the renewal of the cuticle of serpents, and other amphibia, of the larve of insects, and of the shell of the crustacea; the fall of the leaves of trees, &c. This may be called ordinary or natural reproduction. The flag's horn, or antler, as it should be more properly called, is a mass of true bone, pos\textdoublespace;\textdoublespace;\textdoublespace;efing the structure and characters of offensive substances. In its early state it is soft, and traversed by large vessels, which must be reproduced every time the new horn is formed. This annual reproduction constitutes, in many points of view, one of the most remarkable phenomena of animal physiology. It affords a most striking proof, 1st, of the power of the nutritive processes, and of the rapid growth, which is dependent on this in warm-blooded animals. For the horn of a flag, which may weigh a quarter of a hundred, is completed in ten weeks. 2dly. Of a limited duration of life in a part of an animal, entirely independent on the life of the whole animal, which in the flag extends to about thirty years. 3dly. Of change of calibre in particular vessels. For the branches of the external carotid, which supply the horn, are surprisingly dilated during its growth; and recover their former area, when that process has ceased. 4thly. Of a peculiar sympathy, which is manifested between the growth of the horns, and the generative functions. For when a fall of the skin is separated every year, and comes off as a complete sheet, excepting the aperture, through which the animal escapes: the covering of the cornea is fixed with the veil of the external integument.

Crustacean animals (the crab, lobster, &c.) have a skeleton, which surrounds and contains their soft parts, and which serves, at the same time, the purposes of a skin. When it has attained its perfect conformation, it grows no more; but, as the soft parts fill increase, the shell separates, and is detached, being succeeded by a larger one. The calcareous bodies in the homs of these animals, performing the office of teeth, are fixed with the shell. See the article \textit{Cancer}, in the account of the species \textit{Euricula}, and \textit{Gammarus}.

The larve of insects cast their cuticular covering several times before their transformation. An interesting account of the
REP

"I prefer," says he, "in spirits a large water newt (lacerta palustris), from which I extripated nearly the whole eye several years ago; all the humours were discharged, and then four-fifths of the emptied coats were cut away. In the course of ten months an entirely new eye-ball was formed, with cornea, iris, crystalline lens, etc.; and this is only distinguished from the same organ on the opposite side by being smaller." Ibid.

Not only are amputated tentacula speedily replaced in the actinias (sea anemones), but, if the animal be divided by a vertical or horizontal section into two halves, each of these becomes an entire actinia. See the article ANEMONE.

The fresh water polype exhibits very surprising powers in this way. If it be cut into two or more pieces, these become perfect animals. If it be flit half way down, the two halves are rendered perfect, remaining united below: these may be flit again with the same results. The opposite ends of two polypes may be made to grow together, &c. See POLYPE.

See the memoirs on animal re-productions in Spallanzani's tract: also the works of Bonnet.

REPOOF, OBJECTION, in Rhetoric, is distinguished from inveterate; which fee.

REPS, in Geography, a town of Transilvania; 16 miles N. of Fagaras.

REP-SILVER, money anciently paid by servile tenants to their lord, to be quit of the duty of reaping his corn.

REPTILES, in Comparative Anatomy and Physiology. Although the animals, whose structure we are about to explain, are perfectly similar to each other in their principal characters, and ought therefore to be united in one class, naturalists have experienced a real difficulty in discovering an appropriate name for the classes. That of amphibia, employed by Linnaeus and his pupils, although deduced from a striking circumstance in the economy of the more generally known reptiles, namely, the power of exiling for a long time in water, as well as in air, is vague and uncertain in its signification. If we regard as amphibious those aquatic animals, which are able to live for some time on land, or those land animals, which can remain for a certain time under water, all animals are amphibious; for even the human subject and the mammalia can dive. If, on the other hand, the word amphibious be taken etymologically, and understood to denote an equal power of subsisting in air and water, it is applicable to no animals. Although reptiles can remain much longer under water than the mammalia, or birds, they are obliged, as their respiratory organs are only calculated for breathing air, to come sooner or later to the surface for this purpose; and they are drowned, like any warm-blooded animal, if detained in the water beyond that time. To enable an animal to exist equally in air and water, it should have lungs and gills; that is, it should have the power of breathing air, like the mammalia and birds, and of breathing water, like fishes; and it should be able to use either of these methods, to the exclusion of the other. But we know of no such animals. The larvae of frogs and faldamanders, the proteus anguinus, and the sea lacerta (see the latter part of this article), have indeed branchiae and lungs; but as far as our knowledge hitherto goes, none of these could live out of the water. The lungs of the tadpole, and of the larvae of faldamanders, are designed for the service of those animals in their subsequent stage of existence; but do not give them the power of living in air; and the lungs, either of the proteus or fyn, do not seem sufficient to enable them to dispence with the office of the branchial appendages. In its etymological sense, then, the term amphibious is not applicable to any animals we know of.

Linnaeus
Linnaeus places among his amphibia reptiles who never go into the water, and some fishes which never quit it. He could not fail to experience great difficulties in naming a clas so ill conceived as that of his amphibia; consequently, this appellation is objectionable, as being vague and obscure; the genera comprehended in the Linnaean clas amphibia, are too ill assorted to admit of their having a common name suitable to all. Daubenton divided them into two clafes, naming one oviparous quadrupeds, and the other serpents. Lacépède adopted these two clafes, and placed between them a third, that of ovi parous bipeds. Hermann of Strasbourg, in his "Tabulae animalium," propounded to subdivide, for the term amphibia, that of ceryzoa. "Si in novorum nominum impoitione gloria more multorum quereuremus, et ea re sciantia promovecentur, ceryzoae apte vocari poife putaremus, quia omnem fere naturalium corum animalium vox ita exhaure videatur." *Nepus; enim non modo frigidum, fed et horridum luridumque significat." Hermann, Tab. afin. Anim. p. 218.

Without entering further into the objections against the appellations just enumerated, we adopt that of reptiles, already employed by many modern naturalists, and particularly by Cuvier, in his "Tableau Élémentaire d'Histoire Naturelle." In fact, in the progression of the oviparous quadrupeds, as well as in that of serpents, the belly moves against the surface of bodies, over which they pass.

General Observations. — Referring to the article Classification for a view of the genera comprehended under these divisions, we prefix to the more detailed survey of the anatomy of reptiles, a short summary of the principal anatomical characters of the four orders into which the clas is divided.

1. The Chelonian order; Turtles. Body inclosed in a bony shell. They resemble birds in having the masticating surfaces of their maxillary bones covered by strong cutting horny plates. Body supported on four limbs, terminated by a tail, and covered in almost all by scales. They copulate; fecundation takes place internally; the female lays eggs covered by a firm calcarious shell: the young animals come out without incubation, merely by the heat of the atmosphere; and they undergo no metamorphosis. Stomach larger than in the other reptiles, and intestinal canal furnished with a cæcum. The heart has two auricles.

2. The Saurian order, or Lizard kind. They resemble the former very nearly in the structure of their principal internal organs. They have firm bones, like those of the mammalia; curved and long ribs, and a fournerm. Teeth in the jaw. The two branches of the lower jaw conflated. A trachea compofed of cartilagious rings, an os hyoides and larynx, capable of producing sounds, at least in some individuals. Heart with two auricles. A single penis in the male. There is a real internal copulation; the female lays separate eggs, generally covered by a firm shell, depositing them on dry ground, or in holes. The young ones come out of them, and undergo no metamorphosis. The skin is furnished with numerous scales or plates. Body elongated, and ending with a tail. Feet, often high, and strong enough to sustian the body above the ground in progression. Some are quadruped; others biped, having either four or hind feet. Toes furnished with nails; generally five in number; but there may be four, three, two, and even one.

3. The Ophidian order; Serpents. They agree with the two former orders, in having firm bones, curved and long ribs, a larynx and trachea, capable of producing a flight hissing in moat. An external organ of generation in the male. A real internal copulation: the female lays eggs covered with a calcarious shell, which the depositis in holes filled with leaves, under the roots of trees, in warm and rather moist situations. The young ones, when they quit the egg, are like their parents. They differ from the preceding orders, in having a long, cleft-shaped, flexible body, covered with a skin, either furnished with scales or plates, or naked, unprovided with feet, and terminated by a tail, often very long. Numerous long curved ribs, not united together, as there is no sternum. The branches of the lower jaw not united in front. Upper jaw conflating of four branches. Simple, sharp, and numerous teeth; and long, curved, tubulated fangs, in addition to these, in the venomous kinds. They creep along the ground by undulations of their body. Excepting the ophidian, they have no external auditory openings. Heart with a tingle auricle. Double penis. Eggs covered with soft calcarious shells.

4. The Batrachian order; Frog kind. They resemble the preceding orders in having a tail; excepting the frogs and toads in their perfect state: a trachea and larynx, capable of producing sound. Like the chelonian and saurian reptiles, they have feet, and simple jaws, i.e. not formed of two branches, movable on each other. In common with the saurian and ophidian orders, they poofles teeth fixed in the jaws; and with the ophidian, a heart with a single auricle. Many characters differing with them from these three orders. Their naked skin, which is warty or tubercular, more or less moft, and nearly similar to that of the cecile, the laft genus of the ophidian order. Softness of the bones; a sternum without ribs in the frogs and toads; rudiments of ribs and no proper sternum in the salamanders; true curved ribs surrounding the body in the proteus and sire. Four feet, or two only. They all swim; those with long hind legs and no tail leap; the tree-frogs attach themselves to leaves by the round tubercles of their toes; those with four equal limbs, or two only, crawl and swim, but do not leap. An external tympanum in the tree-frogs, frogs, and mott toads; no external ears in the others. No external organ of generation in the males, nor any internal real copulation. The female lays eggs in the water, or humid earth, and the male fertilizes them as they pass out; or in the ovo-oviparous species, as the land salamander, the femisel liquor of the male is absorbed by the sexual organ of the female. The ova are without shells; from them proceed small animals, called tadpoles, which undergo various changes, before reaching their perfect state. They have branchies in their tadpole condition, and thus approach to fishes.

Notwithstanding the obvious differences of organization in the different reptiles, as the turtle, lizard, serpent, frog, and salamander, we may remark that their structure does not deviate essentially in its general plan from that of the human subject. They have a bony vertebral column, and all the principal organs found in man, but with more or less striking modifications.

Reptiles have some relations, in their organization and habits, with other vertebral animals, particularly with fishes. This is seen in the true branchie of the batrachian larvae and sirens; in the scales of the skin in lizards and serpents; in the polygonal horny plates of the salamanders, corresponding to those of some cartilagious fishes; in the elongated form and habits of the sirens, like those of the eel-shaped fishes.

The form of the body presents great differences in the reptiles; nearly all the cheloniens, sauurians, and batrachians have four feet; and there are only two sauurians with two feet. In the cheloniens, the body is orbicular, more or less convex, inclosed in a bony case, and terminated by a small tail; the toes are separate and distinct in some, palmed and fin-like in others. All the sauurians have an elongated body, covered with various kinds of scales, and terminated by
by a very flexible tail, often composed of articulated rings. In the very elongated form of their body, the chelides resemble serpents, though, in other respects, they are true faurians. The skin is quite naked in all the batracians; they have four feet; some have no tail, a flout, thick body, and the hind legs longer than the front; others have the shape of a lizard, being furnished with a tail, and having feet of equal length. Lastly, serpents have a very long, cylindrical body, covered with scales, and without limbs. These variations of figure must necessarily be attended with modifications in the form and position of organs; the internal arrangements will correspond with these outward signs.

Although the animals of this class differ very considerably in outward form, as well as in the general bulk of their bodies, they agree very nearly in the essential points of their organization, and more particularly in the functions of their animal economy. We may influence the mode of taking their food; the long abstinence of which they are capable; their oviparous generation; the length of time, for which they can bear an interruption of respiration; their tenacity of life and extraordinary power of reproduction; and the low temperature of their bodies. The last points, of animal heat and reproduction, two exceedingly interesting subjects of inquiry, which have been investigated of late years with great industry, form the most striking differences between cold and warm-blooded animals; the latter alone possessing that remarkable property of maintaining in themselves a temperature considerably exceeding that of the medium in which they live, while the former are distinguished by the wonderful extent of their power of extending or reproducing injured or lost parts.

An accurate knowledge of the structure of reptiles is not only important from its sublimacy to the classical arrangements of natural history, and highly interesting from exposing to us new and rich scenes in the vast domains of nature, new forms of life, and fresh modifications of organization, accompanied with singular changes of functions already familiar to us in other shapes; but it acquires additional interest from the great use which physiologists have made of different reptiles in their experimental elucidations of the human economy. We must survey in a general view the structure and economy of these animals, and compare them with those of the warm-blooded classes, before we can determine how far the conclusions, drawn from experiments on reptiles, concerning the heart's motion, irritability, the action of the nerves, the effects of opium, &c. &c. can be transferred to the human body.

Organ in concerned in the Vital Functions.—The mouth is situated at the extremity of the head, and directed transversely. If we fancy the head to be divided by a horizontal cut, extending from before backwards, to its very posterior part, we shall have a just idea of the mouth of a reptile. The cranium is very small in this class, and the head consists almost entirely of the two jaws. The lower is articulated towards the back of the head, and thus allows the opening between the two mandibles, constituting the mouth, to be very considerable. Almost all reptiles swallow entire animals, and thus require this extensive opening. The margins of the aperture consist simply of the maxillary arches, which are not covered or enclosed by any thing deferring the name of lips. In no case is there any modification; and the food or prey is taken by the teeth or tongue, so that a movable covering of the jaws, similar to the lips and cheeks of the mammals, is not necessary either for confining substances subjected to the action of teeth as organs of mastication, or for the purpose of reaching or seizing food.

The horny coverings of the mandibles, completely naked, and not concealed even by the smallest fold of skin, form the sides of the entrance into the mouth in the chelidian reptiles. Their food consists of marine vegetable production, teltaceae, infects, &c. and does not require to large an opening for its introduction, as when considerable animals are swallowed whole. The mouth is consequently smaller in this than in either of the other orders; and does not extend completely to the back of the head.

The family of tortoises, which Geoffroy has called tri-nyx, offers a remarkable exception to what we have stated about the absence of lips; they have these folds, and a moveable proboscis at the end of the snout. "The existence of lips in these tortoises is an anomaly, the more likely to surprise us, inasmuch as the affinity of these reptiles to birds seems to afford a motive for the absence of lips, and also for the existence of the horny coverings of the mandibles." Geoffroy St. Hilaire, Mem. sur les Tortues molles; Annales du Museum, v. 14. pl. 1. p. 9.

In the faurians, the slit of the mouth goes to the very back of the head, far behind the ear. Its appearance is very formidable in the crocodile, where the hard strong jaws project into a large snout, and are armed with sharp powerful teeth, delirium even of gums: these jaws open to the very back of the head, and dislocate a tremendous throat. The mouth is as large proportionally in the other faurians; but their fize is too insignificant and their habits too harmless to allow of their inflicting that terror, which the formidable weapons of the crocodile so justly cause. The ophidian have not only a mouth equal in its transverse measurement to the diameter of their body; but they possess also the means of enlarging this aperture, so that they can swallow creatures whole diameter exceeds their own. The batracians have an opening as large as the fize of the head will allow. In the latter, as well as in the ophidian, and most of the faurian reptiles, the integuments make a small fold at the edge of each jaw; these folds meet when the mouth is closed, so as to hide the edge of the jaws, but they possess no power of motion.

In the tadpole, in the proteus and sirem, the mouth is much smaller than in the other reptiles; and they possess folds more defercing the name of lips. In the former there is a kind of horny apparatus within these lips, forming something like a beak. In the smallness of its mouth, and in these horns jaws, the tadpole is remarkably dissimilar to the perfect animal.

The Jaws.—In considering the jaws and their muscles, the teeth, and the tongue, we must bear in mind that these organs are calculated merely for seizing their food, and conveying it to the throat; in no case does the food undergo any modification, as in the mammals.

No reptiles have an upper jaw moveable on the head, like that of birds: the superior maxillary bones are in truth articulated moveably with the head in serpents, and may be extended and retracted, or moved laterally, as we shall describe presently; but, in general, the crocodile and upper jaw are united into one piece, so far as their motions are concerned.

The most opposite opinions have prevailed respecting the crocodile; some to the present time. Herodotus first observed, that it is the only animal polluting an upper jaw moveable on the lower, which remains fixed. The fame opinion was generally held by the ancients, as Aristotle, Pliny, &c.; and several moderns speak in the same way, as Maregrave, Marmol, Jacobus, Velatus, and the Jesuit Missionaries at Siam, who had opportunities of observing the living animal. But the anatomists of the Academy of Sciences...
REPTILES.

Sciences (Perrault and Duverney) undertook to demonstrate the falsehood of the opinion of Herodotus. Geoffroy, one of the French savans, who attended the Egyptian army, has given us an account of the matter, which tallies all these disputes, by proving that the statement of Herodotus is almost rigorously true; and that the crocodile is the only known animal, whose upper jaw, including within its branches the cranium, is movable on the lower jaw, which possesses only an almost indefinable degree of motion. Nothing can be more paradoxical than the head of the crocodile; every thing which is placed laterally in other animals, as the moving powers of the jaw, &c. is thrown behind.

The temporal bone itself extends backwards far behind the cranium, is elongated, and transformed into a double condyle. We have in fact nearly described the crocodile's head, when we say that it consists of two mandibles; for the cranium is so small, and out of place, that it escapes notice at first. We find it below, and a little in front of the occipital crista. The brain is so far forwards, that the eye and ear are above and a little behind it.

"The lower jaw is one-fifth longer than the upper, with the cranium: it presents a cavity with a double surface, in which the condyle of the temporal bone is articulated by ginglymus. The occipital condyle is in the same line as the temporal condyles: thus the head is really held at its articulations, like the lid of a box by the hinge, and is confined entirely to motions upwards and downwards. When a living or stuffed animal is examined, it is difficult to believe that the head ends at the extremities of the jaws. There is a regular fullness of the front of the neck, which might be regarded as the frontal part of the head; this arises from the enormous temporal muscles, which lie between the recti and obliqui. The latter, arising from the cervical vertebrae, and inserted in the occipital crista, elevate the head upon the neck, making it describe an arc of 45°. The skin behind the occiput being thin, yields to the motions of the head; while the lower jaw, on the contrary, is inclosed in a kind of sheath of hard, rough, tough skin. If there were a muscular force capable of drawing it down, this covering would impede its descent, while it is still further confined behind: the long process situated beyond its articular surface, describing a curve, approaches the skin exactly at the point where it is armed with a long scale, which offers an almost invincible resistance to the elevation of the condyle, and consequently to the depression of the jaw. Yet it is not entirely fixed, as Marmol imagined, who stated that it forms a suture bone with the fenestra. Two small muscles have the power of moving it slightly." (Annales du Musee, tom. ii. p. 38, et seq.) This description is accompanied with an excellent figure of the skull, in the elevated state of the upper mandible. An analogous figure of the whole head is given by Humboldt, Recueil d'Om. de Zool. & d'Anat. compare, tom. i. pl. 4. From the figures of the Nilotic crocodile, in Blumenbach's Abbildungen Natur Historischer gegenflände, N° 26; and of the St. Domingo crocodile, in the Annales du Mus. tom. ii. it appears, that the animal most frequently exhibits this elevation of the upper jaw. It cannot be necessary to point out how the raising of the entire cranium and superior mandible, just described, differs from the motion of the upper jaw upon the cranium: this has been already done by Blumenbach. See Syll. of Comparative Anatomy, p. 111, note 8.

The length of the lower jaw is much more considerable in comparison to that of the upper in reptiles, where it is articulated far back, and is even prolonged beyond its articulation, than in mammalia and fishes, where this articulation is placed more forwards. Its composition is more complicated in the reptiles, than in any other order. In the green turtle (tortuus mydas) it consists of seven distinct pieces, a middle one forming the arch, and three others on each side, forming a continuation of its branches. The farthest of the three penetrates like a wedge between the two others, and forms a great part of the articular cavity. In many of the furred animals the number is still greater: the lower jaw of the Nilotic crocodile, and of the caiman (croc. americanus), has no fewer than twelve pieces, arranged as follows: As the two branches are divided, and united by a future, each of them must be composed of fixed pieces; 1, one, in which all the teeth are implanted; 2, another, lying along the internal surface of the former, without reaching to its anterior extremity; 3 and 4, two others articulated with the preceding; 5, an inferior one prolonged to the posterior extremity of each branch, a superior extending as far back as the other in the Nilotic crocodile, but not so far in the caiman. 5. The greatest part of the articular cavity is excavated in a fifth piece within the two former, and constituting the inner and superior part of the portion beyond that cavity. 6. Lastly, a sixth piece forms the front and inner part of the orifice of the dental canal. The lower jaw of the tupinambis (lacerta monitor) is also composed of twelve pieces, two of which form the coronoïd processes, while the other ten are analogous to those described as entering into the formation of the lower jaw of crocodiles, excepting the last. There are eight or ten in most of the other furred. We find four in each branch in the genus anguis; an anterior one united to its corresponding piece in front, and three posterior ones joined to the former. They are only four altogether in the amphibia. The two last mentioned genera are the only ophidian reptiles, in which the jaws are not separated in front. In all the others there is a separation, and each branch has only two distinct pieces; an anterior, in which the teeth are implanted, and a posterior: they are united by future, and vary in relative length, according to the number of teeth. The very open arch, composing the lower jaw of the batrachian order, is made up of six pieces; the middle of which are the molar flender.

The anterior angle, formed by the union of the two branches, depends on the form of the snout in general, on the figure of the two branches, the presence or absence, number and size of the teeth, &c. It is rounded and very open in the chelonian reptiles, and more so in the batrachian. In the ophidian order, which have the branches of the jaws moveable, it is susceptible of change, according as their extremities are approximated or drawn asunder; indeed in the former case only can it be properly said to exist at all. It is rounded in the amphibia; more angular in the anguis; still very obtuse in the gekkos (lacerta gecko), which have wide jaws, with the branches of the lower curved only in the horizontal direction; it is less so in the camelion and flabello (lacerta flabell), the snakes (lacerta f excited), and the lizards, although in all these the two branches are only joined by their extremities. It is acute in the tupinambis and iguana, in which the branches, somewhat curved in the vertical direction, are approximated for a shorter space. The Nilotic and Gangnetiæ crocodiles differ very much in this respect. The two branches are united in the latter in the greatest part of their extent, as in the cachalot, and consequently form a long bill, in the edges of which the two rows of teeth are implanted. In the former, on the contrary, the branches remain separate, and only approximate towards their extremity, increasing a little in thickness at the symphyses.

The portion of the bone, which is incurved towards the cranium in most of the mammalia, and constitutes
the ascending branch of the jaws, does not exist in reptiles.

Motions of the Jaws.—Reptiles may be divided into two orders, according to the conformation of their maxillary bones, and the kind of motion of which they are susceptible. In the first would be placed those which have the lower jaw only movable, as the lizards, the testudines (tortoise and turtle), the frogs, the salamanders, and the genera anguis and amphibia among the serpents. The second would include the colubres, and the venomous serpents, which can move both jaws.

The general disposition of the articulation is nearly the same in reptiles as in birds (see Brain's, in Comparative Anatomy). Instead of a condyle at the posteriour extremity of the jaw, an articular surface is excavated to receive an eminent bearing capable of analogy to the os quadratum of birds, and differing from it only in not being movable; often, indeed, it is only a simple prolongation of the temporal bone. To this morn inferior point of the cranium, and to an articular surface nearly transverse in its direction, and shaped like a condyle, the lower jaw is articulated by a glenoid cavity, of which the middle part sometimes presents a rising line, converting it into a kind of pitule. Behind this articular cavity there is often a more or less considerable bony process, affording attachment to a muscle analogous to the digastric.

The most remarkable differences requiring our notice here are, the form of this prominence or condyle of the temporal bone; the greater or less prolongation of the process behind the articulation; the situation and extent of the temporal fossa; and, lastly, the excellence or absence of the eminent occupying the situation of the coronoid process.

In proportion as the temporal eminence is carried backwards, the jaws approach more nearly to each other in their longitudinal direction. We see this in the crocodile, salamander, frog, turtle, and tortoise. When, on the contrary, it extends vertically, or very obliquely, and is very elongated, as in the camelion and iguana, it forms a kind of pedicle to the lower jaw, which, by separating it from the cranium, produces a much more considerable interval between the jaws. Several kinds of lizards, as the lacerta agilis, draco, &c. occupy the intermediate space between these two extremes.

The crocodile has the largest processes for the attachment of the digastricus. It is sensibly diminished in the camelion, the gecko, the tupinambis, and the testudines; and we see nothing of it in the pipa, the toad, frog, and salamander.

All four-footed reptiles have very deep temporal fossa; they are united at the cavity of the orbit. In some species, the two cavities are separated in front by a bony circle, as in the testudines, the crocodile, the dragon, and the other lizards; but in the pipa, the frog, and salamanders, there is no orbital circle.

There is, in the crocodile, a considerable excavation on each side of the cranium, behind the orbit, terminating below in the temporal fossa, and wanting in the crocodile with bony eyelid (Crocod. palpebrofus, Cuvier). It is bounded externally by a bone corresponding to the squamous portion of the temporal, which joins the lateral frontal bone, and thus forms a second kind of zygomatic arch. The size of this excavation differs much in the different species. No doubt it contains muscles. But we find no express and satisfactory description of it and its muscles, nor of the muscles of the jaw in the writings of the French naturalists already quoted, on the subject of the crocodiles.

The coronoid processes of the lower jaw is not prominent in reptiles. There is a mere rudiment of it in the testudines, the camelion, and some lizards, as the iguana, but there is no trace of it in the crocodile, the frogs, and salamanders.

The muscles of the jaw, in the ossiparous quadrupeds, are analogous to those of the mammalia, and resemble them in number.

The malleus is large and distinct in the tupinambis, occupying all the space comprized between the posterior edge of the orbit and the meatus auditorius. It is directed obliquely from behind forwards, so that it raises and carries the jaw backwards. This malleus is small in the agame marine (lacerta marmorata), and the turtle. It is so slender, that it can scarcely be distinguished from the lower part of the temporal.

The temporal muscle is very large in the turtle, occupying all the temporal fossa, and forming the back of the orbit. It is much smaller in the tupinambis, and common lizard, in which it is almost entirely concealed by the malleus.

The pterygoidei are, in general, but imperfectly distinguished from each other. They envelop the whole branch of the jaw towards its extremity in the tupinambis; their fibres are in a manner twisted. They elevate the jaw and carry it forwards; thus they act in an opposite direction to the two preceding muscles. The same muscles are flat and thin in the turtle; their fibres are nearly transverse, so that they can move the lower jaw more directly from side to side.

In all these reptiles the muscle analogous to the digastric is flat and triangular; the broad portion is fixed to the cervical ligament behind the occiput, and the point terminates at the extremity of the jaw, behind its articulation, and near the pterygoideus.

After describing the muscles employed in moving the jaws of the turtle, Perrault affirms, in his "Mémoires sur les Animaux," that it has more power in its jaws than most other animals, that it can cut very hard and strong sublances, and that the head of a small turtle has been seen, half an hour after it was cut off, to strike its jaws together with a noise like that of callagnettes. Daudin relates the following circumstance, communicated to him by a Dutch naturalist, who resided several years in India. "When we landed in Table bay, we took several hawk's-bill turtles (testudo imbricata), whose stomachs were filled with marine plants, and thick shells, which they easily break down with their horny gums. Three, which could not be brought on board, were tied to the trunk of a tree, with a thick cable, but when the sailors returned on the following morning, they found that these turtles had contrived to turn over on their bellies, and had then cut, with their gums, the cables with which they had been fastened." Holz. Nat. des Réptiles, in the edition of Buffon, by Sonnini, t. i. introduction, p. 38.

The two jaws are not movable in all the serpents. They may be divided into three orders. 1. Thse with the branches of the lower jaw consolidated, and consequently not possessing any power of thrusting forward the upper jaw, or moving it laterally. 2. Thse with the branches distinct, and united in the recent state by an elastic ligament. There are two modifications of the latter; they may either have merely the power of separating the two jaws; or they may, at the same time, separate the jaws, and carry forwards a part, or the whole of the upper. We shall speak of the motions of the jaws according to this division, first describing the bones, and then the muscles.

The Bones.—In the serpents, with the lower jaw consolidated, the head is shaped nearly as in the lizards. This is the case in the anguis and amphibia, the coccida, acrochordus, and hydrophus. In the genus anguis the head very closely resembles that of the iguana. The arch of the upper jaw
jaw is uninterrupted, and corresponds to the curve of the lower; the concavity of the palate is nearly complete in front. The palatine arches are directed backwards, and united to the condyloid pedicle of the temporal bone. This pedicle is short, and nearly vertical, and excavated behind for the attachment of the digastric muscle. The lower jaw has a small process behind its articulation for the attachment of the muscles, which depressing it; and another towards its posterior third portion, analogous to the coronoid, for the elevating muscles.

In the amphibia, although the general configuration is a little changed, nearly the same arrangement is met with. The whole upper jaw is less separated from the cranium; the concavity of the palate is nearly complete. The palatine arches are much larger. The condyloid pedicle of the temporal bone, instead of being vertical, is continued nearly horizontally forwards. In proportion to the cranium, the lower jaw is much shorter; and it is articulated to the condyle by its posterior extremity. It is very wide behind, to produce the coronoid processes. The orbit and temporal fossa are consequently confluent; they are bordered by prominent bony crests, as in the carnivorous mammals; hence, on first view, the head of an amphibia might be supposed to belong to one of the chiroptera.

The serpents of the second kind, whose lower jaw is formed of two distinct branches, and in which the upper is capable of being separated, but not carried forwards, are all the non-venomous colubres, and the boas. The conformation of the upper jaw, in the latter, is very different from that of the lizards, although the bones are nearly the same, as we shall explain in the osteology of the head. The os incisa are not always furnished with teeth; sometimes even, as in the boas, they do not unite the superior maxillary bones. All the other bones of the jaw are moveable on the cranium, which serves merely as a point of support.

The superior maxillary bones are two long branches, in which the teeth are implanted; they form the outer edge of the palate. They are articulated by two points; first, towards their middle, as a lever of the first kind, on a small bone analogous to the os nasi, and forming the anterior edge of the orbit; nearly at the same point, but towards the inner side, the inferior maxillary bone has a process, which slides in a groove, and rests on the palatine arch. It moves on these two surfaces, playing backwards and forwards. The anterior extremity of this upper maxillary bone is free: the posterior receives the end of a particular bone, serving to unite it to the palatine arches.

The palatine arches are the two internal bony branches themselves, formed of two parts. An anterior, which is free in front, and articulated by three points; behind, with a bony branch, which proceeds towards the extremity of the lower jaw within its articulation, and appears to form a continuation of it; on the outside, with a particular bone, uniting it to the maxillary arch; and above, with the bals of the cranium, in front of the orbits. The posterior portion of the palatine arch is analogous to the pterygoid alae or laminae. It is articulated by three points; i.e., in front, with the posterior extremity of the first portion; 2d, behind, with the lower jaw towards the naris; 3d, on the outside, and towards its anterior part, with the bone uniting it to the maxillary arch. Lastly, the third palato-maxillary is a piece nearly cylindrical in its middle, flattened and widened at its two extremities, by which it is supported, being articulated, on the outside, to the posterior extremity of the maxillary arch, on the naris, towards the middle and outside of the pterygoid portion of the palatine arch.

In consequence of this singular formation, the whole upper jaw is, as it were, suspended and distinct from the cranium, and influenced by the motions of the lower jaw. When the posterior extremities of the latter are separated, the pterygoid arches are moved apart. They carry with them the posterior extremities of the palatine and maxillary branches, while at the same time the anterior extremity is moved forwards. On the contrary, when the two internal edges of the pterygoid laminae are brought together, or, what is the same, when the articular extremities of the lower jaw tend to approximate, the anterior ends of the palatine and maxillary arches are carried outwards, and separate from each other.

The serpents of the third order, which have jaws susceptible of separation, and which at the same time can carry forwards the superior maxillary bones, properly so called, exhibit but a slight modification of the structure described as belonging to the preceding division. Their pterygoid arches are articulated with the lower jaw, towards its extremity, on the guttural aspect. They also receive the bone which is to join them to the palatine arches; but the latter are very short, directed forwards, and only containing venomous teeth. This intermediate bone, therefore, goes above the superior maxillary, which is itself articulated in the front of the orbit, or the short and moveable cheek-bone. When the lower jaw is moved forwards, the palatine arch, carried in the same direction, drives before it the bone which joins it to the maxillary. The latter, extremely moveable, is immediately turned up, or carried forwards, by moving on the cheek-bone, which causes a complicated series of motions.

The articulation of the lower jaw is the same in the whole family. The temporal processes are prolonged posteriorly; they receive an intermediate bone; analogous to that designated by the name quadratum in birds. This bone is very short, and poise the little motion, in the species which have the upper jaw fixed, and the inferior condensed.

It is directed forwards in the amphibia towards the lower jaw, which is shorter than the cranium by nearly one-third; a circumstance which belongs only to this species. In the anguis, the os quadratum descends much more obliquely forwards.

In all the other species the bone last-mentioned is much longer. It sometimes descends perpendicularly, as in the boas; but it is commonly directed backwards, as in most of the colubres. The temporal extremity is generally widened and excavated by a small depression. The inferior extremity is rounded like a condyle, and received into an excavation of the posterior extremity of the corresponding branch of the inferior maxillary bone.

From the nature of its articulation, the lower jaw of either side is not only susceptible of elevation and depression, fo as to open and shut the mouth, by playing on the os quadratum, as is the case only in the genera amphibia and anguis; but it may also be carried outwards, and take with it the os quadratum, as is the case in the colubres and venomous serpents, whenever the pterygoid arch is moved outwards. That is to say, whenever the upper jaw is widened, the inferior must follow its dilatation, become the posterior extremities of the pterygoid arches, being articulated with the internal part of the lower jaw, it must move together with them. The arrangement of the muscles accords very well with this formation, as we shall proceed to describe.

Muscles of the Jaws.—The maxillary muscles of the genera anguis and amphibia, and probably of all the serpents with a consolidated under jaw, resemble those of the common
common lizard; but they are very different in those whole lower jaw consists of two distinct pieces; we shall describe them in the rattlesnake.

Here the muscles of the lower jaw are concealed in the lips, and go round the mouth on each side. That which forms the anterior edge of the commissure of the lips is the strongest, and seems to hold the place of the mafeter. It arises by firm aponeuroses from the tendinous sheath, which contains the venomous gland. Its fibres form a considerable cord, which constitutes the whole thickness of the lower lip, and are inserted in the upper edge of the inferior maxillary branch for almost two-thirds of its length.

The muscle immediately behind is analogous to the temporal, and is much flander than the preceding. It is a muscular fasciculus, of which the superior extremity is fixed to the temporal excavation behind the orbit, and the inferior, after going backwards behind the commissure, is confined with the insertion of the last muscle. It is obvious that the contraction of these two muscles must approximate the jaws, and thus close the mouth.

In the commissure of the lips, and behind the two last muscles, we see another resembling them in form, but much shorter. It occupies the inferior part of the os quadratum, and about the posterior third of the jaw, at the outer edge of the dental canal. It is an accessory muscle to the temporal and mafeter.

The muscle corresponding to the digastricus occupies the whole length of the back of the os quadratum, and terminates at the posterior apophysis of the maxillary branch beyond and behind its articulation.

The muscles moving the upper jaw are more numerous. One arises, by aponeurotic fibres, from the capsule of the joint, between the maxillary branch and the os quadratum, and passes forwards and upwards towards the back of the venomous teeth, being partly expended on that back, and on the posterior apophysis of the superior maxillary bone. Its use is evidently to draw down the venomous teeth, when they have been elevated.

Two other muscles act on the pterygoid and palatine branches. Both are situated between the middle line of the basi-sphenoid and the palatine arches. The lower, situated immediately under the skin in the palatine fossa, is a plane of elongated fibres, occupying the whole middle line of the cranium, and going backwards to the internal surface of the bone pterygoid plate, which it will carry in wards and forwards, so as to protrude the superior maxillary bone, and elevate the venomous fangs, at the same time contracting the mouth by the approximation of the two internal arches.

The other muscle, slenderer, and placed above the preceding, towards the basi-sphenoid, extends from the anterior portion of the palatine arch, and the whole length of this arch, to the middle of the basi-sphenoid, crossing the direction of the last muscle, on which it is placed. When it contracts, it carries backwards the whole mass of the upper jaw, at the same time approximating its two branches.

By means of this mechanism, serpents can twist their mouths in seizing objects, and dilate them extraordinarily, so as to swallow animals larger than themselves. Their teeth serve merely for holding their prey; and the muscles moving the bones, in which these teeth are implanted, cannot move them in such a way as would be necessary for mastication, but merely depress, elevate, approximate, separate, protrude, and retract them.

Lacépède thus describes the motions of the jaws in serpents. "While the teeth of one side are fixed in the prey which the animal has seized, and are therefore motionless, those of the other side are carried forwards, penetrate the animal, drag it towards the throat, and there fix it in their turn; when the opposite ones are again advanced to repeat the same process on their side. By these repeated alternate motions of the two sides of the jaws, combined with their lateral expansion, serpents are enabled gradually to swallow animals of a diameter exceeding their own." Hüt. Nat. des Serpens.

The Teeth.—Their structure has nothing peculiar in reptiles. The bone is compact and hard; the enamel thin; and, as they are always thin, there is none of the third substance called by Cuvier the cement. We are not acquainted with any facts concerning the succession of the teeth in reptiles;—whether they have two sets, or that the first grow constantly, or that the jaws are elongated anteriorly, &c. The crocodile forms an exception to this remark: we are indebted to Cuvier for a very interesting account of the succession of their teeth, which we shall state presently.

The chelonian reptiles, like birds, have no teeth, properly so called; the horny substance encasing their jaws, and supplying the place of teeth, will be described at the end of this account of the teeth of reptiles.

The saurian, ophidian, and batracian reptiles may be compared to the cetacea: as they do not masticate their prey, the teeth are calculated merely to hold, and not to divide it; hence they have much less influence on their economy than those of quadrupeds. They accord, however, tolerably with the natural genera and sub-genera.

They are almost always the same in all parts of the jaw, so that they admit of division into different classes, according to their configuration, only in very few species.

Sometimes they are attached to the two jaws only, as in the mammals: this is the case with the saurians (excepting only the iguana, which has palatine as well as maxillary teeth); sometimes they are implanted also in the palate, as in the ophidiens, with the single exception of the amphibia. Their number is of less importance; first, because it is considerable, and it accurately determined; secondly, because they fall out without any hitherto ascertained regularity, either in situation or time.

Teeth of the Saurians.—In the crocodile the enamel is more or less frilled longitudinally. The upper and lower teeth curve when the jaws are shut. They are all conical, hollow, generally a little curved, and marked with two longitudinal projecting lines; an anterior and a posterior one. The five or six posterior teeth on each side are more obtuse and compressed than the others.

In a living crocodile, which Perrault observed at Versailles in 1681, he found that all the teeth were highly bent towards the throat, and that this curvature was the most conspicuous in those near the end of the jaw. When the jaws were drawn together, the teeth of each jaw passed into the intervals between those of the other, so that an uninterrupted series was visible, as there are no lips to hide them. He says further, that the points of the upper teeth entered into excavations of the lower jaw.

The following account is derived from Cuvier's Obi. sur l'Osteologie des Crocodiles vivans, in the tenth volume of the Ann. du Mus. "The number of the teeth does not change with the age of the animal: a crocodile quitting the egg has the same number as one twenty feet long; I have ascertained this fact in a series of heads from an inch to two feet long. The back teeth may be a little concealed by the skin of the gums. The interior is always hollow, although,
although the teeth, as in all other classes, are formed by fucce-
volution.

"The capsule containing the new tooth is not enclo-
sed in a separate cell of the maxillary bone, as in the mammalia,
but lies in the bottom of the socket of the tooth which it
is designed to succeed. This little shell is first on the
internal surface of the root of the tooth in place; it oc-
casions a groove in this part, by which, as it increases in
length, it penetrates into the hollow of the latter, and then
defronds by its pressure the pulp that filled its cavity, and
furnished the materials of its incrusta. Hence, at what-
ever age we may remove a crocodile's teeth, we shall find,
either in the alveoli, or in the cavity of the tooth itself,
small teeth, either in the form of a thin and short shell, or
more advanced and ready to occupy its place, when the
old and enveloping tooth shall have been discharged. This
succession seems to be repeated as long as the animal lives:
hence the teeth always appear sharp and fresh, and although
larger, they are not much more worn in old than in young
crocodiles. I have ascertained all these facts in a recent
head, and in others preserved in spirits of wine: and I
could distinguish very clearly pulps and capsules similar to
those of quadrupeds.

"This process was tolerably well understood by Per-
rault and Duverney; Mem. pour servir à l'Histoire des
Animaux, v. iii. p. 167.

"As the teeth of the crocodiles are generally nearly
perfect cones, and enlarge to their very bases, how can
they come out of the alveoli, of which the animal lives
is much narrower than their base? The new tooth, as it is
developed and fills the cavity of the old, compresse its
substance against the socket, detroys its confidence, makes
it crack, and thus dispenses it to be separated on the slightest
shock at the level of the gum. The fragments are easily
thrust out of the sockets. We often find in the sockets of
crocodiles, when changing their teeth, rings formed by the
relics of the old teeth left behind, through which the new
are making their way : and such are also found in the fossil
jaws of true crocodiles.

"The base of the cone is generally not entire, but
exhibits a more or less deep fissure on its internal side: it
has been already mentioned that this is caused by the pre-
sure of the germ of the new tooth. While the germ is
very small, this fissure does not exist, and the germ itself
never exhibits it.

"Although the teeth may be said to be all alike, and
arranged in an uniform series, some are rather larger than
the rest; and the greater this inequality, the more ir-
ger-ular is the line of the jaws.

"These larger teeth are either received into grooves of
the opposite jaw, or into holes, or they perforate it com-
pletely.

"In the cainans or alligators, the first of Cuvier's
subgenera, (containing the American species,) there are
from nineteen to twenty-two teeth on each side below, and
nineteen or twenty above. The two first of the lower jaw penetrate at a certain age the front of the upper jaw,
and go completely through it. The fourth of the same jaw
are the longest, and go into the holes of the upper jaw,
in which they are entirely concealed when the mouth is
shut. The five front in the upper jaw are intermaxillary
teeth.

"The first and fourth of the lower jaw are long in all
the three subgenera; next to these come the eighth and
ninth of the upper, the eleventh of the lower jaw in the
ture crocodiles and cainans. The cainan with bony eye-lids
(crocodilus palpebroflexus) has the twelfth below and the tenth
above the longest. After the fourth in the gavials (lon-
girostres) they are all nearly equal, so that the jaws in
these have not so waving a line as in the other sub-
genera.

"The fourth tooth below might be called canine, from its
superior length, and because it corresponds to the future
between the maxillary and intermaxillary portion of the
upper jaw.

"In the second sub-genus, or proper crocodiles, there
are fifteen teeth on each side below, and nineteen above.
The first of the lower jaw penetrates the upper; the fourth
pans into grooves, and are not lodged in cavities of the
upper jaw.

"The gavials (longirostres) have 25-27 on each side
below, and 27-28 above. The two first and the two
fourth of the lower pans into grooves, not into perforations
or cavities of the upper.

In the tupinambis of the Nile we find sixteen above, of
which five are intermaxillary, thirteen below; all conical,
and slightly bent backwards: the posterior are the largest
and most obtuse. In a tupinambis from the Moluccas
there were six above, and seven below, all compressed and
pointed.

The teeth of the common lizard, the iguana, and agame,
are cutting, and more or less serrated on the edges; they
are all so in the iguana, where several have six or eight
denticulations, and there are twenty or twenty-one teeth on
each side. The common lizard has twenty-one or twenty-
two, but the anterior are not feebly dentellated, and the
others have merely a groove. The agame has nineteen or
twenty, all with three denticulations. In these three genera
they increace in size from before backwards.

They are triangular, with a little groove before and
behind, in the féllio: there are sixteen or seventeen such
on each side, and two large conical canine teeth. There are,
moreover, two small conical intermaxillary teeth above, to
which nothing corresponds below.

The dragon corresponds to the féllio in its teeth, except
that the canine are proportionally longer than the incisors:
the number is the same. There is a good representation of
them in Blumenbach, Abbildungen Natur-Hilfsflcher ge-
genblnde, No. 98.

The gecko has thirty-five or thirty-six teeth on each side,
all of equal size, close, simple, slender, and pointed. The
flat-headed gecko has seventy or seventy-four on each side.
There are twenty-two on each side, above and below,
in the čink, all conical, short, closely set, and of equal
size.

The camedon has, on each side, eighteen above and nine-
teen below; of which the anterior are very fine, the pos-
terior much larger, and furnished with three points.

Teeth of the Bairacians.—All these have teeth in the
palate; as to the jaws, the falamanders have them in
both, the frogs in the superior only, and the toads in
neither.

The palatine teeth form, in the toads and frogs, a tran-
verse line, interrupted in the middle. They are implanted
in the palate bones. They form two long parallel lines in
the falamander.

The maxillary teeth are small, pointed, and closely set.
The frog has about forty on each side above, eight of
which are intermaxillary; the falamander fifty, both above
and below, and thirty on each side of the palate.

Teeth of the Ophidian.—The serpents are divided first into
two families, those which can, and those which cannot,
separate the two halves of the upper jaw. The former
have no incisor teeth; but they have palatine, maxillary, and

Vol. XXIX.
mandibular, or teeth of the lower jaw. The latter, having all the edge of the upper jaw furnished with teeth, possess, consequently, a kind of incisors.

The second family includes only the angues and amphibians. The former, besides the conical slightly curved teeth of uniform size, which they have in both jaws (eighteen or twenty above, and fifteen or sixteen below on each side), possess others, very small and short, arranged in two rows, on the posterior half of each palatine arch.

The other family is subdivided into two tribes, the venomous and the non-venomous. In the latter there are conical, curved, and very pointed teeth, directed backwards along each maxillary, palatine, and mandibular arch; consequently there are four rows in the upper, and two in the lower jaw, all nearly longitudinal.

On the maxillary branch of the venomous serpents there are only the hollow fangs, attached to the anterior extremity only; consequently, with the exception of these fangs, there are only the two palatine rows above, and the two rows of the lower jaw below.

The following is a table of the numbers of teeth on each side in some species.

**Venomous Teeth and Gland.**—We have stated that the innocent serpents have teeth along the maxillary edge of the upper jaw, and in the palate; that is, four parallel rows, two external or maxillary, two internal or palatine. The venomous kinds, instead of the maxillary rows, have the venomous fangs at the anterior end of each superior maxillary branch; and they puffles the palatine rows, as well as the innocent serpents. There is no difference in the teeth of the lower jaw. The venomous fangs are much longer and thicker than the other teeth; they are conical, sharp-pointed, and perforated by a fine tube. They are moveable at the will of the animal, and can be drawn up from the jaw, or laid down at pleasure. They are contained in a kind of cavity formed in the gums, from which their point projects.

At the end of his account of Indian serpents, Ruffel has given two finely engraved plates, representing the appearances of the teeth in the venomous and innocent species. In the coluber catenularis (tar-tuttah), an innocent serpent, there are two marginal or maxillary rows of simple teeth, and two palatine rows. The vipera elegans (katukah-rekula-podah) has also two palatine, but no marginal or maxillary rows. The teeth are surrounded by a fringed membranous covering, which almost conceals them. The points alone appear, when the membrane is not entirely depressed. At the anterior end of the maxillary bone, on each side, is a large membranous sac, wrinkled, and containing the fangs. The vipera naja, or spectacled snake, has the palatine teeth, and two venomous fangs, like the laft; but the teeth are smaller, the fangs shorter, and the membranous sac less apparent. The bungarum, a species of bungarus, has the palatine teeth, two fangs still smaller than in the spectacled snake, and at the edge of the mouth, behind the orifice of the bag including the fangs, three small teeth on each side, which may be considered as an imperfect maxillary row.

In the vipera elegans, the fang is fixed to a bony basis, which is attached to the inferior maxillary bone: this basis is much longer in the spectacled snake, and has attached to it the three small fimple teeth already mentioned.

Behind the venomous fangs in the vipers and other serpents, are other smaller fangs, said to be designed to replace the former when they are lost.

Blumenbach has given an excellent delineation of the mouths.
mout of the boa constrictor and the crotalus horridus, in his Abbildungen Natur-Historischer gegenstände, No. 37, to notice the fide between the venomous and innocent kinds; an object of the greatest importance, both with regard to the fewer species of the former, and the much more numerous of the latter kind, in order to warn mankind against real danger, and preserve them from groundless terrors. "All serpents (says Blumenbach), whether venomous or not, have the double internal row of palatine teeth, and the inferior maxillary teeth, in common. But the innocent species have moreover the whole outer edge of the upper jaw furnished with teeth; in the venomous kinds, this is toothless. But the latter have, at each anterior corner of the mouth, attached to the upper jaw, the long hollow fangs with a slit at their point. These are connected with the venomous glands, of which they may be regarded as bony excretory ducts, to convey venom into the wound made by the bite.

"When, therefore, we see in any snake four rows of teeth in the upper jaw, viz. besides the two internal palatine rows, an external row on each side running to the corner of the mouth; we may be sure that the species is poisonous, and so far innocent." The poisonous gland, peculiar to the serpents with fangs, and said to be of the conglomerate kind, like the salivary glands of the mammalia, is situated on each side, behind the orbit, close to the branch of the maxilla, and almost immediately under the skin. It is covered by a membraneous or aponerotic femor-transparent sheath, fixed to the bones of the head in front of the gland. The excretory duct extends from the anterior part of the gland, immediately under the orbit, to the bony basin of the fang, and opens into a canal excavated in the fang, running through it from above downwards, and terminating by an oblique aperture on its anterior surface. Two muscles defined to elevate the fangs, to depress the superior maxillary bones, and consequently to clothe the mouth, pass along these bones from before backwards; one on the outer, and the other on the inferior side of the gland. These cannot act without compressing the gland, and expelling its secretion into the excretory duct. See a representation of the gland and the surrounding muscles in the collector major, Phil. Trans. 1804, pt. 2, pl. 8.

In the article Pois on of this work, there is an account of the appearance and sensible properties of the fluid secreted by the venomous gland of the viper, and of its effects on animals. We have a few additional points to mention on this subject, as well as concerning the poisonous properties of some other serpents. Fontana affirrs, that the noxious qualities of the secretion are retained for a long time, even in dry states, and that perox have suffered from wounds inflicted by the fangs of vipers, and other venomous serpents, preferred in pith, or dried, even years after, the death of the animal. The venom retains its colour and transparency in the dead tooth, and is still active enough to kill animals, if it is rendered fluid by immersion in warm water. He also found it active after many months, when dried and powdered.

Leeches, ants, and flies, were not injured by the venom of the viper. The blindworm and common snake were not affected. Of tortoises, some were insensible to the bite, others died at the end of some hours, when bitten by several vipers.

The bites of the vipers of these climates produce more or less alarming symptoms in the human subject, but are not attended with danger. A peafant, bitten by a viper in the little toe, had the foot, leg, and thigh swoln in six hours; the pulse small and intermittent; there was head-ache, pain in the abdomen, latitudine, and oppression; he cried frequently and had no appetite. He gradually recovered in two days, under the use of vegetable decoctions and poultices, which probably did not contribute much to his restoration. Daudin, Hist. Nat. des Reptiles, 8vo, introd. p. 138.

Lepchaîn mentions the circumstance of an young Bafchur, ten years old, being bitten by a black viper (coluber proter, L.) in the foot. "Son pied enfla extrêment en moins d'une demi-heure, et il épuvait tant de douleur dans la partie blessée, qu'il ne pouvait pas remuer le pied sans être forcé de cri; la paix extême de son vilage, ses yeux troubles, et fa respiration gênée, annoncent tres-fortement le danger que courait ce jeune homme, li l'on n'y apportoit un prompt remède." Olive oil externally, and volatile alkali by the mouth, were the successful remedies. Daudin, v. 6, p. 169; (quoted from Lepchaîn, Tagebuch einer Reise, &c. t. 2, p. 165).

While Charas was engaged in researches for his work on the viper, he was bitten in the fore-finger. He immediately fuddled the wound, made a ligature on the root of the finger, and another on the wrist. The bite gave him but little pain. He took some tinctures, which operated in a few hours, and he was cured.

Boyle says that he cured a man bitten by a viper, by holding a red-hot iron near the wound for a quarter of an hour. The truth seems to be, that the effects of the bite are not considerable in the human subject; and this accounts better for the recovery of persons bitten, than any virtues in the remedies employed.

The wounds inflicted by these animals are not, however, always so free from danger. The viper cherica (coluber cherica, L.), says Daudin, is very venomous, and its bite is often mortal. Linnaeus employed olive oil in the case of a woman who had been bitten; but she died, although the remedy had been successfully employed in the bite of the black viper (vipera preter). Daudin, v. 6, p. 148.

The wounds of many Indian, African, and American serpents, are, however, fatal to the human subject. The vipers cornuta of Southern Africa, is described by Pateron as very virulent, inasmuch, that the Bojesmen and Namaquaws employ its venom for poisoning their arrows. Daudin, ibid. p. 139.

A captain Hall made some experiments on the poisonous powers of the rattlesnake, of which he has recorded the results in the Philosophical Transactions. The first dog bitten by this animal died in fifteen seconds, the second at the end of two hours; and the third of three hours. He recommenced his experiments with the same serpent on the following day: the first dog died in thirty seconds; another in four minutes. Three days after, a frog died in two minutes, a chicken in three minutes. A little time after, an amphibia was bitten, and died in eight minutes; and the frog, having subfequently bitten himself, died in twelve minutes.

Sir Everard Hume has described at full length the case of a man, who was bitten on the thumb and fore-finger by a rattle-snake between four and five feet long in this country. He died eighteen days after the accident. Great swelling of the whole limb up to the axilla ensued; the timefation did not extend to the neck, but there was a fullness down the side, and blood was extravasated as low as the loins, producing a mottled appearance. A full trial was given to the volatile alkali, both externally and internally, and to other medicines of the like nature, as ether, brandy, &c. also opium. The cellular elevation had sloughed over the whole swollen part of the limb, so that the skin was separated universally from the muscles. For a further account of this case, and
and of some other cases of bites of Exit and West Indian serpents, see the Phil. Trans. for 1816, p. 75.

Rufiel, in his account of Indian serpents, has furnished us with the most ample and interesting details concerning the Indian poisonous serpents. Of these the cobra de capello, or spectacle snake (coluber anaia), and the katta-ka-rekula-poda (viper elegans), are the most dangerous. It appears, from a comparison of the effects of the venom of the Indian serpents, the rattle-snakes, and the viper in the mammalia, that the symptoms are nearly the same in all, but that the term of their duration differs. The bite of a rattle-snake destroyed a dog in England in two minutes; while that of the most venomous Indian snake has never been fatal to this animal in less than thirty-seven minutes. A chicken bitten by the g-di paragoodoo (bungarus cerauleus) was immediately affected with fever; in ten minutes, it was incapable of remaining upright; a quarter of an hour after it was stretched on the ground, as if asleep; it made some efforts to rise, turning the head to one side and the other, became convulsed, and perished in half an hour.

A stout dog was bitten in the thigh by a serpent of the same species; he howled much from the bite, but walked about freely. He lay down in a quarter of an hour, and howled: when an attempt was made to make him stand by raising him up, it was found that the hind limbs were paralyzed. He grew worse, ceased to howl, and vomited abundantly he became benumbed, and remained lying on the side. He died in two hours, having had very bad convulsions.

A lean bitch, having been bitten near the groin, remained fifteen minutes without exhibiting any symptoms of suffering. In fifty minutes she lay down, and appeared much affected: on attempting to make her stand, it was discovered that the limbs were paralyzed. She vomited a little, and was convulsed till death, which occurred seventy minutes after the bite.

Wounds inflicted by the spectacle snake, or coluber anaia, had the same effects; also those of the katta-ka-rekula poda. Death did not always follow in the latter case, particularly in a dog, who was bitten six times, and once inoculated with the poison. A horse was bitten by the last-mentioned snake on each side of the nose. Prodigious swelling ensued, and extended to the throat; the animal refused his food, vomited, and appeared greatly affected. He had an emollient fomentation, and recovered on the third day.

Experiments with the bodrour pam had the same results: swelling, numbness, paralysis, convulsions, and death.

Rufiel tried inoculation of the venom with needles, thread, &c. Of six trials on dogs, none proved mortal. Eight out of twenty fell were fatal in chickens and pigeons.

Several venomous and innocent serpents were exposed to the spectacle snake: it would not bite them until infuriated to do it, and they died without attempting to retaliate. But Rufiel found, in repeated trials, that two of these animals did not hurt each other; they would fight, and wound each other, but these wounds were not mortal.

Many circumstances modify the results of wounds inflicted by venomous serpents: viz. the quantity of venom, the condition of the serpent as to vigour or weakness, the number of bites he has inflicted, the situation and nature of the part bitten, the size of the animal, &c.

There are many facts to prove, that the secretion of the venomous gland, which is so active a poison, when introduced into a fresh wound, is quite innocent, and probably inoperative, if taken into the stomach. The phyllis, or serpent charmers, so celebrated among the ancients for curing persons who had been bitten by vipers, fucked the wound strongly and repeatedly. Recent wounds made by the fer de lance (viper lancers) of Martinique, the venom of which is very active, are also licked with impunity. Fontana swallowed the poison of the viper, both mixed with water, and pure; it had even a mild taste, instead of producing a caustic and burning fermentation, as some have stated.

The heads of vipers, with their fangs and glands entire, have been eaten by dogs without any ill effects; and even the head of the terrible rattle-snake, with all its venomous apparatus, has been employed, with the rest of the body, in making loup, which has been drunk with perfect impunity.

Having thus described the instruments with which nature has furnished the venomous serpents, for the purpose of attacking, killing, feizing, and swelling their prey, we cannot but much lodi to understand how these objects are effected; yet the prevailing notions on the subject are calculated, instead of elucidating, to involve a plain matter in obscurity and mystery. These will be most effectually dispersed by the following statement of Pallot Beauxois, who had considerable opportunities of observing the habits of serpents in America. "Much has been written on the manner in which serpents seize their prey: some ascribe to them a kind of magical power, the effect of which is to charm and enchant the animals on whom they fix their looks; others, less fond of the marvellous, pretend that they inspire them with excessive alarm, that, not knowing what they do, they run from one side to the other, fly, return, and at last precipitate themselves into the jaws of the monster; a third opinion is, that serpents diffuse around a fetid odour, by the aid of which they suffocate birds, squirrels, rabbits, and the different animals on which they feed. It must be difficult to determine the means employed by these animals in a state of nature, for the purpose of seizing their prey; and it would probably be wrong if we were to suppose that the same means are adopted in all instances. Can we believe, for example, that the black serpent (coluber constrictor), which creeps with astonishing quickness, climbing shrubs, and not at all venomous, should employ the same means as the boaquiria (cratalis durillos), a slow moving animal, never ascending the smallest plant, and furnished, like all the venomous serpents, with two fangs, the wound of which is so quickly fatal? Yet, if we may judge of these reptiles in a state of liberty, by what goes on when they are prisoners, they certainly create only a common alarm, such as any creature will feel, when endeavouring to escape from its enemy. The animals experience no enchantment, nor any attack of madness, when a serpent fixes his eyes on them. Serpents produce no bad smell, till a fetid vapour, capable of suffocating animals. The boaquiria eats indiscriminately all the dead birds brought to it. It will not eat frogs, which the black serpent, on the contrary, seems to prize highly. Fascination and charms are repugnant to reason: forcers and magicians excite no more among animals than men: cunning, addicts, and force, are in both cases a sufficient, as well as the only charm and power, to render the weak tributary and victim to the strong."

"I made, in conjunction with Peake, the following observations on the boaquiria, which he had preferred alive for five years, and on a black serpent.

A living bird (icterus pheniceus) was put into the cage with the rattle-snake, and remained there two days, without any offensive proceeding on the part of the serpent. The bird did not seem at all uneasy. As far as we could judge from the countenance, the air which it breathed was the same as it would be in an ordinary closet cage. During the two days, the reptile ate a dead bird of the same species.
as that in the cage, which he never offered to touch. Another living bird, the loxia cardinalis, instead of being frightened by finding himself in company with the boaquiras, amazed himself with pecking at the cage, and eating millet-seed thrown into him; he changed his situation frequently, and would even perch on the reptile's back; but he moved off at the sound of the rattle. Several kinds of frogs, living and dead, were presented to the same serpent; but he touched none. The black serpent, on the contrary (coluber constrictor), attacked the frogs immediately, and seemed to prefer the tree-frogs. He also swallowed flies and other insects.

"A common rat was put into the cage with the boaquiras, who immediately appeared animated; the rat, frightened, ran towards the side opposite to the reptile. The chafe lifted a few seconds, the animal using every effort to escape, when the reptile, perceiving a favourable moment, flew at his prey, and bit it. The rat continued to run round the cage, but the serpent remained quiet; the former, in about a minute, swelled, became convulsed, died, and was swallowed by his enemy. These convulsions were probably considered by old observers as the effect of the charming power of the serpent, or of extraordinary fear; but they are a regular symptom of the action of the poison.

"Perhaps these experiments do not determine exactly the means which serpents employ for seizing their prey, so likely to escape them by running or flying; but they seem sufficient to authorize us in rejecting all ideas of fascination, or charm, of extraordinary terror or suffocating vapour. On the latter point, I can state, that nine boaquiras were kept for three weeks in the same box; when it was opened, at the end of this time, no particular odour was observed." Daudin's Hist. Nat. des Reptiles, in the edition of Buffon, by Sonini, vol. 5. p. 55. et seq.

These serpents which have not this quick and effectual means of destroying their prey by the poisonous apparatus, accomplish their object in another manner. They throw themselves on the animal which they attack, twine round his body and limbs, and exert, in this manner, a compre-SSive force capable of breaking the bones. When he is thus disabled from resistance, they slay him over with a mucous saliva, and swallow him gradually in the way already described. The enormous serpents of Africa and America, thirty or forty feet long, are strong enough to attack and overcome the larger animals, and can then swallow them entire. See the account of the boa aboma by Stedman, in his voyage to Surinam and Guiana; and of the boa constrictor, in Adanson's Voyage au Senegal, p. 152. et seq.

Proportion of the venomous to the harmless Serpents.—The number of serpents poisoning venomous fangs is more considerable than has been generally supposed. "Ne telis horentibus," says Linnaeus, "execrabili veneno nimium favent, decimam quamque tarnum speciem armavit imperans, et veripellas eos volet, ut dubii omnes metuerentur ab omnibus." Yet Dr. Ruffell found seven venomous species among forty-three, which he observed; and the proportion of the venomous to the non-venomous kinds, among the serpents described by Daudin, in his History of Reptiles, is as 80 to 233. There are not more than 14 or 16 genera of serpents indigenous in Europe, yet among these are five vipers. Of the species described by Daudin, 201 belonged to the ancient, and 112 to the new continent: the venomous kinds formed a fourth in the former, and a fifth in the latter.

Daudin gives the following lists of the poisonous and harmless kinds.

Horny Covering of the Jaws in the Chelonian Order.—This substance is similar in its nature to that which composes the hollow horns of animals (see Horn); and there is no essential difference between it and that of the bill in birds. (See Birds, in Comparative Anatomy.) As in birds, this horny covering is spread over the opposed surfaces of the two mandibles; but the organ so covered is much less susceptible of motion in the lizards, as the upper mandible is always fixed in them. In general it is feebly fibrous in its texture, but sometimes it appears homogeneous. It is very hard, so as to enable these animals to break shells with facility. In this respect, it is analogous to the horny bills of the birds of prey, and the resemblance is so striking in one species of turtle, that it has received the name of hawk's-bill. It is formed on a vascular sub stance covering the bone, as is the case with the hollow horns and the bill of birds. The edges are sometimes simple, sometimes serrated, sometimes divided into large unequal teeth; the extremity is either entire and rounded, or grooved, or brought to a sharp point. The edge of the upper jaw is terminated by a thin sharp plate of horn, within which the lower passes to some height, being rather narrower in its transverse measurement; hence any sub stance may be cut by them as with scissors, for the outer margin of the lower jaw is also brought to a sharp edge. Besides this sharp edge, there is a covering of some breadth in the upper jaw, forming a rigge
a ridge towards the anterior part, received into a corresponding concavity of the lower jaw.

Salivary Glands.—We have already observed, that nothing deserving the name of mastication takes place in any reptiles. They live on other animals, and almost universally swallow them whole. Some tadpoles feed on shell-fish, and break the tellacaceous coverings with their horny mandibles, but they do not chew the contained animals. The salivary apparatus must, therefore, be very different from that of the mammalia.

Several reptiles, however, require the assistance of fluids poured into the mouth for seizing and swallowing their prey. Some, as the frog and caneleon, dart out the tongue, covered with a viscid matter upon insects, which are entangled in the slime, and thus captured. Serpents spread a frothy layer over the animals which they swallow, to facilitate their passage.

In some reptiles the tongue is composed, in great part, of a thick glandular mass, formed of numerous small tubes united at their bases, and separating towards the surface of the tongue. They are so many papillae, giving a slightly appearance to the organ, or rendering it villous, when they are very small. The sides of the mals are perforated by numerous pores, through which the secreted fluid escapes. This gland reeves the muscles of the tongue, and follows the motions, which they communicate to the organ. The gland in question exists in the chelonia; in the teftudo græca the structure just described is very evident. It exists also in several fuarins, as the flat-headed gecko (G. jimbit,ras), the common iguana, and the Schneidern fcinik.

In the agame umbra (iguana umbra, Linn.) the gland is furmounted in front, instead of papillæ, with transverse plates closely arranged. Thesæ lamme cover the whole surface in the cameleon.

The tongue seems to be covered by an analogous glandular substance in the harrucans. Where the tongue is scaly, or smooth, and covered with a simple membrane, the place of this gland is supplied by two others, elongated and glandular, situated under the skin, along the external surface of the branches of the lower jaw-bone, and pouring out their fluid at the outside of the skin of the same jaw. In this direction they are in contact with the palatine membrane. These glands are strongly marked in the tupinambas, the colubres, and the boa. In the amphibia the glands are not situated in the same place, although they have the same apparent structure. They lie immediately under the tongue, between the genio-glæph and genio-hyoides.

The conglominate gland secreting the poisonous fluid of the venomous serpents is spoken of in the description of the teeth.

The os hyoides varies in the different orders of reptiles, but it approximates in general very nearly to that of birds, from which it does not differ essentially in the saurian and ophidian orders. As in birds, its connections with the larynx are very inconsiderable: there is no muscle passing between them: a simple membrane is the medium of union. They are, in fact, completely separated in some genera of saurians; as, for example, the cameleon: and the same observation may be extended to all the ophidia which have a tongue included in a sheath. This circumstance completes the proof of what is rendered very probable by many other reasons, that the essential function of the os hyoides is to support the tongue, and assist its motions.

The form of the os hyoides varies much in the chelonia: sometimes the body is nearly square, thin, and flattened, then the posterior cornua are straight, articulated to the posterior angles of the body, separating from each other as they pass backwards, and having the larynx placed in their interval. The anterior cornua are confluated to the body, a little behind the anterior angles, directed backwards, and curved upwards behind the occiput. In front the body is prolonged into a point, under the tongue, which it supports. Such an os hyoides is seen in the telludo græca. But in the matamata (telludo fimbriata, Gmel.) the body is very solid, bony, and pyramidal, with the basi turned forwards. The anterior cornua, forming angles towards the front, are articulated behind each angle terminating the basi; while the posterior, more slender, and bent like an arc, are fixed near each other to the apex of the pyramid.

Usually the os hyoides consists merely of cartilage in the saurians, as in most other reptiles; its parts are generally slender, elongated, and confluated with each other. Yet it prefers in the crocodile that flattened shield-like figure, which we have described it to possess in the chelonian order, and which we shall discover also in the harrucans. There are only two cornua, articulated nearly in the middle of the sides of the cartilaginous plate. They seem formed of two portions united together, but distinguished by a kind of angle projecting posteriorly.

In the common iguana (I, delicatissima, lacerta iguana, Linn.) the body may be considered merely as the point of union of the seven cornua composing these hyoides. An anterior one is continued under the tongue, without being fixed to it. The fix others are behind. The two lowest are the longest; they are contiguous, slightly curved, and enter the goitre, without affording attachment to any muscles or ligaments. The four others are true cornua of the hyoid cartilage. Two pass first forwards, but quickly bend backwards, and then upwards, to reach the occiput. The others are bent backwards and upwards, so as to remain nearly parallel to the others. They are analogous, in their form and use, to the corresponding parts in birds. The cornua belonging to the goitre are found also in the fciniks, agames, and dragons. In the dragon raye (draco lineatus) their extremity is attached to the large bag forming the goitre, and will draw it inwards, when the tongue pâles out of the mouth. These cornua are not found in the other suarins. Sometimes there are only two hyoidal cornua, as in the gcko fimbriata. They are always perfectly analogous to those of birds.

The os hyoides of the cameleon has four; of which two are straight and directed obliquely forwards. The two posterior go behind the head. The body is prolonged to nearly the anterior third of the tongue, when that organ is in the state of repose; it is cylindrical and slender in the whole of this part, which is between one and two inches long.

In the lizards and tupinambas, the number of cornua is also four. The anterior are formed of two pieces, confluated, or moveable on each other, of which the first is directed forwards, while the second turns backwards, and is curved towards the occiput.

In the ophidia, with a tongue included in a sheath, the hyoid cartilage is composed of two parallel threads, directed from before backwards, approximated to each other, separated in their anterior half by the sheath of the tongue, and in the rest of their extent by the two hyoglophi. The two threads are united in front, nearly between the posterior extremities of the branches of the jaw, being bent into a semicircle under the sheath of the tongue; from the convexity of their union a short point is continued under the sheath. In the other ophidia, as the amphibia, &c., the
the hyoideal cartilage has a triangular figure: the two posterior angles are elongated to form the cornua.

The os hyoides forms a broad nearly square plate, immediately applied to the inferior parietes of the palate and back of the mouth, in all the batrachians, except the salamanders. The anterior cornua go off towards the front from the anterior angles, separate more widely before they turn backwards, then are continued towards the angle of the jaw, and curved from below upwards, in front of this angle, to be fixed to the posterior part of the cranium. The posterior horns are straight, strong, bony, not consolidated with the square plate, but articulated to its posterior angles, and directed obliquely backwards and outwards. The larynx is placed between them. The hyoid cartilage of the salamanders has a triangular form: the cornua go off from the posterior angles, and ascend at the sides of the neck. Their posterior edge is consolidated to a thread of the same nature, bent in the form of a handle, and having its anterior extremity unitied to that of the opposite thread in the middle of the posterior concavity of the hyoid cartilage. On each side of the branches of this cartilage, towards the front, there is a broad cartilaginous plate, nearly parallel to them, and only joined by muscles which go from one to the other. It seems to hold the place of an anterior horn.

In the thirty-fourth plate of the fifth volume of the Leçons d'Anat. comparées, there are figures of the os hyoides of the iguana, the Nilotic crocodile, the Nilotic tupinambis, the lacerta agilis, the gecko limbriatus, amphibia, another serpent, the teltudo greca, the salamander and frog.

**Muscles of the Os Hyoides.** — In these saurians, which have a more or less prostrachile tongue, these muscles contribute greatly to its elongation, by carrying the bone forwards.

We find in reptiles, 1st, a muscle analogous to the myolo-hyoides. It is composed, in the two first orders, of several portions; viz., an intermaxillary, fixed to the lower edge and internal surface of the branches of the lower jaw; a second very thick, ascending behind each angle of the jaw, upon the digastricus, and attached to the occiput; a third passing to different distances in the neck, fixed to the skin above, and embracing the neck like a girth. It is analogous to the cutaneus colli; and embraces the whole extent of the neck in the chelonians. In the common iguana the intermaxillary portion does not extend to the arch of the chin; and in the gecko there is only a thin aponeuros reaching so far. But, in general, the myolo-hyoides is fixed to the os hyoides in these two orders, which is not the case, in the batrachians; in which the muscle seems to exist merely for the purpose of filling the wide interval between the maxillary branches, and supporting and elevating the parts above it. Its fibres are directed transversely from one branch to the other; they are divided in several species by a median line, and attached to the internal surface of the maxillary branches, which enables them to elevate more advantageously the subjacent parts. In the rana ocellata the posterior edge is separated on each side, to ascend within the angle of the lower jaw as high as the palatine membrane.

2. The muscle analogous to the sterno-hyoides is attached in the chelonians, between the two cornua of the same side, and to the posterior cornua; it descends along the neck, palse within the first bone of the shoulder, and is inserted on the inside of the neck of the second bone. It acts, in this course, against the ridges of the esophagus, and is strongly attached to the pharynx towards its anterior extremity.

The same muscle, in the saurians, is attached on the outside of the sternum, between the sterno-maillioidei, and is fixed to the posterior cornua of the hyoid cartilage. In the iguana, it is fixed to nearly the whole posterior edge of the first part of theh cornua; in the gecko limbriatus, to the middle of this edge. In the caiman, after touching the os hyoides, it is continued to the lower jaw, and inserted far back in its lower edge.

It is much elongated in the caiman, and carried far backwards on the outside of the sternum, forming a point in the same direction. This muscle covers another, thinner and broader, but of the same length, equally contiguous to its fellow of the opposite side in the two posterior thrids, and inserted in the extremity of the posterior cornua of the os hyoides. It might be named sterno-ceratoideus. In the agama umbra (iguana umbra, Linn.), the same muscle extends equally backwards on the outside of the sternum. The sterno-hyoides has two portions in the crocodiles, which are only separated beyond the sternum: the lower one is thinnest, and inserted in the edge of the hyoid plate; the outer, broader and thicker, reaches the posterior edge of the cornua, and after a flight tendinous interfection, which serves to attach it to this cornua, is continued in the same direction to the jaw, and forms the first layer of the cerato-maxillary muscle.

In the serpents, the place of the sterno-hyoides is supplied by a crico-maxillary muscle, extending from the anterior ribs to the lower jaw. Its internal fibres go from the jaw and the ribs to the hyoid cartilage.

It is prolonged, in the batrachians, except the salamanders, within the sternum, to the farthest end of this bone, where it is fixed; or it only reaches the middle of the sternum. Many of its fibres are expanded on the pleura. In front it is divided into several portions, inserted successively in the external edge of the hyoid plate. One of these goes as far as the anterior cornua, and is fixed to it by a slender tendon. In the salamanders, the sterno-hyoides is continuous with the rectus abdominis, and partakes in its motions.

3. The omohyoides does not exist in the ophidians.

In the chelonians it ends in the sheath of the myolo-hyoides, which incloses the extremities of the anterior cornua of the os hyoides. This muscle is very considerable in some saurians. In the gecko, for example, it is widened, to be inserted in the greatest part of the posterior cornua; it covers the greatest part of the sterno-hyoides in front.

In the iguana it is contiguous to a muscle, which has the same direction: it is attached to the clavicle behind, and above the body of the hyoid cartilage in front. In the caiman it is also composed of two portions. The external, which is soon detached from the following, is fixed to the palatine membrane near the lower jaw. The internal is attached to the angle of the hyoideal cornu.

It is long and slender in the caiman; it pales on the outside of the sterno-ceratoideus, and is fixed to the body of the os hyoides, on the outside of the sterno-hyoides.

The omo-hyoides of the frog is mentioned in the account of the muscles of the shoulder.

4. Muscle analogous to the myolo-hyoides. This has only been noticed in the frogs and toads. It comes from the back of the head, behind the ear, where it is attached at the side of a muscle analogous to the sterno-maillioidei. It is divided into two portions in the rana ocellata, and into three in the common frog: they are all attached to the posterior cornua.

5. The genio-hyoides. The chelonians have only one, the tendon of which is fixed to the arch of the chin; the two phyley portions separate as they go backwards, and are fixed to the base of the posterior hyoideal cornua. In several saurians the structure is nearly the same; as in the common iguana, and the caiman, for example. It consists of two portions
portions in the cameleon; an internal long and slender one, inferted in the body of the os hyoïdes; an external broader and stronger, contiguous to the former, and attached to the posterior cornua in their whole length: it has an attachment also to the anterior cornua.

In the ophidians the genio-hyoïdei are continuous behind with the coltso-hyoïdei. They are only observed in those whose tongue is not included in a sheath.

The genio-hyoïdei are divided behind into two portions, in the batracians. The external and shortest is inferted on the side of the hyoïdal plate above its edge; the internal is prolonged on the posterior cornua, and furnishes a sheath to the typhoïidus. The ferior-hyoïdeus penetrates between these two portions, to be fixed to the plate.

6. The cerato-maxillare muscles. These are analogous in their attachments and use to the conical muscles of the os hyoïdes in birds: they only differ from them in not being turned round the cornua. They are found in the three first orders, but do not exist in the batracians. They arise from the posterior third of the internal surface of the branches of the lower jaw, and proceed backwards and inwards to the posterior cornua of the os hyoïdes. There are two on each side, attached to the four cornua, in the iguana. This animal has, moreover, a transverse muscle of the cornua, the fibres of which go obliquely outwards from the anterior to the posterior cornua of the same side.

In the agamid umbras the left muscul is long and slender, continued from the extremity of the posterior cornua to the angle of the anterior.

In the chelonians, the cerato-maxillare are inferted into the extremities of the anterior cornua.

The tongue varies considerably in this class of animals: it is employed, in many instances, as the means of procuring their food, by those reptiles which feed on infects. But as none of this class make their aliment, or swallow it like the mammalia, the form of the organ is very different from that which it exhibits in the mammiferous animals.

The chelonians have a small pyramidal tongue, with the bafls turned backwards, the apex forwards. A large part of the saurians and ophidians have a tongue capable of considerable elongation. The most remarkable example occurs in the cameleon, where it is not larger than a quill, but five or six inches long: it is expanded at its extremity, which is covered with a viscous secretion. This weapon lies commonly in a sheath at the bottom of the mouth, contracted to the length of about an inch, or less. The animal can dart it out at pleasure, when the viscous fluid at its end entangles the prey, which is taken into the mouth with great celerity. "Quand les cameleons veulent manger," says Belon, "ils tirent leur langue, quasï d'un demipied, roinde comme la langue d'un oiseau nommé piervéd, semblable a un verre de terre; et l'extremité d'icelle ont un gros nez d'fongieux, tenant comme gu, duquel ils attachent les infécès, favoro eft fautrelles, chenilles & mouches, et les attirent en la gueule. Ils pouiffent hors leur langue, la dardant de roideur ausit viennent qu'un arbatélé ou un arc fait le trafi." Pierre Belon, Observations, &c. liv. ii. ch. 34.

In the common lizards, the tupinambes, &c. the tongue is smooth, extinf, and terminated by two long flexible points, although semi-carthaginous and nearly horny: it resembles perfectly that of the ophidians, excepting the anguis and amphibiana, and perhaps also the cælonia, which have it flat, and merely forked at the end, without the power of elongating it.

In most of the serpents, the tongue, when contracted, is contained almost entirely in a membranous sheath. The

mechanism belonging to these projectile tongues partakes both of that which is found in some mammalia, as the csidna and the ant-eaters, and of that of birds. (See Mammalia and Birds, in Comparative Anatomy.) It depends on muscles acting on the os hyoïdes, and also on the muscles of the tongue.

The fleslios and iguanas have a fleshy tongue, villous on its surface, and poiffelling about the fame mobility as that of the mammalia. In the fharks and geckos it differs from the former onl in being bifurred at the end; and it re-membles, in this refpect, that of the angues, between which and the fenks there is in all points much analogy.

The tongue of the batracians is not only different from that of other reptiles, but also from that of other animals. It is fleshy, of a flattened figure, fmeoth, and covered, in all of the frog and toad kind, with a tenacious mucus.

It is villous in the falamanders, and covered with very long papilis in the horned frog (bufo cornutus, rana cornuta, Linn.). The great peculiarity of the tongue is its being attached by the bafls to the front of the mouth, to the hyogloflus of the lower jaw. This is its thickest part: it is continued backwards in a thinner form, fo as to end in two loofe and flat portions, representing the apex, and lying in the back of the mouth. This loofe part, ordinarily turned back towards the throat, is projected from the mouth, covered by its viscous fecretion, upon the small infects which the animal feeds on, and which are thus entangled and fwal-lowed.

Muscles of the Tongue.—They poiffel nothing peculiar in the chelonian reptiles, which have not an extenfile tongue: they confift merely of two pairs. The hyogloflus come from the anterior half of the posterior cornua, and penetrate into the tongue at the fides of the bafls.

The genio-gloflus are very strong and broad in the vertical direction: they come from the front of the lower jaw, and enter the tongue more outwards and forwards than the preceding, with which their fibres are interwoven. The apex of the hyoid cartilage penetrates between them: they are also separated by a small cylindrical cartilage, to which each muscule is fixed; which is prolonged behind under the body of the hyoid cartilage, extending in front to the apex of the tongue.

The faurians have in general three pairs of muscules going to the tongue from the os hyoïdes or the arch of the chin, and a proper muscule attached to the organ only.

1. The hyogloflus comes from the cornua of the hyoid cartilage. In the common iguana it is attached to the posterior cornua, opposite the omohyoides. In the gecko imbrifati it is fixed to the middle of the cornua, at the side and within the cerato-maxillaris: it forms, with the ftraight genio-gloflus, the bafls of the tongue, and mixes its fibres with those of the proper muscule. The hyogloflus is long and cylindrical in the lizards and tupinambes: it comes from the extremity of the posterior cornua, approaches the oppofite muscule as it advances forwards, becomes contiguous to it at the bafls of the organ, towards the extremity of which it terminates in forming the two portions of cylinders, of which this tongue conflits. In the cameleon it is fixed to the whole anterior edge of the posterior cornua, and is very thick at that part. Beyond the angle formed by the two cornua of the fame side, it is curved and continued directly forwards. The falficuli of fibres, of which it conflits, are inferted in the pofterior half of the fheath of the tongue, which it ferves to draw backwards.

2. The ftraight genio-gloflus come from the inferior edge of the arch of the chin, and are continued to the bafls of
of the tongue; where they meet the hyoglossi, with which their fibres are interwoven.

3. The transfer of genio-glossi are attached to the arch of the chin, and to the anterior part of the inferior maxillary branches, on the outside of the preceding. Instead of being narrow and elongated, they are broad and short. Their fibres pass obliquely from without, inwards and backwards upon the membrane of the mouth, as far as the fides of the tongue; which they will draw outwards and forwards. The two half pairs of muscles do not exist in the camel. 4. The proper muscle is found in those sauropsids only, where the tongue admits of elongation. It is composed, in general, of annular fibres. In the gecko spheniscus, which has a broad tongue, this muscle is divided in front into six or eight small portions, which are united into two towards the middle third of the tongue, and then into one on each side, which form the two pieces of the basis of the tongue.

The flattened tongue of the camel is very thick, and forms a fleshy cylinder surrounding the anterior three-fourths of that part of the os hyoides which penetrates into the tongue. Towards the front it is divided on the sides into two portions, a superior and an inferior; the latter is folded back towards the sheath of the tongue, to which it adheres. There is, moreover, a muscle proper to this sheath, which may be called the retractor muscle. It comes from below the glandular part, and is continued, on each side, as far as the part that is puckered up. When the hyoglossus throws this latter part into wrinkles, and shortens it, and the os hyoides is carried backwards by the sterno-hyoides and ceratoides, the retractor muscle causes the end of the sheath to remain applied to the extremity of the annular muscle which recedes, because when its posterior attachments are the most fixed: on the contrary, when the extremity of the os hyoides and the annular muscle pull the sheath forwards, the anterior attachments have a point d'appui; the posterior portions of the retractor draw forwards the sheath, and unfold it.

By putting together what we have said concerning the os hyoides and its muscles in the camel, in a former part of this article, and what we have just said of the muscles of its tongue, it will be easy to understand how this organ can be elongated, and withdrawn into the mouth. The first office is performed by the annular muscle, with the cerato-maxillary, and the genio-hyoides. The sterno-ceratoidei and hyoidei carry backwards the os hyoides, at the same time that the hyoglossus shortens the sheath and puckers it up.

In most of the ophidiidians the tongue is placed in a membranous sheath, which opens behind the interval of the branches of the lower jaw, and is continued backwards between those of the hyoid cartilage, under the tongue. It is lined internally by the membrane of the mouth. This sheath is carried forwards by a pair of muscles analogous to the genio-glossus. They derive their origin by two portions, one of which comes from between the two branches of the lower jaw, the other from their extremity; they come together and are fixed to the sides of the sheath to its most distant extremity. The hyoglossi are two elongated muscles, contiguous, and even united together by fine cellular laminae. They exactly fill the interval of the cornua of the hyoid cartilage, and are even doubled backwards round their extremity. These muscles go to the basis of the sheath, and draw it backwards, when it has been carried forwards by the two first pairs.

The proper muscle is formed of two cylinders, firm lying together, and separated towards the anterior third of the tongue, for the two portions of which its apex contains; hence they become considerably diminished, and are reduced to a mere thread at the end.

This simple apparatus, combined with that of the os hyoides and its muscles, gives to the tongue of the reptile that wonderfully quick power of extension and retraction. Carried forwards by the genio-vaginal muscles, brandished by its proper muscles, it re-enters the sheath in consequence of the elasticity of the hyoideal cornua, which tend to restore themselves, and of the action of the hyoglossi. One or other of these actions is allied by the softo-maxillary muscles, according as the portion analogous to the sterno-hyoideus, or that which corresponds to the cerato-maxillary, contracts. The extension of the tongue out of the mouth is so much the greater, because it is effected through an orifice near the extremity of the nictid, and because its basis may be brought near to this part.

In the amphibia, which have a flattened tongue, not inclosed in a sheath, nor susceptible of extensive motion, there are, 1st, two genio-glossi attached to the arch of the lower jaw, more internally than the genio-hyoiidei; 2dly, two hyoglossi; and 3dly, two cerato-glossi, which present nothing worthy of particular notice.

The tongue of the batracians, as we have already described, is fixed in front to the arch of the lower jaw, and free behind. In passing out of the mouth, and going back again, it turns upon the fixed point of its attachment to the jaw. Two pairs of muscles, the genio-glossi, and the hyoglossi, execute these motions. 1. The hyoglossi form, in the ranid oscellata, two cylindrical malleus, lying on, and attached to, the posterior cornua. They soon unite into a single mass, which rests on the hyoideal plate, and penetrates the tongue in front of this plate, expanding into small fasciculi, which reach to the leaf edge of the organ. 2. The genio-glossi form at first two small spherical malleus, placed at the arch of the chin on the small transverse malleus; they are subsequently elongated into two contiguous cylinders, of which the fibrous fasciculi separate from each other, decollate with those of the preceding muscle, and go to the leaf edge of the tongue. While the tongue is in the mouth, the hyoglossus is folded on itself, and the genio-glossus is straight. The latter muscle is folded, and the former straight, when the tongue has been projected. In the common frog, these two pairs of muscles are not so minutely divided in the tongue, and the genio-glossi do not form spherical malleus towards the arch of the chin; in other respects they are similar.

Tongue of the Crocodile.—Humboldt has observed a peculiar mechanism in the tongue of this animal, bearing an evident relation to its wants and habits, of which the following is a description in his own words.

"From the most ancient times disputes have existed concerning the tongue of the crocodile; some naturalists pretended that it was entirely wanting, others affirmed that it was very short, and placed at the entrance of the cephagous. According as one or the other of these opinions prevailed, the sculptors and antiquaries of Rome amused themselves with destroying or retouching the tongues of their crocodiles. When we examine attentively the os hyoides of this animal, we find that it is in consequence of its form and small size that a part or rather a fold of the tongue has been confounded with the whole organ. There is in this animal a peculiar mechanism, by which a valve is formed, interrupting the communication between the mouth and throat. When the crocodile appears motionless on the bank of the river, with the jaws opened at an angle of
REPTILES.

95°, the whole mouth appears yellow; the valve is elevated, and the opening of the faucae is not seen. If we surmise him, the valve is generally depressed; and if a person runs the risk of approaching sufficiently, a round body of a beautiful red colour, which is the opening of the glottis, may be perceived. This valve enables the crocodile to seize his prey under water without running the risk of being inundated by the great quantity of fluid that would pass into the oesophagus. When he swallows, the valve must be depressed, and the animal on dry ground. The os hyoidei of the crocodile of the Orinoco is a membranous spatula, broad, concave, and terminated by two short horns. The os hyoidei of the Egyptian crocodile, as delineated by Mr. Duverney, is altogether different from that of the South American animal; another proof of the distinction between the crocodiles of the old and new continent. In an animal of eighteen feet, the tongue is twenty-five inches: it is yellow, fleshy, and covers the whole jaw; but it is attached on all sides, so that the os hyoidei cannot elevate it to the end. The anterior or spatula-shaped portion of this bone enters the membranous substance of the tongue, which it can elevate at a right angle. As the sides and extremity of the organ are fixed, this motion of the bone can only carry with it the membranous part of the tongue, which forms the fold prehending itself like an elevated valve. The os hyoidei is depressed, and the valve immediately disappears. Three conditions are necessary to the execution of this mechanism, a tongue attached to the lower jaws; a ductile and flexible membrane covering it; and an os hyoidei broad in front. The yellow fleshtance in the anterior part of the mouth belongs to the tongue as well as the fold covering the entrance of the oesophagus. Humboldt found that the tongue swelled very much, when subjected to Galvanic influence, by means of zinc and silver. See Recueil d'Observations d'Anatomie comparée et Zoologie, faites dans le Voyage de Humboldt et Bonpland, t. i. pag. 9. pl. 4.

Geoffroy gives a similar description of the tongue, os hyoidei, and their mechanism, in the Nilotic crocodile. He describes it as a yellowish, fragranced skin, exactly like the fleshtance of the palate, pierced by numerous small holes, the excretory ducts of the glands situated on its upper surface, and adhering on all sides to the branches of the lower jaw. He speaks of the broad anterior part of the os hyoidei forming, by its elevation, a veil, which covers all the back of the mouth. Thus, the animal can remain under water with the jaws open, and receive air through the nostrils, the only part above the surface, without the water entering the throat or trachea. Annales du Muséum, vol. ii. p. 42, et seq.

Epiglottis.—In most reptiles the opening of the glottis is neither covered by a valve, as in the mammalia, nor armed with papilles, as in birds. Yet a kind of epiglottis may be observed in the common iguana, and in the Schneiderian fish. There is a rudiment in the crocodiles; it does not appear in several other animals of the same order, nor in the chelonian, ophidian, and batrachian reptiles. The cylindrical larynx of the dragon, and its simple opening behind the root of the tongue, are very well represented in Blumenbach's Abbildungen Natur-Historischer gegenlände, N° 98. Is the absence of the epiglottis connected with the peculiar modification which respiration undergoes in this class? or with their deglutition? On the former point we may observe, that, as they breathe only at considerable intervals, there is no danger of the glottis being opened during swallowing, and its edges may consequently be kept closely approximated. Again, as they swallow their food whole, it is not likely to pass into the larynx.

Faucæ.—The openings of the nostrils are situated very forwards in reptiles, and are not closed by any movable curtain, as in the mammalia. A kind of immovable valve, attached to the anterior edge of the opening, and leaving the orifice free behind, may be seen in the gecko fimbriatus.

There is something analogous to the velum palati in the crocodile. The nostrils open far back, contrary to what we have mentioned concerning other reptiles. They form a round aperture in the most dilatant part of the arch of the palate. The membrane lining this concavity forms a loose production a little in front of the opening in question, which depends on the sides, growing a little broader, until it meets another elevation behind the basis of the tongue. These form together, by their loose edge, the labyrinthus faucium, or entrance of the throat. The first affords some protection to the opening of the nostrils, but cannot entirely close it; the latter contributes, with the rudiment of the epiglottis already mentioned, to cover the glottis.

The entrance of the throat is large in all reptiles, and capable, in many, of still greater size, by the expansion of the lower jaws. There is nothing deferring the name of Ithites. They swallow entire animals, which cannot pass into the nostrils, and hence do not require a velum palati.

Pharynx.—As the nostrils open forwards in reptiles, the pharynx has not the same relation to the nasal cavity, as in the mammalia and birds. The mouth and larynx communicate with it, and there is usually a large aperture corresponding to the Euflachian tube.

The pharynx can hardly be distinguished from the commencement of the oesophagus in reptiles. Their diameter is usually the same; and there is absolutely no difference in the aspect of the membrane forming their internal parietes. It presents a great number of longitudinal folds, which are effaced when a prey of large size is swallowed. There is no external mufcle enveloping the entrance of the canal.

Deglutition may be aided, in the chelonians, by the action of the Ærno-thyroidei, which rest on the oesophagus in the whole length of the neck; and even adhere in front to its parietes, and to the part which may be regarded as belonging to the pharynx. The os hyoidei may also contribute to deglutition, by means of the muscles which elevate it.

This office is particularly evident in the batrachians, and especially in the frogs and toads. The hyoidal plate, which supports in these animals the extensive parietes of the back of the mouth and palate, is put in motion by the mylo-hyoides and the muscles analogous to the hylo-hyoides, only for the purpose of elevating these parietes, and applying them to the concavity of the palate. There is also another muscle coming from the upper and back part of the head, in front of that which corresponds to the hylo-hyoides; it is narrow at its origin, but expands as it passes forwards and downwards, and as it covers that part of the throat which is prominent behind. It is continued to the edge of the hyoidal plate, in which it is inserted, its fibres adhering also to the membrane of the throat, on which they lie. Their action will elevate the hyoidal plate, and apply the membrane which they cover to the opposite surface of the cavity.

The longitudinal fibres, belonging both to the pharynx and oesophagus, are more or less strongly marked.

Oesophagus and Stomach.—The former tube does not present those dilatations which we notice in birds; it retains nearly an uniform diameter throughout, or the change, if any, is gradual. But this diameter is, in most cases, much more considerable, in comparison with that of the stomach, than in the two preceding classes. Under certain circumstances, indeed, the oesophagus is larger than the stomach.
in the ophidians; for example, when the latter is not di-
tended with food, because its parietes contract sooner after
enlargement than those of the ophidophagus. The membranes
are the same in both, and, when the tube increases in size
infinitely to the stomach, it is often very difficult to allign
the limits of the two parts, and consequently the situation
of the cardia. The stomach is generally without any cul-
de-fac, oval and elongated: its parietes usually thin. The
muscular coat is then hardly perceptible, at least in some
part of its extent, and the cellular is confounded with the
mucous or internal. The pylorus is usually without any
valve; it is marked by a simple contraction, by the greater
thickness of the parietes of the stomach, and by the different
structure of the intestinal membranes.

In the turtle, the internal surface of the ophidophagus is
betef with long, hard, conical papillae, of which the points
are directed backwards, with the effect, apparently, of pre-
venting the return towards the mouth of the matters swal-
lowed by the animal. Such, at least, is the notion generally
entertained of the end or purpose of this structure. But the
absence of such provision in all other animals, where the ne-
necesity seems equally to exist, cannot but render us sceptical
on the subject, more particularly as we know no facts con-
cerning the nature of the food, the mode of its deglutition,
nor any peculiar modification of surrounding or connected
organs, to which this singular structure might be supposed
to bear some relation. The stomach is gradually dimin-
ished in size from the cardia to the pylorus: it is bent on
itself, and the portion beyond the curvature is thicker than
the rest, in consequence of the muscular fibres being more
copious. The internal coat has longitudinal folds in this part,
but hardly any in the other. The situation of the cardia is
well marked, and the ophidophagus is distinguished from
the stomach by the sudden dilatation of the latter. The
pylorus has no valve.

Among the faurians, the crocodile has a peculiarly shaped
stomach; it is very distinct from the ophidophagus by its glo-
bular figure. Near the insertion of this canal there is se-
parated from it below a small cul-de-fac, opening into the
intestine by a very small orifice, and having its cavity sepa-
rated from that of the stomach by a kind of lirat. Con-
sequently the general cavity of the stomach is a large cul-
de-fac, of which the parietes are very thick. The internal
membrane forms considerable plaits arranged in a serpentine
form, like the convolutions of the brain. The cellular coat,
which is not very distinct from the mucous in the ophidophagus,
becomes more fo in the stomach. The muscular nearly
equals the two others in thickness; the coats are altogether
much thinner in the small cul-de-fac.

In the other faurians there is no cul-de-fac. The stomach
is oval and very elongated in the iguana, without curvature;
the ophidophagus dilates gradually to form it. The only mark
that can guide us in determining the situation of the cardia is
the effusion of the longitudinal folds of the internal oph-
ophageal membrane. The stomach is suddenly contracted,
and bent a little before its termination at the pylorus. Its
parietes become thick and opaque at some lines from this
aperture, from an increase of the muscular fibres, of which
the transverse are strongly marked. The internal coat forms
no fold; there is no valve at the pylorus, which is very
small.

In the tupinambis monitor the stomach forms a long tube,
shortly into almost a complete circle.

In the Scheniderian ferac we again meet with the same
elongated form, transparent parietes, and difficulty of distin-
guishing the stomach from the ophidophagus, except by the
longitudinal folds of its inner membrane, and the thickenes;
of its muscular coat. But the posterior part of the stomach
contracts suddenly, is bent towards the right, and a little
elongated in this direction before it terminates. The pa-
rietes of the latter portion are more thick and opaque, and
its internal membrane is folded longitudinally.

The stomach begins by a small dilatation in the cameleon,
then it assumes a cylindrical and elongated form, and is bent
on itself; it is considerably contracted before it terminates,
and forms a small cylindrical canal, of which the internal
membrane is folded longitudinally. The muscular coat is
thicker in this contracted part than elsewhere. It forms a
prominent ring at the pylorus.

In the dragon the stomach is shaped like a pear, of which
the large end corresponds to the cardia; it has no curvature;
its parietes are transparent; they become thicker and opaque
near the pylorus; and these characters are the only circum-
stances, by which we can distinguish it from the beginning
of the intestinal canal, which has thin and transparent coats.

The stomach is also pear-shaped in the gecko; the oph-
idophagus makes a curve before it ends, and is inferted at one
side of the bafs. It is narrow, with thick coats, a strong
muscular covering, and broad longitudinal folds of the in-
ternal or mucous coat. The fides of the organ are thicker
at its extremities; and the pyloric end is a little bent. The
internal membrane is smooth.

In the ophidian order the stomach is shaped like an in-
testine, hardly larger than the ophidophagus, and without cur-
vature. The internal membrane is folded longitudinally.

When the stomach is empty, these folds are thicker than
those of the ophidophagus, which are not always obseved.

The ophidophagus of a snake, examined by Spallanzani,
formed a cylindrical tube like an intestine, for about nine
inches: it then became gradually narrower, so as to con-
stitute a funnel of the length of four inches and a half. This
funnel was the true stomach. The fides of the stomach
were thicker than those of the ophidophagus: no glands or
follicles could be seen in the latter; but the stomach was
abundantly supplied with them throughout its whole length;
they discharge part of their liquor on being pressed, and the
internal coat is moistened with it. Difficulties relative to
the Natural History of Animals and Vegetables, v. i.
p. 112 and 113.

Tadpoles and toads the stomach is shaped nearly as in the
cheloneian reptiles. At first considerably dilated in compar-
ison with the ophidophagus, it is gradually contracted, then
curved fo as to form an intestine-like canal, with thick coats,
ending at the pylorus.

It is slightly curved only near its posterior extremity in
the saurians. Its figure is elongated and not much
fovea; the parietes thick; and the internal membrane ex-
hibits small rugae. There is a fold near the pylorus, in
the situation of the curvature. Figures of the stomach and
intestines of various reptiles are given in Cuvier's Lecons,
pl. 41.

Intestinal Canal.—Its length, in proportion to that of the
body, is greater in the mammalia, and diminishes successively
in birds, reptiles, and fishes. In reptiles it is often merely
twice the length of the body, taken from the extremity of
the front to the anus. But tadpoles exhibit in this respect
a remarkable peculiarity. Their intestinal canal is nearly
ten times as long as the space between the front and anus,
while in the frog it is not more than twice the length of the
corresponding space. Other important differences, which
will be noticed subsequefly, exist in the two cafes. This
shortness of the alimentary canal corresponds to the nature
of the food in reptiles, which is derived from the animal
kingdom.

The
The following table of the length of the intestinal canal in various reptiles, is taken from the third volume of Cuvier’s Leçons d’Anatome comparée, p. 457.

* In a common snake of four feet in length, Blumenbach found the intestinal canal about three feet, nearly straight, or at least very slightly undulated: its proportional length was therefore different from that expressed in the table. Specimen Physiol. Comp. p. 30.

The intestinal canal of reptiles has in general no appendix to mark its division into large and small intestines; this division exists nevertheless in most of them. All the chelonians, most of the saurians, the ophidian, and the batracians, with the exception of the Serpent lacertina, have a long and slender intestine, inserted into a short and short intestine, of 9 cm. and, commonly prolonged into the cavity, so as to form a circular margin of a valve-like form. The sides of the large intestine are almost always thicker and stronger than those of the small. The membranes differ too; the muscular in respect to its longitudinal fibres, and the internal in its folds. The guana is the only animal of this class, in which a true cacoon has been noticed.

Of the Intestinal Canal.—All reptiles have the intestinal canal very short, but not of the same diameter in its whole length. In the first and most considerable portion, the capacity is much inferior to that which it is found to possess near its termination; so that it may be divided, as in the mammals, into small and large intestines. A circular valve is most frequently found separating the two divisions; it is formed by a prolongation of the small intestine, which becomes dilated, and sometimes is extended into a kind of sac, projecting more or less into the cavity of the large intestine, and rendering the parietes double at that part. It is thus found in the Schneiderian fenk.

In tortoises, the diameter of the small intestine gradually diminishes from the pylorus to the point of its insertion into the large; the area of which is four times greater than that of the small, and its parieties have the same structure as in the other reptiles. The cavity is regular throughout, there being no partial dilatations or sacculi. The internal membrane has folds, more or less broad, and of a membranous structure, in different species, sometimes connected in a reticular form at the commencement of the small intestine, having a longitudinal and parallel direction in the rest of its extent, and arranged more or less irregularly in the long. The large intestine proceeds in a straight direction to the anus, whilst the small makes many irregular turns in its course.

Blumenbach found the intestinal canal of the hawk’s-bill turtle (teltudo caretta) five times as long as the whole animal. The small intestine, as it is called, was longer than the short portion of the large intestine; the whole internal surface was covered internally with an abundance of mucus. Syll. of Compar. Anat. p. 173.

The internal coat of the intestine of the turtle is covered with innumerable thin longitudinal procerc, lying close together, and increasing the surface of the gut to a vast extent. They are most numerous in the upper part of the canal, and gradually diminish in number, until they cease altogether, below. In the latter respect they resemble the valvulae conniventes of man, and the villi of all animals. For these structures are always most distinct at the commencement of the canal, where absorption goes on to the greatest extent. The alimentary matter is deprived more and more of its nutritive parts, as it descends in the intestine; and hence a lees extensive absorbing surface is sufficient, in the lower part of the canal, for taking up the remains of really nutritious particles. Yet Blumenbach says that he found these folds so numerous in the rectum of the hawk’s-bill turtle, that a section of the gut resembled a broad radiated band. Lib. cit. p. 173, note.

In the crocodile of the Nile, the small intestine may be distinguished into two portions, the one more capacious, having thinner coats, and making four turns in such a manner as to form four permanent angles; the other, more contracted and having thicker parieties, inclines between its internal and muscular coats a layer of glandular substance, semi-transparent, of a grey colour and pulpy consistence. In the internal membrane lining the glandular substance, there are seen longitudinal folds arranged in a zigzag form, and connected together laterally, by smaller folds, so as to form a reticular surface. In the first portion of the small intestine, where the glandular substance is not manifest, the folds arranged in a zigzag form are replaced by fine villous eminences. Near the termination of the small intestine there are only seen some waving folds, connected by a few, proceeding transversely. In the large intestine, the folds are arranged irregularly, forming a velvet-like surface.

The form of the rectum (under which term is included the large intestine of fishes and reptiles) is cylindrical in the crocodile of the Nile; and the small intestine, where inserted into it, is nearly of equal diameter. In the gavial (Gaetetic
(Gangetic crocodile), the large intestine has a pyriform figure, the termination of the small being inserted into its broadest part.

In the lizards, the rectum is cylindrical, and much broader than the small intestine which is inserted into it; the latter, after having turned forwards from the pylorus, is folded backwards, and proceeds in a tortuous direction as far as the rectum, which parries a straight course to the anus. The parietes of the intestinal canal are thin and transparent; the internal membrane has folds arranged in a zigzag form.

In the cænanoe, the coats of the intestine have the same structure; the capacity of the small is not much inferior to that of the stomach and large intestine, in the greatest part of its extent; but it becomes much contracted a little before its insertion into the latter. There is no valve indicating the separation between the different portions; the internal membrane has waving folds, the loose edges of which have a fringed appearance; they are directed longitudinally, and contracting as they approach the rectum, disappear at some distance from that intestine, where the internal membrane becomes smooth and without any folds. The mucous coat is thicker in the rectum thay in the small intestine, where it is indistinct. The cellular coat is not manifest.

In the dragon, the intestinal canal forms two turns and a half before it arrives at the anus; the commencement is distinguished only by the different appearance of its coats, which are much thinner than those of the stomach.

In the iguana, the parietes of the intestinal canal are thin and transparent, gradually contracting from the pylorus to the insertion of the small intestine into the rectum; the latter is of an elongated form, but contracted at one part, by which it becomes divided into two portions almost of a cylindrical shape. The internal membrane has some folds directed longitudinally in the small intestine. In the common iguana, which has the intestinal canal long and very capacious, there is a true cæcum, distinguishable from the large intestine by the greater thickness of its coats, and by a partition separating their cavities, so that it is through a very narrow orifice that the fecal matter passes from the cæcum into the succeeding part of the large intestine. The intestine of the small into the former takes place near its middle. The coats of the cæcum have in some degree a facculated form. The internal surface is smooth and without folds. In the large intestine the internal membrane has the same structure, except at the commencement, where there are found about six transverse valves, which do not extend around the whole tube of the intestine. In the small intestine there are longitudinal folds. The pouch formed by the cæcum is about three-fourths of an inch in length, and twice as much in breadth.

In the gecko a gouttelettes the parietes of the intestine are also transparent, the small has but little capacity, but is unequal at different parts; it is inserted into the centre of the first portion of the large intestine, which is of a globular form; and is separated, by a contraction in its coats, from the second portion, which is elongated and oval, the small extremity corresponding to the anus. In the Schneiderian a cæcum and some tender coats of the intestinal canal are much dilated at the commencement of the small intestine, and contracted at the part where it is introduced into the large. We have already mentioned that it is dilated into the form of a bladder, and enveloped by the first portion of the large intestine, similarly dilated. The excrements, which pass through the small aperture in the vesicular dilatation of the small intestine, find their way partly into the interval between the latter and the internal surface of the large. Beyond the first portion the rectum becomes cylindrical. The small intestine is divided into many pouches by contractions which pretty nearly correspond to its different turns.

In the oblong order the intestinal canal parries a serpentine direction as far as the rectum, and prefers nearly the same diameter throughout, dilating but little in the large intestine. In the small, the internal membrane forms broad longitudinal layers, folded in the manner of ruffles; it is rugous, and in the rectum forms thick, irregular folds, which are continued to the anus. In the colubriform, according to Blumenbach, the whole length of the intestinal canal does not equal that of the animal. The small intestine forms a very considerable valve at its entrance into the large. Lib. cit. p. 174.

In the salamanders, the small intestine is very narrow in comparison with the rectum, where the internal membrane forms thick and fimbriated folds. In toads and frogs, we find a nearly analogous conformation and structure, there being only a slight variation in the form of the rectum, which is more or less of a conical or pyriform shape, as in many frogs, or cylindrical, as in toads. But in the tadpoles of both, the intestinal canal is altogether very different from that of the same animal in the perfect state. Long, narrow, and nearly of uniform diameter in the small intestine, making irregular turns in its course, its volume augments at the rectum, which becomes of a facculated form, and makes two spiral turns upon itself, before it proceeds to the anus. There is no valve separating the two portions of the intestine.

In the sirens lacertina the intestinal canal proceeds almost in a straight course from the pylorus to the anus, making but one small turn near its middle, from which it proceeds straight to its termination. Its coats are transparent, and its diameter nearly equal throughout, not admitting of any division into small and large intestines.

Physiology of the digestive Organs.—Bonnet affirms that most reptiles are omnivorous, while some are confined to one species of food, as the bufu or rana calamita, which feeds on a few species only of insects, and those alive. (Specimen Physiol. Comp. p. 29.) We cannot help doubting the accuracy of the first part of this statement: the food feeds us almost entirely animal. Serpents, frogs, and lizards, live on the smaller animals or insects; and even the turtles, which eat particular kinds of marine plants, feed also on the mollusca. The simple snakes, the short and thin alimentary canals of the whole order, correspond very clearly to what we understand concerning their carnivorous habits. Newts seem to care for living insects and worms only, which they seize with their jaws, and swallow whole.

Two apparently contradictory circumstances have been noticed in this order; great voracity in many instances, but in all a wonderful power of abstinence. Salamanders sometimes devour their own excrement, and earth. Serpents often take in a quantity of food, which diffuses their bodies inordinately, and leaves them inactive, and hardly capable of motion. The salamanders will sometimes stuff themselves to such a degree with worms, that they crawl up again out of their throats. See Spallanzani's Diiertations, vol. i. p. 110.

"A newt," says Bonnet, "having devoured a large earthworm, I supplied it with another above four inches long, and thick in proportion. It immediately swallowed the whole, except a line or two that hung out of the mouth; but the worm was soon thrown up, and the fame repeated twice, but the worm still lived." Spallaznani's Traicts, vol. ii. p. 366.

The influences which are recorded of the abstinence of reptiles seem at first almost incredible. Not to mention the toads,
toads which have been found inclosed in blocks of stone, and which probably have been in a torpid state, nor the more common influences (see L. Th. Gronvius ad Plinium de Aquatiliun Natura, p. 38.) we have the respectable authority of Caldei for the fact of toadlets having remained without food, and not in a torpid state, for a year and a half. Blumenbach reports of a toadlet, which he kept for three quarters of a year, that the harmless creature never ate any thing the whole time, although every thing that the house and garden afforded was offered to him. For the last three months (from November to February) he exhibited the lowest degree of vitality, manifested, in addition to extremely slow locomotion, with almost closed eye-lids, merely by the single fane of touch or feeling, particularly of warmth and drafts of air. When he died, the muscles were as flathy and flesh-coloured as in the best nourished toadlets. Abbildungen, &c. No. 66.

Redi had a land toad live eighteen months, a camcleon eight, and vipers ten, without food. (Spallanzani's Tracts, Introduction, p. 42.) Toads were quite lively at the end of fourteen and eighteen months, inclosed in pots. Ibid.

Blafius mentions, in his "Anatomia Animalium," that a land toad which he kept ten months would take no food during the whole time.

Bonnet, speaking of newts, says, "these animals can support the want of food very long. Some of mine havè kept two months without it. Sign. Spallanzani had remarked the same; and observed, that although long deprived of nutriment, they reproduced their members equally well as those plentifully supplied with substanca."

(Spallanzani's Tracts, v. 2. p. 304.) Blumenbach has kept salamanders eight months without taking food, or appearing to suffer from the want of it. (Händbuch der Natur geschichte, p. 220.) Daudin affirms that snakes and vipers may be kept for six months without food, yet seem to lose none of their activity: 1. 1. Introd. p. 276.

Some profe, which Dr. Schreibers of Vienna had kept in his pollienion for two years, had taken no food, and were quite well. (Cuvier, Rech. sur quelques Rept. douteux; l'Anat. du Profe.) Bruce states that he had kept the ceraltes in a bottle for two years without food, and Lacépède reports, on the authority of Shaw, that a Venetian apothecary kept two of these falling for five years. (See Daudin, vol. vi. p. 186.) This power of falling belongs, in a greater or less degree, to the whole order. For a comparison between the power of abstinence of warm-blooded animals and reptiles (the late of torpidity being excepted), see Dill. Academ. Inlilt. Bonon. 39 Benedictum 14. Post. Max. de fervor. Dei Beatiationes, lib. 4. p. 1. pag. 328.; also Becarius in Comm. Inlilt. Bonon. t. 2. p. 1. pag. 423.

No reptiles masticate: the herbivorous amphibia graze off the vegetable productions on which they feed, but they do not chew them. The structure of their jaws, teeth, and tongue, gives them the power of swallowing entire animals: this process of deglutition, being often exercised on animals as broad as themselves, and broader, is very slow, and occupys at times no less than six or eight hours. The eophagus must of course possess a great power of dilatation. In his account of the newt, Bonnet says, "that worms are seized with a sudden motion of the animal's jaws, and swallowed alive, with gentle shocks of the whole body, and particularly of the anterior part. The prey is always swallowed without mastication: the minute teeth, which are not employed in chewing, serve to prevent the escape of the animal, which turns itself about most actively. Long worms are devoured entire, not withstanding all their exertions to escape. They twine round the neck of the newt like a serpent; every moment they become shorter, and gradually disappear. Thus have I seen a newt swallow a worm more than six inches long in less than five minutes. A large worm, seized by the middle, is seldom swallowed in the same position, because it is too large, if doubled in the mouth, and the newt gradually shakes it out, until it can seize one of the extremities; which being accomplished, the worm is soon devoured. However, I have observed a large one swallow a worm taken by the middle, without seizing an extremity; but a quarter of an hour was occupied in the meal. The succedive motions of deglutition are very sensiblie; it is performed by repeated shocks. Though they have flexible jointed fingers, they make no use of the hand, either to seize their prey, convey it to the mouth, or retain it there."

Spallanzani's Tracts, v. 2. p. 304.

The length and capacity of this tube, and its large communication with the stomach, are well suited to the nature of serpents. The prey, always swallowed without mastication, is often too long to pass entirely into the stomach: it remains in the cæophagus until room is made for it. Travellers have even asserted that one end of an animal sometimes hangs out of a serpent's mouth, while the other is in the stomach.

As there is no mastication in this class, nor any provision like the gizzard of birds, for commemorating the food when swallowed, the process of digestion must be effected by the action of the stomach alone on the prey swallowed entire. The juices of the organ are fully adequate to this effect; and the process has been demonstrated by experiment in several genera by Spallanzani. He introcled food in tubes, and conveyed them into the stomach of the frogs, the newt, and different serpents; and always found that it was dissolved in a longer or shorter time: it thus appears that the essential nature of digestion is the same as in the warm-blooded animals: but the process exhibits some modifications, as the different nature and habits of the animals would naturally lead us to expect. The chief difference is that the solution requires a considerably longer time than in warm-blooded animals; the flesh in the tubes, conveyed into the stomachs of frogs, was not completely dissolved until the third and even the fifth day. (Difertationes, v. 1. p. 102.) Yet although the gallic liquor of frogs acts so slowly, it is capable in time of dissolving even bone: Spallanzani met with a mouse in the stomach of a frog; all the soft parts of the limbs were gone, so as to have only the naked bones, which were considerably wasted, and converted into a semi-gelatinous substance. (Ibid. p. 102.) Earth-worms enclosed in tubes were converted into a whitish pulp in thirty hours, in the stomach of the water newt; p. 104. He found numerous small white worms in the stomachs of three-fourths of all the newts he examined, from five or six in number to a hundred and more. These were so delicate that they would not bear even slight pressure; and thus afford a proof that nothing like trituratation can go on in the stomach, but that digestion is simply solution by the gallic liquor; p. 104—111. In serpents the process occupied from two to five days. The tibics of frogs were almost completely dissolved in five days; § 118—122. As the animals swallowed by serpents often lie in part in the cæophagus, a question arises, whether they undergo any digestion in that tube, or whether this function be the exclusive attribute of the stomach. A viper, says Charas (De Fercip, Anat. de la Vipère), vomited a lizard, which had been swallowed twelve days before. All the front of the body, which had been in the stomach, had merely
merely the bones remaining, while the other parts were nearly as perfect as if they had been fluid soaked the same day. Spallanzani confirmed this want of digestive power in the caecophagus, by direct experiment; § 125. Naturalists, says this indefatigable inquirer, were already apprized of the tawdneys of digestion in serpents. Bonnare, in his Dict. d'Hill. Naturale, gives an account of a serpent at Martinique, which retained a chicken in its stomach for three months, and did not completely digested it. "It is remarkable that flesh does not become fatid from remaining long in the stomachs of these cold animals, which I had occasion to observe particularly in a viper. A lizard was retained in its stomach for sixteen days, at the end of which time it had no odour but that of the gallic juice. Yet such was the heat of the season, that another lizard, which I had placed in a close vessel, containing a little water, emitted an insupportable fæculent before the expiration of the third day; § 127. The gallic liquor of a linke approaches in colour to that of foot; it had the fluidity of water, and evaporated very slowly; it had both a flat and bitter taste, and was not inflammable. It strongly resembled the gallic fluid of other animals, and this resemblance extended to the odour, which was exactly like that of the correspondine juices of birds of prey; § 129.

The idea of Blumenbach, that the venom of the poisonous serpents supplies the place of mastication, and promotes digestion by some fective power, seems completely unfounded. It is a provision calculated merely for purposes of offence. Where is this fective power, or what supplies its place in the harmless serpents, and in all other amphibia?

The whole alimentary canal of the amphibia abounds with a vivid tenacious mucus, the abode of several genera of worms.

Blumenbach failed completely in very numerous and diversified attempts to cram frogs and lizards with madder root, and thus to produce in their bones that beautiful rote colour, which is so quickly produced in the mammalia of birds, when thus fed. Specimen Physiol. p. 31.

Absorbing Vessels. This fystem has been very little examined by anatomists, probably on account of the minute ness of the tubes, and the consequent difficulty of injecting them. We have nothing to add to the account given by Hewson, who first described them in the Philosophical Transactions, 1769.

No lymphatic gland has been yet seen in a reptile: birds have none in their mefentery, but they are seen connected to the large lympthatics of the neck.

It has been ascertained that the chyle is colourless, and hence anatomists have explained why the vessels were so long unidentified. In animals which have white chyle, the appearance of this fluid through the transparent coats of the lacteals supplies the place of injection, and affords an easy method of demonstrating them. Mr. Hewson states that he saw white chyle in a crocodile.

The distribution of the lacteals (if that term may be employed where the chyle, instead of being like milk, is transparent) on the intestine of the turtle, forms one of the most elegant preparations in comparative anatomy. By fixing the injecting tube in a vessel near the intestine, and waiting with a little patience, the quicksilver will gradually find its way into the minute ramifications of the lacteals. The large trunks on the mefentery contain valves, so that we cannot succeed in filling the absorbers of the intestine from them; but the ramifications on the intestine itself are deficient of these folds, so that when once the quicksilver has reached the surface of the gut, it will run forward without any obstacle. The peritoneal surface of the gut is completely covered with flatly parallel branches, running according to the length of the intestine. Its inner surface is no left thickly covered with lacteals of a different appearance. When dried it seems as if the quicksilver were contained in small cells, covering the whole internal surface of the intestine so completely, that the point of a pin could scarcely be placed between them. Mr. Hewson has particularly described this appearance, and was doubtful whether it ought to be referred to extravasation or not. But we are convinced, from frequent examinations of this cellular structure, that it is a part of the natural organization; because the cells are regular and uniform in their size and arrangement; no force is used in the experiment; and a real extravasation presents an appearance altogether different. The extent of the absorbing fystem, as demonstrated in this way, is beyond any thing we could form an idea of from injections in man or warm-blooded animals.

After leaving the intestine, the lacteals accompany the blood-vessels on the mefentery, running at their sides, and communicating across them. Each artery has two veins, and there is a lacete or more at each side of each of the three veins; so that their number considerably exceeds that of the blood-vessels. A coarse representation of them, on the mefentery, is exhibited in Monro's Physiology of Fihes, tab. 30.

Near the root of the mefentery the large laceteals anato- moose, so as to form a net-work, from which several large branches go into some considerable lymphatics on the left side of the fpine. These latter can be traced downwards almost to the anus, and belong to the parts situated below the mefentery, and particularly to the kidneys. At the root of the mefentery, on the left side of the fpine, the lymphatics of the spleen join the laceteals, and immediately above this union a sort of plexus or net-work is formed, which lies upon the right aorta. From this plexus a large branch arise, which passes behind the right aorta to the left side, and gets before the left aorta, where it affilts in forming a large receptaculum, lying in front of that artery. The thoracic ducts arise from this receptaculum. From its right side goes one trunk, which is joined by that large branch which came from the plexus to the left side of the right aorta, and then passes over the fpine. This trunk is the thoracic duct of the right side; for having got to the right side of the fpine, it runs upwards on the inside of the right aorta, towards the right subclavian vein. And when it has advanced a little above the lungs, or within three or four inches of the subclavian vein, it divides into branches, which, near the same place, are joined by a large branch that comes up on the outside of the aorta. From this part upwards, those vessels divide and subdivide, and are afterwards joined by the lymphatics of the neck, which likewise divide into branches before they join those from below; so that between the thoracic duct and the lymphatics of the same side of the neck a very intricate net-work is formed. From this net-work a branch goes into the angle made by the jugular vein, and the lower part, or trunk, of the subclavian: this branch, therefore, lies on the inside of the jugular, whilst another gets to the outside of that vein, and seems to open into it a little above the angle between that vein and the subclavian. Into the above-mentioned receptaculum the lymphatics of the flomach and duodenum enter; they have numerous anatAmooses, forming a beautiful net-work round the artery which they accompany. From this receptaculum likewise, besides the trunk already mentioned, which goes to the right side, arise two other trunks, nearly equal in size; one of which runs upon the left side, and the other upon the right side of the left aorta, till they come within two or three inches of the left

REPTILES.
left subclavian vein; where they join behind the aorta, and form a number of branches, which are afterwards joined by the lymphatics of the left side of the neck: so that here a 'net-work or plexus is formed, as upon the right side. From this plexus a branch issues, which opens into the angle between the jugular and the lower part or trunk of the subclavian vein. In these net-works, formed by the lymphatics near their termination in the veins, this system in the turtle differs remarkably from that in birds. Hewson's Account of the Lymphatic System in Amphibious Animals, Philos. Trans. vol. 69. p. 198.

The Liver, which is divided in the mammalia into several lobes distinct from each other, and is more uniform in birds, is still less divided in reptiles. Often it has no division of lobes, but is merely irregularly figured on its free and thin edge. Its proportionate size, however, is more considerable than in the two classes just mentioned. Occupying usually the two hypochondria, it extends far backwards under the intestines, and is supported in its position by folds of the peritoneum, analogous to those which exist in the mammalia. Its colour is no longer that reddish-brown which is seen in the mammalia and birds; but it partakes more of yellow.

In the chelonia the liver exhibits a peculiar arrangement, being divided into two rounded irregular masses, of which the right occupies the same hypochondrium, and the other is connected to the small curvature of the stomach. They are united by two narrow productions of the same substance, in which the principal vessels pass. In the green lizard, the geckos, the dragons, the iguanas, it forms a single mass of various figure, flat or convex below, concave above. Its free edge has two fisses in the dragon, dividing it into three lobes, of which the right is prolonged into a sort of tail. There is only one fissure in the geckos, and the right part is equally more extensive than the left. In the common iguana it is lengthened into a long appendix. In the crocodile and camelion the liver has two very distinct lobes; and moreover, in the latter, a long appendix. It has only one lobe in the serpents, in whom it is long and cylindrical. Like other organs, it assumes in this order a figure corresponding to the elongated form of their bodies. There is one lobe only in the salamanders, but two in the other batracians.

Hepatic Canals.—The common trunk of these canals is usually separate from the cystic duct, and not involved with the latter in the intestinal canal, in reptiles, as well as in birds. This has been observed in the chelonia and saurian orders, in several ophidians, and some batracians. Yet this arrangement is not constant. For, in the crocodile, where the hepatic is sometimes separate from the cystic duct, it sends at other times a branch to the gall-bladder, which is inserted a little above its neck, and is itself united to the cystic canal, not far from the intestine. The mouth of the common canal was distant from the pylorus, says Cuvier, 0.25 in a crocodile, whose whole intestinal canal was rather more than a metre (about 39 inches) in length.

In the teltudo græca the hepatic canal sends a branch of communication to the cystic canal, not far from the gall-bladder; but these two canals open separately into the intestine, though near each other; the former before the latter.

The Gall-Bladder has its fundus usually directed backwards. Its proportional volume is less considerable than in mammalia and birds; and it is more intimately connected with the liver than in these classes. In the teltudines it is almost entirely concealed in the right lobe of the viscera; and is placed under the same lobe in the crocodile. Where the liver is not divided into lobes, the situation of this refer-}

voir is marked out by a fissure. In the ophidians the gall-bladder is absolutely separated from the liver, and situated at the side of the stomach, near the pylorus, a short distance beyond the posterior extremity of that viscus. Its form is generally oval, but it approaches to the cylindrical figure in the iguana.

The connections of the cystic and hepatic canals have been already mentioned. The former remains generally distinct from the latter, by the side of which it is interposed into the intestine. Sometimes it receives the branches of the latter in succession.

The Pancreas is a conglomerate gland, as in mammalia and birds, and possesses the same structure (with some unimportant modifications of colour, consistence, lobular divisions, &c.) as in man. Its position and figure vary in reptiles. In several chelonia it is triangular. That of the Nilotic crocodile is divided into lobes: it is irregular in the ophidians, and is situated on the right of the origin of the intestinal canal. In the frog its figure is equally irregular, and it is situated in the arc formed by the stomach towards the front. It is placed in the first curve of the intestine in the salamander.

There is either a single or double pancreatic canal. In the Nilotic crocodile, for example, there are two, inserted in the intestine after the biliary canals, while there is only one in the land salamander, the formation of which precedes that of the biliary tubes.

The Spleen.—This is a viscus, of which the use is not hitherto understood. It exists in all the vertebral animals; but its importance seems to diminish as we pass from mammalia to birds, from the latter to reptiles, and from these again to fishes: at least, if we may judge from the successive diminution of its volume in these four classes.

Its figure varies considerably in these classes. It is shaped like the kidney in the teftudines; small and spherical in the frogs and toads; elongated in the salamanders, as well as in the saurian and ophidian orders.

The abdominal Cavity, Peritoœcum, and its Processes.—The offices of this membrane, in covering and inflating the various viscera, confining them, by its continuations and folds, more or less closely to the sides of the cavity, and facilitating, by its smooth surface, their motions with respect to each other, and to the containing cavity, will convince us of the importance of the membrane, and lead us to expect that it should exist very generally. We, consequently, find it in all the vertebral animals. Generally white, delicate, and transparent, it is sometimes black in reptiles.

In this class, as in birds, there is no diaphragm, and consequently no division of abdominal and thoracic cavities. All the viscera are contained in one large cavity, and surrounded by one membrane. Geoffroy, however, describes some muscular fibres coming from the sternum, and fixed to a membrane covering the convexity of the liver, which seem like the rudiment of a diaphragm. Annales del Museo, v. ii. p. 50.

In the chelonia, the membrane produces certain subdivisions of the common cavity of the thorax and abdomen. We remark, 1st, the cavity of the lungs, which are continued far backwards, above the heart, liver, and intestines; 2dly, that of the heart, or pericardium, which touches the following behind; 3dly, that of the abdominal viscera, containing the stomach, liver, intestines, ovaries, testicles, and urinary bladder. In front it covers the liver, forming a sort of membranous diaphragm, separating it from the heart; and it closes the cavity of the pelvis behind. It also furnishes the mesenteric folds. The texture of this membrane appears stronger in the teftudines than in other reptiles.

Vol. XXIX.
The mefentery exhibits, in the different orders of reptiles, some varieties, which we shall shortly notice. The first fold, which is attached to the small intestine in the teftudines, does not come immediately from the vertebral column, and does not form the mefentery properly so called, until after it has fixt the arch of the colon by means of a mesocolon. The duodenum is confined in the right hypochondrium, and loins, by laminae of the common membrane, which cover it, and are then continued to the abdominal parietes. The mefentery of serpents is a narrow fold, not coming immediately from the vertebral column, the blood-vessels form numerous anastomoses between its laminae, as in warm-blooded animals. The furrians have a mefentery tolerably developed. The production, which goes to the large intestine, like that which belongs to the small, comes from the vertebral column. There is no transverse mesocolon.

Reptiles have no omenta; but structures apparently analogous to these fatty membranes occur in some of them. The serpents have membranous process, containing much fat, and extending, like the great omentum of the mammalia, under the intestinal canal. Many furrians have also two productions of peritoneum, loaded with fat, advancing from the front edge of the pelvis under the abdominal viscera; there are fatty lobes attached to the tefticles and ovaries of frogs. The latter are not regarded by Blumenbach in the light of omenta. "The yellow appendices," says he, (ductus adiposi, appendices lateris,) "which are found in the frog, on either side of the spine, and sometimes form one mass, sometimes are divided into several smaller portions, were considered by Malpighi as a kind of omentum. (De omento et adipolis ductibus, oper. t. 2. p. 35, &c.) That this resemblance is very remote, appears from several circumstances; and particularly from the constant and remarkable variations of size which occur in these parts at the pairing season." Comparative Anatomy, translated by Lawrence, p. 193.

These bodies, being apparently connected to the tefticles and ovaries, are described with the generative organs by Swammerdam and Roefel. They consist of a pedicle, attached more particularly to the emulent vein on each side, and of two, three, to seven or more pieces joined to it, varying in size according to the age and season. They are proportionally large in the tadpole. They may be seen small in female frogs, which have not yet laid their ova, although Roefel assures that they increase in size with the generative organs. In this small llate, Cuvier observes, that a vessel, filled with venous blood, and producing no branches, may be seen in the axis of each fringed portion. These vessels all join to form a common trunk in the pedicle; and this trunk terminates in the emulent vein.

The absence of omentum in this clafs does not accord with its supposed use to keep the intestines warm. Is there any proof that the intestines are warmer with it, than they would be without it? And is there not as great a necessity for preventing the escape of heat in reptiles, or in birds, (which also have no omentum,) as in the mammalia? Cuvier observes, that many of the hibernating mammalia have two lateral omental appendices, which, with the principal omentum, are abundantly furnished with fat in the winter, so as to form "an adipous covering for the intestines, which no doubt contributes powerfully to retain their natural heat, to prevent the access of cold, and to supply the place of food." All reptiles are torpid in the winter, yet they have no omenta.

Urinary Organs.

The Kidneys.—These are distinguished from the same glands in mammalia, and resemble those of birds and fishes, in the impossibility of distinguishing in them the two faculties (see Kidney), and in the absence of infundibula and pelvis. Their situation, form, and relative size, vary in the different orders.

In the chelonians and furrians, they lie far back in the abdominal cavity. They adhere closely to the pelvis in the lizards properly so called, under the facrum, and penetrate even under the tail; they go as far back, but they advance farther in front, in the salamanders. They lie altogether farther forwards, and very near each other, in the other batracians. In these three orders both kidneys are situated at the same height, and covered by the peritoneum on their inferior surface only. In the ophidians, the right is placed further forwards than the left; and they are connected, on each side of the vertebral column, merely by a prolongation of peritoneum, which surrounds and fulfills them, without fixing them to the spine. There is a manifest relation between the peculiar arrangement, and the great mobility of the column in these animals.

Their form is short and thick in the chelonians, more or less elongated and flattened oval in the furrians and batracians, and extremely elongated in the ophidians. They confift, in the latter, of numerous separate lobes, placed in a chain one before the other. They are also minutely divided in the chelonians, at least on their two surfaces; for all the lobes are united in the centre. They form, on their surface, a kind of convolutions resembling those of the brain, and giving the glands a peculiar aspect.

Among the furrians, the crocodiles have them much divided, at least at a certain age. In a small crocodile, about a foot in length, Cuvier saw no division, while there were many in a larger individual of the same species. It would be singular if this should turn out to be a constant difference, as it is exactly the converse of that which exists in man. They are without lobes, or only slightly divided in other genera of the same order. They have no divisions in the batracians.

The origin of the ureters is analogous to that of birds; and their length varies according to the situation of the kidneys.

They end in the urethra in the chelonians, and the urine passes from that canal into the bladder. They are short, large, and thick-fided in the crocodile, and pierce the superior surface of the cloaca, at a considerable distance from each other.

The principal ramifications of the urinary canals are easily seen in the ophidians, ending successively, as they come out of each lobe, in a common trunk, which follows the internal edge of the kidney, and forms the ureters. Arriving near the cloaca, each is dilated into a small oval bag, and then terminates separately.

In general they terminate in the cloaca or bladder, according as the latter resevoir exists or not.

Urinary Bladder.—Reptiles vary much in respect to the excellence of this part. The chelonian and batrachian orders have it; and it is found in the following genera of furrians: the iguana, tapiinambis, cameleon, dravid, etc.; while it is wanting in the crocodile, lizard, agame, gecko, other genera of the same order; and in the ophidians.

The bladder is very large, with thin sides and weak muscular fibres in the chelonians; and it has a more or less marked division at its fundus into two portions. A very short urethra opens on the inferior surface of the cloaca; its cavity presents two prominences on each side, of which the anterior is pierced by the orifice of the vas deferens, the posterior by that of the ureter.
The bladder always receives the urine by its neck, or by a beginning of an urethra, which opens immediately into the cloaca.

There are two large membranous bags in the frog and toad, occupying the situation of the urinary bladder, generally considered as such, and so described by Blumenbach and Cuvier. Townson doubts whether they ought to be considered as part of the urinary apparatus. (See his Treatises and Observations, p. 66. tab. 3.) They have no connection with the ureters. Indeed it is very clear, that the latter tubes open on the superior surface; while these two receptacles terminate on the inferior surface of that intestine. They contain a pure water. Their size, which exceeds all ordinary proportion to the bulk of the kidney, renders it likewise probable that they are not receptacles of urine.

_Rev. Coll. Soc._—The parts to which this name has been given, and which are found in the three chief orders of reptiles, are still smaller in proportion, than in mammals and birds, and are completely separate from the kidneys. In the chelonia, they are connected to the emunctory veins. In the saurians and ophidia they lie in the fold of the peritoneum, which unites the mesentery and oviducts.

For a description of the fringed fatty appendices, which are found in the batrachian order near the testicles and ovaries, and the vessels of which join the emunctory veins, see the account of the omenta.

*Organ of Circulation._—The whole of nutrition is effected at one operation in zoophytes: chyle passes into the parts in proportion as it is made; in insects also it bathes them as soon as it is formed, and they appropriate it. In the inferior animals, there is an intermediate operation: a particular fluid only, always moving in a certain fluid of vessels, immediately nourishes the parts; and this fluid is renewed by the chyle. The motion of this peculiar fluid, of this blood, is called circulation; a process confined to the superior classes, that is, to the vertebral animals, the mollusca, the worms, and the crustacea.

There are two principal points for our consideration in the circulation: its agents, and the routes of the blood.

That part of the latter is particularly interesting, which conducts the blood to the respiratory organ. One of the chief purposes of the circulation is to conduct the blood constantly, in greater or smaller quantity, into an organ, where it may undergo the mediate or immediate action of oxygen; and, as the qualities of the blood depend much on the degree of force of this action, and in the modification which the blood receives from it, while all parts of the body, being nourished by this blood, partake of its qualities, it follows that the whole nature of an animal will be in some sort determined by the distribution of its circulating organs, and by the route which this distribution marks out for the blood.

Hence arises the importance of the structure of the heart, in reference to natural history, and the correctness of the characters drawn from it for the formation of classes. Men of genius had foreseen, rather than demonstrated this importance; but it has been established on rational principles only in modern times.

The circulations through the body and the lung are called, respectively, the great and the minor. In the former, all the blood returning from the body by the veins, which joining together from all parts, ultimately ends in one trunk, goes again to these parts by the arteries, of which a common trunk is gradually divided and subdivided, until the last divisions, as well as their union with the roots of the veins, escape the eye.

If the common trunk of the veins communicated directly with the common arterial trunk, there would be a single circulation; the blood brought back to the centre, would be sent again immediately to the parts, to return again directly, and so on; but this never takes place entirely.

Before the blood, brought back to the common trunk of the veins, can again enter that of the arteries, it must be sent in part, or altogether, to the pulmonary organ, in order to undergo the action of the atmosphere.

If the circulating organs be so arranged that every drop of the blood goes through the lung, by the minor circulation, before it can enter the arterial trunk, the common trunk of the veins of the body sending all its blood into the pulmonary arterial trunk, whose ultimate ramifications communicate with veins united into a common trunk, sending all its blood into that of the arteries of the body, there is a double circulation.

If, on the contrary, the common trunk of the general veins, instead of being distributed entirely to the lung, should only send to it a branch, while the rest of its blood would go directly into the common trunk of the general arteries, the minor circulation would be only a fraction of the great, more or less considerable, according to the size of the branch devoted to it. In each circuit of the blood, respiration would be exercised on a part only of this fluid, and the rest would go again into the body by the arteries, without having passed through the lung. This blood, and the parts nourished by it, would participate less, ceteris paribus, in the qualities which respiration imparted to it. This is what takes place in reptiles; their pulmonary circulation is only a fraction of the great, more or less considerable in the different genera. The other classes, viz. the mammalia, birds, fishes, mollusca, and worms, have a double circulation, and no part of their blood can return into the great, until it has gone through the minor circulation.

Yet we are not to conclude that the ultimate effect of respiration is the same, because circulation is the same. The mode of respiration may be different, and, as this is one of the factors, the product will be affected by its alteration. All the animals I have enumerated have an entire pulmonary circulation, while, in reptiles, it is only a fraction: let them be, for example, as to 3. Now fishes, mollusca, and worms, breathing in water, and that oxygen only, which is mixed and contained in this water, may be considered as having a half-respiration, while reptiles, breathing air itself, have an entire one. An entire respiration, multiplied by a half-circulation, and a half-circulation by an entire respiration, give the same product: which is, in both cases, a half-oxygenation of the blood, using this term merely to express the changes taking place from breathing.

Mammalia have an entire circulation and respiration; and consequently an entire oxygenation. The quantity of the latter is much greater in birds, for, in consequence of the peculiar manner in which air is introduced into all parts of their body.

The fraction of 3 is only adopted for the purpose of illustration; the quantity probably varies in the different genera of each class, and cannot be rigorously appreciated.

By these considerations we may calculate, in a manner estimate, the nature of each animal. As respiration gives to the blood its heat and energy, and through its medium imparts excitability to the organs, its quantity will determine the degree of vigour in the animal functions. Hence we deduce the great force of the moving powers, the acuteness of the senses, the rapidity of digestion, and the heat of the passions in birds. Hence the more moderate degree of all these in the mammania; hence the inertness, the inactivity, and apparent stupidity, of the other classes. Hence, too, the various modifications of vital temperature natural to each.
REPTILES.

...each of these classes, which are in an exact ratio to the degree of their other qualities.

The circulation is effected by means of muscular powers, which are applied particularly to the arterial system; the venous seeming to be merely passive. A hollow muscle, called a ventricle, possessing great and continued irritability, and contracting forcibly on the blood whenever it arrives, is placed at the union of the venous and the corresponding arterial trunk. Valves are placed at its two openings; one valve allows the blood to enter, and prevents it from going back again, while the other permits its exit, and cuts off the return. The ventricle then contracts without disturbing the arteries, pushing forwards the blood, which they contain already, and thus producing the pulse. The ventricle, having expelled the blood which irritated it, is relaxed and dilated, and then immediately filled with a fresh quantity of blood from the veins. Before entering the ventricle, the vein is dilated into a muscular fac, called the auricle, with much less considerable muscular sides. This is irritated by the blood received from the vein, contracts on it, and sends it into the ventricle. It is hardly necessary to add, that the auricle and ventricle contract alternately.

Animals with a simple circulation have a single ventricle; but they possess sometimes two auricles. When the circulation is double, there may be a ventricle at the origin of each artery, or at that of one only. Mammalia and birds have two, and the fepia among the mollusca.

All other animals have a ventricle at the origin of one only of the two arteries, but not of the same in all. It is placed, in fishes, at the origin of the pulmonary artery, in the mollusca at the origin of the artery of the body, or of the aorte, which is the name of that artery.

The union of the auricle and ventricle constitutes the heart. We find, therefore, in fishes and mollusca, a single heart, pulmonary in the former, aortic in the latter. Reptiles, also, have a simple heart, at once pulmonary and aortic. Mammalia, birds, and fepia, have a double heart, or rather two, a pulmonary and an aortic, hearts.

In mammalia and birds the two hearts are united, and form one mass, which commonly bears the name of heart, as if it were a single organ. This is not the case in the fepia. See VERMES, in Comparative Anatomy.

We may now understand what naturalists mean, when they say that mammalia and birds have a heart with two auricles and two ventricles; reptiles and fishes have a heart with a single auricle and ventricle. The latter phrase, besides comprising, in a common expression, two things really very different, contains also an error of fact; for many reptiles have two auricles.

Respecting the hearts of mammalia, birds, fishes, and mollusca, see the articles Mammalia, Birds, Fishes, and VERMES, in Comparative Anatomy. For the physiology of the circulation, the powers and actions of the heart, and the other organs concerned in it, see CIRCULATION and HEART.

The essential structure of the heart is the same in all animals; there are only modifications of greater or less importance. It is covered externally by a smooth membrane, the reflected portion of the pericardium; its cavities are lined by another smooth membrane, continuous with the linings of the blood-vessels; and there is more or less muscular substance interposed between them. The existence of the pericardium is as general as that of the heart; its nature and disposition are so nearly alike in all animals, that it is not worth while to notice the modifications.

Of the Heart.—In the different orders of reptiles, the heart is found to vary in some parts of its structure; there is, however, no essential difference, when viewed in relation to its functions. The three first orders have a heart consisting of two auricles and a single ventricle, which is sometimes divided into many cavities, communicating with each other. On the other hand, in the batracians there is but a single auricle and ventricle, with its cavity of a simple form. We shall enumerate successively the differences of structure in the four orders of this class of animals.

First, in the chelonians. In the animals composing this order, the heart has a form altogether peculiar. The length of the organ is much exceeded by its breadth; in some instances, it resembles the segment of a sphere; in others, it is of a square but elongated form, and curved in its longitudinal direction. In its natural situation, it is found beneath the lungs, in front of the liver, and partly between the two lobes of the latter. The pericardium, which is capacious and strong, is in contact with the membrane investing those organs, and is as firmly adherent to it as the pericardium is to the diaphragm in man.

The magnitude of the two auricles is much greater in proportion, than in any animals of the classes of mammalia or birds; the capacity of each is at least equal to that of the ventricle; they are situated in part above the latter, projecting upon its lateral and anterior parts. They possess somewhat of a rounded form, are without any appendix, and have their parietes thin, with some fibrous faciculi in their structure. The right auricle, which exceeds in a trifling degree the size of the left, receives, by a single opening at its upper part, the blood returning from the body. Two valves are placed around the borders of the opening, giving it the appearance of a simple fyllem. The pulmonary veins alone terminate in the opposite auricle; their termination is provided in the same manner with two valves. A simple membranous partition separates the cavities of the two auricles and their openings into the ventricle. It is on the ventricle that depends the form which we have described as belonging to the heart. Its cavity is very small in comparison to its fyllem, which is owing to the great thickness of the parietes. These are found to be composed exteriorly of a moderately thick layer of fibres, which have a direction parallel to the external surface of the ventricle. Beneath these, there are other numerous muscular faciculi, varying in their direction, but proceeding principally from the superior to the inferior surface; the greater number of them are only contiguous, or separated from each other, allowing the blood to pass through the intervals formed between them as through a sponge. It results from this structure, that the cavity of the ventricle is diminished to one-third of its volume; it occupies the middle and right side of its base. In its greater part, it is lined by a continuation of the membranous fold which covers the auricular orifices, performing to them the office of a valve; it is of a square form, attached at the middle of its external surface to the partition between the auricles, and by its superior and inferior sides to the corresponding parietes of the ventricle; it is only loose and unconnected in its right and left borders. The fyllem is extended over the opening of the auricle on the same side, and the latter over that of the opposite auricle; so that these openings appear in the ventricle separated by the breadth of the fold, while in the auricles there is but the thin septum intervening between them. The blood returning from the lungs into the left auricle is directed into the ventricle by means of the valve belonging to the former, in a course directly contrary to that leading to the opening belonging to the arteries of the body. It must, therefore, necessarily pass through the whole cavity of the ventricle, from the left to the right, and...
REPTILES.

The heart and the inferior vena cava of the abdominal cavity are connected by the inferior vena cava and the inferior vena cava of the liver. The inferior vena cava projects into the latter. The inferior vena cava projects into the latter.
additional strength, but greatly diminishing the cavity of the ventricle. These falciculi are mostly separate from each other, allowing the blood to permeate between them as through a sieve; thus effecting the more perfect admixture between the portion arriving from the lungs and that from the body. The openings of the auricles are found close to each other, at the middle of the base of the heart, above the septum. Each orifice is closed by a semicircular valve of a membranous structure, the free edge of which corresponds to the auricle of the heart. The termination of the arteries is found in the right side of the base of the organ; that belonging to the pulmonary artery is situated towards the left and in the lower part, corresponding to the inferior cavity. On the left of the latter is found the opening of the left aorta, corresponding to the same cavity, and placed opposite to the opening which forms the communication between the superior and inferior cavity. The opening of the right aorta is found immediately behind the left, and corresponds more particularly to the inferior cavity, in which is received both the blood from the lungs and that from the body; the two portions united are projected partly into the right aorta and partly into the inferior cavity, and from thence to the left aorta and pulmonary artery.

In the fourth order of reptiles, the batracians, the heart presents a structure the left complicated of the whole class. It consists of a single auricle of a rounded figure, broader than the base of the organ, with its parietes strengthened by fleshy falciculi. At the base of the auricle is the orifice of communication with the ventricle, which is fleshy, having a single cavity, with fleshy columns, not separated from each other. At its base is found the common trunk of the arteries, arising by a single orifice, situated more to the right and lower down in the ventricles than the opening of the auricles. The heart of the frog has been delineated by Swammerdam, Bibl. Natur. vol. 49; and by Roefel, Hist. Ranar.

Of the Blood-veins. — The distribution of the blood-veins in the four orders of reptiles is varied according to the structure of the heart, and many other circumstances in their organization. In the batracians the arrangement differs in the greatest degree from that of mammalia and birds. All the arteries arise by a single trunk; consequently there is but one opening in the heart. In the three other orders, there are at least two openings, frequently three, which give origin to as many distinct trunks, one of which is defined exclusively to the lungs.

Of the Arteries in the Chelonians. — The arteries of the body arise from the heart by a single or double trunk in different species; those of the lungs by a single trunk. They are firmly connected together for a short distance from their origin. The trunk of the pulmonary artery arises on the left, lower down than that of the body. It quickly separates into two branches, one of which proceeding to the right lung, turns from the left to the right, then advances forwards to arrive at the anterior part of the organ, where the insertion of the bronchus takes place. The other proceeds in a contrary direction, passing across the esophagus, it arrives at the summit of the left lung.

The trunk of the arteries of the body takes its origin at the right extremity of the base of the heart, and divides almost immediately into two great branches, the right and left posterior aorta. When the trunk is double at its origin, they separate, forming these two branches. The right aorta furnishes, near its origin, another considerable artery, which may be denominated the anterior aorta. This four divides into two branches, each of which is again subdivided into two others, the internal of which, the smallest, is the common carotid, and the external, the subclavian or axillary artery. The common carotid proceeds by the side of the neck, concealed by the muscles going to the esophagus, sending branches to the pharynx and adjacent muscles. It arrives at the head, to the parts of which it is ultimately distributed, without dividing previously into two principal branches analogous to the carotids of mammals. The subclavian or axillary artery furnishes nearly the same branches, as the arteries bearing the same name in mammalia, with the exception that there is no branch corresponding to the inferior thyroid. The continuation of the trunk forms the brachial artery. The two posterior aorta proceed on each side upwards and outwards; then bending backwards, they approximate again, and are connected by a communicating branch, which the left aorta gives to the right; nearly opposite to the fifth dorsal vertebra.

The right aorta, previously to communicating with the left, furnishes many arteries to the back or upper shell, corresponding to the intercostals. The left aorta furnishes considerable arteries to the viscera of the abdomen, which compose great part of its blood. When the trunk arrives beyond the cardia, it divides into three branches; the first, which is the smallest, furnishes a branch to the stomach, and then is distributed to the stomach. It is analogous to the coronary stomachic of mammalia. The second, almost as considerable as the trunk from which it proceeds, distributes arteries to the intestines, spleen, pancreas, and liver, in the following manner. The hepatic artery is the first given off on the right side; it turns backwards and downwards to arrive at the liver, and divides into two branches, near the base of the vicus, from one of which proceeds a small branch to the pancreas, and numerous others to the duodenum. The second branch is one of small size, and is distributed to the second turn which the colon makes to the right. It is the colica dextra. The third branch passes from the right to the left, and distributes its branches to the transverse colon. It is the colica media. After having given off these branches, the trunk pursues a short course between the layers of the peritoneum, in a direction downwards and backwards. It then distributes the following branches. The pancreatic, which passes from behind forwards upon the left border of the pancreas. The splenic, a very small artery, distributed exclusively to the spleen. A very considerable branch, belonging to all the right part of the colon and cecum. It is a second colica dextra. A small artery, which, after having given a branch to the cecum, proceeds to anafiomose with the next, the proper mesenteric artery, which is larger than any of the preceding, and ramifies in the mesentery of the small intestine, to which it is ultimately distributed. Lastly, the third branch, resulting from the division of the posterior left aorta, the second in magnitude, proceeds obliquely to the right and backwards, and anafiomosing, as has been mentioned, with the right aorta, without furnishing any branch. The common trunk, formed by their union, appears rather as a continuation of the right aorta; it extends along the vertebral column to the pelvis, giving off the following branches in its course. Five or six small branches on each side, corresponding to the intercostal or lumbar arteries. The spermatics. One or two branches on each side to the kidneys. A small artery corresponding to the posterior mesenteric, which is distributed to the cloaca.

The common posterior aortic trunk terminates by four branches, in the individuals belonging to the telfudo greca, which we have dissected. The first on the left was the external iliac of that side, then came the internal iliac of the
fame side, and opposite to it the primitive iliac on the right side. Between the two latter arose the artery of the tail, corresponding to the middle facial artery. The branches of the internal iliacs are very analogous to the iliac arteries in mammalia. The trunk divides into two branches; one发放 branches to the bladder and cloaca; the other dipp- ping into the pelvis, and corresponding to the ilíohiatic and posterior iliac arteries. The external iliac proceeds for- wards upon the border of the pelvis, furnishes an analogous branch to the epigastric, from which arises the anterior iliac. The first descends upon the internal and inferior parieta of the upper shell, and passes in a direction from behind, forwards. A second branch, which arises from the external iliac, opposite to the epigastric, descends along the anterior border of the pelvis, as far as the lymphatic of the pubis, and is lost in the muscles of that part. After having furnished these two arteries, the external iliac passes out of the pelvis, takes the name of cranial artery, giving off first the circumflex arteries, then the profunda, and in the end of its course is analogous to what it is found in mammalia.

The distribution of the principal arterial trunks in the saurians differs but little from that which has been described in the preceding orders. In the crocodiles there are three arterial trunks, each having a distinct opening in the ventricles, provided with two semi-lunar valves. The pulmonary artery, which arises from the cavity bearing the same name, is situated to the left, and somewhat superiorly; the posterior left aorta, which arises from the right and inferior cavity, and is situated between the pulmonary trunk and the next to be mentioned; the posterior right aorta, corresponding to the superior cavity. These three trunks are connected together for a short distance from their origin. From the latter proceed, in the first place, the trunk common to the subclavians and left carotid, which remains attached for some extent to the posterior left aorta, then advances obliquely forwards, passes beneath the bronchi, and divides beyond that canal. Secondly, a similar trunk for the same arteries on the right side. The posterior aorta, after having given off these branches, turns in a direction, first from below upwards, then from before backwards, and divides in a direction ob-liquely inwards beneath the spinal column, without furnishing any remarkable branch until it receives the communi-cating branch from the left aorta. This latter turns around the bronchus on its own side, and passes backwards and in- wards in the same way as the preceding. After having passed the cardia, it divides into many branches, which proceed to the stomach, spleen, pancreas, and duodenum. These receive the greatest part of the blood of the trunk. The latter has no communication with the right aorta, but by an artery, the diameter of which is nearly equal to a fourth part of the trunk from which it proceeds.

We have already alluded to the consequences resulting from this arrangement of the arteries, in the description of the heart. All the other arteries derived ordinarily from the abdominal aorta, with the exception of the celiac trunk, here take their origin from the right posterior aorta. It is remarkable that the anterior mesenteric takes its origin at a very considerable distance from the celiac trunk, or from the arteries ordinarily composing it; while, in the cheloniens, it most frequently arises very near, or is even a branch derived from it. The splenic is also given off by the celiac. After having passed through the substance of the spleen, from its anterior to its posterior part, and distributed to its substance many small branches which arise at a right angle from the trunk, it passes out almost as large as at its entrance, and proceeds to be distributed to the rec-tum, and the termination of the small intestine; that branch of the splenic having the latter distribution, forms a con-siderable communication with the anterior mesenteric.

The pulmonary artery, very soon after its origin, divides into two branches, which proceed to the lungs in the same manner as in the cheloniens. Their diameter is nearly equal to that of the trunks formed by the carotids and subclavians on each side.

In the common iguana, which has the heart placed very far forwards in the chest, the arteries of the body have, in the same manner, two distinct trunks arising from the two cavities of the heart, although they are united at their origin. The left posterior aorta does not furnish any branch before it becomes united to the right. The latter gives origin to the carotids and subclavians, as in the crocodiles; but with this difference, that the latter do not arise from the same part as the former, but much farther backwards, on account of the heart being placed so much anteriorly.

In the lizards properly so called, the two aorta advance forwards out of the chest; the right having first divided into three branches, the left without forming any division. The latter turns backwards upon the sides of the neck, to proceed afterwards along the vertebral column; and at the point where it takes a direction from before backwards, it receives the left branch of the right aorta, which forms a curvature in front of it. From its convexity arises the left carotid. The two other branches of the right aorta turn backwards, and unite in the same manner on the right side of the neck, forming two arches in front of each other. The carotid of the same side arises in a similar manner from the anterior arch, formed by the middle branch. The subclaveans arise from each aorta a little before their junction. We have seen that in the crocodiles and the common iguana, they are produced both by the right aorta. The trunk formed by the union of the two arteries, which unite speedily after their origin from the heart, produces the different pairs of interscapular arteries in succession. It gives off, near its commencement, an artery to the oesophagus; farther on, a small artery which proceeds to the liver; and still farther, an artery which quickly divides into two branches; the anterior of which distributes its ramifications to the stomach, spleen, pancreas, and duodenum. The posterior belonging to the intestinal canal is properly the anterior me- senteric. From the trunk the following arteries next proceed: the lumbar, the spermatics, the posterior mesenteric, which proceeds immediately to the rectum, the anal, which is among the latter given off, since the kidneys are situate very far back in the abdominal cavity. Lastly, it produces the iliacs and middle facial artery. The latter is of so considerable a size, that it may be regarded as a continuation of the aortic trunk, of which the iliac appear only as branches. This circumstance evidently depends on the great fize of the tail, in comparison with the extremities.

The distribution of the principal arterial trunks in the third order of reptile, the Ophidians, becomes much simplified from the deficiency of extremities, and there being but a single lung. The number of the trunks is the same; the relations be-tween their openings in the heart have been already men- tioned in the description of that organ. The pulmonary artery ascends and turns backwards upon the base of the heart, and speedily arrives at the inferior surface of the lung, where it passes from before backwards to the left of the vein. The right aorta ascends on the same side, bends backwards, passes above the oesophagus, and obliquely backwards and inwards, to join itself to the left aorta, some distance beyond the point of the heart. It gives off, near its origin, some small arteries, which proceed to an orbicular
orbicular gland, placed in front of the bafe of the heart, likewise to another gland of a more considerable size and elongated form, fittate beneath the jugular. The trunk then furnifhes the common carotid, the only one continuing in this order of reptiles. It paffes obliquely to the left, and advances, by the fide of the left jugular, between the trachea and the esophagus, and laftly beneath the baffle. It fends a great number of ramifications to thefe organs, and divides near the head into many branches diffributed to the adjacent parts. Near to the vertebral column, the right aorta produces a confiderable branch correfponding to the vertebrals and inferior intercostals which proceeds along the spine, fending to it branches, and wholly penetrating into it near the head. When the communi-
cation takes place between the right and left aorta, the diameter of the former is become very small, fo that the greatest part of the blood which it has received from the heart is diffributed to the parts in front of that fivus; it is properly the anterior aorta. The left aorta affends and turns backwards to the left, paffes beneath the esophagus; then by the fide of and always beneath the lung, receiving the right aorta beyond the heart; and continuing to pafs in a direction backwards, it gives off branches correfponding to the intercostals, likewise arteries to the vifera. Thofe branches proceeding to the fomach, pulmonary bladder, and liver, are detached fucceffively from the aorta, as it proceeds backwards; thus there is no caeliac trunk. Nearly oppofite to the pylorus, the aorta furnifhes the anterior mefentric, which proceeds parallel to the intestinal canal one half of its extent, fending to it branches. Further backwards the intestinal canal receives three other small branches in fucceffion, from the fame artery: as it paffes backwards, it alfo fends similar branches to the kidneys, ovaries, &c.; arrived at the lower part of the abdomen, it penetrates beneath the vertebræ of the tail and is loft in that part.

In the left order of reptiles, the Batracians, the aorta, which proceeds from the bafe of the veficle, foon divides into two branches, which separate and purfue a very oblique direétion from within, outwards and a little forwards. Each branch gives off a pulmonary artery, a common carotid, an axillary, a vertebral, and arteries correfponding to the intercostals; then turning backwards, and approaching its fellow, it fpeedily becomes united to it. The trunk formed by their junction gives off, fift, the caeliac trunk, then all the other arteries which arise ordinarily from the abdominal aorta, prefenting nothing worthy of remark.

Of the Veins.—In the Cheloniens there are two pofterior vena cava, which paff through the liver on each fide, and receive in their courfe numerous fhmall hepatic veins. Immediately after their exit from the liver, they are joined by two anterior vena cava, one on each fide, or by the common trunk of the jugular and subclavians. They all terminate in the right ariule by an opening in the form of a fiffure, provided with two valves; they do not terminate in the cavity of the ariule, but in a receptacle communicating with it. The pulmonary veins united in a fingle trunk terminate in an analogous receptacle, which opens into the left ariule; around the borders of the opening, there is placed a fleshy valve in the form of a half moon.

In the Sauvians and Ophidians, there is but one pofterior vena cava, and two anterior, that belonging to the left fide paffes acros, and above the heart, in a direction from left to right, and terminates in the common receptacle by the fide of the pofterior vena cava. This receptacle, familiar to that found in the cheloniens, has in the fame manner its entrance into the right ariule, in the form of a fiffure, and provided with two valves. In this order, likewise, the anterior vena cava are more properly confidered as the jugulars. They have also a double azygos, one formed by the intercostal veins in front of the heart, the other pofterior to it. They both join the right ariule by the fide of the right jugular. It appears that they are rendered neceffary by the situation of the vena cava, which is very remote from the vertebral column, and more inferiorly.

The pulmonary veins in the faurians are familiar to thofe of the cheloniens.

In the opifidion order there is oniy one, which terminates in the fame manner in the left ariule. Its volume exceeds that of the artery, which we have not obferved in the other reptiles.

In the batracians the veins have a distribution similar to that of the arteries which results from their terminating in a fingle ariule, in the fame way as the latter arise from a fingle venticle. There are two anterior vena cava which receive the blood from the head, neck, anterior extremities, and from the veins analogous to the external manmary, which are very confiderable, extending beneath the skin to the groins, and likewise a pofterior vena cava, which receives the veins from the other parts, prefenting nothing worthy obfervation.

The blood-veffies of the tadpole are difcribed in the account of that creature in the division concerning the generative functions; and thofe of the protes and firen, in the separate defcription of thofe animals at the end of this article.

Phyfology of the Circulating Organs.—The nature of the blood in reptiles, the points in which it differs from the cor-
responding fluid in other classes, its difference in the various orders and genera, its relations to the food and to the fecre-
tions and excreitions, are fometimes interefling topics of inquiry, on which we have absofutely no information to offer. Chemiftry does not yet appear to be sufficiently advanced for the fuccefsful investigation of these and fimilar matters.

We may obferve, in the firft place, that the reptiles of these climates at leaff, polples, in comparifon with warm-
blooded animals, a much fhimmer quantity of blood in pro-
portion to their size: hence their muscles are whiter, and some of their vifera, particularly the lungs, which are loaded and gorged with fuch a profufion of blood in the warm animals, prefent in this refpeet an appearance alto-
gether contrary in reptiles.

"I made an experiment," says Blumenbach, "on the water falamander, (lacerta lacustris, L.) of which I fippetted twenty-four, adult, lively, recently taken in the early spring, and weighing together 1/2 ounce, in order to meafure the quantity of blood they contained: I could preferve from the whole of the bodies of all, only two scruples and a half. This fhimmer quantity of blood is to the whole body as 5/2 to 35; while in an adult and healthy man the proportions are calculated at 1 to 5. Haffelquiff observed the fame circumstance of the fhimmer quantity of blood in proportio to the body, in the crocodile of the Nile." Voyage dans le Le-
vant & en Palefîne.

It is alfo remarkable, that the arterial blood of our reptiles differs in external appearance in the fmalleft degree, if at all, from the venous, fo that one can be diftinguifhed from the other only by the situation and courfe of the vef-

fels; while, on the contrary, the bright scarlet arterial blood of the mammalia offers fo remarkable a confrat to the dark livid or purple venous fluid; unless when they have been for some time in a warm bath or other warm medium, when it appears from the elegant experiments of Dr. Craw-
ford,
fard, that the venous blood, becoming gradually less and less dark coloured, approaches more nearly to the vivid reds of the arterial stream. (See Phil. Transact. v. 71. p. 487.) Haller observed that there is no difference between the arterial and venous blood in the frog. (Oper. minor. v. 1. p. 183.) And Spallanzani noticed the same fact in the salamander or water newt: "avorti eguali di diametro, il colore del sangue venoso e assimilissimo al colore del sangue arterioso." De' fenomeni della circolazione, pag. 105. And again, "il sangue arterioso in nulla differisce dal veno, sia nel colore, sia nella densità." P. 193.

In this circumstance reptiles resemble the fuscus of warm-blooded animals; in which, so long as it remains immersed in its uterine bath, we know that the arterial and venous bloods are of the same colour.

Yet all animals of this class are not alike in this respect. Accurate observers have affirmed, that in the tortoise the venous blood is black, and the arterial crimson, as in the warm-blooded classes. (Caldei. Oflervazioni Anatomiche intorno alle Tartarughe, p. 60. Mery, Hil. de l'Aced. des Sci. de Paris, 1669. v. 2. p. 216.) This difference probably corresponds with the diversity of structure observable in the respiratory organs, which are calculated in the different orders of reptiles, to admit of a more or less intimate exposure of the blood to the air in respiration.

The colour of the blood varies in our amphibia according to the state of their nutritious functions: it is paler when they have failed, of a deeper red when they have been well fed. If, under the latter circumstance, it be drawn from a vein, and exposed to the air, it exhibits a bright florid redness as it forms the coagulum.

The component elements of the blood of amphibia, considered in a general way, seem nearly to resemble those of the warm-blooded animals, except that in the former, when examined alive, there are almost always seen bubbles of air mixed with their purple fluid, performing, like the blood itself, the circulation, and dividing that fluid in the vessels into intervals, as the mercury is interrupted in a badly made thermometer. Redi and Perrault observed this fact in tortoises; Jacobeus in frogs; Daudin in the green lizard, frog, and salamander (Hil. Nat. des Reptiles, Intr. p. 184.) and Blumenbach in the amphibia of Germany. Now, although in certain states the veins may be very turgid, and elastic air may be found in them after death, nothing of this kind is ever known to take place in a healthy and strong individual. The air indeed is supposed in the mammalia to constitute one-thirtieth of the blood, but it is so dissolved, and so intimately mixed in the vital stream, that it can only be extracted and exhibited in its elastic aerial form by artificial means.

The phenomena of the circulation are common on the whole to the reptiles with the warm-blooded animals, and are very familiar in the former, since the wonderful circulating motion of the blood was not only first actually seen and described in frogs by the great Malpighi, but is also fully examined to the present time in those animals. The branchiae of the tadpole are very favourable objects for investigations of this kind.

As the circulation can be actually seen in these animals, we may inquire on this subject, whether the globules of the blood, entering the minute vessels, can be really observed to change their figure, and become oval instead ofpherical.

"In warm-blooded animals," says Blumenbach, "I have never heard or read that any one has seen such a change; and I certainly have never seen, either in the incubated chick, in which the circulation of warm blood may be most clearly and beautifully observed, particularly on the fifth and following days, or in the frog or lizard, any oval globules; yet Reiche affirms that he has seen globules changed from spherical to oval in the mesentery of the frog, and has given an elegant plate in illustration of the fact. See Experimenta de Sanguine ejusque motu, fig. 3." Blumenbach. Specim. Physiol. p. 10. He doubts, however, whether this change can be considered as a natural occurrence in the healthy circulation, or ought to be referred to the disturbance naturally following the sufferings of the animal.

The motions of the heart, confuting in our amphibia of a single auricle and ventricle, agree in the alternate contractions and relaxations of those parts, with the analogous succession of systolic and diastolic changes observable in the double auricles and ventricles of the warm-blooded classes.

A question was formerly raised, concerning this systole or contraction, whether the ventricles are really shortened, or experience merely a diminution of diameter? The former, says Blumenbach, has now been proved by the most careful observations both in cold and warm-blooded animals; he adds, that he has never seen it demonstrated more clearly, and beyond every suspicion of inaccuracy or mistake, than in the common snake (coluber matrix), in specimens of which, two yards long, from the woods of Germany, he has observed, and frequently demonstrated, a shortening of the ventricle equal to two lines. Blumenbach states further, that the ventricle is completely emptied in its systole, not the least drop of blood flowing back into it from the aorta, in the snake, frog, and toad, and also in the incubated chicken.

But he does not venture to decide, whether the same thing occurs in man and the other mammals, or whether the semilunar valves may intercept former drops of blood, which thus are made to flow back into the ventricle.

Reproduction.—As the nutrition and growth of parts, in the healthy state, are among the most important functions of the blood-vessels, so the repair of injury, and the reproduction of what is mutilated, constitute another very striking instance of their powers, and a very imprefive example of those prerogatives, which belong exclusively to living organized beings. Although this power of reproduction, taken in its most extensive acceptation, cannot be said to be withheld entirely from any animal, several genera of reptiles poifon it in a more remarkable degree than any of the other vertebral classes. The relations of an interesting account in the Memoirs de l'Aced. des Sciences de Paris, 1666, particularly of the reproduction of the newts of lizards. Spallanzani, Bonnet, and Blumenbach, have employed themselves in researches on this subject. The former first called the attention of the public to it in his "Prodromo d'un' Opera da incominciare sopra le Reproduzioni degli Animali." Bonnet published his memoir on the reproduction of the limbs of the water newt in the Journal de Physique, 1777. His enquiries were again published in his "Oeuvres d'Histoire Naturelle," t. 5, and there are three memoirs by him on the subject, translated into English, in Spallanzani's "Tracts on the Natural History of Animals and Vegetables," v. ii. The experiments of Blumenbach are contained in his "Specimen Physiologiae comparativae," where the experiments have been made chiefly with the water newt; on the lacerta agilis of the terrestrial kind, see P. T. Hartmann, Dubia de generatione viviparorum ex ovo, p. 26; respecting the lizards of the Antilles, see Oldendorp Geschichte der Carabifchen Milflon, p. 97.

"It might be supposed," says Bonnet, "that the amputation of the limbs is most painful, and that the animals would suffer long and severely from it; however, one of my observations apparently inferre the reverse. I cut the left hand
hand and the right foot off a large newt; and a stream of blood, as thick as a hog's bristle, continued spouting out nearly two minutes without intermission. Not only did the animal seem not in the least enfeebled by the loss of blood, but, in fearlessly a quarter of an hour, to my great surprise, it swallowed two earth-worms."—Spallanzani's Tracts, v. ii. p. 367.

The following narrative is extracted as a specimen of Bonnet's experiments. "On the 6th of June I cut off the right arm and left leg of a large newt close to the body. (It seems from the accompanying figure that the sections passed through the femur and humerus respectively.) A stream of florid blood spouted a minute and a half from each wound; however, the vessels soon closed, and the newt was apparently as well as though unmitigated. But it will easily occur, that it did not swim with equal facility. When about a month had elapsed, I began to perceive a papilla, of a violet grey colour, near the edge of the trunk or section. This was the origin of a new arm and leg, which gradually increased, and were quite perceptible, although still very small, on the 14th of July. The two papillae grew more in length than in thickness; they became minute humps, and on the 1st of August were two lines long. A kind of cleft hardly perceptible announces the appearance of the two toes: no cleft appears on the originating arm. The new parts were very distinguishable from the old by their lighter colour. The two toes were easily recognised on the seventh: they were real miniatures, and truly most minute. The flump of the arm had increased, but there was no indication of fingers."

"It is pleasing to observe the little hand fully unfolding, while only three fingers of unequal length are visible; the middle one is the longest. The arm has made no sensible progress. The new foot had four toes also of unequal length; the first and second of which are longest; the other two only begin to appear; the fourth is scarcely perceptible. Evolution advanced every day. The regenerated members began to deepen in colour, so that the line, differentiating the old parts from the new, was no longer so conspicuous; but the black specks on the toes of unmitigated newts were still imperceptible. On the 22d of August four well-shaped fingers were already on the hand; but only four toes out of the five which the foot regenerates; and they all have to acquire more size, confidence, and colour. I continued my observations on the daily evolutions of the members; and the following were their dimensions in length on the 30th of September.

Old Members.

Even in the beginning of October, the fifth toe of the new foot was not visible."—Lib. cit. 372, et seq.

There is a kind of semi-transparency in the reproduced parts, which the original members have not. This continues long, and changes slowly as the reproductions colour. The transparency is evidently greater on the edges of the fingers than elsewhere if examined with a magnifier they seem included in a fine diaphanous envelope: but nothing of this is evident in the old fingers. (P. 376.) "It is incredible how long the new fingers require to attain the size of the old. I have had newts, whose fingers, in thirteen months and more, were not as large as those of unmitigated members." (P. 393.) "When the tails of large newts were amputated near their origin, the whole died in a certain time. If the part be cut off about its middle, reproduction will follow. A tail was cut on the 11th of July, and on the 14th of August, the reproduced part was about three lines and a half long, and four and a half in diameter at the base. The new portion was ten lines in length on the 20th of September, and shaped exactly like the tail of a newt. I could observe no difference between the motions of this regenerated tail, and those of tails unmitigated. On the 2d of October the regenerated part had a peculiar transparency, waiting in the ret of the tail."

P. 381, et seq.

"The fingers and toes are not evolved in the same proportion as the arm and leg. Now, when I write this, on the 10th of October, the new arm and leg of the newt, mutilated on the 6th of June, have nearly attained the size of the original members, while the regenerated fingers and toes have not acquired half their natural size: yet they are perfectly well formed, and execute all their functions."—P. 392.

Blumenbach found that the true salamander (lacerta salamandra) possesses the same reproductive power as the water newt (lacerta lacustris); that a third part of the tail, or a toe, would be perfectly but very slowly reproduced, and remained even at the end of a year considerably inferior in size to that of the original parts. Specimen, p. 32.

Bonnet made other experiments to determine whether reproduced members possessed the same powers of reproduction as those amputated. He cut off an arm and a thigh of a large newt on the 2d of June; as soon as the hand and foot were visible, he cut them off, and they were renewed: he repeated this four times, the last operation being on the 13th of October, and the parts were each time restored. P. 394, et seq.

He dissected the arms of one and the thighs of another newt, so that the members immediately after were pendent, as if dead, the animal having no power over them. On the following evening each newt moved the disjointed limbs with a liberty and facility which announced that nature had already repaired the disorder. P. 431.

The most surprising fact in Bonnet's Memoir is the reproduction of the entire eye. "With a fealpel," says he, "I extracted the right eye of a large newt on the 13th of September, 1779; but I did not obtain the globe without much injury to the tunics. A deep bloody wound in the socket of the eye was the consequence of this cruel operation. And the reader will not be surprised if I hardly expected any thing from it, and that the newt would probably remain blind for ever. How great was my astonishment, therefore, when, on the 31st of May, 1780, I saw a new eye formed by nature. The iris and cornea were already well shaped, but the latter wanted its peculiar transparency, which is very considerable in these animals. The restoration was complete on the 1st of September; the cornea being transparent, and the iris having acquired its yellow gilded colour. On the 8th of November 1780, it differed from the other eye only in being a little smaller, and in the iris, or golden circle, going only half round the ball."—P. 432, et seq.

"I repeated," says Blumenbach, "the experiments of the celebrated Bonnet, concerning the reproduction of the eye in the water newt. I cut out the whole globe, at the insertion of the optic nerve, in three infusions, in neither of which was the organ reproduced: but a white and firm fungus, floating from the cut end of the nerve, gradually filled the orbit, the animals themselves becoming affected with a kind of dropical swelling, and dying in a few
few months. Instructed by these failures, I proceeded to 
operate in a different way on a fourth animal, in May 
1784. I first divided the cornea, to let out the lens and 
other humours, and then cut away the remaining empty 
and collapsed coats, leaving a small portion of the com-
mon coverings of the bulb, which, from a careful exa-
mination in water with a glafs of the parts removed, I 
judge to have been Farely equal to one-fifth of the whole 
globe. In the following months the whole orbit seemed 
clofed by the approximated eye-lids, which, however, began 
to separate in the fifth month after the operation, and 
thus difclofed a new little bulb springing up from the bot-
tom of the orbit. This new globe was still much smaller 
than the other in April 1785, when the animal died acci-
dently, though in other respects it was moft perfect, ex-
hibiting the golden iris with its regular papillary aperture 
behind the cornea, all which points are clearly distinguish-
able in the preparation which I preferve." Specimen, 
P. 31.

"On comparing," says the author laft quoted, "the 
facts juft detailed with the very limited and much lefs per-
fect reproduction observable in warm-blooded animals, we 
shall become fensible of the wide difference between them 
and the amphibia. I am daily more and more convinced, 
that no parts are reproduced in man and the other mam-
mals, except fuch as are compos'd merely of cellular sub-
fiance, and enjoy no other kind of vital power except 
common contrailty; and I cannot find sufficient proof 
that the irritable mucular fibre, the fensible nervous me-
dulla, or those parenchymata which are endowed with a 
peculiar modification of vitality, have ever been truly re-
produced in a warm-blooded animal." Ibid. p. 32.

TENACITY OF LIFE.—This subject is fo far analogous to that 
which we have juft confidered, that we pafs naturally from 
the view of the facts, in which the furprifing reproductive 
powers of the clafs is evidenced, to the no lefs altonizing 
examples of their very hardy vitality; of the energy and 
permanence of their vital forces, both in individual parts, 
and in the body at large.

The amputated tails of water newts, and the divided 
fragments of the blind-worm (anguis fragilis), exhibit very 
lively motions for ten hours and more. The heart of a 
frog or ferpent continues to palpitate on irration many 
hours after its separation from the body; and the limbs of 
frogs are excitable by the Galvanic influence for a long 
time. Some reptiles, as the ferpents and teududines, can 
open and shut the month long after the head has been fe-
vered from the trunk. General Gage informed Blumen-
bach that he had seen the amputated head of a ratlaffeke 
bite long after its separation; and another British officer 
flated to him that when he put a ftick between the jaws of 
an American turtle, the second day after decapitation, it 
was firmly held.

The lime energy of the vital force in the parts, and the 
indepedence of one clafs of functions on another, in the 
amphibia, are further evinced by many well known facts; 
the limbs of turtles have moved for eleven days, nay, on 
the thirteenth day after decapitation (Giddendief, The-
oria virium corp. hum. primitivarum, p. 74.); and a rat-
llafke lived fome days after the skin had been removed, 
and molt of the vifcera taken away. Tyfon, in Philo-
draphical Transacciones, No. 144.

In the beginning of November, Redi opened the skull of 
a land tortoise, and removed the whole brain. The 
animal did not feem to fuffer, it moved about as before, but 
groping its way; for the eyes foon flutter after losing the 
brain, and never opened again, a fliiy integument formed, 

which covered the opening of the skull, and in this fate 
the animal lived till May. Spallanzani deprifed four frogs 
of the brain; two lived till the fifth day. He also deprifed 
three newts of the brain; they suffered violent convuflions; 
their eyes clofed, they hardly moved from one place to 
another; and expired about the middle of the third day. 
He cut the heart out of three newts; they took to flight, 
leapt, fwan, and executed the fame functions as before; 
however, all died in forty-eight hours. Four frogs, deprifed 
of the heart, kept their eyes open, and preferved the use 
of their limbs. They survived thirty-six hours. Spallanzani's 
Tracts, Introduction, p. 45.

Captain Cook met with a turtle, in which there was a 
wooden harpoon about fifteen inches long, and barbed, 
between the shoulders. The opening by which it had en-
tered was quite healed.

Redi and Boyle faw fome figns of life in ferpents after 
they had been twenty-four hours in vacuo. And they will 
live more than four hours in fpirits of wine. See Daudin, 
v. 6. p. 100; and v. 1. p. 270.

In our account of the phyfology of the digestive organs, 
we have already noticed the singular power which reptiles 
posses of remaining for fuch long periods without food. 
They are equally remarkable for being able to bear, perma-
nently, confiderable degrees of heat and cold. Not only 
are moft of the Clafs inhabitants of the warmeft regions, 
but fome of them, like fome flies, are known to live in warm 
flperings, inhabiting them spontaneously, and appearing to 
be healthy. (See Coccii in Spallanzani, Opuscuii di feifica 
animali e veftabile, v. 1. p. 46.) They live in the warm 
flperings of Pifa, which vite to 37° of Reaumur, 15° of 
Fahr.

"Besides a hoft of fuphicious narrafive," says Blumen-
bach, "of newts, and other amphibia, which have lived for 
a confiderable time in the human body, there are many un-
exceptional and induhitable examples of this remarkable 
phenomenon." See the narrative of Th. Reinfous, a most 
reprechefable authority, concerning a girl of Altenburg, in 
Hitt. de l'Acad. des Sciences de Berlin, 1770, p. 40; a 
mais of citations in Jacobus de ramis et laccetis, p. 12; 
Paulini de Bufone, p. 38; J. Helwig Observ. p. 249 and 
Curiof.; Collect. Var. Vaislavienf. et Commer. Literar. No-
ic. &c. These facts are not fo remarkable on account of 
the degree of heat to which the animal is expofed, as 
from the other concomitant circumftances. We muft obferve, 
however, that these animals inhabited the thomach fo long 
as they continued alive, while the individuals troubled by 
these unual guests were led, by their fuffering, to drink 
copiously of water, and thus in a manner supplied the newts 
with their natural element.

"Reptiles have the power of bearing intense cold as well 
as great heat. One morning found a tree-frog, which I had 
kept for some time, in confequence of a ffort suddenly let 
in the preceding night fo as to reduce the thermometor to 
30° Fahr., completely inclofed in a cake of ice, like iilcft 
in amber; of course it was motionlefs, the eye-lids flutter, &c. 
As the ice melted, the animal recovered, firft moving its 
hind legs, when they were difengaged; the head and trunk 
flill being moft firmly detained; when the solution was 
complete, the whole animal was refcored, feemed as well as 
before, and furvived a long time. De Faye atfcts the fame 
circumftance concerning water newts; Mem. de l'Acad. des 
Sciences de Paris, 1729, p. 144. The amphibia are ex-
poed to be frozen in their winter fleep; but we are the lefs 
furprifed
surprised at the occurrence, becau se all the functions are either entirely suspended, or most languidly performed." Specimen, p. 10.

Organs of Respiration.—After describing the heart, and viewing the phenomena of the circulation, we proceed to the lungs, which are not only most important parts in the economy of all animals that poiffe blood, but constitute, in the peculiarity of their structure and functions, the most striking marks of diiference between reptiles and warm-blooded animals.

All reptiles breathe by means of lungs, which in their bulk considerably exceed those of the mammalia, while the latter are as far superior in the abundance of their vascular ramifications, and the wonderful minuteness of their internal subdivisions. Thesef large, but leave and rare vesicular lungs, are contained, not in a particular cavity, separated from the abdomen by a diaphragm, but, with the other viscera, in a general cavity of the body. Hence the mode of respiration is as different from that of the mammalia, as the texture of the organ.

To the general position, that reptiles breathe by means of lungs, there is an exception in the batracian order; in some of which (the proteus and firen) there are branchial appendages or gills, as well as lungs; while in the frst state (the tadpole) of others, there is a similar conjunction of these two modifications of respiratory apparatus. See the anatomy of the tadpole, in the account of the generative organs, and that of the firen and proteus, at the end of this article.

The Air-tubes.—The trachea is not divided into bronchi in the ophidian order, which have a single lung; neither does this division take place in the green lizard (lacerta agilis), whose trachea, having reached the anterior extremities of the two lungs, opens into each by a large orifice; but it is found in all the other animals of this class. The division is effected very early in the chelonians, which have consequently a very short trachea, and long bronchi; more particularly because the latter, instead of entering the lungs directly, first make a turn in the chest. The trachea is divided much later in the crocodile, where the tube is bent from behind forwards, divided into bronchi, which also run forwards, and then turn from before backwards, remaining for some time joined to each other. The bronchi are extremely short in most other reptiles: they begin, in the batracians, immediately below the larynx.

Reaching the lungs, the bronchi generally terminate abruptly by one or more large orifices, which open into the cavities of these viscera. This is what occurs in the ophidian; but in the chelonians and the crocodile, each bronchus is continued into the interior of its lung, before it terminates. They are continued, in the telfudo graecus, into the most remote part of the lung, without undergoing any sensible change of diameter; and they communicate with the large cells composing these viscera, by ten or twelve wide orifices, of which the outlines are circular, like the commencement of canals. In the turtles, each bronchus penetrates in like manner to the farthest part of the lung, but gradually diminishing in diameter. Their fides are pierced with numerous holes, opening into the pulmonary cells.

The relative size of the trachea and bronchi does not exceed what we observe in the mammalia and birds, except in the ophidians, where the diameter of the former is very considerable. These air-tubes never exhibit any inequalities, such as are seen in birds.

They are generally composed of complete cartilaginous rings, and consequently are little susceptible of changes in size. We must, however, except the crocodile, in which animal the front end of the trachea presents, on its upper surface, a membranous interval, which is wider the nearer we come to the larynx; (see Humboldt Recueil d'Oberations, &c. tom. i. p. 11. of the crocodile of the Orinoco; and Geoffroy in Annales du Museen, tom. ii. of the Nilotic species); the camel on, where the annuli are incomplete in the last portion of the trachea, and at its bifurcation; and the ophidians, in whom the trachea poiffeles cartilages only in one third of its circumference. These cartilages are also visible for a short space along the front end of the lung, in a groove of its inferior surface, containing also the pulmonary vein. The trachea, however, ceases suddenly on touching the lung, and dilates immediately to form its fac.

In those reptiles which have bronchi running throughout the length of the lungs, the portion of the tube, contained in these viscera, has only imperfect and irregular pieces of cartilage, which neverthefs surmount its circumference. They are more thinly scattered in the turtles, in proportion as we observe them farther back in the lung.

This cartilaginous structure of the air-tubes (the trachea and bronchi) of reptiles, renders them very incapable of changing their diameter. They seem entirely defitute of transverse muscular fibres; nor do we perceive any longitudinal ones to diminish their length. The membranous trachea of the ophidians, poiffeles cartilages only in the inferior third of its circumference, seems equally defitute of muscular fibres. On this membrane we discover a fine white and opaque net-work, which is continued into the inferior of the lung, where its meshes, as we shall see, border the cells, and are formed of stronger threads, apparently of a tendinous structure, and perhaps capable of contraction.

Vesicular Structure of the Lungs.—We have mentioned that the lungs of reptiles are very large; they are immense in the telfudines and camelon, and are even considerable in the native amphibia of these climates, if you compare their relative bulk to that which they poiffe in warm-blooded animals. We have just seen that the bronchi do not divide, that they do not usually enter the lungs, but terminate abruptly by one or more large orifices, as soon as they have reached these viscera. In the batracians and furians, the lungs form two faces, varying considerably in their form and relative fize, and having their internal surface divided by membranous plates into polygonal cells, in which other smaller plates form more minute divisions. They have been justly enough compared by Blumenbach to the reticulated structure, in the second stomach of ruminating animals. These cells are more numerous, smaller, and deeper in the anterior part of the fac: they become more open towards the posterior part; and when the latter terminates in one or more appendages, we fee only a net-work, with loose and extremely fine meshes. Afterwards the paries of the pulmonary fac are quite simple, and without any division. Such is the structure in the appendices which terminate posteriorly the lungs of the camelon, and the agama or lacerta marmorata; and of the great bladder in which the single lung of the ophidian order ends.

The lungs of the falamander, the proteus, and firen, form also fimple faces without any division.

"In frogs and toads," says Blumenbach, "the lungs are made up of polyhedric and large cells; the same structure is observed in the lacerta agilis and falamander. They form an oblong bladder in the aquatic lacerta (water newts). The lung of the coluber matrix forms a single bag of large fize, hollow throughout; and the same structure seems, from the reports of anatomists, to exit in other serpents. (See Coler Obs. Anat. Chir. p. 126. Charas Nouvelles.
REPTILES.

Nouvelles Obs. sur la Vipère, p. 39. Tyfeo in Phil. Trans. N° 144. p. 36. tab. 1. fig. 1. tab. 2. fig. 4. Seba Theaurus. vol. ii. tab. 109. fig. 1—5). The pulmonary bag of this coluber exceeds a Paris foot in length. Rather more than the anterior half has thick fides, with an elegantly reticulated internal surface, resembling in its general habit that of the internal surface of the second stomach of the ratling mammalia. The remaining posterior portion is a simple thin membranous bladder." Specimen, p. 12.

The structure is rather more complicated in the chelonian order. Each of the openings of the bronchi, which we have stated to be about ten or twelve in the deltudo greca, is the entrance of a particular fide, the fides of which are composed of polygonal cells, in which there are still smaller ones. Each of these cells is bordered by whitish and as it were tendinous chords, which appear designed to support their fides, and fix the fides to the orifices of the bronchi. The fides or principal cells are much smaller, and more numerous, in the turtles, and correspond to the numerous orifices with which the bronchi are pierced. We see also the cords forming and supporting the cells, and giving to the lungs of those animals the appearance of a cavernous tissie.

The form and fize of the pulmonary cells may be somewhat different in the crocodiles, but their essential structure is the same. In this respect the crocodiles depart from the lizards, and approach the turtle and tortoise. Geoffroy in Annales du Museum, vol. ii. p. 46.

How different a notion do these details convey to us, of the structure of the lungs in reptiles, from that which they profess in the warm-blooded classes! Although they may be described in the latter as cellular, spongy, and light, yet, when compared to the same organs in the former class, they are vastly more compact, made up throughout of an infinite number of ramified air-tubes, and of countless short minute bronchial cells connected to them, united and interwoven with common cellular tissie. Hence, if we compare any mammiferous animal with a reptile of the same fize, as the vepertlio murinus with the rana bombina, the lungs of the latter are indeed the largest, but are beyond all comparison inferior to those of the former in the very incon siderable number of their cells.

As the lungs of warm-blooded animals so wonderfully surpaif those of reptiles, in the minuteneas and number of their cells; so they fill farther excel them in the astonishing abundance of their blood-veffels. The simple appearance of the organs, without any anatomical preparation, is sufficiently to shew this fact; and microscopical examination, after successful injection, fully confirms it. For, although the lungs of the amphibia exhibit their derfe vascular networks, beautifully painting the fides of the organs, there are not to be compared to the number and fulness of the ramifications, eluding even the affilied eye, which every where fill up the lungs of warm-blooded animals.

Since, in the mammalia and birds, all the blood of the body must pass through the lungs, before it can return again to the organs, it was necessary to have a large number of vefels for its conveyance, and a surface for their expansion, both extensive on account of their number, and the neceffity of exposing the blood in minute portions to the air, and yet confined as much as possible to one spot, that its bulk might not be inconvenient. Thus we explain that inextebrace tissie of blood and air-veffels, and small vefels or cells, which compose the lungs of mammalia and birds. All these circumstances are different in reptiles. If we may judge from the diameter of the pulmonary arteries, they receive at most a third of the circulating mafs, and sometimes much less. It is not necessary that this blood should pass back again through the lungs to return to the body: it may proceed by another route, as we have explained in the account of the circulating organs; because it does not require to be so frequently submitted to the action of the air, as in the two classes mentioned above. Hence have resulted the two great differences already pointed out betwixt the lungs of the warm-blooded classes and of reptiles: differences which are obviously related to each other, the numerous vascular ramifications requiring numerous cells and viscera.

The pulmonary serve also as bronchial vefels in reptiles; at least we find no arteries or veins of the latter description. The arterial and venous bloods are mixed in the heart; and the fane that goes to the lungs is conveyed to all other parts of the body for their supply.

Yet the pulmonary are not the only arteries conveying blood to the lungs in reptiles: the vefers, at least, offer an exception. The ramifications of the pulmonary artery are confined to that part of the lung, which has a reticulated internal surface. The posterior part of the organ, compofing the simple membranous bag, receives blood only from the arteries of the body. A part of the twigs that supply it comes from the branches of the posterior aorta, which are also distributed on the stomach. Other very minute ones are detached successively from the vertebral column. The vains corresponding to these arteries pour their blood into the vena cava. In this singular structure, we find a part of the lung executing the office of the cells of birds; and a portion of the blood, very small indeed, contained in the arteries of the body, is again submitted to the action of the air.

That portion of the general ferosus membrane which covers the lung has nothing peculiar in reptiles.

The form and bulk of the organs vary much more in this class, than in the mammalia and birds. Both are determined in the mammalia by the cavity of the thorax; in birds, by the peritoneal cells, which limit them on one side, and by the ribs, which cover them on the other. In reptiles, on the contrary, nothing seems to limit their development, nor to give them a peculiar figure. Commonly they form oval bags, which extend in the chelonians along the back to the pelvis, above all the viscera; they are less extensive in the faurians and batracians. The vefers have a single very long lung, prolonged over the oesophagus, stomach, and liver, beyond the latter parts. In this situation it is exposed to preffure every time the animal swallows a large prey. Does this check the pulmonary circulation, and contribute to the torpor which vefers experience at these times?

In the cameleon, and the agame marmorata, each pulmonary face is very extensive. They are divided into large coical appendages, prolonged as far as the pelvis, placed among the viscera, and capable of holding so much air, as to inerace the animals' bulk considerably when they are dif tended. The lungs of the firon lacertina are two long cylindrical faces, continued to the end of the abdominal cavity. In the larvae of the falamander, there is a small oval cavity, opening by a narrow canal in the faucies.

Branches or Gills.-The first orders of reptiles (the chelonia, faurians, and ophidians) never profess this kind of respiratory organ: they have only lungs. The batracians in their first flate, and the protus and firen during life, have both lungs and branchies, or rather branchial appendages (appendices limbrati). See the anatomy of the tadpole, and that of the protus and firen, at the end of this article.

Expandence Power of the Lungs.—" A singular power," says Blumenfch, "charactérifie thefie viscera in reptiles, and
is a point, in which they exceed those of the human subject, and of the other mammalia; namely, a particular kind of tone, or energy, by virtue of which, even when the chest is opened, and they are exposed to the external air, they are still distended and support themselves, while those of the mammalia, when the sternum is removed, and the thoracic cavities exposed, allow the air to rush out, and collapse. (See Morgagni Adverfar., Ant. 5, 29, and the elegant experiments on the tortoise by the Paritian academicians; Hist. des Animaux, part ii. p. 194.) It is even asserted, that when the lung is compressed in a tortoise opened alive, it has the power of defending itself again. (Coster Odd. Anat. Chr. p. 127.) A tortoise, from whom the lower shell had been removed, the thorax consequently being opened, and the lungs exposed to the air, survived for seven days. (Hist. des Animaux, just quoted.) The cause of these phenomena can only be found in the peculiar vital properties of the lungs; as it cannot be referred to contractility, irritability, or nervous influence. I have never been able to detect, in the lungs of amphibia, any more appearance of truly muscular texture, than in those of the mammalia, to which a modern author has too liberally alluded. (Vannier in Hist. de la Soc. de Médecine, 1779.) The design of this peculiar vitality in the lungs of amphibia will appear very obvious, when we consider that it exists in animals who have a very imperfect bony thorax, or none at all, or one in great measure incapable of motion. Such is the case with frogs and toads, who are entirely destitute of ribs; with nearly all the tortoises and turtles (excepting, perhaps, a few of the soft species), in whom the whole coverings of the trunk are immovable, so that neither the thorax, nor the abdominal muscles, can execute those motions in respiration, which they perform in warm-blooded animals.

Mechanism of Respiration.—In this, as well as in other points, the several orders of reptiles differ from each other. The chelonians, whose ribs are in the form of large oblong plates, consolidated to each other, and motionless, are, in effect, like the batrachians, some of which have no ribs at all, while in others these bones are too short, and too little susceptible of motion, to be capable of aiding in the processes of respiration. In all these animals, then, we can no longer regard these bones as the principal agents of the respiratory function. They also want the diaphragm, like all other reptiles. Consequently, the mechanism of respiration differs in them, in its essential points, from that described in the article Lungs, which belongs to the whole class of mammalia, where the respiratory organs, included in a peculiar cavity, follow all the motions of that cavity.

In fact, it is now well ascertained, that the batrachian reptile suffers air into their lungs. They close the mouth, and dilate the throat, when the external air, rushing through the nostrils, fills the empty space. The ferno-hyoides, carrying the os hyoides downwards and backwards, are the great agents in this dilatation of the throat; the coraco-hyoides affist them. When the former muscles are cut, respiration ceases. The elevation of the os hyoides, principally by the stylo-hyoides, contracts the cavity of the throat, and drives the air into the lungs. The escape of this air from the throat by the nose is, no doubt, says Cuvier, prevented by a valve; but no such structure has been demonstrated. The action of the abdominal muscles, and perhaps a contractile power of the lungs themselves, expel the air from the viscera in expiration. Townson, who has investigated this subject most attentively (see his Observations Physiologique de Respiration Amhphibiorum, Svo. Vienna, 1798, with figures; also translated into English in his "Traets,") observes, that he does not know whether the muscles extending from the glottis to the tubes should be called oblique or not. They surround the lungs in their whole extent, and have a considerable compersive force. They probably conflict with different muscles; their fibres extend more or less transversely, and are therefore well calculated to produce the effect he has alluded to them. He states that he has always seen the frog's lungs collapse when the glottis was opened, whether the animal was dead or alive.

If the muscles and the membrane of the throat are removed, leaving only the ferno-hyoides, the motions of the os hyoides, which take place in respiration, are continued, although respiration itself is destroyed. The latter effect is a consequence of the restriction of the throat; no cavity can now be formed to receive the air, which the animal swallows in breathing. The os hyoides, however, is alternately depressed and elevated, and the glottis continues to open and shut, but the lungs are permanently collapsed. If all the muscles employed in moving the os hyoides are cut, the glottis, whose muscles are entire, is opened and closed. In the same way, when warm-blooded animals have received a large wound in the chest, they make vain efforts to breathe, and to get rid of the painful sensation of suffocation.

It will appear, from the preceding description, that the frog's mouth must be shut when he breathes; and this is historically necessary, that the animal perishes from suffocation, if his mouth be kept open. Herholdt and Rafn alluded to this in a communication to the Academy of Sciences at Copenhagen, and the point has been verified by Cuvier and Dumeril. See Bulletin de la Société Philomatique, No. 50, an. 7, p. 43.

The same mechanism is employed in the chelonians. Delegation is the only means they can employ for introducing air into their lungs. Having the mouth closed, they alternately contract and dilate the throat, like the batrachians, and by the same powers. The air is expelled from the lungs by two pairs of muscles, analogous to the abdominal muscles. These fill the posterior interval between the sternum and the back shell, in which the posterior extremities are folded when at rest. We perceive, at this part, in the chelonians, those motions of contraction and dilatation, which are observed over the whole abdomen in the mammalia.

The first, or outer pair, correspond to the external oblique muscles; it is attached to the whole anterior edge of the pelvis, to the back and front shell, and is extended in the whole posterior interval of these parts. The internal muscle consists of transverse fibres, attached above to the posterior half of the back shell, near the vertebrae, descending on the outside of the viscera, inclining them, and terminating below in a middle aponæurosis. The latter palisades partially under the bladder, and will serve to evacuate that organ when the muscles contract. They comprise immediately only a small portion of the lungs; but they press strongly on the abdominal viscera, and through the latter on the lungs, so as to expel the air. Perhaps, too, the lungs may contract by some powers of their own.

The mechanism of respiration, in the faurians and ophi- dians, is very analogous to that of birds, insomuch as this function is particularly executed by the motions of the ribs and of the abdominal muscles. In most of the faurians, the ribs are perfectly similar to those of birds, consisting of two portions, united by a moveable articulation, and forming an angle, which is opened in inspiration, and closed in expiration. The muscles which put them in motion are analogous to those employed for the same purpose in birds.

The ribs of serpents, forming simple arcs, composed merely
merely of an offensive portion, are inclined backwards, and
brought near the vertebral column in expiration, and are
extended in inspiration. Elevators of the ribs, similar to
those of man, but larger in proportion, produce the latter
effect, in which they are shifted by intercostal muscles. The
muscles carrying the ribs backwards, and thus producing
expiration, lie within the chest. They are fixed to the sides
of the vertebral column, and correspond in number with the ribs.
They are narrow and flattened, forming a kind of
muscular ribbons, palling from the vertebral column, over
one rib, to be fixed in the next. Other muscular ribbons are
attached to the inside of the ribs, destined to be joined to-
gether, and then extend across, ending in a thin aponerous,
which unites the ribbons of each side. These compose the
abdominal muscles, and compose the Vieera of the great
cavity.

Respiration, which consists in warm-blooded animals of
a constant regular succession of alternate inspirations and
expirations, hardly admitting even a very short interruption,
is performed in reptiles at irregular and long intervals, ad-
mitting of very long suspension, and capable, therefore,
in a much greater degree than in the former classes, of
modification by the will of the animal. Hence Linnaeus
slighted a "pulmo arbitrarius," or voluntary power over the
respiratory function, as a distinguishing attribute of the
chaps. The difference, however, between the reptiles and
warm-blooded animals is in the length of time for
which they can do without respiration; after a longer or
shorter interval, its renewal is equally necessary to both.

All reptiles continue breathing constantly as long as
they are awake; and the turtles most frequently of all.
It is well known that they cannot remain long under water;
but are obliged, at short intervals, to come to the surface
for a fresh supply of air. Blumenbach observed water
newts, when placed in a deep vessel of water, swim up to
the top frequently for the purpose of drawing breath.

"On the whole, however," continues Blumenbach,
"reptiles cannot only go much longer without breathing
than warm-blooded animals, but they can also continue
without in vitiated air for a much more considerable time.

"Tortoises have been known to live more than a month
with their jaws tightly tied, and their nostrils closed with
feather-wax. (Merry, in Mem. de l'Acad. des Sciences,
avant 1699, v. 2.) On the same point we may mention
the puzzling, but sufficiently authenticated instances, of
boads found alive in the middle of solid trunks of trees,
and even in mazes of marble and other stones. (See Lui-
dius in Lithophylac. Britann. p. 112. Le Cat in Allion
du Lac, Melanges d'Histoire Naturelle, v. 3. p. 95:
Gentleman's Magazine, v. 26, 1756, p. 74.) Guettard in
Hist. de l'Acad. des Sciences de Berlin, 1782.) There are
numerous citations in Haller, de Corp. Hum. Fabrica et
Function. v. 7, p. 151, and Kaetner, in the Preface to
the German version of the Stockholm Transfections, v. 3.

"Reptiles can also bear to breathe fixed and phlogisticated
air much longer than warm-blooded animals. In my ex-
periments at the celebrated cavern of Pyrmont, I con-
stantly found that pigeons could hardly be restored to life if
their immersion in that bath of carbonic acid gas was pro-
tracted into the second minute. Frogs, however, recovered after
laying in it five, six, seven, and even nine minutes.
The event of similar trials, made in the famous grotto del Cane,
near Naples, corresponds to these. (See Nollet, in the Mem.
de l'Acad. des Sciences de Paris, 1750, p. 72. Murray,
in the Swedish Transfections, 1775, v. 36. p. 249.) Della
Torre found that a toad lived for half an hour in that grotto,
and that a newt was still alive, after having been immersed
in this pernicious atmosphere an hour and a quarter.

"Carminati has already shown how much sooner confined
air proves fatal to warm-blooded animals, than to the am-
phibian. (De animalium ex mephitibus et noxios halitus
interim, p. 96.) When I have enclosed two sparrows under
one bell-glass, and two frogs under another of the same size,
the former have perished in convulsions from the vitiated
state of their air, while the atmosphere of the other glass
had experienced so little change, that a candle or burning
coals were not extinguished by it." Specimen, p. 1.

The experiments of Boyle (Philol. Transf. 1670, N° 62.),
and the Florentine academicians, which have been since
most frequently repeated, have shown that serpents, frogs, 
&c. can remain very long (from two or three to ten or
twelve hours) under an exhausted receiver.

The nature of the changes produced in the air by the
respiration of reptiles, has been examined by Spallanzani
(=Rapports de l'air avec les etres organisés, publies par Sene-
bier, 3 tom. 8vo. Geneve, 1807); Mr. Ellis (Inquiry into
the Changes produced on Atmospheric Air, &c. 1807, and
Further Inquiry, &c. 1811.) and others. The latter author
presents us with a summary of all that has been ascertained,
as well as with experiments of his own; we, therefore,
extract them in his own words from the works just quoted.

"To obtain a knowledge of the specific changes which the
air suffers in the respiration of the amphibian, the following
experiments were instituted. A toad, supported on a small
hoop, was inclosed in one hundred and eight cubic inches
of atmospheric air contained in a jar inverted over water,
and standing in a room varying from 55° to 60° Fahrenheit.
He died on the fifth day. The water had risen considerably
in the jar, and the residual air was still further diminished
by agitation with lime-water, which it rendered turbid.
Fifty parts, after being washed in lime-water, were next
shaken in the cuvetometer with the liquid phuret of
potash, and lost only one part of its bulk. The experiment
was repeated by confining another toad, in the same manner,
in another jar containing forty cubic inches of atmospheric
air, inverted over mercury. Under the hoop which sup-
ported the animal, was placed a small cup, containing 1.5
cubic inch of the water of potash, which floated on the
mercury. The whole was then set aside in a room, of the
temperature of 64°. By the twelfth hour, the mercury
had risen nearly half an inch into the jar, which was thickly
moldened with vapour, and the breathing of the animal
seemed rather languid : by the twenty-first hour, he breathed
very faintly ; and, by the twenty-fourth hour, he had
ceded to breath. The jar was allowed to stand some hours,
at the end of which time the mercury floated about eight-
tenths of an inch high, and one-tenth of an inch of fluid
was deposited on its surface. The jar was now raised, and
the diluted sulphuric acid being poured into the alkaline solu-
tion, excited in it a very brisk effervescence. It is inferred,
therefore, that these experiments, that the oxygenous por-
tion of the air almost entirely disappears during the respi-
ration of these animals, after which they cease to breathe;
and that a large portion of carbonic acid is at the same
period produced.

"Proceeding on the supposition, that the loss in the bulk
of air, evinced by the ascent of the mercury, in the tail of
the foregoing experiments, arose from the attraction of the
carbonic acid by the alkaline solution, we endeavoured to
ascertain the proportion which this loss of bulk bore
to that of the whole air originally employed. With this
view a frog was procured, and placed in a jar of the capa-
city of forty cubic inches. Under the hoop which sup-
ported
REPTILES.

ported him, about half-way up the jar, was placed a small cup, containing one cubic inch of the water of potassa; and the jar being then filled with atmospheric air, was inverted into a dish of mercury, and kept steady by a weight precluding upon it. In the room in which the animal was placed, the barometer stood at 29.2 inches, and the thermometer at 61°. At the end of twenty-nine hours, the animal was reeling quietly on the hoop, with no appearance of diffe- rent, and the mercury in the jar, when that in the dish was brought to a level with it, had risen six-tenths of an inch. In twenty-four hours more, the frog was still alive: his respir- ation seemed now to labour, and he rose often to the top of the jar, as if deirous of escaping, or of obtaining fresh air: the mercury had now risen to 1.15 of an inch. From this time, the difficulty of breathing continued to increase, and, at the close of the fifty-ninth hour, from the com- mencement of the experiment, after having lain quiet for a considerabk time, he gave a convulsive struggle, and moved no more. The mercury in the dish was now brought to a level with that in the jar, and its height was 1.2 of an inch. The barometer, at this period, was 29.8, and the thermo- meter 65°.

"In order to examine the residual air, we plunged the dish under water, which rising into the jar, displaced the mercury, and the cup, with its solution, was then withdrawn under water. The residual air suffered no diminution by being shaken with lime-water, nor by contact with phosphorus, but it lost rather more than \(\frac{4}{29.2}\) by agitation with the liquid sulphuret of potassa. The jar originally held forty cubic inches, but the animal, with the hoop, cup, and solution, occupied a space equal to four, so that the actual bulk of air employed was 36 cubic inches. Having placed the jar on its bottom, water, to the quantity of 27 cubic inches, was poured in till it reached the point to which the mercury, during the experiment, had risen; and this, therefore, indicated the volume of residual air: it then required nine cubic inches more of water to fill the jar completely, which, consequently, was the bulk of air that had disappeared. Hence, therefore, we have

\[
\frac{27 \times 29.8}{29.2} = 27.5547, \text{ but } \frac{4 \times 27.554}{483} = 22.819 \text{ and } 27.554 - 22.819 = 27.32651, \text{ the cor- rected volume of air at the close of the experiment.}
\]

But farther, \(36 - 27.32651 = 8.67349\), and \(\frac{8.67349}{36} = \frac{1}{4.868}\), so that the diminution of bulk which the air suffered

in this experiment is rather greater than \(\frac{1}{4.54}\), the propor- tion of oxygen gas which the atmosphere contains. In a second experiment, another frog lived in the same volume of air about 60 hours, and the diminution which it suffered, after making the necessary reductions, amounted to \(\frac{1}{4.868}\) of the whole. Where the carbonic acid, formed by the respi- ration of another frog, was suffered to remain, the jar, after the death of the animal, adhered firmly to the saucer in which it was inverted, and, when cautiously elevated, the surrounding mercury rushed in; and occupied only about one-tenth of the space in which it filled in the above-mentioned cafes: the inferences deducible from these facts, instruct us, that the diminution which atmospheric air sufferers by the respiration of these animals, bears a near proportion to the oxygen gas which it contains, when all the carbonic acid is removed; and as a small loss of bulk likewise takes place when this acid is allowed to remain, we must ascribe a part of the observed diminution to the necessary loss which always accompanies the conversion of oxygen gas into car- bonic acid.

"It follows from the preceding series of experiments, that the oxygenous portion of the air is changed by the respiration of amphibious animals in the same manner as by that of the other classes, carbonic acid, in proportion thereto, being, in all cafes, produced; and that when the whole, or nearly the whole, of that gas is so changed, the animal no longer survives. But, if the animal die when all the oxygen gas is changed, and all the air that has disappeared when the carbonic acid is removed, be oxygen gas, then the bulk of air that remains, and is unchanged, must confine wholly of ni- trogen gas; and as this nitrogen gas, joined with the oxygen gas that has disappeared, makes up the whole bulk of air originally employed, it follows also, that, while the oxygen gas of the air has diminished and suffered change, the nitrogenous portion has continued undiminished and unaltered.

"During all these changes operated on the air contained in water, by the respiratory functions of aquatic animals, the water itself seems to suffer little or no alteration. Mr. Car- rilie took separate glasses, each containing one pound of distilled water, which was previously boiled to expel all its air, and then inverting them over mercury, he put into them one gold fish, one frog, two leeches, and one fresh-water muskell. The animals were confined several days in these- situations, and exposed to the sun during January, in tempera- ture 43° and 48° Fahrenheit; but no air-bubbles were produced in the vessels, nor was there any sensible dimin- ution of the water. The frog died on the third day, the fish on the fifth, the leeches on the eighth, and the mus- kell on the thirteenth day. This experiment was made to ascer- tain the changes produced in water by the respiration of aquatic animals; but the water had not undergone any chemical alteration. See Croonian Lecture in the Philo. Tran. 1805." Inquiry, p. 83—88.

Mr. Ellis adduces some additional evidence in his Further Inquiry. "The experiments already detailed in the former work clearly prove, that frogs and toads which belong to this class, entirely convert, by rapiration, the oxygen gas of the air into nearly an equal bulk of carbonic acid, without pro- ducing any change in its nitrogenous portion. Dr. Car- nozor described these animals lived much longer when they were immerged in water that had a free communi- cation with the atmosphere, than when the air was ex- cluded. (Phil. Mag. vol. 16. p. 245.) According to Spallanzani, frogs die sooner in boiled, than in common water. In their respiration, they confine oxygen, and form carbonic acid. Thoie which have been recently fed, confine more of this gas than those which have suffered a long abstinence. Under great cold they become lethargic, but their heart still continues to beat, and they live, in a smaller degree, continue to change the air: but the con- sumption of oxygen increases with the increase of temper- ature. These animals also change the air by their skin, as well as by their lungs; and act upon it after death, and under putrefaction. (Rapports, &c. tom. i. p. 568.) The ova of frogs were likewise found to require air to carry on their evolution. Small tadpoles, while yet attached to the egg, were confined in vesseles half filled with water, while the other half contained air, or oxygen or nitrogen gas. Thoie in the two former vessels were perfectly developed, and became large enough to swim about; but those confined with nitrogen perished. Rapports, &c. tom. i. p. 466.

"Spallanzani extended his experiments to many other ani-
REPTILES.

Vital Temperature.—"Since the respiratory organs," says Blumenbach, "may, with great probability, from the numerous investigations and discoveries of the moderns, be regarded as the principal source of animal temperature, we follow a natural arrangement in passing from the consideration of their structure and functions, to a short view of the differences between the natural heat of reptiles and warm-blooded animals.

"Animals, whose lungs are most compact, receiving the greatest supply of blood, and furnished with all the apparatus necessary for sending the whole circulating mass through the minor circulation, are obliged to keep up the respiratory process uninterruptedly from the time of birth, expelling, instead of the pure aerial fluid which they inspire, a noxious air, which corrupts the surrounding atmosphere if confined, poises a high natural temperature, about the 8th degree of Fahrenheit's scale in man, rather higher in some mammalia, and particularly in birds. In reptiles, on the contrary, poising lungs of a rare and loose texture, with comparatively flender supply of blood, respiration is irregular, interrupted, and in some measure arbitrary; they very slowly vitiate confined air; and exhibit a temperature exceeding, by a few degrees only, that of the surrounding atmosphere. One or two degrees, I say, according to the results of accurate observation on tortoises (Wálbaum Chelonograph. p. 26.); for my own experiments on amphibia have not exhibited results sufficiently confident to allow me to draw any certain inference from them." (Specimen, &c. p. 18.) Braun, indeed, has asserted, in the Nov. Comment. Acad. Petrop. t. 13. p. 427, that frogs poises only the temperature of the surrounding medium; but the facts which we shall advance presently, completely disprove this assertion.

The power which modern investigations have proved warm-blooded animals, and more particularly the human subject, to possess in so high a degree, of being able to endure exposure to heat much above the natural temperature of the body, without having their own heat increased; and, on the contrary, of bearing, with equal facility, the most intense cold, is not withheld from the amphibians, as is proved by the facts which we have related, in order to shew the tenacity of life in these clafs. It is not, indeed, clear in these cases, as in the experiments, of which man and different mammalia have been the subjects, that the reptiles, when exposed to a degree of heat greater or less than their own, have maintained their own temperature at an uniform standard; on the contrary, indeed, it seems that in a great cold their heat is abraded, and they become frozen; and it will also be seen, from facts to be brought forward presently, that their heat is variously changed under different circumstances. Now we know that the temperature of the mammalia is not rated beyond its natural level by exposure in an atmospheric medium of 260° Fahr. (see Tillet in Mém. de l'Acad. des Sciences, 1764); and that its standard is equally undisurbed, when the atmosphere is below the freezing point of mercury. (See Heat, Animal, and Man.) We may therefore safely assert that man and the mammalia very far exceed reptiles in the power of retaining either great heat or cold; that is, of maintaining a standard temperature under the action of a surrounding atmosphere, considerably exceeding or falling short of their own temperature. The following summary of facts, concerning the temperature of reptiles, is taken from Mr. Ellis's Inquiry.

"Amphibious animals exhibit a great variety in the structure of the respiratory organs, and, consequently, in the degrees of animal heat. Frogs and land tortoises poises a temperature about five degrees higher than that of the medium they inhabit, according to Dr. Martine. The same may be said of sea tortoises, toads, vipers, and all the serpent kind, all of whom have lungs of the same fabric and the same cold constitution of body. (Essay on Thermometers, p. 142.) Mr. Hunter observed that the frog and toad were about four or five degrees warmer than the atmosphere when it was at 35° or 36°; and that, some hours after death, they gradually fell down to the temperature of the surrounding air. (Treatise on the Blood, p. 298.) The difference of temperature appears to increase in a warmer atmosphere; for Mr. Carlyle kept three frogs for many days in an equable atmosphere of 54°, and their fosaicles preferred a temperature of 62°. (Philos. Transact. 1805, pt. 1.) In an atmosphere of 58°, Mr. Hunter found the thermometer, introduced into the fosaicle of a healthy viper, to stand at 68°; but, after the animal was put into a pan, and the pan into a cold mixture of 10°, where it remained about ten minutes, the heat was reduced to 37°, and, in twenty minutes more, to 31°, nor did it sink lower; its tail now began to freeze, and the animal was very weak. A frog also, whole temperature was 44°, when put into a cold mixture, soon fell down to 31°; and beyond this point it was not possible to lefen the heat without destroying the animal. (Obf. on the Animal Economy, p. 104.) A toad being placed in cold water, just deep enough not to cover his mouth, the whole was put into a cold mixture between 10° and 15°. The water froze around the toad, and, as it were, clofed him in, but he did not die, and therefore was not frozen. Why the animals, mentioned in these experiments, died before they were frozen, while those which are exposed...
exposed to the atmosphere, in very cold climates, do not die, is a point which Mr. Hunter does not pretend to determine; not knowing the difference, he says, between the effects of a natural and artificial cold. Ibid. p. 89, 90.

"The experiments of Mr. Hunter farther prove that the temperature of molt of the foregoing animals not only falls rapidly in a colder medium, but that it rises more quickly in a warmer one than that of those which possess a higher standard temperature. In the stomach of a frog, the thermometer rose from 45° to 49°; the animal was then placed in an atmosphere made warm by heated water, where it remained for 20 minutes, and upon introducing the thermometer again into the stomach, the mercury rose to 65°. (Ibid. p. 96.) A healthy viper was put into an atmosphere of 108°, and, in seven minutes, the heat of the animal, both in the stomach and anus, was found to be 92°.5, beyond which it could not be raised in the above heat. An eel, very weak, whose heat was 44°, was nearly that of the atmosphere, was put into water heated to 65°, for fifteen minutes; and, upon examination, it was of the same degree of heat with the water. The heat of a tench was, in ten minutes, raised from 41° to 55°, both in the stomach and rectum, by being put into water at 65°.

"He found also, that a living and dead tench, and a living and dead eel, put together into warm water, received heat equally fast; and when they were exposed to cold, both the living and the dead admitted the cold likewise with equal quickness. (Ibid. 104, 105.) Hence, therefore, the animal heat, in all the classes of animals hitherto mentioned, whether they inhabit the air or the water, seems to follow nearly that of the medium in which they are placed; and their standard temperature cannot, in consequence, be restricted to any fixed point, but must be considered always in relation to that of their surrounding medium.

"Notwithstanding, however, the low degree of heat which these several classes of animals possess, hardly, in some instances, exceeding that of the medium in which they live, yet this small excess is a proof that they possess, within themselves, a power of producing heat. The loss of heat which infects suffer under cold, the fall of temperature which many of the vermes class undergo from the same cause, the melting of snow by the heat of fishes, and the decline of animal heat which the amphibian, when exposed to great cold, experience, all demonstrate that the surrounding medium, whether it be air or water, is constantly drawing off their heat, which renders necessary as constant a re-production of it." P. 218—221.

The great size and beautiful structure of the lungs of reptiles lead us to conclude that they are very important organs in the economy of these animals, although their uses and relations are not yet all satisfactorily ascertained. It seems tolerably certain, that besides their office as respiratory organs, they render the body lighter for swimming in many instances; in this point of view they may be compared to the swimming bladder of fish. It is by the inflation of its large lungs, that the cameleon can defend its body so remarkably.

"The lungs, too," says Blumenbach, "are subfervient in many reptiles to the production of sound; — I say in many, because some species, even of our reptiles, are, so far as I know, completely dumb: viz. the salamander, lacerta agilis (green lizard), and anguis fragilis (blind-worm); and others utter sound very rarely, and only when in great danger, as the water newts; resembling, in that respect, the mole and hare, which do not cry out until great violence is offered them.

"It has been reported that some mammalia lose their voice in particular situations, as dogs in certain parts of America: the same thing has been reported of reptiles, for example frog, which G. F. Müller found to be dumb in many regions of Asiatic Kuffia. Sammlung Russicher Geschichten, vii. p. 123.' Blumenbach, Specimen, &c. p. 15.

Organs of Voice. —The larynx, varying in different genera, as in the other classes, has these characters in common; viz. that it has no epiglottis, and is composed of pieces analogous to those of the upper larynx of birds. This is the only vocal organ; there is never an inferior larynx, as in birds. The voice cannot be modified by lips or velum palati, since they do not exist. The degree of aperture of the mouth, and the motions of the tongue, are alone capable of modifying the action of the larynx.

The cartilaginous skeleton of the crocodile's larynx contains five pieces: a nearly square plate, composing all the under surface of the cavity. Two circular pieces or handles, fixed near together at one end, in the middle of the front edge of the plate, and at the other, in the middle of the side. Their body is a little elevated above the square plate, and leaves on each side, between it and that plate, a membranous hollow. The anterior extremity of each piece forms a lateral and vertical prominence, constituting a kind of pillar under the glottis. To the posterior external angle of this plate, a branch is fixed on each side; these join together above, and form, with the back edge of the plate, a complete ring, which is the beginning of the trachea.

The glottis is merely membranous, extending from the junction of the two last-mentioned branches to the middle of the os hyoïdes, where the membranes composing it are attached. There are neither ventricles nor chordae vocales. Two muscles act on this apparatus. One comes from below the great plate, surrounds the larynx, ascending obliquely backwards, and joins the corresponding muscle of the other side behind the glottis, which it has the power of closing. The other comes from below the back edge of the same plate; decussates the former, ascending obliquely forwards, and is fixed to the edge of the glottis, which it opens. The first half of the glottis corresponds then to the broad and flat cavity of the larynx; the second, beginning from the two pillars in front, is merely a long and narrow slit. It is only in striking against the two pillars, that the air can produce a whistling noise, if indeed any such be produced at all.

The glottis of the crocodile of the Orinoco, says Humboldt, is surrounded by a thick fishy ring with circular fibres, which the animal can contract to such a degree, that the slit or opening of the trachea cannot be distinguished. The glottis reaps on a round and flat cartilage, analogous to the thyroid of mammalia. The upper part of the trachea presents a singular structure, which we mention here, because it seems subfervient to the production of sound. The first nine cartilages are not complete rings, but are joined together above by a transparent, very fine and tendent membrane. (See Humboldt Recueil d'Observations de Zoologie et d'Anatomie comparées, t. 1, pag. 11, pl. 4.) Geoffroy observed ten annuli thus united in the Nilotic crocodile; Duverney sixteen, in a crocodile dissected at the Academy of Sciences, and the Jefuit Millionaires in Siam a larger number. To this membrane, fracted like the parchment of a drum, and thrown into vibrations by the air, the deep and terrific howlings or bellowsings of these dangerous reptiles are ascribed; the glottis being at the same time closed by its mucosal ring. Annales du Muscum, t. 2. p. 46.

In the iguana, the pillars are fearcely more prominent within than the rest of the parotids; the glottis is very short,
short, and the inferior plate goes forwards and becomes broader, being turned up to form the rudiment of an epiglottis.

The same simplicity of structure prevails in the tupinambis, the common lizard, the tortoises, and serpents; an inferior plate, and two lateral pieces narrowing a little the edges of the glottis. These animals can only be capable of producing hissing sounds.

The mud-tortoise has, at the bottom of its organ, a rounded depression, which is not so well marked in the turtle; but it has not any vocal chords. In a great land tortoise of Madagascar, there is a triangular membranous cleft, attached to the lower part of the larynx, and ascending in the glottis, which it divides into two. This is analogous to a structure very common in the upper larynx of birds. The edges of the glottis are flat, sharp on the outside, and touch completely.

In the chink, the edge of the glottis is turned a little inward to form a tenue membrane, directed backwards.

In the celled there are pillars, nearly as in the crocodile, but they are each furnished with a tenue membrane directed backwards, and very fit for vibration. In front of them, on each side, a flabby protuberance is observed, contracting the glottis, which is very short, and terminating in front by a transverse fit. But the most remarkable circumstance about the larynx of the celled, is a small membranous sac opening below, between the inferior plate of the larynx, and the first ring of the trachea.

Neither the iguanas nor the dragons possess a similar sac, although we observe in them grooves on the outside; these prominences have no relation to the vocal organs.

The frogs, which are so noisy, have a larynx suitable to this character in the size and prominence of its vocal chords. The inferior plate of the larynx is a slender transverse branch, bearing on each side a large ring, which is the origin of the bronchus; for, in these animals there is no tracheal tube. On the front of the transverse branch, two oval pieces are articulated, convex externally, and concave internally, so as to resemble kettle-drums. On the lower edge of each a membrane is stretched internally, which opposes at right angles the course of the air. The edge of this membrane forms the chorda vocalis, which is consequently more isolated than the cartilages, and freer than in any other animal. Above it is the opening of the ventricle of the glottis, occupying all the concavity of the kettledrum cartilage. The upper edge of this cartilage forms the margin of the glottis properly so called. Vieq d'Azyr conceived that the ventricles communicate by their bottom with the bronchi, and thus affered three openings to the larynx of frogs: but this is a mistake.

Besides this apparatus, which is extremely sonorous, male frogs have two bags, each of which opens by a small hole, not in the larynx, but in the bottom of the mouth, at its sides. They pass under the arch of the lower jaw, to make a prominence under the skin on each side under the ear. These bags are distended when the frogs are croaking. They are covered by a muscular tissue capable of compressing them. The female frogs, and toads of both sexes, and the tree-frogs, are destitute of the bags; but the latter have a single sac under the throat. In this larynx there is a muscle on each side to separate the oval cartilages; and a transverse one in front, passing between them, and calculated to approximate them. For representations of these laryngeal sacs in the frog, see the German collection of Camper's smaller writings, vol. 1. pt. 1. pag. 144. tab. 3. fig. 1.—4. Vieq d'Azyr has represented the rima glottidis of the tortoise, frog, and serpents, in the Memoires de l'Acad. des Sciences. 1779, tab. 13; and Tyron that of the rattlesnake, in the Philof. Transl. vol. 14. The chordae vocales, too, are larger in the male than in the female frog.

**Voice of Reptiles.**—The tortoises and turtles are said to have the power of producing a more or less strong hissing, when affected by any lively feeling; but we do not know of any very clear and satisfactory testimony on the subject. Pliny's observation about the roaring of turtles when floating asleep: the water, has not been confirmed. The large iguanas utter sharp whistling or hissing sounds as they run about the tops of trees. Several serpents hiss, and the large species very loudly. The noise made by the tail of the rattlesnake is not a vocal sound, but produced by a peculiar organ, which we shall describe.

Daudin affirms, that salamanders produce two kinds of feeble sound out of the water; the first is a low sound, produced in the throat, which they swell for that purpose; the second consists in a slight hissing of the two lips together, without any motion of the throat.

According to the traveller Bartram, crocodiles produce most prodigious noises. The sound is terrific, particularly in the spring, when these dangerous animals copulate. The noise resembles distant thunder, shaking the country and making it re-echo far and wide. When they are thus buffeting by hundreds and thousands at a time, we might suppose, says Bartram, that some violent shock agitates the globe, and skakes it to its very foundations. He also states, that when they strike their jaws together they make a surpalling noise, like that of a heavy plank forcibly beaten against the ground.

Humboldt says that the young crocodiles make a noise like cats; and that they utter very piercing cries, just after escaping from the eggs, if attacked by a dog. He never heard any vocal sound produced by the old crocodiles; although he lived among them five years, and the fire often attracted them within a few paces of the tents at night. The Indians affirmed that the crocodile makes a noise like that of a cow; that its voice is very terrific, but seldom heard, and sometimes just before an earthquake, the approach of which they are said to discern. Recueil d'Obf. de Zool. et d'Anat. Comp. p. 11.

**Organs of the Generative Functions.**—There is a very close analogy in the structure of these parts between reptiles and birds; in both classes there is a cloaca, that is, a cavity common to the generative organs, the feces, and the urine; in both the male has testicles inclosed in the abdomen, while the female organs consist of ovaries and oviducts. The young being leaves the mother in the form of a small egg, which is generally developed out of the body. The generative processes, however, in many instances, exhibit in this class very striking peculiarities.

**Male Organs.**—The testicles: the situation and structure of these glands in the three first orders are very analogous to those which they have in birds. They are constantly found in the abdominal cavity, united to the inferior surface of the kidneys (in the chelonia), in front of the latter visceras on each side of the vertebral column (in the saurians and ophiids), or immediately under their anterior portion (in the batracians). Their form varies in the different genera; they are separated, in the salamanders, into two spherical bodies, placed one before the other.

The kidneys, testis, and epididymis, lie close together in the tailadines, according to Blumenbach; but each of the three organs may be distinguished by its peculiar colour and structure on the side view. There is much obscurity in the different descriptions of the male organs in the turtles and tortoises. Schneider has collected the various observations.
vations on this subject in his natural history of the genus

tetudo.

Their substance exhibits, in the testicles, large fasciculi, of
which the divisions pass in various directions, united by
vascular tissue: these fasciculi are fine, cylindrical, and easily
separable in the lizards. In the crocodile, according to
Geoffroy, the testes are like those of fish, narrow and elon-
gated, and lying above and in front of the kidneys (prob-}
ably more correctly in front of and below these glands). In
the batracians we can distinguish merely an agglomeration of
smallest white grains intermixed with blood-vessels. No cor-
pus Higlhorni can be discerned.

Yellow appendages, confluent of a fatty substance sur-
rounded by a membrane, and floating in the abdomen, are
connected to the front end of the testes in the frogs and
toads.

The epididymis of the chelonians is a packet made up by
the convolutions of a large canal (the vas deferens), which
is tortuous in its whole course, and ends in the cloaca at the
part corresponding to the bafs of the penis and its canal.
It forms, in the lizards, a detached body, large and pyra-
midal, larger than the testicle, adhering to it only by a small
thread, and evidently made up entirely of the convolutions
of the vas deferens. The latter passes along the outer edge
of the kidney to the cloaca, in which it opens.

In the crocodile the fermen is conveyed into two vessels
of considerable size, contiguous to each other, placed at the
back of the common cloacas, and partly included in a carti-
laginous fag. They open into the cloaca by six or seven
holes on each side, arranged in a circular form round the
meatus urinarius. Geoffroy. If these are vesiculae feminales,
it is the only example we know among reptiles of such
organs.

The testis is long and slender, and the relative bulk of the
epididymis is less in the ophidians; it soon changes into a vas
deferens, also very tortuous, opening in this, as in the pre-
ceding orders, into the cloaca. In the latter only the canals
are inserted in a papilla, which has been incorrectly
described as a penis. A more minute account of these
organs in the vipers, may be seen in Cataras, Description Anato-
miique de la Viperes.

Veuficula Seminales.—There is no corresponding analogous to
the vesiculae seminales properly so called, nor to the accen-
tory vesicle of some mammalia in any of the other classes of
vertebral animals. They have been spoken of in the viper
and the batracians, as well as in some birds; but it seems
that a simple dilatation of the vas deferens has been mis-
taken for them. Possibly future researches may shew that the
arrangement mentioned above in the crocodile constitutes an
exception to this remark. This is the statement of Cuvier,
Blumenbach speaks of large vesiculae seminales in the frog,
which are wanting in the toad. § 321. (See Roesel Hilfgr.
Ran. Noftr. tab. 5, 6, and 21.) Cataras, in his description
of the vipers, speaks of two reservoirs connected with the
vasa deferentia, and always full of a fluid, like that of the
testicles, under the name of vesiculae feminales.

The secretion of the testicles, as observed by Spallanzani
in the frog and toad, was a transparent fluid like water.
From the parts, which he calls vesiculae feminales, of the
frog, he could procure at the time of copulation from two
to three grains of this fluid. In the water newt it was, in
colour and confluence, like thick milk. He could not dis-
cover in it any remarkable sensible property—nothing pung-
gent—nothing acid or alkaline. (Dissertations, v. 2.) He
also found the seminal fluid, both of the frog and newt, to
abound with the living vermiculi. Tracts, v. 1. p. 300
and 301. Organs of Copulation.—There are two species of union
between the male and female. In the greater number there is
a male organ introduced into the body of the female, and
conveying the fecundating liquor; but in the batracians,
which have no male organ, there is merely a conjunction
of their bodies, it is a prehension by the male rather than a
true copulation.

In the males of those batracians which copulate thus,
there is a peculiar organization of the skin of the hand.
Firm tubercles, composed of hard, blackish or brown pa-
pillae, cover not only the thumb, but also the palm of the
hand. These being pressed into the skin of the female, give
the male a very firm hold. They disappear after the seafon
of copulation, and are not seen again until that season recurrs.

The copulation of the frog kind is effected in the following
way: the male ascends to the back of the female, pulls his
front limbs under her axilla, and carries them round the chest
until the fingers crofs in front. He continues grasping her
firmly in this way until the laying is finished. The posterior
part of his body pulls beyond that of the female, so that
she can fecundate the egg as they are expelled, and he is said
to shift in that operation. They remain joined for several
days, and the grip of the male is so firm, that great force
is necessary to separate them. Contusion and laceration of
the crocodile, and even the death of the female, follows
the violent thrashing of the male. (See Spallanzani's Dis-
sertations, vol. i. p. 15.) The males are more brillant at
the season of copulation, which takes place only once a-year, in the early spring: they inflate their vocal
bladder more frequently, and indulge in their roaking
noises. In the salamanders a cress, with divided edge, ap-
pears on the back and tail, and is afterwards, in great me-
asure, lost.

The duration of copulation in the frogs is inverely pro-
ditional to the warmth of the atmosphere. When this is
considerable, the female will be free in five or six days; but,
in a cold season, the embraces of the male continue for eight
or nine days. The season of re-production is the begin-
ging of spring; in the very first days, the frogs begin to
attract themselves in our marshes and ponds: they copulate,
and fecundate their eggs very soon. At the same season,
the toad, lizards, and serpents, accomplish the same
process. Sometimes frogs are found united even before the
frogs have ended. Daudin found two frogs in copulation
in the middle of February, the termometer of Reaumur at
5° above zero; it defended in the night to 4° below 0; and
the pond was frozen for two days; at the end of which
time the female began to lay. Hilt. Nat. des Reptiles, vol. i.
p. 207, 208.

One of the toads, on which Spallanzani made his experi-
ments, copulates in the beginning of March or end of Fe-
bruary, before all the snow is melted; the processes last ten,
twelve, fourteen, or even twenty days, if the season be cold.
Spallanzani, ch. 3.

The abdomen swells greatly in both sexes during copula-
tion; in the female, from the enlargement of the ovary; in
the male, from the deposition under the skin of a very limpid
water, which disapperaers after the laying.

The tree-frogs, at least that of Europe (hyla viridis) do
not copulate like the frog and toad. The male fixe himself
on the female, by merely applying his anterior paws under
her axilla, and employing the tubercles of the fingers. He
remains in this situtation for twelve or fifteen hours, or even,
according to Roesel, three days.

The salamanders do not copulate at all; the male places
his head on that of the female, and discharges the seminal
fluid, which is received by the female organs. See Spall-

zani.
REPTILES.

xani, Diff. vol. 2; and Latreille, Histoire Naturelle des Salamandres de France.

Penis.—The chelonians have one; most of the faurians, and the ophidian, have two; and the batracians none. There is a papilla in the cloaca, in place of the penis, but none in the toad.

The relative size of the organ is more considerable in the chelonians than in the mammalia and birds. It is long, nearly cylindrical, and expanded at the end, which terminates in an obtuse hook-like point, somewhat resembling the end of the elephant's trunk. A deep groove runs along the whole upper surface of the member, and is even deeper near the end. It terminates on the expanded end of the latter, by an orifice divided into two by a papilla. The approximation of its edges converts this groove into a canal; it supplies the place of the urethra. This penis is composed of two corpora cavernosa, confluent together in a part of its extent. They begin by two vascular swellings analogous to the bulb of the urethra: their tunic is continued into two canals, of which the fibrous peristome, at first thin, soon become very thick, while their cavities diminish, and are united near the cloaca into one. The whole large swelling corposing the glands is merely a development of the vascular tuiue of the latter, covered by a loofe and plaited skin, and supported by a prolongation of the fibrous shea of the corpus cavernosum.

The skin of the groove is covered by a cavernous texture, analogous to that of the ophichthys; and there is, on each side of this groove, a canal, the orifice of which is in the cavity of the peritoneum, on each part of the bladder, while the canal itself is prolonged in the surface of the penis, as far as the glans, where it ends in a cul-de-sac, without its sida appearing perforated in any part.

This penis has two retractor muscles, arising in the pelvis, and reaching as far as the glans. They fold back the penis in the cloaca, so that, like the penis of the ophichthys, it shutts the orifice of the rectum, and that of the bladder. Erection, and the action of the sphincter, bring it out of the cavity.

The penises of the lizards and serpents are short, cylindrical, commonly bent with white, hard, and pointed papilae, which have been tolerably well compared to the prickles of the hedge-hog. These organs, in their collapsed state, are drawn within the skin of the tail; when erect they are protruded, and appear at each angle of the external silt of the cloaca. They have two retractor muscles, arising under the first canad vertebræ. Tyron has figured the penis of the rattlesnake and viper in the Philof. Trans. v. 13, tab. 1; and the latter is minutely described by Charas.

The penis of the crocodile is single, and lodged in a fold of the anterior part of the cloaca. It is composed of a firm cartilaginous fibulamin, terminated by a glass of softer texture. It is excrated in its whole length by a deep groove. It has a very large retractor muscle, which is so considerable as even to cause a swelling of the tail.

In the faurian reptiles, as in the frog and salamanders, the male fixes himself on the female, and obliges her to turn towards him the posterior part of her body, and a real copulation ensues.

The act is differently accomplished in the serpents: the male and female twine round each other, are closely connected by several turns, and remain thus adherent for one or two hours. Is the small horney spurs, situated on each side of the anus in the box, and retractile under the skin, employed at all by the serpent as an organ of prehension, like the cutaneous tubercles of the hand of the ranap? The faurians and serpents conceal themselves carefully for this purpose.

Although the chelonian reptiles seem to little calculated for copulation, this process takes place in them, the male fixing himself to the female by attaching the nails of his front limbs to the soft skin of her neck. Naturalists are still uncertain, whether turtles are joined platton to platton, as Lacépède has asserted in his Natural History of Oviparous Quadrupeds, or whether the male mounts on the back of the female, as Bomare has represented it in his Dictionnaire d'Histoire Naturelle. From the word cavale, employed by the French mariners to denote this union, we may infer that they copulate like the frogs: the expression denotes clearly that the male is mounted on the female as the flalion is on the mare (cavale). Catesby, in his Natural History of Carolina, affords that they remain united for many days.

Female Organs of Generation.—Reptiles have two ovaries, usually more considerable than the single ovary of birds. For most of the year these bodies are small; but they acquire, at the propagating season, an extraordinary development, and thus dilate the abdomen very remarkably. This is particularly observable in the frog kind.

In autumn and winter, says Spallanzani, the immature eggs lie all in the ovarium, which is divided into two lobes: these lobes consist of leffer lobes, each of which is invested with a peculiar membrane. The eggs are of two sizes; some very small, so as to be scarcely visible with the naked eye; others seven or eight times larger; both kinds are globular. The smaller are of a livid grey colour: of the larger one hemisphere is white, the other black. The lightest touch is sufficient to burst them, after which they are resolved into a cataractous viscid liquor. (Different, v. 1. § 4.) The black spots of the surface, supposed by Valinieri and others to be the rudiments of the tadpole, are attached to the internal membrane, and have no connection with the eggs. In the spring the eggs of the largest kind are still larger, and they are mature when copulation takes place. In the first periods of copulation, they are found in the back of the ovarium; during the succeeding times, partly in the ovarium and partly in the oviducts, where they become enveloped by their covering of viscid transparent mucilage.

The ovaries of the salamander contain a multitude of little eggs of a yellowish-white colour, smaller than husked millet, and not floating loose in the cavity of the ovaries, but adhering to their sides. These increase in size at the approach of spring.

The ovaries are connected to two long productions of peritoneum, which are fixed on each side of the spine down to the pelvis. The ova are ranged along the loofe edge of this fold, either in a single row, as in the chelonians, or agglomerated in a much larger number, as in the batracians. Their blood-veins extend between the laminae of these membranous productions. In the batracians there are yellow fatty appendages to the ovaries, like those of the teeticles.

In the serpents, like all their other viscera, they partake of the elongated figure of the body. The ova, consisting of yellow vesicles, resemble rows of beads.

Ophidians.—There are two in all reptiles, like their ovaries. They are membranous canals, fixed on each side of the vertebral column by a production of peritoneum. They commence by an expanded orifice (fimbriated opening of the Fallopian tube in mammalia), at which the ova enter. The tube is first conical, diminishing a little in size; then it is cylindrical in the rest of its course, which has a much greater propor-
REPTILES.

An uterus is also spoken of by some in the frogs, although the generation of these animals has nothing in it like utero-gestation, and the ova are simply transmitted through the tubes, without being retained in them to undergo any part of their development. "The frogs of this country," says Blumenbach, "have a large uterus divided by an internal partition into two cavities, from which two long convoluted oviducts arise, and terminate by open orifices at the sides of the heart. As the ovaria lie under the liver, it is difficult to understand how the ova get into the above-mentioned openings. The uterus opens into the cloaca." (Comparative Anatomy, translated by Lawrence, p. 446.) "The toads have not the large uterus, but their oviducts terminate by a common tube in the cloaca." (Ibid.) For delineations of these parts in the frog and toad, see Roefel, tab. 6, 7, 8, and 21. The rana pipa (Surinam toad) has the same structure. See Camper in the 9th vol. of Commentat. Soc. Reg. Scient. Gotting. p. 129. Also in his Kleine Schriften, v. 1. pt. 1. tab. 3. fig. 1.

Female Organs of Copulation.—The male penis in copulation pales into the female cloaca. Does it go into the oviducts? The chelonian reptiles have a clitoris very analogous to the penis of the male, from which it differs only in its smaller size. It is long, grooved lengthwise, and terminated by a rounded glans. Retractemuscles, analogous to those of the penis, draw back the clitoris into the cloaca, when it has been extended.

No clitoris has been discovered in the other reptiles.

Dorsal Cells of the Rana Pipa (Surinam toad, bufu dor-figer).—It is singular enough to meet with in a toad a structure analogous to that of the abdominal pouch of the martupial mammals. The skin of the bulk is excited in the female pipa by a large number of cells, (of which, Cuvier says, eighty have been counted,) in which the ova are placed, and changed into tadpoles, and the latter grow and are metamorphosed. As far as an examination of individuals, preferred for a long time in spirits of wine, will enable us to judge, the parietes of these cells do not seem to have any thing in their organization different from the rest of the skin.

Naturalists supposed at first, that the ova grew on the back of the female, and that the male fecundated them in that situation: but observation of the living animal, and anatomical investigations, have shewn the incorrectness of this notion; have proved, that the generative organs resemble those of other female toads; that the pipa lays her ova like the other toads; and that the male fertilized on her, as in the ordinary mode belonging to this order, covers her with the eggs after they have been fecundated. The eggs are then enveloped in a fluid, which causes the skin of the back to swell round them; thus they are contained in rounded cavities. The tadpoles are produced there, with their membranous tails, and are developed in this situation, which they do not quit until they have reached their perfect state. The female then causes the cells to disappear from her back, by rubbing it against hard substances. Before the works of Camper already referred to, concerning the anatomy of this extraordinary creature, see Blumenbach's Abbildungen, N° 36, for excellent figures of the animal, and of its young in three states: 1st, as a long-tailed tadpole, with small procelles of hind legs, and no trace of fore limbs; 2dly, as a four-footed creature, with the tail reduced to an insignificant size; and 3dly, with the tail entirely removed. "The skeleton is figured by Schneider, in his Hist. Amphib. Facies. 1.

Physiology of the Generative Organ.—In the whole class it is quite obvious, that the germ or rudiment of the new being is produced by the female in the ovarium, a point which does not admit of direct proof in the mammalia. This "pre-existence of the germ" to the act of copulation, and its formation in a peculiar organ of the female, demonstrated so clearly in reptiles, illustrate one of the most curious points in the theory of the natural reproduction of organized beings, or generation, and turn over many of the speculations on that subject. These germs acquire considerable size in the ovaries, and are therefore distinctly visible before the approach of the male. They pass from the pores just mentioned into the oviducts, and thence out of the body through the cloaca, having received in their passage through the ducts some external coverings. An application of the fecundating liquor secreted by the male is necessary to the evolution of these germs; they may be ejected from the body without the embraces of the male, as in the frog, toad, or newt, if they are forcibly separated from the male after copulation has begun, but then they are not evolved.

Swammerdam and Roefel were of opinion, that the eggs were loose in the abdominal cavity, and taken up thence by the oviduct. Spallanzani found them in the abdomen only three in more than two thousand dissections; and hence supposes that the circumstance must have been a deviation from the accustomed course in these instances.

Although the motions and vital functions of reptiles seem very languid in comparison to those of the warm-blooded class, they exhibit considerable ardor and manifestations of lively feeling in their amours. "As soon," says Spallanzani, "as the eggs begin to be discharged, the agitation of the female is extreme; the darts backwards and forwards, rises towards the surface of the water, and then sinks, keeping the hind legs constantly stretched out, and croaking in a low voice. The male, keeping his hind legs close to his body, throws himself into strange contortions, and accompanies the croaking of the female with a kind of interrupted noise, which I cannot express by words." Differens, v. 2. § 11.

In the work just quoted, which contains the most original and interesting collection of facts concerning the whole affair of generation, Spallanzani gives the following account of the amours of the water newt, which are the more curious, inasmuch as there is not only no real copulation by the introduction of a male member into the female organs, but not even any conjunction of the bodies, as in frogs and toads. "The male pursues the female, which at first makes a show of flying, but then raps of her own accord. He then approaches her in such a manner, that the lower part of his head comes in contact with the upper part of the head of the female; and this is done while the animals are in such a posture, that their bodies form an angle,
angle, of which the point is made by the union of the two heads; or they may only join muzzle to muzzle. The bodies are always very near together, so that the angle formed by the two heads or muzzles is always very acute. Thus the male erects that darted prominence, which is placed on his back, and agitates it in a curious manner: he also moves his tail briskly, bending it about, and liriking very gently the sides of the female. During this time he emits from the aperture of the anus, now unusually timid and dilated, a copious jet of semen, which mixes with the water, and thus diluted arrives at the anus of the female, also more enlarged than usual. In this important operation, then, the anus of the male is never in contact with that of the female, which maintains a greater or smaller distance, and never shows any part characteristic of her sex. After the male has discharged this jet of semen, he retires for a while, on some occasions quitting the female; he then returns to his employment, and repeats the contortions of his tail, and the emission of semen.” § 89.

In the hand newts there is a momentary copulation: “in the clearest days, and in the places most exposed to the sun, the male newt after the female, and when he has overtakes her, he twines himself about her, and unites his genital to her’s, but this union may be termed momentary, after which they part.” § 90.

The evanescence of the semen in amphibia is so remarkable, that they actually will copulate with other species, as frogs with toads, &c. No example of hybrid offspring, from such a conjunction, has been recorded. It has also been known, that frogs, in want of a female, have copulated with other males, or with dead females.

That the animals are entirely absorbed by the powerful emotions accompanying this act is evinced by a series of disgusting experiments of Spallanzani, proposed and multiplied with an unrelenting and unnecessary cruelty, and regulated quite coolly, without evidence of remorse or the slightest apology. He pricked, cut, and hacked the male frog and toads, without making them loose their hold; amputation of the limbs, and of the head, was equally ineffectual.

Males, after suffering amputation of the fore or hind limbs, renewed their situation, and completed the generative act. “Nay, even the decapitation of a frog did not stop the embraces or fecundation. It is well known, that these animals are so tenacious of life, that that operation does not take it away immediately. That of which I am speaking was thrown into convulsions; but neither the fore-feet nor legs quitted the breast of the female, which brought forth her fetuses in an hour and three quarters, and I was an eye-witness to these animals begor sprinkling them with semen that they were fecundated can there be no doubt, since they came to life at the usual time. As soon as he had performed this operation, he deferred his situation, and died in four hours afterwards.” Diversations, v. 2 § 90 and 100.

All reptiles may be said to be oviparous; an egg, containing the germ, and as much nourishment as is necessary to support it until it is sufficiently developed to leave this shade, is formed in the body of the mother, and enters the oviduct in all. But there is a subdivision, according to the subsequent progress of the egg thus produced. In the greatest number of reptiles, the eggs or eggs are laid by the female in that slate, and the young reptiles are developed afterwards: but in some, as the venomous serpents, and the true lizards, the ovum may be laid to be hatched in the oviduct, although the animals still come into the world so far enveloped by the membranes, that the character of an oviparous generation is preferred. The reptiles of the latter kind are called ovo-viviparous.

In both these cases, a real egg, like that of birds, is produced, and has no connection with the body of the mother; it is a very different thing from the ovum of the mammiferous animals, in which there is no supply of nourishment for the fetus; and the latter is connected by the umbilical chord with the vessels of the mother, and derives from this source the materials of its growth. Here, as no true egg is produced in any part of the procods, and as the young are always brought into the world alive, they may be justly termed viviparous. See Lacépède, Hist. Naturelle des Serpens, t. i. p. 31.

In using the common term ovum, we do not mean to represent that the thing produced is the same in all; nor that it is like the egg of birds in all. There are varieties in the different orders, and, in the batrachians at least, there is not a close analogy to the ovum of birds.

The eggs of reptiles are covered with a membranous, rather than calcareous shell; but there is some earthy matter in it. In the green turtle this shell is flexible, but contains earthy particles. It is composed of a soft membrane, containing albumen, which heat does not harden, and a yolk about which it does. The eggs of lizards have a more or less hard shell; it is flexible in the grey lizard, hard in the feck macouyo, and the crocodile. It has been allerted, that the eggs of the iguana are not hardened by boiling. The covering of the egg is soft and calcareous in serpents. The batrachians lay gelatinous and femtirrernparent eggs, without any covering.

A part, corresponding more or less closely to the yolk of a bird’s egg, is produced in the ovary, escapes from its membranous covering, and enters the oviduct, where it receives its external investment, as the yolk of the bird’s egg receives its shell and albumen. In the turtle, the procods seems very similar to what we see in birds. There are numerous large yolks observed in the ovarium, contained in calyces, and these, when boiled, are very similar to the yolks of birds. In the crocodile and serpents, it is nearly the same. But in frogs, and newts, the egg in the ovary does not seem to be a yolk, but the rudiment of the tadpole, and it comes forth, surrounded by a quantity of transparent glutinous matter. In the toad and newt, these rudiments are formed into long cords by the glutinous medium, which cords are double in the toad. In the frog they come out separately in so many spheres of the gelatinous matter, about the size of large peas.

In all the reptiles which have a penis, fecundation is effected within the body; but in the batrachians, which have no male organ of copulation, it occurs externally. When frogs are joined, it may be seen, that an obtuse, tumid point, occupying the place of the penis, is elongated, and brought towards the eggs nearest the vent. By taking them out of water while this laying is going on, an actual discharge of seminal fluid upon the eggs may be seen from this point. In the same way the male of the water newt discharges his fluid into the water near the anus of the female, and thus fecundation takes place. Spallanzani has instituted an immense number of experiments on this subject; they prove, that if breeches be put on the frog, so as to receive the seminal fluid, no fecundation occurs; while, on the contrary, the seminal fluid from the epididymis, or the juice of the testicles, will produce artificial fecundation of eggs laid by the female after the male has been removed, and otherwise unproductive, or of eggs taken out of the lower part of the oviduct immediately after death. Dilution of the seminal fluid, although it diminished the effect of its application, did
did not altogether prevent it. When three grains of feed were added to twenty-two pounds of water, some tadpoles were evolved in it, but much fewer than in a stronger mixture.

As fecundation is effected in these animals by the feminal fluid discharged in water, it probably is always produced by an extremely small proportion. Spallanzani has made some calculations, in order to find out the expression in numbers of the quantity of semen that was efficacious in some of his experiments. He mixed three grains of feminal fluid with eighteen ounces of water, and found that a globule, 1/4th of a line in diameter, taken out of this mixture, was often sufficient to fecundate a tadpole. The ratio of the tadpole to the particles of feed diffused in this drop of water, is found to be as 106,477,777:1 to one. The weight of the feed is 1 of a grain, and its bulk 199,468,750,0 300,212,042,0 of a cubic line. Diwertationes, v. i. § 655.

He found, however, that although so minute a quantity of feminal fluid is sufficient to produce the effect, there must be contact of the gross and visible part of the fluid; that no vapour or effluvium, no aura formatica will suffice. Diff. ch. §. § 161—170.

The feed of one species will not fecundate another; that of the water newt has no effect on the embryos of frogs and toads; nor reciprocally: neither is there any action of the feeds of frogs on toads, nor vice versa. § 171—172.

The number of eggs is subject to much variety: it is inconsiderable in the serpents; from ten to twenty in the vipers and lizards; one or two hundred in the crocodile, according to Bartram, Travels in America; two or three hundred in the turtle; but the most numerous in the frog kind. In the toad, where the eggs are laid in a double row, forming a cord of a glutinous nature, these rows measured 43 Paris feet, and contained 1207 eggs. Spallanzani Diff. v. ii. § 45.

In the teududines, serpents, and lizards, which have a true yolk, this is to be regarded as a supply of nourishment for the young animal, whose evolution probably goes on in a manner analogous to what is observed in birds; although the process has not been actually watched, nor the order and succession of the changes observed, as in that class. Blumenbach has delineated the eggs of the crocodile, with the young one coming forth; the shell is flexible, as in the other amphibians, and confined of a thick, leathery, and tough, external stratum, marked throughout with extremely fine undulated lines, and lined by a more delicate smooth membrane. The recent eggs, and the young crocodiles which they contain after evolution has commenced, are eaten by various African tribes. The relation in size between the egg (about equal to that of the goose), and the full grown animal (the Nilotic speces), which reaches to thirty feet in length, or even more, is at first view remarkable; and Herodotus has called the crocodile the largest animal from the smallest egg. (Blumenbach's Abbildungen, N° 27.) Seba has also figured a young crocodile, with the membrane of the yolk adhering to the abdomen, as in birds. Thetaurus, t. i. pl. 104, fig. 7.

In the animals just enumerated, the eggs, whether deposited in the sand of the sea-flore, or of the banks of rivers, in the holes of trees, the chinks of walls and rocks, &c. undergo no process of incubation like those of birds, but are developed in the ordinary temperature of the atmosphere, and the young animals come forth from their confinement, differing only in size and proportions from their parents.

In the venomous serpents, and the salamanders, the care is different. The egg containing, as in the preceding instances, the young animal, and a sufficient supply of nutriment for its growth, until it is of size to quit its original abode, is hatchet in the oviduct of the mother, and the young come forth from the cloaca alive, but surrounded by their membranous coverings. The young vipers and other venomous serpents, when they are born, are freed by the mother from this kind of after-birth.

A very curious circumstance has been observed in some of these, recalling to our minds the abdominal pouches of the marsupial mammalia, and the mode in which they serve as a shelter for the young, while yet too small to flit for themselves. Palifot Beauvois thus relates the fact we allude to. "Having perceived a rattlesnake at some distance, I approached as gently as possible, when, on lifting my hand to strike him, he founded his rattle, opened his mouth, and received into it these small serpents, about the size of a quill. I retreated and concealed myself, when the animal, thinking the danger at an end, opened his mouth, and let out his progeny. When I appeared again, they immediately took to their natural retreat." He had heard this fact from American planters, and it has since confirmed by other travellers. Daudin, Hist. Nat. des Reptiles, v. 5. p. 68.

The young of the salamander, like those of the viper, are born alive. The female brings forth very delicate oval vehicles, which may be compared to hydaticis, each of which contains a perfect young salamander, an inch in length, moving its tail, and lacerating its coverings at the time of birth, and emerging in the form of a four-footed tadpole.

"In this same strange animal," says Blumenbach, "I have observed a curious fact, already noticed by Wurff in his Salamandrologia, p. 83. viz. that a female, kept by herself, and absolutely without intercourse with any other of her kind, has produced young ones. I have kept in a glafs at home, for five months, a female salamander, whose tail I had cut off, and in the mean time had no other in the house, nor even seen one. Yet this solitary female, which, to my surprise, sustained so long a falt without growing thin, has begun within a few dayes to bring forth young, of which thirty-four are now before me, not only living, but very lively. This observation will lead us to two conclusions; first, that salamanders really copulate, and that the male does not fecundate the ovae as they are discharged, like what we have described in the case of the water newts; secondly, that salamanders have the fame nature in this respect as hens; which, when they have been once impregnated by the cock, will lay fruitful eggs, not for a whole year, as Fabricius ab Aquapendente affirmed, but, according to the most accurate researces of Reaumur (art de faire éclore les oiseaux domestiques, t. 2, § 327), for five weeks after separation from the male.

Thee young salamanders have a two-edged tail, broadly pinnated on each edge, excellently adapted for swimming, and furnished on each side of the neck with flinbried branchial appendages like throes of the tadpole, which however soon disappear, the two-edged tail being at the same time converted into a cylindrical pointed one." Specimen, &c. 34.

All the reptiles of the frog and toad kind, and the aquatic salamanders, have this remarkable peculiarity, to which nothing at all analogous has been observed in the economy of the warm-blooded classes or the fishes; viz. that they undergo a metamorphosis; and have, in their two states, not only an altogether different external form, but also important differences in many of the great internal organs. In their first state, they are little aquatic animals with tails...
and large heads; from their twirling movements of the former, and the great size of the latter, they have been called in Latin gyrini, in French tétards: the English name is tadpoles, and the German kaugruppen.

Development of the Frog.—As the spawn of frogs is deposited in ponds, ditches, or other stagnant water, the contained ova are evolved in the ordinary temperature of the atmosphere. In one species of toad, Spallanzani says, that it proceeds at 6° above freezing of Reaumur. He found that a temperature of 111° Fahrenheit, did not interfere with the subsequent evolution; that the number of tadpoles produced was much diminished after exposure to 122°; and that very few were evolved after the eggs had been immersed in water of 132°. A heat of 111° was fatal to tadpoles and frogs; although the latter bear 111° in the warm springs of Pisa. (Traité, vol. i. p. 32.) Each egg lies in the centre of a transparent spherical mass of mucilage; many of which, aggregated together, form what is called frog’s spawn. Round the eggs are two concentric membranes, of which the innermost, when pierced with a needle, discharges a fluid as limpid as water. The egg is round, and has a smooth surface, of which one hemisphere is black, and the other white. When the hot sun is far advanced, the observer soon perceives the lineaments of the tadpole. The egg grows for some hours without losing its round shape; it is next elongated; the white hemisphere becomes darker, and the black changes into a longitudinal furrow, terminated by two perpendicular processes. And, as it increases in bulk as well as length, the internal circular membrane is dilated, and contains more fluid. By tracing thus the progress of the evolution, we come to perceive that these bodies are not eggs, as naturalists suppose, but real tadpoles. The furrow and the processes become longer; the suppurated egg assumes a pointed figure, the whitish hemisphere dilates, and the black is incurvated. The pointed part appears to be the tail of the tadpole, and the other the body. Further, the opposite end takes on the appearance of the head, in the fore part of which the form of the eyes is visible, though they are yet closed. The two processes also, by which the animal fastens itself to bodies, when it is tired of swimming, become evident, as likewise the vestige of the aperture of the mouth, and the rudiments of the gills. As the organs are further unfolded, the tadpole, which has not moved hitherto, begins to stir, and loosen its fetters; at this time it appears clearly, that the internal circular membrane is the amnion, in the liquor of which the tadpole floats; the umbilical chord at last is seen, and becomes still more visible the first day after the animal has quitted his confinement. The cord is not, as in other animals, attached to the belly, but to the region of the head. (Spallanzani’s Difsertations, v. 2. § 14—16.) We take the liberty to note what is here said about the umbilical cord as a subject for further research.

The branchiae are visible towards the end of the sixth day: in the course of the seventh and eighth all the tadpoles quit the viscous sub stance, which had been floating on the water, and which had hitherto served them for food. By the fourteenth and fifteenth days they are so much grown, that two small but prominent eyes, an open mouth, no small eyes, &c. can be distinguished. About the nineteenth and twentieth days the branchial appendages are withdrawn within the skin, and no longer visible. The heart can be seen to move, and the caudal vertebrae are recognisable. On the twenty-fourth day the front limbs, which had already existed under the integuments, appear in the place of the branchiae, or rather near where they had been. In ten or twelve days more the hind limbs come out. In this state they swim about in the water, and grow. The tail gradually disappears, and in about two months after they have been hatched, they are metamorphosed into frogs. Those at first are small, and then become gradually larger. Except in the case of the rana paradoxa, and the bufus fuscus, in which the tadpoles become so large, that the animal, when it has changed, is of the adult size.

Anatomy of the Tadpole.—The points in which the animal differs from the organic arrangements of its perfect state, are the large tail, which bears a very considerable proportion to the body, and is afterwards entirely lost; comparative size of the mouth, to the under lip of which a small organ is attached for fixing the tadpole to other objects; a kind of horned plate for jaws; two tuberous at the neck, which the animal can direct at pleasure; the rudiments of the lungs; the intestines convoluted in a spiral mass, which swells the abdomen, and far exceeds, in its ratio to the length of the body, the intestinal canal of the adult animal; the branchial appendages, and the vesicles connected with them; the fore limbs, situated at first under the skin. For the series of changes, and the anatomy of the young animal, see the plates of Roesel, Hist. Ranar. No. 11.

Further particulars of the anatomy of tadpoles, and particularly of the circulating and respiratory organs. In his “Recherches sur les Reptiles douteux,” Cuvier has entered at some length into a consideration of the anatomy of the tadpole. The following account, which is translated from his memoir, as published in the “Reuel d’Observations de Zoologie et d’Anatomie comparée, faites dans le Voyage de Humboldt et Bonapante,” v. 1. p. 165, is to be understood as applying to the full grown tadpole.

The tadpoles of frogs, tree-frogs, and toads, differ from those of salamanders, principally in having their branchia concealed: we have already observed, that in their earlier stages the branchie of the former are also external: the only way by which the water can escape from them is through two holes, formed in different situations, according to the species: there are even several which have only one hole, on the left side. Such are the tadpoles of the jackie (rana paradoxa), and of the brown toad (buco fuscus); but the tadpole of the common frog has two, both placed below.

We find, on opening the skin of a tadpole longitudinally, that the internal organs are divided into two parts, or contained in two membranous sacs. The first extends from the horny and false jaws, which form the mouth of the tadpole, to behind the branchie, enveloping the latter entirely. The other contains the abdominal viscera; it is the peritoneum, on which vestiges of the abdominal muscles are already visible.

The first sac is very thin and transparent, and penetrated, like the skin, by holes for the exit of the water from the branchie.

The latter form on each side four transverse rows of small tufts or fringes, supported by the fame number of small cartilaginous arcs, which are marked on the side next to the mouth by small rounded tubercles. These cartilaginous arcs are articulated on one side behind the cranium, on the other to a species of os hyoides, and have the same motions as in fishes. In their intervals the water can pass freely from the mouth to the branchie, to be discharged subcutaneously through the small external apertures.

The organization of the branchie in the tadpoles of frogs is, therefore, the same as in certain fishes, for example the callionymi and others, where the water can only pass out by narrow apertures; there is, however, this difference, that...
among these changes, which convert the tadpole into a frog, we cannot enumerate the appearance of the generative organs. the tadpole already possesses telatcles, ovaries, and their fatty appendages; and if these parts are not so large as in the frog at the season of reproduction, they approach nearly to their size at other times of the year.

what we have just said concerning the tadpole of the frog is equally applicable to that of the toad; but the different species exhibit considerable varieties in the period and the size at which the change occurs, as well as in the rapidity of the change. the jackie (rana paradoxa) loses its tail very late, and long after its branchiae; while the latter do not entirely disappear until it has reached the full size of its perfect state: the pipe, on the contrary, loses both very early, and while it is still very small. the species which lose their branchiae late, are larger in the tadpole than in the perfect state, because these supernumerary organs swell out the front of the body, while the tail prolongs it behind. they seem, therefore, to become smaller under their metamorphosis, and grow no more when they have become frogs. on the other hand, those which lose their tail and branchiae early, have still a long time to grow, and may be seen of all sizes in the perfect state. this has given rise to the mistaken notion that the jackie is changed into a fish; the tadpoles being larger than the adult frogs, it was not thought possible that the latter could be the second state.

we might restore to the larvae of falamanders the name of cordyl, which they bore among the greeks, according to the remark of schneider. they ought not at least to have that of tadpole (étard), because they have not a large head, their branchiae not being concealed under considerable coverings, but floating loosely on the exterior of the body. they are tufts arranged like the teeth of combs, firmly fitted or membranous, and attached by pedicles, which allow them to float loosely in the water. the cartilaginous arcs of the fides merely serve to limit the small apertures through which the water passes out of the mouth; for, although the form and arrangement of the tufts seem to expose them sufficiently to the action of water, there are still openings from the mouth, enabling the animal to establish a current of the fluid. in other respects, the circulation is carried on as in the branchiae of the tadpoles of frogs, and it undergoes the same changes when the branchiae are obliterated.

the larva of falamanders, observed by cuvier, had the name vicera as the adult animals, and possessed no horny bill, although their branchiae were still very complete. he therefore concludes, that in this respect, as well as in their feet, and in the organization and permanence of their tail, there is a much more close resemblance between the larva and the adult falamanders, than between tadpoles and frogs.

these remarks on the anatomy of the tadpole, and of the larvae of falamanders, are illustrated by four figures in the 13th plate of the work quoted above. figs. 1, 2, and 3 represent the anatomy of the tadpole of the bufo fufius; and fig. 4 that of the larva of the falamandra aquatica.

the co-existence in the same animal of branchiae and lungs, that is, of organs calculated for breathing air, and of those which are fitted to extract air from the water, is not peculiar to the larva of frogs and falamanders; it is observed also in the firen lacertina and the protoeus anguinus, two animals whose construction is in many respects singular, that the opinions of naturalists concerning them have been long extremely unfeltted. many have supposed them to be the larva of some large reptiles, for which opinion, other
other circumstances in their organization and habits, besides the potteolution of branchiæ and lungs, have been added as arguments. Others have contended that they are perfect animals; and the more exact researches of modern naturalists and anatomists seem to have finally proved that this is the case. The anatomical details, by which this conclusion is supported, will be found towards the end of the article.

As the firen and proteins, truly, perfect animals, have been sometimes considered as larvae or imperfect states of unknown reptiles, so the contrary error has been committed, of deprecating the larvae of known species as perfect animals allied to the firen and proteins. Laurenti, one of the first naturalists who endeavored to reduce the classes of reptiles to regular order, established a genus (proteus) for such intra-branchiæan reptiles as, according to him, possest both branchiæ and lungs. To this genus he has assigned the tadpole of the rana paradoxa, under the name of proteus raminus; and another, which he himself inspected, and which has since been ascertained to be the larva of an aquatic falamander, under that of proteus tritonius. (See his Specimen medium exhibens synopin reptilum.) The firen operculata of M. de Beauvois (Transact. of the Philosophical Society of Philadelphia, vol. iv.) is considered by Cuvier as a similar instance, and perhaps as the very axolotl or Mexican animal, which will be described presently. He regards, in the same light, an animal described by the very learned writer on amphibia, Mr. Schneider, as found in the lake Champlain; see Hift. Amphib. Nat. et Litter. Facie. 1. p. 50. He says it may be objected that we cannot so easily conceive that so complicated an apparatus as that of the branchiæ, their cartilaginous arches, and the muscles moving them, should disappear and leave no trace behind; but, as the larva of our falamanders experience such a change, the singularity of the phenomenon cannot be pleaded as an objection to it. Recherches, &c. p. 117.

Anatomy of the Axolotl, or large Mexican Salamandrine Tadpole.—Another animal of this kind is one found very commonly in the lake surrounding the city of Mexico, and noticed by the early writers in their accounts of those countries, and of the interesting objects they produce, although not methodically described or scientifically investigated until very lately. Hernandez speaks of it in two places; in one, under the name of the edible tadpole (gyrinus edulis), or atolocatl (Hift. Anim. Miner. Nov. Hift. lib. unice. Tract. 5. cap. 4. p. 77; this book is placed at the end of the abridgement by Reechi); in the other, under that of lubus aquarum, picis laceribus, or axolotl (ibid. cap. 2. p. 76, and in the large abridgement by Renzoni of the whole work of Hernandez, lib. 60. cap. 4. p. 316.) This account, accompanied by a figure of some other animal, was copied into other works with various errors.

Dr. Shaw described an individual fent immediately from Mexico to the British Museum, and gave two good figures of it; in the Naturalist’s Miscellany, No. 343, under the name of gyrinus mexicanus; and in the General Zoology, vol. 3. pt. 2. pag. 612. pl. 146, under that of firen pelfiformis, considering it as allied to the genus firen.

Mr. de Humboldt met with it in Mexico, and recognized it as the axolotl of the Mexicans and firit Spaniards, under which name it is still known. He brought specimens of it to Europe, and entwined their anatomical investigation to the experienced hand and profound judgment of Cuvier, whose description we extract from the Recherches fur les Reptiles douteux, already quoted, pag. 109. et seq. pl. 12. Anatomia of the Axolotl.—In its size and general configuration it very closely resembles the falamander terellris (lacerta falamandra) of Europe. No one would hesitate in calling it a falamander, were it not for the branchiæ, which latter resemble very narrowly those of the larvae of falamanders, and foat loosely at the sides of the neck.

The openings communicating with the mouth are four in number, and much larger than in the firen. A fold of the skin of the head forms a species of operculum for the four. There are four arches, as in fishes, and we should hence expect five openings, but the fourth is immediately united to the trunk. The two intermediate arches have, towards the mouth, two rows of pointed denticuli; but the first and fourth poftfs, each, only a single row. None of these denticuli exist towards the operculum, to that the fift of the four openings is not denticated in any direction. Each of the four arches has, towards the outside, a fharp membranous crifta, which might deceive superficial obfervation by causing a resemblance to the gills of a fish; but there is no facular net-work for respiration, and the arterial trunks follow, without any division, the three firt arches to arrive at the branchial tufts, which are the only true gills. There are three of these tufts on each fide, attached to the three firt arches, where the skin joins them together; the operculum and the fourth arch have none. These tufts are much more ramified than thofe of the firen, but their ramifications femble a lock of hair, and are not arranged with fo much regularity.

O methodology.—The head is the fame as in the falamanders, except that the cranium is rather broader. The teeth are placed in the same way on the edges of the jaws: there are moreover two plates immediately behind the edge of the upper jaw; but the two longitudinal series, which are observed along the palate of the European falamanders, could not be perceived. The head is articulated in the atlas by two condyles, as in the firen and falamanders.

The apparatus for supporting the branchiæ is very fimilar to that of the firen; and, at the time of the metamorphosis, a part of it probably remains to form the os hyoides of the falamander. The middle piece is cyfindrical, fhort, and terminated behind by a forked extremity. The front end supports two cartilages, the ends of which, fuspended to the angles of the jaw, correspond to the hyoideal branches of fih: they are immediately under the membranous operculum. From the posterier end of this middle piece proceed two other branches on each fide; a broad one supporting the firit cartilaginous arch, and a more flender one triturated to support the three other arches. The four branchial arches are fuspended, by their outer extremities, to the firit vertebra.

There are seventeen vertebrae from the head to the pelvis; and twenty-three from the latter to the end of the tail. The fpinous proceses of both are longer than thofe of the falamander; and they exift on both aspects of the caudal vertebra, which makes the vertical measurement of this part exceed that of the European aquatic falamanders.

There are thirteen small ribs on each fide, fimilar to thoje of the falamander.

The osteology of the limbs refembles in all respects that of the falamander, excepting the more pointed form of the Iait phalanges, which has occasioned them to be taken for nails.

Organs of Sens. — The eye is smaller in proportion than in European falamanders; but not smaller than that of the species brought from the Alleghany mountains by Michaux.

Organs of Circulation.—The vena cava receives the termination of the veins of the head; of the branchiæ, and their arches; of the lungs; of the fore-feet; lailly, of the inferior vena cava, which has traveled the liver, and received, as usual,
REPTILES.

Utual, the blood of the vena portarum. It enters a large and single auricle; there is also a single ventricle, giving origin to a large muscular artery, similar in all points to that of fishes, of the spleen, and of tadpoles. It produces for the branchize three arteries on each side, which proceed, as we have already mentioned, along the three first arches. The branchial veins are quickly united behind into a single trunk, under the back of the head, and this vessel, following the direction of the spine, becomes the great artery of the body. This is exactly the circulation of the batrachian larva; and the axolotl, being larger than any of the European species, affords a convenient opportunity of examining this kind of arrangement in the circulating organ.

Organs of Respiration.—The branchize of the axolotl, exhibiting on a larger scale the same motions as those of the salamandrine larva, the mechanism can be better understood; and the following description of the muscles will, therefore, be received with interest.

Each of the cartilages analogous to the hyoidal branches has a very strong muscle, defending from the basis of the skull along their convex sides to their inferior extremities. These muscles open the branchial arches, by separating their inferior extremities from the palate.

The arches are approximated by a muscle fixed behind to the inferior extremity of the larynx, advancing under that of the three others, and giving a slip to each. Its antagonist is a small muscle, fixed, on one side, to the inferior extremity of the hyoid branches; and proceeding backwards as far as under the first branchial arch, to which it is attached, opposite to the slip of the preceding.

The os hyoides is carried forwards by two genio-hyoidei, and backwards by two plicano-hyoidei: which latter supply the place, as in the salamanders, both of the stern-hyoidei and recti abdominis. It is elevated by a muscle similar to the mylo-hyoideus of the same animals.

Lastly, the three tufts are themselves elevated and depressed by as many pairs of muscles, which are attached above and below to the convexities of the branchial arches, and have their other fixed points in the bases of the tufts.

The lungs are two large bags, on the internal surface of which the blood-vessels form a loe but very copious network. There are no cells. They open into a common, membranous, opaque, and tolerably wide canal, supplying the place of trachea, but unfurnished with cartilaginous rings, and contracted to form a small larynx with two membranous lips. The glottis is small, formed by two membranous projections, behind each of which is a small hollow or ventricle, which may be supposed to produce a more powerful voice than that of the sire.

Organs of Digestion.—The tongue posseles but little power of motion; it is free in front, but fixed behind to the anterior extremity of the os hyoidei.

The oesophagus is short, folded longitudinally, and continuous with the stomach, which is large and membranous, but considerably narrowed, and more muscular towards the pylorus. It was filled, in the two individuals from which this description was drawn up, with fresh-water cray-fish, like the European, which had been swallowed without mastication, so that entire limbs were found even in the rectum.

The intestinal canal is tolerably large, particularly behind, and of moderate length. It makes two principal folds, and has neither cecum nor any internal valve. The liver is rectangular, without any deep notches; no gall-bladder was observed. There is a small spleen in the centre of the mesentery, which is simple, as usual.

All these intestines are like those of the salamander.

Generative Organs.—The ovaries, small, flaccid, and hardly containing visible ova, resemble, in their situation and fatty appendices, those of the salamander. The oviducts were so delicate, that they could scarcely be seen.

From all the circumstances just detailed, and from the close resemblance of all its organs to those of salamanders, and their larva, we may conclude, that the Mexican axolotl, or fire salamander of Shaw, is the larva of some large salamander.

Growth.—The age of puberty seems to be the limit of growth in many of this class, as in birds, and we may almost lay, in all mammalia. But others, particularly the crocodiles, turtles, and serpents, grow constantly; of which continual increasce the whirls seem to afford an example among mammalia; at least, no limits can at present be assigned to their stature. We know little about the length of life of the amphibia. Many, particularly the tortoises, serpents, and crocodiles, are prodigiously long-lived; coming forth originally from an egg, which is very small in comparison to their future stature, growing very slowly, and reaching an immense size. Niebuhr law at Surat a tortoise 152 years old.

Organs of the Animal Functions.

Organs of Motion. Description of the Bones.—We know of nothing peculiar in the organisation of the bony substance of reptiles. In the larger species, the bones produce as much firmness as in the mammalia; but in the smaller, as the frogs for example, they are more cartilaginous. Cuvier states, in general, that the bones of reptiles contain more gelatine than those of the mammals. Calden affirms, that there are no medullary cavities in the tortoise; according to Cuvier, there are considerable ones in the crocodiles. Leçons d’Anat. Comp. tom. i. p. 110. They have never been tinged with madder.

The Head.—A very diminutive cranium, and enormous jaws, make up the head in this class.

As the brain of reptiles and fishes occupies only a small part of the cavity of this cranium, no important consequences can be deduced from its shape and size. In the tortoise, this cavity is large, narrow from right to left, elevated anteriorly and depressed posteriorly. Its lateral surfaces are almost vertical, and its base is parallel to the palate. The external form of the head, and its apparent magnitude, are occasioned by the accesseory bones, between which and the cranium there is a large space occupied by muscles and glands. The greatest part of the skull is occupied by the large lateral hollows, holding the eye, and the powerful muscles, that move the lower jaw.

The small size of the cavity of the cranium, with respect to the external bulk of the head, is still more extraordinary in the crocodile. In an individual four metres long (between thirteen and fourteen feet), that cavity will hardly admit the thumb, and the area of the facion of the cranium is not one-twentieth part of that of the whole head. (See a section of the skull of a crocodile in the Annales du Muséum, tom. x. pl. 4. fig. 5.) The length of the cranium is not one-fifth of the length of the head in the gavials (longirostris, Cuvier) and it is less than one-fourth in the alligators or caimans (alligatoris, Cuvier, and in the true crocodile (crocodili, Cuvier). The figure of the facion is oblong, rather larger anteriorly, and deprecating posteriorly. There is a considerable depression for the pituitary gland. Its breadth is equal to its height; and the lateral parts of the head, as in the tortoise, cover only the temporal fossa.

The relative size of the cranium and jaws undergoes a very remarkable change, in proportion to the gradual development of the crocodile. The head, when it comes out of the shell, is thick and rounded, and the forehead prominent; see Sch. Sca.
Seba, Thefaurus, tom. i., pl. 104, figs. 3 and 6; and Blumenbach's Abbildungen, No. 27. The eyes are now equidistant from the end of the snout, and the posterior extremity of the head; of which the cranium forms nearly one-third. When we look at the adult animal, we are at a loss to find the frontal prominence gone, leaving the head quite flat, and the jaws so elongated, that the eyes are three times farther from the end of the snout than from the back of the head; and the proportion of the face to the cranium is 20 instead of 3 to 1. Geoffroy St. Hilaire in the Ann. du Mus. vol. x. p. 77.

The caméleon exhibits also a great dispropportion between the cranium and the rest of the head. Its brain, according to the description of the Parisian diflectors, does not seem larger than a pea; and the remainder of the head, which is of considerable size, consists of the large maxillary bones, the orbit, and immense temporal fossa, which, not being separated by any partition, give the cranium a very singular appearance. Description Anat. d'un Caméleon, &c.; or Blasii Anat. Anim. vol. i. p. 14.

The cranium of frogs and salamanders is almost primitive. The French naturalists have furnished excellent descriptions and engravings of the heads of various crocodiles. It will be as well for us to enumerate here the sources of information concerning the osteology of this animal altogether, and to give a few references to good figures of the skeletons of other reptiles.

There are tolerably good representations of the crocodile's skeleton (the East Indian) in Grew's Museum Societatis Regiae, and in Faujas St. Fond, Histoire de la Montagne de St. Pierre de Maefricht, pl. 44. The head of the crocodile of the Nile (croc. vulgaris, Cuvier), is figured by Geoffroy in the Annales du Musuem, vol. ii. pl. 37, fig. 2. In pl. 4, vol. 10 of the same work are four figures of the skull to illustrate a paper of Geoffroy St. Hilaire, entitled "Détermination des Pièces qui composent le Crâne des Crocodiles;" and pl. 1, of the same volume, contains thirteen figures of the heads of various crocodiles in different views, to illustrate Cuvier's paper "Sur les différentes Espéces de Crocodiles vivans & fur leurs Caractères distinctifs."

In the 12th volume of the Annales, Cuvier has given his "Observations sur l'Osteologie des Crocodiles vivans," with two plates, in which most of the bones are carefully figured. For the skeleton of the tupinambis, see Cuvier, Léçons, v. 5, pl. 3; of frogs, Roefel, Historia Rananum Noritrium; of the salamander, Latreille, Histoire des Salamandres de France; of the tortoise, salamander, frog, caméléon, lizard, and a serpent, Daudin, Histo. Nat. des Reptiles, vol. 1.; of the proteus, sire, and Mexican axolotl, Humboldt, Recueil d'Observ. de Zool. &c. t. 13; of the tortoise, Blasii Anatomia Animalium; Cuvier, fur les ossements fossiles; and Geoffroy St. Hilaire, fur les tortues molles, in the Annales du Musuem, vol. 14. The skeleton of the tortoise is also figured in Chefselden's Osteology; in Coiter's Lectiones Falleplopi de Partibus similaribus, fol. Norib. 1575; and in J. D. Meyer's Zeitvertreiben mit Betrachtung curioso Vorstellungen allerhand Thiere. t. 1. tab. 29; t. 1. tab. 62; and the separate parts in Caldei osservazioni anatomiche intorno alla Tartarughe. Firenze, 1697. The skeleton of the common green lizard may be seen in Coiter, pl. 4; in Meyer, t. 1. pl. 56; that of the salamander and water newt, and of several snakes, in Meyer: that of the caméléon is prefixed to Chefselden's 6th ch. Schneider has figured that of the rana pipa in his Histor. Amphib. faeseic. 1.

For the form of the head in the different species, a point belonging rather to natural history than comparative anatomy, we must refer to the figures already quoted. The surface is more or less rugged in different specimens; and in many very considerably so; these differences are specific, only where individuals of the same age are compared, for the rugosities increase in size and prominence in each species with the increase of years. The bony fulness is often perforated by many small holes, as it were carious or worm-eaten. The futures are conflant; they are not effaced in the oldest heads observed by Cuvier.

The Cranium.—The cranium of the crocodile, viewed from behind, has the form of a very irregular truncated pyramid; of which the point or narrowest portion is downwards, and the base excavated to lodge the brain, is upwards. This pyramid has three surfaces, one posterior, which forms the occiput, and two lateral. The occipital surface is almost triangular; one of the angles (the apex of the pyramid) is inferior, the other two are superior, and greatly prolonged backwards and to the side, in order to form the enormous articular processes, which receive the lower jaw. Their position is almost horizontal. The foramen magnum is situated in the middle of this surface, and under it the single condyle for articulating the head with the vertebral column.

The futures depart from the foramen magnum, which divide the occiput into particular bones. The superior part of the cranium is formed by a single parietal bone. Anterior to it there is an os frontis, also single, which forms the roof of the orbits.

The olla temporum are situated on each side of the parietal bone, and are partly supported by that articular process for the lower jaw, already mentioned.

A small arch on each side, different from the zygoma, leaves between it and the parietal bone a large round hole, which perforates the temporal foro. The arch is partly formed by a process of the os temporum, and partly by a particular bone articulated to the junction of the parietal and frontal. The particular bone occupies the place of the post-orbital process of the os frontis in the mammalia; for it descends behind the orbit to join the cheek-bone; and with it it finishes the frame of the orbits.

The unusual configuration of the whole head in the crocodile necessarily involves very extraordinary modifications of the individual bones, which it is in many cases exceedingly difficult to refer to their corresponding ones in the crania of the mammalia. For a more minute account of this matter, which could not be easily understood without plates, we refer to the memoirs and engravings, already quoted, of Geoffroy and Cuvier.

A cranium similar to this of the crocodile, is found in the other lizards, notwithstanding the great differences in the form, proportion, and direction of the parts. In the caméléon, therefore, the foramina by which the temporal fossa communicate with the cranium, are so large, and the bony edges which form them so thin, that the latter represent three flender branches rising to support the kind of helmet which distinguishes this animal. The articular processes are not directed backwards, but downwards.

The last peculiarity is also observed in the other lizards, but they have not the crests of the caméléon, and the upper part of their cranium is broad, like the crocodile.

In frogs and salamanders the cranium is nearly of a cylindrical form, flat superiorly, and enlarged posteriory; the frontal bones have the shape of an elongated rectangle, and occupy the interval of the orbits. The Surinam toad has the cranium much flatter than the other genera.

The eminences intended to affix in the articulation of the jaw are turned directly towards the sides.
The structure of the cranium of tortoises bears more resemblance to that of crocodiles than of frogs. The frontal bones form only the roof of the orbits, and the cranium does not pass between these cavities. They are very short, and the parietals are three times longer. The latter are not confined to covering the cranium. They extend on each side, and form an arch over the temporal fossa. In the sea tortoises this arch is completed by two peculiar bones, which extend from the os parietale to the zygoama, and the anterior of which bounds the orbit behind.

The articular processes are directed downward, as in the chameleon. Above these and the meatus audiorius, we find considerable malleolar processes, which are pointed superiorly in land tortoises, but are rounded and marked by a longitudinal furrow in the sea tortoises.

Serpents have two frontal bones almost square, and a single parietal bone. Their cranial arise forward between the orbits, as in frogs. The occipital bone has a process directed backward, and connected with a particular moveable bone, analogous to the square bones of birds, to which the lower jaw, and the arches which form the upper, are articulated.

The general form of the cavity of the cranium of reptiles is oblong, and almost of an equal breadth, being merely a little contracted between the ears. The tortoise has a kind of fella turcica, the four clinoic processes of which are directed forward. The sphenoidal fossa is somewhat depressed in the serpents, but it has no clinoic processes. It is a femi-lunar depression, the plane of which is situated from before backwards.

The basilar fossa is lower than the other fossa in the crocodile, and in some tortoises.

**Foramina of the Cranium.**—The interior part of the cranium is frequently not closed by ossification in reptiles and fishes, and the olfactory nerves pass through a large vacant space, which is not subdivided into particular holes. This at least is the case with the chameleon, the iguana, tortoises, the pike, the anarhichas, &c. In others, the olfactory hole is contracted, but is still fimple, as in the crocodile. It is double in frogs and chameleons. The rays and the farks have also two holes, which are considerably removed from each other.

The optic holes are likewise sometimes united into one, as in the crocodile: those of the tortoise are much removed from each other, and are distinguished from the great hole in the front of the cranium, by only a small bony partition. The structure of the cranium in the pike is similar. In the frogs, the rays, the anarhichas, and it should seem in the greater number of fishes, the optic holes are at a great distance from each other, and perforate the fides of the cranium. These animals have no sphenoid-orbital fissure, and the small nerves transmitted to the eyes pass each through a particular foramen.

There is, in general, only one hole on each side for the three branches of the fifth pair of nerves, which, therefore, supplies the place of the foramen rotundum, foramen ovale, and in part of the sphenoid-orbital fissure. This hole, however, is divided into three in the carp.

The meatus auditorius internus exits in reptiles. The Fact. — In the crocodile the face resembles one-half of a cone irregularly flattened on its convex surface. It is chiefly formed by two ossa maxillaria, and two ossa nasi, which are situated almost parallel to each other, and two ossa intermaxillaria, which form the end of the muzzle, and surround the aperture of the nose like a ring.

The bones analogous to the lacrymalia are four in number, two on each side. The os male, which is very large, after forming the inferior, and affording a small process to the posterior edge of the orbit, extends directly backwards to join the great malleoloid protuberance: thus the temporal fossa has no communication outwardly, except by a hole which is smaller than the orbit, and the greater part of which is covered by these bones, as by an arch.

The nasal fissure is continued in a long and narrow tube under the foramen magnus. They perforate the os palatii, and a particular bone which is analogous to the pterygoid process of the os sphenoides. This bone is situated almost precisely under the cranium, and is enlarged on each side until it forms a kind of square and almost horizontal wing. An osseous branch unites it laterally to the os maxillare and os male, in such a manner that a large hole is left on each side of the arch of the palate.

In the chameleon the face is concave superiorly, and bordered by a serrated ridge throughout the whole of its circumference. We observe two holes which communicate with the orbits, and two other oval foramina, which correspond to the incisive holes in the palatine surface. The bones which compose the face are nearly the same as those of the crocodile. The other lizards exhibit still less difference.

The frog and the salamander have the nasal and intermaxillar bones very short, and broader than long, which renders their face round anteriorly. The os maxillare is very narrow, and is fearcely contracted in forming the zygomatic arch. The orbits are large, but have no inferior surface, and therefore communicate with the palatine fossa. The os palatii form the anterior edge of the orbital fossa inferiorly. They resemble portions of a circle. They are furnished with pointed teeth on their circumference. The canal of the nares is very short in the salamander. There is only a simple hole in the frog.

The face of the Surinam toad is very flat, but the bones are the same as in the frog. The orbital fissure are oval, and no aperture similar to the canal of the nares can be distinguished.

The face of serpents is rounded nearly in the same manner as that of lizards. Between the os frontii and os parietale, there is a particular bone which terminates the frame of the orbit posteriorly. These animals have no os male. We can, however, easily distinguish two os nasal, two os maxillaria superiiora, two os maxillaria inferioria, and some analogous to the palatine arches of birds, which are furnished with teeth, and which are articulated to the bone which supplies the place of the os quadrate, with respect to the lower jaw. Two particular bones unite these arches to the maxillaria superioria.

In those that have teeth, or poisonous hooks, as the vipera, the rattlesnake, &c there are besides two pairs peculiar bones, articulated and moveable, which support the teeth. They are situated upon the intermaxillary bones and the anterior extremity of the osseous branch, which joins the superior maxillary bone to the arch of the palate.

The face of the tortoise is circular before, and rounded on every side. It is composed of nearly the same bones as that of the crocodile. The intermaxillary bones are, at a very early period, consolidated with those of the upper jaw. The bones analogous to the os male are three in number, one articulates with the os temporum and with the two others; it is situated posteriorly, and forms the zygomatich arch. The other two portions are received on its anterior extremity; one extends upwards, and unites with the orbitale of the os frontii; the other is directed downward,
downward, and articulates with the posterior and external process of the os maxillare suprerior.
The osse ala is broad, and form the posterior arch of the nasal fossa.

The bones of the face of tortoises commonly cover each other at their edges, which are refined into thin laminae.
It is therefore very difficult to distinguish the futures.

In the sea tortoises the temporal fossa, which are very deep, are covered by an osseous lamina, which forms a very solid arch above them.

The description of the jaws, and the temporal fossa, is given at the beginning of the account of the digestive organs.

Cavities of the Face.—1. Nafal Cavity. It is a broad space in the tortoises, occupying the whole thickenes of the fium in front of the eyes, and very short from before backwards. Its front opening is large, and nearly square, with its plane but little inclined; surrounded by fix bones. There are two round openings behind, corresponding nearly to the middle of the palate.

In the crocodile it is a long and narrow canal, extending from the end of the fium under the occiput: its bony opening, formed entirely in the two intermaxillary bones, is turned upward.

Other lizards have the nafal apertures situated nearly as in birds: that is, the front or outer side of the fium, and the back or inner in the middle of the palate. They are still shorter in the frogs.

2. The orbit is never separated from the temporal fossa in reptiles by a partition, but merely by a bony branch; and even this is complete only in the lizards and tortoises, not in the frogs, salamanders, or serpents.

The plane of its margin is lateral in the tortoises, serpents, and crocodile. It is more or less directed upwards in the crocodile, salamanders, and frogs. The figure varies from circular to triangular. The inferior surface or floor is never complete: either it is altogether deficient, or it is perforated by a very large aperture. The same remarks are applicable to the inter-orbital septum.

The zygomatic fossa is spoken of in the description of the jaws, and their movements, under the division of Organ of the Vital Functions.

Foramina of the Face.—Where there is no distinction between the orbit and temporal fossa, the sphenoid-maxillary fissure is of course wanting. There are no internal orbital holes, as the relation between the orbits and nose is altogether different from what is observed in the mammals.

The crocodile, frog, and salamander, possess a large foramen incisivum. The tortoise has two small ones: the structure of the lizards is not known.

There is no suborbital opening, reptiles having no lips to receive the artery and nerve, which it transmits in the mammals.

The sphenopalatine canal appears as a simple hole in the os palat.

Motions of the Head.—The articulation of the head of reptiles is considerably behind, but the motions vary in different species.

In the crocodile there is only one condyle, situated at the under side of the foramen magnum: the atlas is formed of two portions: the posterior is shaped like the segment of a ring: the anterior, which is thicker, receives the condyle, and is articulated to the second vertebra: there are two lateral processes, long, flat, and turned backward, which supply the place of transverse processes.

The odontoid process of the second vertebra is short and thick; it is articulated within a cavity in the body of the atlas. This second vertebra has transverse processes similar to those of the first.

All other lizards have nearly the same conformation; but the condyle seems divided in two by a longitudinal superficial furrow.

The tortoises have likewise only one condyle. In the land tortoises it is prolonged, and divided into two, as it is in the lizards. In the marine species it presents three articular faces, like a trefoil leaf. As this condyle penetrates deep into the corresponding cavity of the atlas, the lateral motion of the head is much confined. The other motions of the head of the tortoise are those of projection and retraction; they depend upon the flexion and extension of the cervical vertebrae.

The frog, the toad, and the salamander, have the head articulated by two condyles upon the first vertebra, which is almost immovable.

Serpents have three surfaces, in the manner of a trefoil, close together, upon one condyle, beneath the occipital foramen. The head is not more moveable on the atlas, than the rest of the vertebrae are upon each other.

Bones of the Spine.—The number of vertebrae, and every other attribute of the spine, are more varied in this class of animals than in any other.

In the tortoises, seven vertebrae are aligned to the neck: the first is only a fiddle tubercle, the annular portion of which is very distinct. The surface, by which it is articulated with the head, is formed of three planes: one anterior, and two lateral. The point in which they unite is the most prominent, and to this is attached a strong ligament. The surface which unites it to the next vertebra is a glenoid cavity; the second and the following vertebrae have a prominent longitudinal ridge upon the fore-part of their body. The articular processes defend below the body: there are no spinal processes, except one to the second vertebra, which points forward, and one to the third in the form of a simple tubercule. The two last vertebrae, at a certain age, become anchyloved. There are eight dorsal vertebrae; but they are all anchyloved, together with the ribs, and the back-sell, in one immovable piece. They have three foramina, neither processes nor articular surfaces: they are all narrower in the middle than at the ends. The lumbar and fascial vertebrae are likewise consolidated with the back-sell, but those of the tail are free and movable. The condyle, which forms the body of these vertebrae at its articulation with the others, inclines backward, and not towards the head, as those of the neck do. There are likewise upon the fore-part of the body, at its base, two small tubercules; but all the processes of these vertebrae resemble those of the mammall.

In the family of lizards, the crocodile has seven cervical vertebrae, distinct indeed, but so closely articulated as not to be moveable. The processes are so numerous, long, and close, that the animal cannot bend its neck, and the cervical column may, therefore, be regarded as a single piece. This corresponds with the reports of travellers, that the crocodile is unable to turn his head round. The anterior surface of the body is concave, and the posterior convex, throughout the vertebral column of the crocodile. The atlas is composed of five pieces, which appear to continue separate through life: the vertebra dentata has five only. The other cervical vertebrae have on each side two short transverse processes, which serve to support the small ribs or appendices, which limit the flexion of the neck. Each has two pedicles, attached to the two processes just mentioned: the appendix projects into a sharp process before and behind, which touch those of the contiguous vertebra. The five
REPTILES.

five first dorsal vertebrae have a lateral tubercle for the head of the rib, and another on the transverse processes for its tubercle: thus the rib is articulated only to one vertebra. But the first of these articular surfaces is wanting in the remaining ribs, while each of their transverse processes has two articular faces. The same number (seven) is found in most lizards, though the camelion has only two. The facilitate vertebrae are very few in every species, and none of them have a large os facrum.

As frogs have no ribs, no distinction can be formed with respect to the three first orders of vertebrae in them. They have in general eight between the neck and the pelvis, all furnished with pretty long transverse processes. The last are the longest, and touch the offlia rib. In the toads, the transverse processes are very large, and shaped like hatchet blades. The os facrum consists of a single bone only: it is long, pointed, compressed, and has no coccyx. In the pipe, which has the transverse processes of the second and third vertebra much longer than the others and almost like ribs, this bone is offlided with the rta vertebra.

The salamanders have fourteen vertebra between the head and the facrum; they have all nearly the same shape, except the first, which receives the head, and the last, which is articulated to the facrum. The two extremes of the spine alone want the velvites of the ribs, which consist of small oblong moveable bones, actually articulated to the transverse processes, which here take a posterior direction. The articular processes are large, and wedged together. The posterior rest upon the anterior, so as to impede the motion of the spine backward. The facrum consists only of a single vertebra, but there are twenty-seven in the tail.

In serpents, the vertebral alone constitute almost the whole skeleton. It appears in general, says Blumenbach, that the number of vertebra, in red-blooded animals, is in an inverse proportion with the size and strength of their external organs of motion. Serpents, therefore, which entirely want these organs, have the most numerous vertebra; sometimes more than three hundred. (Comp. Anat. p. 118.) In confirmation of this remark, we may observe how numerous the vertebrae are in the elongated fishes, as the eel, and in the whales, as the porpoise, (above one hundred in the former, and between sixty and seventy in the latter). Birds, whose wings give them such vast power of locomotion, have very few vertebra, if we consider the anchylofed ones as forming a single piece; and the frog, with its immense hind extremities, has a very short spine, confenting of still fewer pieces than that of birds. The vertebrae of this order are nearly of the same form, from the head to the tail; the body, as well as the spinous, articular, and transverse processes, are easily distinguished. In certain kinds, for instance the boa, the spinous processes, which are continued throughout the whole length of the back, are separated from each other, and allow reciprocally a motion sufficiently conspicuous. Wherever this disposition of the spiny processes prevails, the body of the vertebra, on the side next the belly, presents only an obscure projecting line. In other kinds of serpents, as for example the rattlesnake, the spiny processes are long, and so large as to touch each other. They have, for their basis, the articular processes, which lie on each other like tiles. In consequence of this structure, the motion of the spine towards the back is very circumcised, but its motion towards the belly and sides much augmented. The bodies of the vertebrae play very easily in these directions upon one another, and are armed with a sharp spine tending towards the tail, which only obstructs their motion when it might produce a luxation. The first vertebra differ from those of the rest of the body, only in having the rudiments of the ribs much smaller: there is no neck in these animals. The vertebrae of the tail differ no farther than in having no ribs, and that their spines, both ventral and dorsal, are double, or form two ranges of tubercles. The articulation of the bodies of the vertebrae with each other is very remarkable; the anterior part of the body of the vertebra presents a smooth hemispherical tubercle, and the posterior part a corresponding cavity; so that each vertebra becomes connected to those next it by a sort of knee-joint. This mode of articulation fully explains the motion of reptiles, which is performed winding from side to side, and not up and down, as it is represented by painters.

Of the Ribs and Sternum.—The thorax of reptiles is very various in its structure. Frogs have a sternum, but no ribs; serpents have ribs, but no sternum; tortoises have the ribs ossified to the back-flail, and the sternum included in the breast-plate; the crocodile and lizard have perfect ribs, but their sternum is almost entirely cartilaginous. In the crocodile, the first portion of the sternum is ossified and elongated. It receives the two clavicles. The remaining part is entirely cartilaginous. It is united with the os pubis, and sends off eight cylindrical cartilages to the pariety of the abdomen. This structure, constituting a species of abdominal sternum, apparently for supporting the viceria, is quite peculiar to the crocodile. The ribs are twelve in number, the two first and two last of which are not attached to the sternum. The intermediate ribs have upon their posterior edges cartilages partly ossified, which supply the place of the angles of the ribs in birds. All the posterior ribs, beginning at the fifth, are only articulated to the transverse processes of the vertebra, which are of great length. The five first articulate with the vertebra at two points, one on its
its body, and the other on the transverse processes. The
iguana and the tupinambis have only the upper part of the
sternum ossified: it is broad, and receives six ribs and the
clavicles; the other ribs are free. The cameloon possesses
likewise the upper portion of the sternum; but almost all
the ribs have cartilages, which extend to the middle line,
and are there united to the opposite ones. Frogs, though
they have no ribs, have nevertheless a very conspicuous
sternum. It forms on the anterior part a cartilaginous ap-
pendix, furnished by a disk situated below the hyaen. It
next receives the clavicles, and then expanding, it terminates
at last in another disk situated under the abdomen, and
which affords an origin for mufcles. There is a peculiar
bony cyll of unknown use on the internal surface of the
sternum, in the rana pipa.

The salamander has ribs, so short that they seem to be the
transverse processes of the vertebræ; they have only one
point of articulation, upon which they have but little
motion. These rudiments of ribs are twelve in number on
each side. This reptile has, properly speaking, no sternum,
but its place is partly supplied by the bones of the shoulder,
as we shall presently see.

The skeleton of the chelonian reptiles exhibits to us
what appears on the first view as a completely anomalous
organization. In the bony house which these animals
carry about with them, there is such a deviation from
the ordinary figure, connection, and position of the parts,
compounding the skeleton of other vertebral animals, that
a hasty view would lead us to infer that the general mo-
del to which Nature in all her modifications of form and
position ever adheses, has been completely lost sight of,
and another substituted in its place. This inference
would be altogether incorrect; a more accurate examination
enables us to discover in the external bony shells of
these singular creatures, all the offious pieces which
belong to the chest of a mammiferous animal or bird;
so that no essential part is wanting in their thorax, and
the singularity depends merely on the more or less complete
offiliation of the whole pectoral cape, and the peculiar
forms resulting from this circumstance. Thus, instead of
the anomaly, which a hasty glance leads us to anticipate,
we actually discover, on the contrary, a new proof of the
confiancy, with which an original model is retained
throughout whole classes of animals, even under the widest
differences of external form, as if Nature, having fixed on
one general principle of organization, would not be at the
trouble of inventing others, but rather chuses, by the strangest
modifications, to accommodate the organs to new situa-
tions and forms. It is a new illustration of that principle,
in conformity to which the sin of a whale contains all the
bones of an upper limb of a quadruped, the wing of the
bat the regular digital phalanges, the sin of a penguin or
seal the usual bones of the extremities of a bird or mam-
miferous animal, &c.

The bones of the chest in the tortoises form & more or
less convex shield-like covering, which constitutes the upper
surface of the animal; we call it the upper shell (carapace,
bouchier, &c.) and a nearly flat portion adapted to its
concavity below, constituting the inferior surface of the
animal: this is the under shell (plastron).

The back shell is formed by the expansion of eight ribs
or osseous staves, which arise from the joints of the vertebræ,
and terminate in a border that surrounds the whole shell:
these bones are united together by real sutures, situated
transverfely. Above, and all along the middle part of
the shell, we observe a row of little osseeus plates, almost square,
intimately connected together, and to the plates formed by
the ribs, by synarthrosis, and equal in number to the ver-
tebre. These plates represent the rings and spinous pro-
ces of the vertebræ. The offious margin is made up of
a great number of pieces, (seven on each side, and a single
one in the middle, before and behind, therefore 2. in the
whole,) folded together, which by their union form an
edge or border with three surfaces, viz. the inferior, which
belongs to the back shell; the interior, which is joined to
the breast-plate by a very thick leather-like skin; and the
internal, which presents a groove for the reception of the
extremities of the ribs. These pieces, which Geoffroy
compares to the flernal or cartilaginous portion of our ribs,
are wanting in the soft tortoises, (trionyx, Geoff.) or at least
remain confinantly cartilaginous or membraneous, so that the
middle only of the upper shell is sustained by an offious disk.

The turtles, and the soft tortoises, are the only genera
in which the ribs, confounded in the upper shell or carapace,
are nevertheless distinct, both by a prominence very ap-
parent on the inside of the shell, and by a free unattached
portion of their ends projecting beyond the edge of the
shell. But the offious disk, composed of articulated pieces,
and already mentioned, extends round the ribs in the tur-
tles, receiving their ends, but is wanting in the soft tortoises.
Its solidity is increased in the former by the great plates
which cover it, while it remains flexible in the latter, and
is covered only by a species of epidermis.

The offiliation of the intervals of the ribs, forming the
carapace, is perfected gradually, and is not finished until
long after that of the ribs themselves: it generally ad-
ances from the middle towards the edges. Thus, in a
young turtle the ribs will be found separate from each other,
towards their external extremities, for half their length;
while in an adult individual of the same species, the anterior
ribs are united throughout, while the intermediate ones
are separated only through about one-sixth of their length.

The carapace is always oval and pointed behind in the
turtles; elliptical and gibbous in the land tortoises; el-
liptical and flatter in the fresh-water tortoises. Its surface
is rough in the soft tortoises; elevated into various pro-
minences in the chelydes and the serpentine, and more or
less smooth in the others.

The margin of the upper shell assumes a different appear-
ance at its anterior part; it is there a square piece of bone,
convex above, and concave below, which sustains a spine
for the attachment of mufcles. Its anterior edge has more
the form of a crescent (lunula); there are also some little
peculiar pieces above the tail.

The breast-plate of the tortoise is its sternum; and when
deprived of the thick skin that covers it, exhibits, in some
species, only one fold, placed, formed of several pieces,
united by synarthrosis: in others, this plate is perforated
quite through, and formed of several bones, some of which
are situated in the middle line between the anterior and po-
terior part, while others are placed laterally, and fastened
together by the help of the former, which support them.
For further information concerning the osseeous fabric of
the chest in these reptiles, two memoirs in the 14th vol. of the
Annales du Museum may be consulted; "Sur les Tortues
molles, par Geoffroy St. Hilaire;" "Sur les osseminiens Fof-
files de Tortues, par Cuvier."

In the draco volans the ribs form the skeleton of the
wings, or those expansions of the integuments between the
front and back limbs, which are so called. The five po-
terior ribs are elongated and bent backwards for that pur-
pose. Here progressive motion is performed by these
ribs; but they are superadded for this purpoze, and make
no part of the organs of respiration. The animal cannot

Vol. XXIX.
REPTILES.

in truth be said to fly: its lateral membranes act like a parachute, and enable it to take long leaps.

The ribs are usually articulated to the vertebrae by means of a convex surface, which moves upon a slightly concave one formed in two of the vertebrae, so that the hollow receiving each rib is situated between two vertebrae of the back. But in the snake tribe the head of the rib has two slightly concave surfaces, which move upon a convex protuberance belonging to each vertebra; so that the rib runs on a single vertebra. The consequence of this peculiarity is, that the ribs do not interlace with the motions of the individual vertebrae, and thus that the latter are left free to execute their movements on each other, which take place to a considerable extent in the progression of serpents. The articulations of the vertebrae to each other, and to the ribs, are represented of the natural size from the skeleton of a large boa, in the Philos. Trans. 1812, pt. 1, pl. 6.

We have already seen the ribs, instead of contributing to the business of respiration, employed for purposes of locomotion in the draco volans. They are still more extensively employed for the same purpose in the serpent tribe, in which they amount sometimes to 250 pairs, as observed by Sir Everard Hume. These bones, in all snakes, are continued to the anus, while the lungs field occupy more than one-half the cavity covered by the ribs. The hind ribs can only be employed for the purpose of protractive motion, and thus correspond to the elongated ribs of the posterior riblets in the Draco volans.

The ribs of a snake may be seen to move forwards successively when the animal is in motion, like the feet of a caterpillar, and the ends of these bones can be distinctly felt on the palm of the hand, as the animal passes over it.

At the termination of each rib is a small cartilage in shape corresponding to the rib, only tapering to the point. Those of the opposite ribs have no connection, and when the ribs are drawn outwards by the muscles, are separated to some distance, and rest through their whole length on the inner surface of the abdominal scuta, to which they are connected by a set of short muscles; they have also a connection with those of the neighbouring ribs by a set of short straight muscles.

When the snake is going to put itself in motion, the ribs of the opposite sides are drawn apart from each other, and the small cartilages at the ends of them are bent upon the upper surfaces of the abdominal scuta, upon which the ends of the ribs rest; and as the ribs move in pairs, the scuta under each pair is carried along with it. This scutum, by its posterior edge, lays hold of the ground, and becomes a fixed point, from whence it sets out anew. This motion is beautifully seen, when a snake is climbing over an angle, to get along a flat surface.

The culbcr and boa, having larger abdominal scuta, which may be considered as hoofs or shoes, are the best fitted for this kind of protractive motion; there is, however, a similar structure of ribs and muscles in the anguis and amphibians. In the anguis the ribs are proportionally weaker, and as these have nothing to correspond to the scuta, this mode of protractive motion is probably less necessary to them. See "Observations intended to shew that the protractive Motion of Snakes is partly performed by means of the Ribs," by Sir Everard Hume, Philos. Trans. 1812, pt. 1, p. 183, with figures. We are also indebted to Sir Everard Hume, in conjunction with Dr. Ruffel, for describing more particularly a fact noticed by Blumenbach, (Comp. Anat. p. 117.), viz. an adaptation of certain ribs in the cobra de capello (culbcr naja, L.) to the accomplishment of a particular mechanism in that animal.

This serpent is called the hooded snake, from a power of expanding the skin of the neck, which is effected by the motions of the ribs. In other serpents, the ribs, from the first vertebra to those of the middle of the trunk, gradually increase in length; thence they gradually shorten or decline, to near the end of the tail, where they disappear, or are transformed into short eminences. In the naja, the cervical ribs gradually lengthen to the tenth or eleventh, after which they successively shorten to the twentieth. Again increasing in length, they are, at the middle of the trunk, nearly as long as the middle cervical ribs, and then declining as in other serpents, disappear on the tail.

The first twenty ribs, instead of bending equally with the others towards the belly, go out in a lateral direction, having only a slight curvature, and when depressed lie at the side of the spine upon one another. The first is shortest; they lengthen to the tenth, and are again shortened to the twentieth; so that, when they are extended, they represent an oval figure, of which the spine is the middle line or long axis. In the extended state of the ribs, the skin of the back is brought over them, forming the hood; and in their depressed state it recedes. From the rounded form of the hood, the skin has the appearance of being inflated; but the most careful examination did not discover any communication between the trachea or the lungs and the cellular membrane under the skin. See "Remarks on the voluntary Expansion of the Skin of the Neck in the Cobra de Capello," &c. by Pat. Ruffel, M.D. and Everard Hume, Eqn. Philos. Trans. 1807, pt. 2, pag. 346.

The existence of ribs has been denied in the fren lizards, and proteus anguinosus; they have in truth only very insignificant rudiments of ribs, that might be easily overlooked. These have nothing to do with the respiration of the animals, indeed they are too small to answer any purpose. See the description of these animals at the end of the present article.

Such rudiments of ribs are said to exist in the genus cerceia, among serpents.

Ribs of the Shoulders. — In oviporous quadrupeds the gno- doid cavity of the shoulder is partly composed of the scapula, and partly of the clavicle. The scapula, which is elongated, has no spine; it contracts and becomes thicker towards the neck. The clavicle is simple, short, and flat, and united to the sternum in the crocodile and lizards. It is broad, and almost square, in the iguana and camelion; in the tipu- nambul it is oval, and very large and long between the front and back, and has two un-offiliated parts. The frogs and toads have two clavicles to each shoulder, attached to the two extremities of the sternum. The scapula is bent, and composed of two articulated pieces, with the superior one inclined towards the spine. The same confirmation obtains in the Surinam toad. The anterior clavicles appear to correspond to the os forcorum of birds. The clavicle, the sternum, and the first piece of the scapula, are ankylosed together. The salamanders have the shoulder formed in a most singular manner, the scapula, clavicle, and sternum, confit only of a single bone, which receives the head of the humerus. The shoulder is almost all cartilaginous, but the part answering to the scapula is more distinct than the rest. It inclines towards the spine, where it receives the muscles by which it is moved. The clavicular part is directed towards the head; that which supplies the place of the sternum turns towards the breast, but without uniting with the bone of the opposite side; the part on the right side slides over that on the left. This confirmation allows a greater dilatation of the breast in respiration. The tortoise has
REPTILES.

has also these three bones, which unite to form the glenoid cavity, and correspond with the scapula, fork, and clavicle. But as their respective disposition is very remarkable, it appears necessary to give a particular description of them. One of the bones extends from the base of the rudiment of the first rib, to which it is fixed by a ligament, as high as the humeral cavity, where it is intimately connected with the other two. The second bone may be considered as the continuation of the first, which it joins at the humeral cavity, of which it forms part. Its other extremity is attached to the breast-plate, and strong ligaments likewise unite the extremity to that of the posterior bone. These two bones, thus united, are slightly bent outwards, so as to leave between them and those of the opposite side, an oval space, through which the ophagus, the trachea, and several muscles, pass. The first seems to correspond to the clavicle, and the second to the os furciforme. Finally, the third bone of the shoulder is situated below the abdominal and thoracic viscera, nearer the breast-plate. It is long, and extends from the humeral cavity, of which it forms the lower part, as far as the abdomen. It seems to supply the place of the scapula by the number of muscles inserted into it, but its situation is just the reverse of that bone. A very strong ligament unites this bone to the femur.

Bone of the Arm.—The humerus of the tortoise has a very remarkable shape. As in birds it is articulated at once to the scapula, clavicle, and os furciforme, by a large oval head, the greatest diameter of which lies in the direction of the flatness of the bone. A considerable eminence rises above this large head, which, by its curvature and its shape, has some relation to the olerocanon, a process which, in this animal, the bone of the fore-arm wants. Below the head there is another eminence, less projecting, but more rough, which likewise serves as a point of insertion to some muscles, and fiddles the place of the little tuberolity. The rest of the body of the bone is flattened and narrow towards the middle. In the crocodile, the humerus is round, but a little bent like an S in its whole length. At the extremity that joins the scapula, it resembles the tibia; its head, instead of being round, is flat; and its tuberolity, which is single, is anteriorly in the form of a ridge, and somewhat inclined forwards. In the other lizards, and in frogs, the humerus exhibits nothing peculiar. Serpents having no limbs, have consequently no humerus.

Bone of the Fore-arm.—The humerus of the crocodile terminates in two round tubercles. The hollow head of the radius turns upon the external one. Between them the round head of the ulna is situated, but it has neither olerocanon nor sigmoid cavity. In the upper part it is the largell of the two bones, but the smallest below. There is nearly the same conformity in the cameleon, but the bones are more elongated, and the inferior head of the radius is less than that of the ulna. In the frog the single bone of the fore-arm is articulated by a concave head, with a large round tuberolity on the base of the humerus, between its two condyles. On each side, where the lower part of this bone becomes larger, we observe a furrow, which is the only vestige of a division into two bones. Troja has pointed out a singularity in the structure of the bone of the fore-arm, and of the leg in frogs and toads. The bones consist of a single piece, which is solid in the middle, but divided at either extremity into two conical portions, having manifest medullary cavities. See Memoria lopera la struttura flogolare della tibia e del cubito nelle Rane e nei Rapsi, in his Sperienze intorno alla Rigenerazione delle Ossa. Nap. 1779. p. 250, t. 7, 8.

The two bones of the fore-arm of salamanders are situated one above the other. The ulna, which is the lower, and somewhat longer of the two, has no olerocanon; but there is a sort of rotula in the tendon of the extensor muscles. The ulnar extremity of the humerus is much enlarged. The articulate surface which terminates it is convex, and permits the radius and ulna to turn together in every direction. The two bones of the fore-arm in the turtle are always in a forced state of pronation. The radius, which is much longer than the ulna, and fixed to it by a cartilaginous substance, is the lowest, and extends even under the carpus. These two bones much resemble each other in the humeral extremity, being formed by a single concave surface received upon a correspondent policy of the humerus. Their articulation is such that it allows them to move together laterally, and a little upward and downward in the action of swimming.

Bones of the Hand.—The frog, the toad, the salamander, have three ranges in the carpus. The first consists of two bones, one radial and one ulnar; the second consists of three bones, the largest of which bears the rudiment of a thumb with two joints; the third range has likewise three bones. The second fingers proceed from the first of these bones; the fourth finger is articulated with the second bone; the middle finger articulates with both bones; the little finger joins the third bone. The first range touches the third inferiorly, because the second is cuneiform. There is no bone without the range. In the mud tortoise, the first range is a single bone, which separates the radius from the ulna; the second range consists of two bones, and a small one out of the row, situated on the ulnar edge; the third range consists of five bones, one for each bone of the metacarpus. The sea tortoise has three bones in the first range, the ulnar bone being the longest. The two anterior bones do not advance much farther. The third range consists only of three bones for those of the metacarpus, and one small bone out of the row, situated upon the radial side.

In the crocodile, the first range consists of two long parallel bones. It has besides two little external bones without the range on the radial side. The number of the phalanges varies in these animals. The crocodile has the hand rounded. It has two phalanges to the thumb, three to the second finger, four to the middle and fourth fingers, and one to the little fingers.

The cameleon has three fingers on one side, and two on the other, which form, with the three opposite to them, a kind of forceps. The number of the phalanges is the same as in the crocodile, with the exception of the little finger, which has four. In the salamander the little finger is oblique, and the thumb has only two phalanges.

The frog has only one phalanx to the thumb. The two following fingers have only two phalanges. The other two fingers have three.

The hand of the sea tortoise is long, and compressed in the form of a fan; there are two phalanges to the thumb, three to the two succeeding toes, and two only to the last. A similar conformity is observable in the mud tortoise; with this exception, that its hand is rounded.

Bones of the Pelvis.—In the turtle, that part of the os innominatum which corresponds to the pubis, is the most considerable. It proceeds from the cotylar cavity by a thick portion, which comes forwards and widens into a thin flat lamina, divided into two parts; one is turned towards the middle line, by which the two corresponding bones are united; the other is free, and is directed to the external side. The portion which corresponds with the ilium is short, narrow, and thick; it rests on the shell, and is joined to the acetabulum; finally, the portion which is analogous to
the tibia is turned backward and downward, and forms the real osseous circle of the pelvis. This conformation is so singular, that the parts of the pelvis of the turtle, when the whole is viewed out of its natural position, may very easily be mistaken for one another; for the pubis resembles the ilium, the ischium the pubis, and the ischium the ilium. There is, besides, another very remarkable peculiarity in the pelvis of tortoises; the ilium, and consequently the whole mass of the pelvis with which that bone is united, is moveable on the vertebral column.

In the crocodile, and in the tupinambis, the disposition of the pelvis has a great resemblance to that of the tortoise. In the crocodile the pubis receives the ventral ribs. In the camel and the iguana it is narrow, and the bones of the ischium form, by this union, a projecting crest. In the frog, and in the Surinam and common toads, the os illi are much elongated; the pubis and the ischium are short, and united in a single solid piece, the symphysis of which forms a crest, more or less round. In the salamander, the conformation is precisely the same. The os illi are narrow, and almost cylindrical; and the os pubis completely united with the ischium, form only a large bony plate without any hole.

**Thigh-Bone.**—The femur of oviparous quadrupeds resembles that of other animals; it has, however, a double curvature, more or less evident. In front it presents a convexity towards the tibial extremity, and a concavity near the pelvis. In the tortoise the trochanters are well defined, but they are not to be found in the lizards and frogs. The figure of the femur is in general round, except in the Surinam toad, in which it is very flat.

**Bones of the Leg.**—Oviparous quadrupeds have the tibia and fibula distinct and separated from each other throughout their whole length. These two bones are nearly of the same magnitude in the tortoises and lizards. The frog has but one bone, but a furrow seems to indicate the union of the tibia and fibula. In these animals the tibia and fibula are, for the most part, directly articulated to the thigh-bone.

**Bones of the Ankle.**—The alargatus is articulated to the tibia, and the os calcis to the fibula in all reptiles. The talus of the crocodile has five bones, viz. an alargatus, an os calcis, two cuneiforms, answering to the two middle metatarsal bones, and one out of the range, which answers to the external metatarsal bone. There are four metatarsal bones. The bone situated without the range serves to support the little toe in the mud tortoise. In the sea tortoise it is very flat. The os calcis and alargatus are very small. In frogs, the alargatus and os calcis are very long, and might at first sight be taken for the tibia and fibula, if they did not form the third joint of the posterior extremity. There are on the fore part, four little cuneiform, five metatarsal bones, and one in the form of a hook, which is very minute. These are similar in the Surinam and common toad.

**Bones of the Toes.**—The number of the toes varies much in reptiles; as may be seen from the following table.

Number of the phalanges of the toes of reptiles, exclusive of the metatarsal bones, beginning at the pollex, or internal toe.

The saurians present us with arrangements in their extremities, not met with in any of the mammalia. We have species possessing only fore-limbs, or only hind-limbs; others with four limbs, and one toe only on each; and other unusual combinations in the number of toes on the fore and hind-limbs. These circumstances are noticed in those lizards which approach to the form of serpents, and whose small imperfect limbs seem more like rudiments than complete members, serving as intermediate links between the saurian and ophidian orders. See Lacépède in the Ann. du Muséum, ii. p. 351, with figures of a lizard monodactyle, and tetradactyle; and Danin in his Hist. Nat. des Reptiles, vol. iv. in the history of the genera Seis and Chalcide. We know nothing, however, about the osteology of those—we might almost say—ridiculous limbs, they are so obviously inadequate to the purpose of locomotion.

**Of the Muscles.**

**Muscles of the Spine.**—There are few spinal muscles in frogs. The muscle which is analogous to the ischio-coccygeus is large and thin, and occupies all the space comprend between the two bone of the coccyx and the ilia. Its fibres are oblique, and it serves to draw the coccyx into the direction of the spine. That which is analogous to the lumbo-collalis, arises above the last by a sort of point attached to the coccyx. It extends quite to the head, into which it is inserted, and detaches fibres in its progress to each of the transversal processes, which form a kind of interposition upon its surface. The obliquis superior arises from the head at the margin of the foramen magnum, and is inserted into the transversal processes of the first dorsal vertebra. There is only one small rectus anterior, it arises from the bane of the cranium, below the foramen magnum, and is inserted into the first of the transversal processes. The inter-transversals are like the human. The spinal muscles of the salamander much resemble those of the frog; those of the tail are very similar to the muscles of fishes. The spine of the tortoise has no motion except in the parts belonging to the neck and tail. Those of the back and loins, which are ossified together, have no muscles. The muscles of the neck are very different from those of man. The motions they produce are those of elongation, by which the head is protruded from the shell; and those of retraction, by which it is withdrawn, the neck being bent in the form of a Z. The first of the muscles proper to the neck is attached to the under part of the anterior lateral border of the back-shell, and into the transversal processes of the first vertebra; it raises the neck and draws it back. Another proceeds from the anterior and middle part of the shell; it is inserted by four fleathy lips, which are separate throughout a considerable portion of their extent, into the articular processes of the third, fourth, fifth, and sixth vertebrae of the neck. It draws the neck back when the head is much extended, and pushes it out when it is retracted. A muscle also arises from the articular processes of the third, fourth, and fifth vertebrae of the neck, by three fleathy portions that afterwards unite, and terminate in two tendons; one of which is inserted into the transversal processes of the first, and the other into the spinous processes of the second vertebra. This muscle bends the neck upon itself, making it describe a curve, which is convex downwards; this motion brings the head under the shell. A muscle analogous to the longus colli arises from the under part of the body of the second dorsal vertebra, beneath the shell; it ascends along the neck, and furnishes a penevetric slips to all the transversal processes,
as far as the second vertebra, where it is inserted. This also is one of the retractors of the head. There are very distinct inter-arteniculars, which by their action elevate each of the vertebrae, and consequently extend the neck. The transverse-fibular is situated on the posterior part of the neck; it arises from all the superior transverse procusses, and is inserted into all the spinous procusses as far as the sixth. Finally, a short muscle proceeds from the upper part of the first dorsal vertebra below the shell, and is inserted into the articular procusses of the sixth and seventh cervical vertebrae. This muscle is peculiar to the tortoise, and begins the extension of the neck when the head is concealed within the shell.

**Muscles of the Ribs, Abdomen, &c.—** In the frog, which wants ribs, and the tortoise, where they are immovable, the muscles which usually have their insertions in them, are in those animals extended to other parts. Thus in the tortoise, whose back-plate occupies the place of the abdominal muscles, they are inserted into the pelvis, which they move. With respect to those animals, one very remarkable observation may, in general, be made. It appears that the very singular shape of the muscles and bones depend upon each other. Indeed, as the muscles are not placed upon the bones, they have not, if we may be allowed the expression, fashioned them; and the want of motion in the bones, which has given an unnatural figure to the trunk, has also given to the muscles other forms and other uses. The abdominal muscles of the frog present nothing peculiar, except that the skin does not adhere to their surfaces, and that instead of being inserted into the ribs, they are fastened to the sternum by a strong aponeurosis. The same observations may be made with respect to the faramanders.

We have described, in the osteology, the adaptation of the ribs of serpents to the purpose of progressive motion; and now proceed to point out the muscles by which they are moved forwards or backwards, and connected to the abdominal scutum. The ribs are brought forwards by five sets of muscles placed on the outside of the chest, and passing obliquely from above, downwards, outwards, and backwards. 1. One from the transverse processes of each vertebra to the rib behind it. 2. The next set arises from the ribs, at a short distance from the spine, passes over two ribs, bending a flap to each, and ends in the third. The third arises from the posterior edge of each rib, passes over two ribs, and is inserted into the third rib behind it. The fourth set passes over one rib and is inserted in the second. The fifth goes from rib to rib.

The muscles carrying the ribs backwards are found on the inside of the chest, and from the spine forwards and outwards. A strong set arises from the anterior surface of the vertebra, goes over four ribs, to be inserted into the fifth about its middle. The serrated portions of a strong flat muscle, forming the muscular covering of the abdomen, arise from this part (the middle of the internal surface) of each rib. The right and left muscles unite in a beautiful middle tendon. Thus it is obvious, that the inferior half of each rib (below the origin of the serrated portion just described) is external to the abdominal muscle, and consequently free for the purpose of progressive motion.

The ends of the ribs are connected to the abdominal scuta by a set of short muscles: they are also connected together by short and strong muscles. Another set goes from the heads of the ribs obliquely backwards to be fixed in the skin at the edge of each scutum. See Sir E. Hume’s paper quoted in the osteology; and particularly plates 4 and 5 from Mr. Clift’s drawings, in which the parts are represented.

There is a complicated muscular apparatus for extending and retracting the ribs, and carrying the skin forwards and backwards in the cobra de capello. The ribs are raised or carried forwards by four sets of muscles, arising from and inserted in the ribs of the neck, and directed obliquely from above, downwards and outwards.

The skin of the back is brought forwards on the neck by a large set of very long muscles, arising successively from each of the first twenty ribs, by a tendon, which soon becomes feathery. The length is about two inches. They go backwards to be inserted into the skin, which they can bring forwards to a great extent when the ribs have been first extended.

The muscles which carry the ribs back again lie on the inside of the chest under the spine. One set goes from the vertebrae of the neck to the lower edges of the ribs: but they pass obliquely upwards and outwards over three ribs, to be inserted into the fourth, thus acquiring a length of fibre, by which the range of motion produced is much increased. The second set goes from the ends of the ribs to the skin, which they will draw back. The third set from the root of one scutum to the scutum immediately above it, so as to bring it down upon the other. Sir E. Hume’s and Dr. Rulel’s paper, and particularly the engravings from Mr. Clift’s drawings. Phil. Trans. 1804, pt. 2.

**Muscles of the Head.—** The muscles of the head of the tortoise cannot be described under names similar to those of mammiferous animals and birds, because the shell affords insertion to the greater number of them. We will, therefore, only distinguish them by the points of attachment. Thus, on viewing the back part of the neck, we remark, 1. At the anterior part of the back-shell, near the angle of the humula, a broad muscle, which extends to the lateral and posterior parts of the head, into which it is inserted. It pulls the head backward. 2. Beneath, and from the middle of the anterior humula of the back-shell, there arises another muscle, which is thin and round, and which, in separating from that of the opposite side, forms an angle like the letter V: it is inserted on the outside of the preceding muscle, and has the same name. 3. A muscle analogous to the plesials capitii arises from the spinous procusses of the fourth and fifth cervical vertebrae, by distinct slips, and is inserted into the occipital arch. Its use is to raise the head. 4. A muscle analogous to the rectus major antiquus arises from the inferior tubercles of the fourth vertebrae next to the atlas, and is inserted, feathery and thick, into the depression of the cuneiform procusses below the condyles. 5. The transverso-maloloides arises from the inferior tubercles of the second and third cervical vertebrae, by two thin aponeurotic tendons; it is inserted, by a very thick and entirely feathery portion, into the protuberance that answers to the mastoid process. Its use is to bend the head laterally. 6. Lastly, at the superior part of the cervical spine there is a short muscle, which proceeds from the inferior part of the foramen, formed by the temporal fossa, and is inserted into the spinous procusses of the first, second, and third vertebrae of the neck. On viewing the neck in front, we observe the muscle analogous to the internecleido-maloloides attached to the strong aponeuroses that surround the humerus at its articulation with the clavicle. The lower part of it, for one-third of its length, can only be seen, the remainder being concealed by a muscle composed of transverse fibres, which supplies the place of the mylo-hyoides, and platista-myoïdes. It is inserted into a process corresponding to the mastoid. Its use is to draw
REPTILES.

The head is inwardly drawn, and to produce a small elevation of the shoulders. The longus capitis arises from the third vertebra of the back, and is inserted by a slender tendon into the concave or curved process of the occiput. The frogs have very few of the muscles of the head; most of them, which are in the area employed in moving the superior extremities, or are proper to the vertebral column. The muscle analogous to the obliquus superior, arises from the first transverse process of the spine, and is inserted into the superior part of the occiput; its direction is oblique from without inwards. That which is analogous to the rectus capitis, anticus minor, arises from the transverse process of the first vertebra, and is inserted into the basis of the cranium below the foramen magnum. These are the only two muscles proper to the head in frogs; they are similar to the head muscle of the fowl.

Muscles of the Shoulder.—In the frog (which has no ribs) the serratus major has an extraordinary shape, which appears to be occasioned in part by the want of the cervical vertebrae; it forms three distinct muscles. The first arises from the occiput, near the foramen magnum. It divides into two bellies, which are inserted into the superior spinal angle of the scapula; one on the internal, and the other on the external side. The second proceeds from the second transverse process, and passes under the dorsal portion of the scapula, towards its spinal edge. The third proceeds from the third transverse process, and passes underneath the preceding muscle, and is inserted into the inner posterior edge of the scapula. There is besides another muscle proper to the scapula, situated upon its internal surface, between the two constituent parts, which make it appear broken. It appears to divide these two parts closer together, and by its contraction renders the angle they form with each other more acute. There is no muscle analogous to the pectoralis minor of the frog. The place of the levator, or angularis scapulae, is supplied by a very considerable muscle which arises from the base of the occiput; it becomes perceptibly smaller as it approaches the scapula, and is inserted into the posterior edge of the cartilaginous part of the scapula. The omohyoideus is long and thin; it comes from the great inferior horn of the os hyoideus, and is inserted under the neck of the scapula. The trapezius is wanting. The muscle analogous to the rhomboideus is very thin. It arises from the dorsal process, and is inserted into the spinal edge of the scapula. There is no subclavius muscle. The sternomastoideus has only one belly, which extends obliquely from the posterior part of the head, behind the ears, to the neck of the scapula. Its action is evidently that of pulling the scapula towards the head, and raising it up. We shall describe the muscles of the sternum separately, as they differ considerably from those of other red-blooded animals. They are only three in number. One of them, though very unlike the trapezius, is similar in its use; it rises from the lower surface of the back-shell among the ribs, from the second to the fifth. It is very thin, and passes to the external margin of the third bone of the scapula, which seems to correspond with the scapula. A muscle analogous to the levator scapulae, is inserted into the curve formed by the joint of the two first bones of the shoulder. It arises by seven feathery heads from the transverse process of the second vertebrae of the neck. Another long muscle arises from the inner surface of the back-shell near the rectal extremity of the first rib, and is inserted into the dorsal extremity of the first bone of the scapula. It is perhaps analogous to the colo-

Muscles of the Arm.—The pectoralis major of the frog is composed of two portions, placed one above the other. They produce two tendons which are inserted on each side of the humeral groove. The latissimus dorsi arises from the inferior part of the back, where it is thin. It becomes thicker, and is attached to the broad part of the scapula, which it entirely covers. It is inserted, by a strong tendon, into the internal surface of the humerus, above one-third of its length from its superior end. In the frog there is neither the suprarr nor the infra-spinatus. The subcapitularis or coraco-brachialis, (for the muscle of which we now speak supplies the place of both,) arises from the internal surface of the scapula, at its junction with the clavicle, and is inserted into the inner part of the humerus about one-third from the head. The deltoide is formed of three portions. The first, which is the longest, and very slender, proceeds from the anterior part of the scapula, to the internal surface, runs over the bone beside the joint, then sends a thin tendon to the first in its passage, and is partly inserted in the linea aspera, and partly in the inferior portion of the humerus. The second is in the space between the first and the scapula and clavicle, and is inserted into the scapular extremity of the humerus. The teres major and teres minor are wanting. Besides these muscles, in which we discover an analogy to those of mammiferous animals, there is one which arises from the second transverse branch of the sternum, and is inserted into the fusiform groove of the humerus by a broad tendon. It may be regarded as an antagonist to the pectoralis major. This conformation appears to prevail in the fowl.

If the tortoise has fewer muscles proper to the shoulder than common, it has an extraordinary number inserted into the humerus. That which corresponds to the pectoralis major is composed of five portions. Two are superficial; one arises from the edge of the anterior part of the breast-plate, and proceeds to its insertion in the lesser tubercle of the humerus. The other is much more extensive; it arises from a great part of the internal surface of the breast-plate, and is also inserted by a flat tendon in the lesser tubercle of the humerus; but it is prolonged by a fan-like aponeurosis, which extends over the inferior surface of the arm, and even of the fore-arm. One of the three deeper portions of the pectoralis major arises from the greater part of the second bone of the shoulder, and is inserted into the humerus, below its scapular articulation; another arises from the expansion of the interosseous ligament, which unites the second bone of the shoulder to the third, and proceeds to join its tendon intimately with that of the preceding portion. Lastly, the third, which is the most deep-seated of all, arises from the superior surface of the third bone of the shoulder, or that which is next the back-shell. Its tendon is connected with those of the preceding. The muscle analogous to the deltoid is also composed of two portions; one arises from a ridge on the anterior part of the breast-plate; the other, which is its accesorium, is placed more deeply, and united to its corresponding muscle. They are inserted by one common tendon into the lesser tubercle of the humerus, which they draw towards the neck in the action of swimming. There is another muscle much deeper seated, which seems like a tendon to the deltoid. It arises from the dorso-extremity, and all the internal edge of that part of the shoulder which corresponds with the clavicle, and proceeds to be inserted into the humerus below the lesser tubercle. On the external surface of the humerus, we find a muscle rising from the loose second of the external face of the third bone of the shoulder: it is inserted in the humerus, about one-third from its lower end, by a thin tendon. It bears some relation to the sternoradialis of the frog, and performs the same office.
The levator brachii is a very thick muscle, which arises from the third bone of the shoulder, the exterior edge of which it surrounds, and is inserted into the process of the humerus resembling the olecranon, which it pulls upward and outward. A muscle analogous to the teres major arises from the neck of the third bone of the shoulder, externally, and is inserted into the humerus between the two tuberosities. It pulls the humerus backward. Another muscle, which seems a substitute for the latissimus dorsi, arises from the interior part of the back-shell, to which it is attached obliquely, to the interval between the two first ribs. It is inserted into the body of the humerus behind the greater tubercle, by a flat tendon. It pulls the humerus towards the upper shell, when the animal stands upon all its four feet. A muscle, the use of which seems the same as that of the levator brachii, arises from the whole internal surface of that bone of the shoulder which answers to the clavicle, and is inserted into the whole length of the olecraniform process, or great tuberosity of the humerus. It is very flabby, and appears to be formed of two portions. Finally, the muscle analogous to the scapula-radialis, or biceps flexor cubiti, arises from the anterior border of the humeral cavity, and is inserted into the external and superior surfaces of the humerus by a small tendon, which reaches as far as the base of the radius. It extends the member, and brings it toward the head.

**Muscles of the Fore-arm.**—The frog has, properly speaking, no biceps; its place is supplied by another, and much stronger muscle, situated on the breast, under the pectoralis major, with which it has the same actions. At the articulation of the humerus it sends out a strong tendon, which passes along the groove of the humerus, and through a tendinous ring, formed by the two parts of the pectoralis major, under the deltoids. It is inserted into the humeral extremity of the radius, and may be named *flemo-radialis*. There is no brachialis internus. The triceps is composed of three parts, nearly as in man, but they are proportionally larger. There is but one supinator, which arises from the external condyle, and is inserted into the carpus. There is also but one pronator, which arises from the internal condyle, and is inserted into the carpus. In the turtle, these muscles are almost entirely aponeurotic, and produce but very little motion, the place of the member being supplied by a fin, as in the cetacea. In general, the muscles of the humerus produce the motions of the fore-arm.

**Muscles of the Hand and Fingers.**—In the sea tortoises, which have the carpus compressed and fitted for swimming, the muscles are only simple bands of aponeurotic fibres, which strengthen the several articulations. The muscles of the hand of the frog and salamander are very similar to those of man. Those of the thumb are wanting, except the extensor, which comes from the external condyle, and is inserted into the last phalanges. The other muscles vary very little.

**Muscles of the Pelvis.**—In the tortoise, the muscle analogous to the quadratus lumborum expands under the back-shell, between the last anterior ribs; it arises from the ilium, towards the articulation of that bone with the os sacrum, which in this animal is moveable. This mobility of the pelvis is afforded by a muscle analogous to the rectus abdominis, which, as we have observed, instead of extending under the belly, is attached under the posterior extremity of the breast-plate by two flabby portions, the one anterior, the other posterior, which are both inserted in the anterior margin of the external branch of the pubis. There is no plosus parvus in frogs. The quadratus lumborum extends from the long transverse process of the third vertebra, to the origin of the long bone of the pelvis, which is analogous to the ilium. It is inserted in this bone, which it raises towards the head; their ilium being moveable, like that of the tortoise.

**Muscles of the Thigh.**—In the frog there is only one gluteus, which is in the place of the medius. It arises from the elongation which supplies the place of the os ilium, and is inserted below the head of the femur. The pyriformis comes straight from the point of the coccyx, and is inserted about one-third from the top of the os femoris. The gemini and the obturator internus are wanting. The quadratus femoris is long. It arises from the posterior synphysis of the ischium, and is inserted into the inner side of the thigh-bone, about one-third from the head. They have neither the plosus magnus nor parvus. The iliacus is proportionally elongated. The pectineus descends to the middle of the thigh-bone. The three adductors have the same origins and insertions as in man. The obturator externus is to be found, though there is no foramen ovale. It arises from the symphysis pubis, and its fibres are attached to the capitular ligament. In the tortoise, the muscles of the thigh produce motions proper to swimming; that is to say, the abduction, the adduction, depression, and elevation of the thigh. The muscle analogous to the adductor longus arises from the symphysis pubis, and is inserted into the internal part of the thigh-bone, about one-third from its tibial extremity. Another muscle, which cannot be easily compared to any in man, arises from the interior of the facrum, and is inserted into the little trochanters. It is another adductor femoris. A muscle, composed of different radianated fascicles, arises from the broad inferior surface of the os pubis, and forms a thick tendon inserted into the little trochanter. It occupies the place, and answers the purposes, of the *pectineus*. That which is analogous to the adductor brevis arises from the synphysis of the bones of the ischium, and the interosseous ligament of the pubis. It is inserted into the os femoris, below the little trochanter. The muscle answering to the gluteus maximus arises from the spine, opposite to the last rib, and is inserted into the thigh-bone, below the great trochanter. The muscles analogous to the gluteus medius and minimus can hardly be distinguished from each other. They rise from the internal surface of the os pubis, and are inserted into the great trochanter. That which resembles the obturator internus arises from the internal surface of the ilium, and the superior edge of the cotyloid cavity, and is inserted into the great trochanter.

**Muscles of the Leg.**—The frog has the thighs round, like those of a man, and the muscles of the leg are very confusious. The triceps femoris is formed only of two very distinct portions. The *vatus externus* and *cruralis* are manifestly but one. There is no rectus anterior. The biceps flexor cruris has only one belly. It arises from the posterior and internal part of the ilium, and is inserted into the exterior and anterior surface of the tibia, for there is no fibula. The femi-membranous is like the human; but the femi-tendinosus is composed of two bellies, one of which rises from the synphysis pubis, and the other from that of the ischium. The factorius is situated exactly in the front of the thigh, without any obliquity. There is nothing remarkable in the gracils. There is no distinct poplitans. Some differences occur in the muscles of the leg of the tortoise. Thesee have a relation to the faculty of swimming, for which its extremities are fitted. The muscle which takes the place of the femi-membranous arises from the interosseous ligament of the pelvis, and proceeds to form a strong aponeurosis at the inferior part of the leg. That which corresponds to the femi-tendinosus arises also from the interosseous ligament;
ment; it passes under the ham, and is inserted into the tibia, which it bends. That which is analogous to the fuctorius arises from the os pubis, near the interosseous ligament, and passes over the knee, to be inserted into the tibia, which it extends. A muscle composed of two flabby portions, both of which arise from the lateral parts of the facrum, is inserted below the head of the tibia, and bends the leg. In its action, it much resembles the biceps, from which, however, it differs with respect to its attachments. Another muscle, resembling the fascia lata, and very thin in its flabby part, arises from the sides of the coccyx. It passes under the skin of the fin, to its insertion, almost opposite to the heel. It bends the leg upon the thigh, and extends the foot upon the leg. The muscle analogous to the biceps arises from the facrum and ilium. It goes to the external surface of the leg, where it is inserted into the fibula. The extensor of the leg presents nothing particular. The muscle analogous to the rectus anterior arises from the internal surface of the pubis, and joins the common tendons of the extensors.

Muscles of the Ankle.—In the frog, the gastrocnemius has only one belly; it has, however, a small tendon, by which it is inserted into the outward side of the head of the tibia. Its tendon runs under the heel, and there dividing over a leaf-ridge, expands itself under the foot, to form the plantar fascia. There is neither foleus nor plantaris. The tibialis anterior arises by a strong tendon from the lower part of the os femoris. About the middle of the tibia it divides into two bellies, one internal, the other external. The tendon of the first is inserted into the tibial base of the long bone of the tarfuris, and that of the second into the same bone, a little more outwardly. An afflent to this muscle arises from the middle and anterior part of the tibia, and proceeds to the internal side of the base of the long bone of the tarfuris. The tibialis posterior resembles the human, but it is only inserted into one bone of the tarsus, viz. that which is long, and situated at the internal side. There is but one muscle, to which the term peroneus can apply. It arises by a slender tendon, from the external condyle of the thigh, and is inserted into the base of the tibia, on the outside, by two tendinous portions, one of which extends to the bone of the tarfuris. It extends the leg with respect to the thigh, or, more properly, the thigh with respect to the leg. Besides these muscles, which extend from the leg to the foot, there is another which arises from the metatarsal extremity of the tibia, at its internal edge, passes between the two bellies of the tibialis anticus, and proceeds very obliquely to its insertion, at the digital extremity of the long bone of the tarfuris, on its inner side. In the sea tortoise, the muscles of the feet are supplied by aponeurotic fibres, somewhat flabby, which serve only to strengthen the articulations, and keep the fins properly extended.

Muscles of the Toes.—There is no extensor longus digitorum in the frog; neither is there any flexor proprius plantaris. The extensor brevis digitorum is very distinct, it arises from the whole length of the long external bone of the tarsus, and extends obliquely to all the four toes, the last excepted. It is inserted into the talar phalanges. There are superior and inferior interosseous muscles, which are very apparent, to the number of ten. Their direction is very oblique. The flexor communis digitorum is situated under the long bone of the tarsus, on the inner side, and is covered by the aponeurosis of the gastrocnemius. When it reaches the little bones of the tarsus it divides into five tendons, which receive, at their inner side, allant flabby fibres, apparently proceeding from a muscle situated below the long bone of the tarsus, on the inner side. It may perhaps represent the flexor longus. In the sea tortoise all these muscles have their places supplied by bundles of aponeurotic fibres.

On the Support of the Body, and its Motions in Progression. Standing is an attitude common to all animals, but the circumstances attending it differ very considerably. In most of the oviparous quadrupeds, the knees and elbows are directed forwards as they stand, and even during their various progressive motions. The posterior members, articulated more in proportion at the fides of the body, are so bent, that the belly descends to the ground, and moves along it.

Turtles rest on their plastron, and on their four flattened, elongated, and fin-like members. They may be compared to seals in their mode of executing movements. They employ their members, either in swimming, or in walking on the sea-shore, or in digging holes in the sand to receive their eggs.

In tortoises, standing is nearly the same as in other oviparous quadrupeds; and the direction of their body is horizontal. Batracians, and frogs in particular, generally have their body, when at rest, in an oblique elevation; the arms sustaining the front part, while the back remains on the ground. The formation of the posterior limbs does not render them adapted to raise the body in a vertical direction, but merely to push it forwards.

Serpents, in a state of repose, coil up their body in several circles, either rising one above the other, or arranged one within the other; and the head is elevated above this coil. Those which inhabit trees are twisted round the branches. The chalices and biped lizards may be compared to serpents when at rest, for they are coiled up, and their limbs serve merely to prevent the body from rolling.

Walking exhibits different modifications, according to the number and form of the limbs, and the relative size of the fore and hind-feet. Where they are of equal length, the animals move with great velocity: hence the names of certain species, as hera agilis and velox. When, however, the limbs are too small and weak for the body, the movements are slower, as in the crocodile, the chalices, and the toad.

The feet of the camelion, and its prehensile tail, make it a better climber than most reptiles.

The limbs being all of nearly equal length in the finks, they cannot leap well, while the iguanas and tupinambos exhibit considerable agility. The frogs are the great jumpers, from the great length and strength of the hind limbs. But they can hardly walk; moving the front legs only with facility, and being obliged almost to drag the hind ones after them.

Serpents can leap or project their bodies by the sudden extension of several articulations; they form several curves with their body, and then suddenly straighten them, either in whole or in part, according to the leap which they may wish to make.

Climbing, properly so called, belongs only to serpents, and consists of a projection of the body backwards or forwards, produced by the alternate motion of one or several of the lower parts against the ground. The following modifications are exhibited in different instances. 1. Climbing by vertical undulations. 2. By horizontal undulations. 3. By two or three undulations of the posterior third part of the body, while the two anterior thirds are elevated vertically. 4. A gliding kind of crawling, by small undulations formed by the alternate approximation and separation of rows of scales placed transversely under the body. 5. The
The same kind of motion, produced by the alternate formation and disappearance of folds in the skin of the sides.

Without any undulation, merely by the alternate approximation and separation of rings of the body.

The reptilian motions, by which reptiles move their bodies forwards in water, are nearly the same as they employ in jumping; but they must be much quicker. To rive in the water, they must strike back the water below and behind them, and diminish the breadth of their body, as much as possible, by carrying their swimming organs backwards after each stroke. Thus we see the frog, after striking, extend its long hind legs, so as to offer no resistance to the passage of the body through the liquid. The act of swimming offers the following modifications. 1. External swimming (on the surface of the water, breathing air) by vertical undulations, without swimming organs. The serpents. 2. The same by lateral undulations, affixed by the feet. Iguanas, lizards, &c. 3. Swimming under the surface, breathing externally; by four palmed feet, and without tail. Hyla palma (Rana maxima, Linn.)

4. The same with four legs and no tail. Frogs properly so called. 5. The same with four feet, an elongated body, and depressed tail. Crocodiles, salamanders. 6. The same by means of four fin-like fealy members, and no tail. 7. Swimming under water, breathing by means of branches.

The dragons are the only reptiles capable of flying. Their flight is nearly the same with that of the pataouche, or flying squirrel. Daudin, Hist. Nat. des Rept. t. 1. p. 256.

The Brain.—The brain of reptiles does not fill more than one-half of their very small cranium; hence its relative size to that of the body is very inconsiderable. Its proportion to the body is said to be, in the tortoise, in the turtle, in the coluber, in the frog.

Blumenbach justly observes, that anatomists have hitherto bestowed but little labour on the brains of the amphibia. The dura mater forms no process in this order; the interval between it and the pia mater is filled with fluid; the brain is small and simple, and confined of five roundish eminences. Of these, the single one, placed at the front of the medulla spinalis, is clearly the cerebellum, as in all animals which have a nervous system. Whether the four others are to be regarded as the two hemispheres, and the thalami nervorum opticorum, is more doubtful. According to Blumenbach, the cerebellum does not exhibit the arbit vitae. All the parts of the brain of reptiles are smooth, and without circumvolutions. The optic thalami are situated behind the hemispheres, but are not covered by them. They contain each, as in birds, a cavity which communicates with the third ventricle. At the extremities of this ventricle, we observe the anterior and posterior commissure, but there is no soft commissure, nor tubercula quadrigemina.

In the tortoise the hemispheres form an oval. Their anterior part is separated from the posterior by a sulcus, and represents a kind of bulwark, which serves as a root to the olfactory nerves. The size of this bulwark is about equal to one-third of the hemisphere. The interior of the hemisphere is, as usual, excavated by a ventricle, and contains a substance analogous to the corpus striatum, and which pretty much resembles in its form that of birds.

The optic thalami are not larger than the bulbs of the olfactory nerves. Their form is nearly round. They extend downward and forward, under the hemispheres, to produce the optic nerve. The valve of the cerebrum is situated between them and the cerebellum. No tubercle is either placed above it or before it, and it gives origin, as usual, to the fourth pair of nerves.

Before the optic thalamus, and under the posterior part of the hemispheres, there is a tubercle which corresponds to that we have remarked in birds.

The cerebellum is nearly hemispherical. The fourth ventricle penetrates a considerable way into its substance.

In the frog the hemispheres are longer and narrower. The optic thalamus are larger in proportion to the hemispheres. Their ventricle is very distinct. It is the contrary in salamanders, which have the optic thalamus very small, and the hemispheres almost cylindrical.

The cerebellum of these two kinds of reptiles is flat, triangular, and lies posteriorly on the medulla oblongata. In the serpents the two hemispheres form together a mass which is broader than long. The optic thalamus are almost round, and one-half less than the hemispheres, behind which they are situated. The olfactory nerve has no apparent bulb. The cerebellum is exceedingly small, flat, and in the form of a portion of a circle.

In all these animals the inferior surface of the brain is nearly smooth. The optic thalamus make no projection downward, and the pons Varoli does not exist.

Cuvier assigns, as the distinguishing character of the brain in reptiles, the position of the optic thalamus behind the hemispheres. And he states the following as the points in which reptiles, fishes, and birds, differ from the mamalia. The want of corpus callosum, fornix, and their dependencies. Some tubercles, more or fewer, between the corpora firiata and the optic thalamus. The thalamo-containing ventricles, and being distinct from the hemispheres. The absence of any tubercle between the thalamus and the cerebellum, as well as the absence of the pons Varoli. Reptiles and fishes are distinguished from the mamalia and birds by the want of the arter vitae.

The brain of the tortoise has been delineated by Calderi, offecracioni intorno alle Tartarughe, tab. 2. fig. 5: that of the frog by Ludwig, de cinerea cerebri substantia; by Vicq d'Azyr in the Mem. d'Acad. des Sciences, 1783; and by Ebel, in his Observat. Neurol. ex Anat. Compar.; and that of the viper, by Vicq d'Azyr.

Origins of the Nerves.—The olfactory nerves arise, as in birds, from the anterior extremity of the hemispheres. The optic nerves seem to derive their origin from a common eminence, situated under the middle of the hemisphere. The other nerves exhibit no particularities as to their origin.

Distribution of the Nerves.—The olfactory nerve proceeds to the olftrils in this class nearly in the same manner as in birds; but it is longer. The canal which receives it is partly olefine and partly cartiligenous. The two canals have only one common aperture within the cranium. The olfactory nerves of reptiles are generally much more solid than those of the preceding classes.

The two optic nerves are joined together, as in the mamalia. There is nothing worthy of remark about the third, fourth, and fifth pairs.

Reptiles have the three branches of the fifth pair. In the sea tortoises the ophthalamic palpes, some way, in the dura mater before it enters the orbit. It transmits filaments to the muscles of the globe of the eye, and particularly to the two lachrymal glands. The superior maxillary branch is the largest of the three. It is united to the inferior branch at its origin, but when it reaches the interior of the orbit, it separates from it to take another direction. It pales along the floor of the orbit, describings a very marked curvature, the convexity of which is external. A very great number of filaments proceed from the concave or internal
fide, which are lost in the lacrimal gland. The trunk is afterwards divided into two branches—one internal, which corresponds to the sphenopalatine and sub-orbital nerve. It furnishes filaments to the palate and to the nose; and when arrived at the anterior part of the orbit, it proceeds outwardly and spreads upon the face. The other branch of the principal trunk is external; it pales also upon the floor of the orbit, to which it gives many filaments, and at length fining from the inferior part of the orbit, it expands upon the face, anatomically with the other facial nerves.

The inferior maxillary branch proceeds almost vertically downward to the posterior part of the orbit, before the petrous and articular processes of the os temporum. In its course towards the lower jaw, it pales between the temporal and pterygoid muscles, to which it sends several filaments. Having arrived at the lower jaw, before the articular surface, it enters the oblong aperture, and divides in the substance of the bone. It forms several branches on the inner part of the jaw, which are lost in the muscles of the tongue, and on the outside some others which ramify under the skin.

The facial nerve exits in birds and reptiles, but its size is small, because these animals have no lips, and because their mouth, as well as a great part of their face, is covered with a horny or scaly substance, in consequence of which these parts have but little motion or sensibility. We find, however, some of the branches: they are not indeed easily followed in dissection, but their trunk always exists.

The auditory is united to the facial nerve as in the mammalia, and pales into a meatus auditorius, whence its branches go into the ear. They will be described in the account of the ear.

We have nothing remarkable to state respecting the par vagum or eighth pair of nerves in reptiles. We observe evidently that it is distributed to the lungs, the heart, the oesophagus, and stomach, and that it forms plexuses on these organs, in the same manner as the great sympathetic nerve produces them round all the arteries of the trunk. On leaving the cranium, the par vagum forms decullations with the lingual and glosso-pharyngeal nerves; they afterwards separate from each other: the glosso-pharyngeus is posterior, the par vagum in the middle, and the lingual anterior. The par vagum does not always come out of the cranium by a single hole; it is formed of two or three filaments, which afterwards rejoin, upon receiving a communicating filament from the glosso-pharyngeus, and one farther down from the lingual; the nerve then swells somewhat in diameter, and descends into the breast.

We have nothing to remark concerning the glosso-pharyngeal and hypoglossal nerves.

Tortoises have eight pair of cervical nerves, which are distributed nearly in the same manner as in mammalia. The three last pairs join in forming the brachial plexus. The green lizard has four pair of cervical nerves, but only the two last enter into the composition of the plexus. In fowl and man, and frogs the cervical nerves cannot be properly distinguished from the dorsal, as the animals have no ribs. A pair comes out between the first and second vertebrae, which is sent to the muscles of the inferior part of the neck, and under the skin that covers them. These nerves also afford some filaments to the shoulder. From this distribution they may be regarded as real cervical nerves. In frogs only two pairs enter into the composition of the plexus. In the fowl and the frog there are distinctly four.

We refer to the tables which indicate the number of the vertebrae in reptiles, in order to shew the number of nerves which issue from their foramina. The distribution of these nerves is the same as in other animals, and to point it out would be only repeating what we have already described in man.

Nerves of the foreLimbs.—In the tortoise the three last pairs of cervical nerves, and the first of the dorsal, proceed to the thoracic member, where they form a plexus in the following manner: the fifth cervical pales the other four pairs, crotes them in their course, and unites with them in its passage. They then runs round the scapula, which in this animal is articulated with the first dorsal vertebra. We shall return to the description of this nerve. The fifth cervical pair proceeds directly along the scapula on its internal surface; it is crossed posteriorly by the fifth, and to wards the lower third of the scapula receives the seventh cervical pair. The seventh is slender, crossed by the fifth and the first dorsal pair, and united with the fifth in the manner we have pointed out. The first dorsal pair partly joins the seventh cervical, almost at the point where it comes out of the vertebral canal; it is then sent to the muscles of the shoulder.

We shall now pursue each of the cords we have mentioned to their termination.

The large nerve produced by the fifth cervical pair, having arrived behind and near the true articulation of the scapula with the spine, divides into three branches; one, which is but a filament, appears to be distributed to the articular capsule; a second, which is very flat, and from the sides of which a vast number of letter branches extend to the muscles of the skin, appears to take the place of the musculo-cutaneous; the third branch, which accompanies the muscles of the scapula under the skin, descends to the humerus, without producing any remarkable branches. At this place, however, it sends off several ramifications to the external muscles of the fore-arm. The trunk continues its direction forward, expands and loses itself under the skin, and may be followed as far as the hand; it may, perhaps, be regarded as supplying the place of the ulnar nerve.

The fifth pair of cervical nerves having, as we have shewn, allided in forming the brachial plexus, pales along the internal surface of the scapula; about the lower third of that bone it receives the seventh pair; the nerve then becomes thicker, but soon after divides into two branches; one, which is slender, pales into the groove, between the furca and the clavicle, and then spreads over the articular capsule of the humerus, after furnishing numerous filaments to the muscles which surround it; the nerve may be regarded as analogous to the articular in man. The trunk of the nerve, which evidently supplies the place of the median, upon reaching the articulation of the humerus with the scapula, transmits filaments to the adjoining muscles. On arriving at the palmar surface of the fore-arm, it divides into three portions, two of which are on the ulnar side, and sink deeply into the muscles; the third, which is much larger, follows the radial side of the fore-arm, and at the base of the thumb proceeds to the palm of the hand, and detaches filaments to each of the fingers.

The seventh cervical pair unites, as we have stated, to the sixth, at the posterior part of the scapula, to form the median and articular nerves. We have, therefore, no occasion to return to its description. The first dorsal pair is lost in the muscles of the shoulder, and is not continued throughout the arm.

The brachial plexus of the lizard differs a little from that of the tortoise; it is formed by two dorsal, and the two last cervical pairs: the first of the cervical furnishes only one of its branches to the plexus; the other going to the neck.
REPTILES.

In the frog, the nerves, which are to be distributed to the arm, proceed from a very thick cord, which comes from between the second and third vertebrae; this makes the largest nerve in the whole body; it is soon after joined by a filament from the succeeding pair, with which it intimately unites; this cord proceeds towards the axilla; it sends off a branch, which pales above the shoulder, and is left in the muscles of that part. The trunk continues its course to the arm, and very soon forms two principal branches, and besides these, it also sends some filaments to the extremities of the fore-arm, and the articular capsule of the head of the humerus.

Of these two nervous cords, one is directed forward upon the humerus, and represents the median nerve; it detaches some filaments to the muscles of the skin. Arrived at the fold of the fore-arm, the nerve plunges amongst the muscles, along with the tendon of the flexor radialis, which supplies the place of the biceps; it afterwards divides into two branches, placed one above the other; the mull flender is situated between the flexor muscles of the fingers; the larger upon the surrow, which indicates the union of the two bones of the fore-arm; they pafs under the ligaments of the carpus; having reached the palm, the superficial branch is lost in the skin, which covers that part, and the deep-seated is distributed to each of the fingers, nearly as in man. It also furnishes some filaments to the muscles of the hand.

The other cord represents the radial nerve; it puts round the humerus, and furnishes, in the first place, some branches to the extensor cubiti; continuing to defend round the humerus, it arrives before the articulation with the bones of the fore-arm; it is afterwards divided; one of the branches is lost under the skin, the other pales under the back of the hand, and terminates on the convexity of the fingers. From this description it will appear, that the nerves of the arm in frogs very much resemble those of the wing in birds.

In the salamander, the nerves of the arm are distributed as in the frog, but the brachial plexus is formed by two cervical, and two dorval pairs, if we may regard as dorval vertebrae, those which furnish rudiments of the ribs.

There are no brachial nerves in serpents.

Nerves of the hind Limbs.—In lizards, there is only a small nervous filament, which proceeds from the femoral nerve, and supplies the place of the obturator. The femoral nerve is itself formed of the two lateral branches, and supplies the bones of the pelvis to be distributed in the muscles of the anterior part of the thigh. The sciatic nerve is produced by the three pairs of nerves, which follow, and which also receive a filament from the lateral branch; the only cord they form proceeds along the inside of the thigh, subdividing in the muscles, and extending to the toes.

The distribution of the nerves in the abdominal member is nearly the same in the salamander; there are no differences, except in the manner in which the pelvis is formed. The femoral is produced by a single lumbar pair, which transmits a branch to the sciatic plexus, formed by the two succeeding pairs.

In the frog, three pairs of nerves enter into the composition of the femoral plexus, before which they run the whole length of the olfa illii, which are very long: when arrived at the thigh, the plexus sends off a nerve, which corresponds to the anterior femoral; it is distributed in radulated filaments to the front part of the thigh. The rest of the plexus proceeds into the pelvis, and forms a large cord, which pales to the posterior part of the thigh, and may be regarded as the femoral nerve. A great number of filaments are afterwards detached from it to the muscles: about the middle and posterior part it divides into two branches, which pass under the ham, and represent the two popliteal nerves, the external and internal: these are afterwards distributed to the foot of the posterior leg, nearly in the same manner as to the human foot.

Great Sympathetic Nerve.—There is no description of the distribution of this nerve in reptiles, except in the mud tortoise; in which animal it was dillected by Cuvier. It is only distinct in the interior of the back-shell; it has a distribution analogous to that of the cervical ganglion. The pneumo-galleric nerve, however, adheres so closely to it, that they cannot be separated; we did not perceive any filament on the neck, which could be regarded as the trunk of the nerve.

On the peritoneum, and on the bodies of the vertebrae, there appear very distinct nervous ganglia, which are manifestly produced by the great sympathetic.

The ganglia are exactly similar to those of birds. There are two superior and two inferior filaments, which pass over the transverse processes of the vertebrae, that is united to the back-shell; from the internal edge of each ganglion, a spinal nerve proceeds, which forms a plexus round each of the arteries produced by the aorta; it is also sent to aid in forming the pulmonary plexus.

This nerve may be very easily traced to the internal parts of the hind vertebrae of the tail.

Physiology of the Nervous System.—The obvious differences of structure between the warm-blooded animals and reptiles, in this system, the exceedingly small brain and large nerves of the latter, contrasted with the slender nerves and large cephalon of the former, lead us to expect no less striking differences in their economy, than those which we actually discover. Are we to explain by this difference the little influence that the brain exercises over the other functions, and the great individual and independent vitality, if we may use the expression, of the parts, which appear in so many instances in the amphibia? The severest injuries, which in man or the warm-blooded animals would excite a sympathetic disturbance of every function, highly dangerous, and in most cases fatal, are borne with little apparent suffering, and restored with facility. (See the facts adduced in the physiolog of the circulating system, to prove the tenacity of life in this class.) Can we explain in the same way the reproductive powers of this class? Blumenbach seems to consider the explanation sufficient. “The extraordinary strength,” says he, “of the reproductive power in several amphibia, and the astonishing facility with which the process is carried on, must be explained, if I mistake not, from the great magnitude of their nerves, and the diminutive proportion of their brain. The former parts are in consequence less dependent on the latter; hence the whole machine has less powers of motion and displays less sympathy; the mode of existence is more simple, and approaches more nearly to that of the vegetable world, than in the warm-blooded classes; but, on the contrary, the parts posses a greater individual independent vitality. Since, in consequence of this latter endowment, stimuli, which operate on one part, or one system, do not immediately affect the whole frame by sympathy, as in warm-blooded animals, we are enabled to explain the peculiar tenacity of life, which is displayed under various circumstances in this class; viz., frogs continue to jump about after their heart has been torn out; and tortoises have lived for months after the removal of the whole brain from the cranium. The long continued power of motion in parts which
which have been cut off from the body, as in the tail of the water newt, and in fragments of the blindworm, may be explained upon the same principles." Handbuch der Naturgeschichte, ed. 6. § 98. p. 221.

The close connection between the brain, heart, and lungs in warm-blooded animals, in consequence of which the cessation of action in one very speedily stops the others, and consequently brings on general death, has been fully explained in various articles of this Dictionary; viz. DEATH, HEART, LUNGS, NERVOUS SYSTEM.

Observations and experiments have not yet been sufficiently multiplied, to enable us to understand all the minutiae connected with this subject. But obvious phenomena, which we have already alluded to, show us a vast difference in this respect between mammals and reptiles. The interruption of respiration, which is fatal in two or three minutes in the human subject, does not stop the action of the heart and brain until after some hours in reptiles. The removal of the heart, or of all the blood from the circulating system, does not prevent the action of the brain, and thus prove fatal, until after some hours. And, lastly, the removal of the whole brain, or decapitation, which, by interrupting the action of the muscles employed in breathing, is almost suddenly fatal in warm-blooded animals, does not very greatly affect reptiles. At least, they only seem to die from inanition after the operation. Hence breathing cannot be under the immediate influence of the brain in these animals, for its interruption is fatal in a few hours. Le Gallois affirms that death follows much more quickly, when decapitation is effected below the occipital foramen, than above it, because in the latter case the part of the brain is left, which he has asserted to be necessary to respiration; viz. the origin of the eighth pair. (See his Expériences sur le Principe de la Vie, p. 42.) He does not, however, afford us the materials of drawing any accurate comparison, and he allows, that when decapitation is performed in the first vertebra of the neck, the animal survives the operation much longer than it can survive the interruption of respiration. He says, that salamanders live three or four months, and seem to die only from inanition, when decapitation has been performed above the foramen magnum.

To the small influence of the brain upon the nerves, Blumenbach is inclined to refer, in some degree, the low temperature of reptiles. Although he considers it now as certain, that the lungs are the source, and the oxygeneous part of the atmosphere the material, whence the heat of living animals is derived, he ascribes to the action of the nervous system a considerable influence in exciting and supporting the evolution of animal heat. Specimen, p. 22.

The brain seems to exercise as complete and prompt a dominion over the voluntary muscles in these, as in warm-blooded animals. Their motions are equally lively, and the force of contraction does not seem at all inferior.

We know of very few facts that throw light on the intellectual faculties of reptiles. Yet there is sufficient evidence of their poising memory and a capability of instruction. The frog and tree-frog can be taught to seek food from the hand; and acquire a flight attachment to their matterer. (Daudin, v. 8. p. 88.) The rattlesnake, the hooed-snake (col. naia), the boa, and the colourer matrix in Europe (at least commonly in Germany), are taught to dance, and exhibit various motions at command. (Kampfer, Aenimentes Exoticæ, p. 565.) In the historical accounts of the religion of ancient Egypt, we learn that the priests of Memphis bred up crocodiles in their temples, and succeeded so far in depriving them of their ferocity, as to employ them in religious ceremonies. Besides the accounts of Herodotus, Strabo, &c. on this subject, we have the authority of a respectable eye-witness concerning very surprising successes in taming a crocodile; see J. Graves's Miscellaneous Works, p. 525: and for the like successes in the common toad, see Blumenbach, Specimen, &c. p. 27. We know not on what grounds the serpent gained his character for wisdom, intelligence, forefright; why he was selected as an emblem for the gods of prudence, or chosen by the Epidurians as the representative of Efculapius.

Of the artificial instincts, which are so frequent in the mammalia and birds, not even a trace is to be met with in the whole class of reptiles.

There is no regular sleep, or intermission of activity, in the organs of sensation and voluntary motion, recurring at stated intervals, in reptiles: unless, perhaps, in the turtles, of whom it has been reported by lomme.

Winter sleep, on the contrary, seems to prevail through the whole class. Herodotus observed this of the Nilotic crocodile, which, he says, pales four months of the winter without eating. Catesby has remarked it of the crocodile of Carolina; and Lacordaire reports, that those of Louisiana take themselves to the muddy marshes when the cold comes on, and remain so torpid, that they may be cut without shedding signs of sensibility. But the warm days of winter re-animate them. Journal de Physique 1782, t. 20. p. 333.

No animals, except insects, are so sensible to heat as reptiles. The warmth of the sun seems to give them new life: as it incrases, their vivacity and agility are augmented. Cold, on the contrary, benumbs them, and would be actually destructive, if they did not withdraw from its pernicious influence. They retire into the crevices of walls or rocks, the hollows of old trees, holes in the earth, or the bottoms of ponds, &c. to await the return of the genial favour. The phenomena of this winter sleep are the same in reptiles, as in warm-blooded animals. The suspension of the actions of the nervous system is followed by an universal torpor of the other functions. As the brain and the organs of voluntary motion become inactive, the circulation languishes, respiration is barely continued, and vital temperature is reduced to the lowest degree. Spallanzani found that when the temperature was reduced to 16° below zero, the heart of a serpent beat only twice in a minute, and respiration was susbended. (Rapports de l'air avec les etres organises, t. i. p. 230.) In a temperature of 5°, the heart soon recovered its action, and beat ten or twelve times in a minute: in still higher temperatures, the pulsations were 28 or 30 per minute. (Ibid.) In the lethargic state, these animals changed the air very little. Frogs became equally lethargic in reduced temperatures; the heart beating very slowly, and the air being slightly changed. Ibid. p. 470.

Cold appears to be the immediate cause of this winter torpor: hence both reptiles and warm-blooded animals may be preferred in situations artificially warmed throughout the period of their winter sleep, without becoming torpid: but if the torpidity has commenced, they cannot be artificially awakened without danger. It is well known that the salamander, the water-newt, the tree-frog, and the alpine marmot, may be kept awake through the winter in a room warmed by a fire. Gleditsch witnessed the fatal effects of violent excitement in the winter sleep in the frog (Mem. de l'Acad. de Berlin, 1762, p. 17.): it has been observed also in the marmot, the dormouse, and the swallow.

It may be remarked further, of warm-blooded animals, as well as reptiles, that some species assemble together, and are gregarious in their torpidity, while others are solitary. The
The bat, swallow, frog, and salamander, exemplify the former.

Organs of the Senses.

Organ of Vision.—Reptiles, like all vertebral animals, have two movable eyes occupying the cavities of the head called orbits, and poofleeting in their structure the same essential parts as in man. Their structure has not been much investigated: there is some information in a memoir of Petit, in the Acad. des Sciences, 1737; and an account of the tortoises in Caledon.

They occupy the sides of the head, except in the crocodile, where they are placed above, between the cranium and jaw.

In the proteus they are covered by the integuments, and thus concealed until the latter are removed; this animal, therefore, like the zemati or mus typhlus among mammals, and consequently blind. All other reptiles have the sense of sight, and some pollicis even large and prominent eyes.

The tortoise, has, at the anterior part of the sclerotic, similar ollaceous lamina to those of birds. They are inclosed in that membrane, without being continued into its substance, and may be easily separated from it. There are similar laminae in the camelus and several other lizards, but they do not form the anterior disk; they merely surround the lateral part. Daunin has found this structure in the common iguana and the great tupinambis of America.

In the tortoise," says Cuvier, "the ciliary processes project so very little, that we could scarcely recognize them, were it not for the elegant impression they leave on the vitreous body; but in the crocodile these processes are very beautiful, and very conspicuous; they are each terminated by a nearly right angle. I have observed these processes in the form of elongated threads in a large foreign tree-frog; there are also fuch, though not distinct, in the toad. I have not observed them in the common lizards, nor in the serpents.

The iris of reptiles resembles that of fishes in its golden colours; sometimes it is red or brownish. The veins are more vivid than in fish: they form a beautiful network on the iris of the crocodile.

The figure of the pupil varies; in the crocodile it is vertically oblong, as in the cat: in frogs rhomboidal. The tortoise, camelus, and common lizards, have it round; the gecko rhomboidal.

The optic nerve in all reptiles passes through the membranes of the eye directly, and by a round hole, as in quadrupeds; it forms internally a small tubercle, from the edges of which the retina proceeds.

The ciliary is more spherical in the turtle and frog, than in the mammalia: the ratio of its axis to its diameter is in the former 7 to 9, in the latter 7 to 8; these proportions are nearly those which it has in fishes.

Muscles of the Globe.—There are fixed in the tortoise, disposed like those of fishes: and besides, four small ones, which closely embrace the optic nerve, and spread over the convex portion of the sclerotic, after being interrupted by the muscle of the third eye-lid. The same structure is found in the crocodile.

In frogs and toads there is a great funnel-like muscle, which embraces the optic nerve, and is divided into three portions; its inferior fibres advance more towards the edge of the eye than the superior. There is only a single straight muscle on the inferior part, and consequently only a single depressor. There is one very short oblique muscle attached to the anterior part of the orbit, and inserted directly into the adjoining part of the globe. The muscle of the third eye-lid is so close to the inferior part of the suprarenal muscle, that it becomes stretched when the latter swells; which accounts for the elevation of the third eye-lid when the eye is lowered.

Blumenbach remarks, that no influence of the leucanthropic formation, or deficiency of the colouring matter of the choroid coat and iris, has ever been seen in reptiles; although it is so common in the two warm-blooded classes, and in the human subject. Specimen, p. 27.

Many reptiles shun the light, lying hid by day, and coming out to feed their food at night. Others appear very fond of light, whether that of the sun, as the green lizard and green frog; or of artificial flame, like that of a candle, as the tree-frog.

It seems peculiar to the camelus to have the power of moving the two eyes at the same time in different directions, so that he is not necessarily obliged, like other animals, to bring the two optic axes into the same direction.

Eye-lids.—Reptiles vary singularly with respect to the number and disposition of their eye-lids: serpents have none; crocodiles and tortoises have three, and the third is vertical, as in birds: there are also three in frogs, but the third is horizontal like the other two. The third eye-lid is the part called membrana nictitans.

The crocodiles are remarkable for having none in the upper eye-lid; in general there is only a single bit near the anterior angle; but in the crocodilus palpebrofus the whole eye-lid is occupied by a plate divided into three pieces. See Cuvier in Annales du Museum, v. 10.

The horizontal eye-lids of crocodiles and tortoises close exactly; they have each an enlargement at their edge, but no cilis; the third eye-lid is semi-transparent; it moves from behind forwards, and may cover the whole eye; it has only one muscle, which is analogous to the pyramidalis of birds: it is fixed in the same manner to the posterior part of the globe inferiorly. After having turned round the optic nerve, it repasses under the eye to lend its tendon to that eye-lid; but there are neither the mufculus quadratus, nor its sheath, as in birds.

In the other lizards there are also very remarkable varieties. The common lizards have, for eye-lids, a kind of circular veil extended before the orbit, and perforated by a horizontal fissure, which is capable of being closed by a sphincter muscle, and opened by a levator and depressor; its inferior part has a smooth round cartilaginous disk, as in birds; there is, besides, a small internal eye-lid, but it has no proper muscle; it is entirely wanting in the camelus, in which animal also the slit of the eye-lids is so small, that the pupil can scarcely be observed through it. The gecko has no moveable eye-lid; its eye is protected by a light margin of the skin, as in serpents. A similar disposition seems to prevail in the seinks.

Blumenbach has examined more particularly the structure of the part which covers the front of the eye in serpents. "These animals," he observes, "are commonly said to throw off the external layer of the cornea with the veil of their epidermis when they change their skin. On examining this matter more minutely in the coluber natrix, I find that this part of the epidermis, which is perfectly transparent and stretched before the eye, is not actually connected to the cornea, but separated from it by a small quantity of water. It is immovable, so that the globe moves behind it, as behind a window." Specimen, loc. p. 26.

In frogs and toads the superior eye-lid is only a projection of the skin, and almost immovable; the inferior is more moveable, and has a shelf edge; but the third, which moves from below upward, is most employed by these animals:
mals: it is very transparent; it has on: muscle situated tranvversely, behind the globe, which forms a thin tendon on each side of the eye, to be inserted into the free edge of the third eye-lid.

The falamanders have only two eye-lids, which are horizontal, fleshy, and little movable; it appears that they may entirely cover the eye.

Reptiles vary as much with respect to their lachrymal glands as to their eye-lids.

The sea tortoife have a very confiderable gland at the posterior angle; it is reddish, granulated, divided into lobes, and extends under the arch which covers the temple.

In the fresh-water tortoife we find two small blackish glands, which also exist in toads and frogs; but their excretery ducts have not yet been accurately observed.

Serpents, like fishes, have no gland in the eye; they have, however, a peculiar structure near the eye, the office of which is not very obvious; the following account of it is given by Sir Everard Hume.

"An oval cavity is placed at the inner angle of the eye in some reptiles, the opening into which is within the inner angle of the eye-lid, and directed towards the cornea. In this opening there are two rows of projections, which appear to form an orifice capable of dilatation and contraction. These cavities are lined with cuticle, which is filled with the rest of that integument. From the situation of these oval cavities, they must be considered as reservoirs for a fluid, which is occasionally to be spread over the cornea; and they may be filled by the falling of the dew, or the moisture shaken off from the grass, through which the snake pales."—Phil. Trans. 1804, p. 75, with a figure.

Organ of Hearing.—Such an organ is possessed by all reptiles. Its construction varies considerably in the different orders and genera: these varieties affecting the external or accessory parts, as the tympanum, officula, &c. more than the essential portion of the organ, its membranous labyrinth, on which the auditory nerve is expanded. No reptile has any external ear; and the crocodile affords the only example of a kind of external meatus. Frogs, tefludines, and most of the lizard kind, have a tympanum and Eustachian tube; but these parts are wanting in the falamander, and most of the serpents. The ear of the turtle, tortoife, frog, lizards, and serpents, are described and delineated by Brunelli in the Commen. Influt. Bonon. v. 7. Comparetti has exhibited figures of the same subjects in his Observationes Anatomiae de auro interna comparata, Patav. 1789, 4to. Scarpa has given most beautiful engravings of the ear in the turtle, crocodile, green lizard, falamander, viper, and blind-worm, in his Disquisiciones de Auditu et Olfactu.

The Labyrinth.—The membranous Labyrinth of the ear, in reptiles, is, in general, composed, as in fishes, of three canals and a fac; but there are some species which have an additional part.

In the falamanders, whose ear, like that of fishes, consists of the labyrinth only, the three canals are situated above the fac; they are depreffed superiorly, and form together a triangle which is almost equilateral; each has its ampulla, and the fac contains a body of the confidence of itch, as in the rays and tharks.

Frogs and toads differ very little from falamanders, with respect to the membranous Labyrinth; they have the same parts in the same position, and their fac also contains one amylaceous substance: their three canals form nearly a complete circle, by their junction with the fac.

Crocodiles and lizards have also three canals, but they are larger, and each approaches nearer to a perfect circular form: the fac is situated proportionally more within the head; its membranous parietes are furnished with several blood-vessels, which are particularly conspicuous in the crocodile. The solid parts it contains are three in number, and they are smaller, and even lofter, than those of the chondropterygious fishes. Lately, their labyrinth is rendered remarkable by having an additional part to that we have already described: this is the first velum of the cochlea; it is the production of the fac, in the form of a cone lightly arched; it is about the face of the cranium, towards the middle line, and is divided into compartments, or rather canals, by a double cartilaginous septum; one apartment communicates with the fac; the other, which is a continuation of the first, reflected on itself, terminates at a very small hole, which is closed by a membrane that separates it from the cavity of the tympanum.

This organ is precisely similar to that which is found in all birds. Comparetti was the first who described it in lizards. It is very large in the crocodile, and may be easily prepared from young subjects.

It is more difficult to find this in the camelion and the marbled lizard. A velum of it may be observed in the serpents. The production which may be compared to this trumpet, or rudiment of the cochlea in the tortoise, is very similar to the part we named the fac, strictly so called, in fishes; and this resemblance consists not only in its form, but in the small amylaceous substances it contains: this seems to leave no doubt of the analogy between the fac and the cochlea in man, or of that between the part we call the sinus, and the vestibule. We must, therefore, judge of the perfection of the labyrinths of these different ears, by the degree in which the cochlea is developed.

Tortoises and serpents have the semi-circular canals, like other reptiles. In the tortoise they are proportionally very short.

The efferve labyrinth of reptiles resembles that of the chondropterygii; that is to say, it envelopes the whole of the membranous labyrinth, but in a manner more or less closely.

In the tortoise, the septum, which separates the vestibule from the cranium, is not ossified; it remains partly membranous. The membranous semi-circular canals are much smaller than the bony cavities containing them.

In the crocodile and other lizards, the efferve labyrinth closely embraces the membranous, or completely covers it by a thin and hard lamina.

Cavity of the Tympanum and its Appendages.—Among reptiles, the falamander has the labyrinth completely inclosed within the cranium, and deprived of all external communication, as in the fishes that have fixed branchiae. But the other genera of the same order have all a fenestra, called oval, supporting an efferve plate, analogous to the bone called flapes in man. The lizard genus has another aperture, closed only by a membrane, and called fenestra rotunda.

The barrel, or cavity of the tympanum, cannot be said to exist in serpents: the flake of the plate, filling the fenestra ovalis, is surrounded by the flesh, and its extremity touches the skin, near the articulation of the lower jaw.

In toads and frogs, the whole of its posterior part is membranous; it communicates immediately with the back of the mouth, by a large hole, which may be seen on opening the mouth of the animal. It is very small, and almost entirely membranous in the pipe, in which the labyrinth is connected with the fenestra ovalis by only a very long canal.

It is also membranous posteriorly and inferiorly in the common lizards, and in the camelion: it communicates with the bottom of the palate by a short wide canal.
The barrel of the crocodile may be divided into two parts: one external, which is very wide, and cloths on the outside by the membrane of the tympanum, and the skin, but entirely surrounded by the bones; and one internal, which is separated from the former by a contraction, and which communicates with the two fenestra, and with some cavities analogous to the mastoid cells of man, but much larger. One of these cavities is placed between the semi-circular canals, and the other is directed backward and outward. The barrel is situated towards the superior part of the cranium.

The cavity of the tympanum in the tortoise is placed more laterally: it is not so wide externally, and the contraction, which separates the external part from the internal, is less conspicuous, because the projection, which it forms, is rounded, and not acute, as in the crocodile. The internal portion is prolonged backward, in the form of a large round cell; in the bottom of the cavity, opposite to the membrane of the tympanum, there is a narrow canal, in which the officulum is sunk, and which communicates with the fenestra ovalis. The Eulachian tube is a canal of a moderate length, which proceeds downward, and a little backward, and terminates in the palate, behind and within the articulation of the jaw.

The Membrana Tympani and its offses Frame.—Animals which want the barrel of the tympanum, as fishes, salamanders, &c. have no membrana tympani. That membrane is also wanting in several reptiles that have a barrel, as the chameleon; the skin pales over the external aperture of their ear, without undergoing any change, either in its thickens or its structure; and the exilence of the organ of hearing can only be ascertained by deflection. On removing the skin, and some portions of the musculcs, we find, in some species, and particularly in the flow-worm (anguis fragilis), a kind of membranous expansion.

In the turtle, the large external aperture of the barrel is closed by a very thick cartilaginous plate, which is itself covered by a scaly skin, perfectly similar to that of the reft of the head.

In frogs and toads, the membrana tympani is on a level with the head, and the skin that covers it being thinner, it is rendered perceptible by an oval spot, which is smoother than the rest of the head, and usually of a particular colour.

In common lizards, the membrana tympani is also level with the head, but very thin, smooth, and transparent; and at that part the skin becomes as smooth and fine as the cornea of the eye.

In the crocodile, it is of the same nature, but more fink into the head, and covered by two fleshy lips, which supply the place of the external ear.

In lizards, though the point of the cone formed by the membrana tympani projects less than in birds, it is also directed outward, as in them. The membrane is nearly plane in frogs and tortoises.

The membrana tympani is on a level with the adjacent parts of the head, and consequently is nearly vertical in all animals in which its situation is superficial; but in those in which it has it fink, its inclination, whether considered with relation to the head itself, or to the external meatus, varies considerably.

It inclines obliquely upward, and to one side, in the crocodile.

The offese frame, to which the membrane is attached, is not marked by any prominent edge: it is interrupted posteriorly. Its great axis is vertical in the tortoise and the common lizards, and its anterior arch is more convex.

In the crocodile, it is a regular oval, the great axis of which is directed obliquely backward.

Officina Auditi.—The frog and the toad have two officula in the ear: one supplies the place of the malacous and the incus; it is attached to the membrana tympani by a slender branch, which forms an acute angle with the part that passes into the barrel: that part has the shape of a club; its internal extremity is the thickest, and articulates by a double surface to the second officulum, which corresponds to the flapes. The latter has a semi-elliptic form, and is applied to the fenestra ovalis by its plane surface: both these bodies, which are officous in other animals, are cartilaginous in the frog and toad.

Lizards and tortoises resemble birds, in having a single officulum with a thin hard flalk, and an oval or triangular plate (colurnella). It is attached to the membrane of the tympanum in lizards, and particularly in the crocodile, by a cartilaginous branch; but in the tortoise, its outward extremity is directly implanted in the cartilaginous mafs, which corresponds to the membrana tympani itself.

In the crocodile, the plate is an elongated ellipse, the great axis of which is situated longitudinally.

In the tortoise, the bone is enlarged in the form of a trumpet, and is applied to the fenestra by a regularly oval and concave surface.

Serpernts have an officulum, but no membrana tympani. Its external extremity touches the bone that supports the lower jaw: it is surrounded by the flalk, and is applied to the fenestra by a concave plate, the edges of which are irregular.

In the chameleon, the plate also represents the wide end of a trumpet; its flalk becomes cartilaginous, and is lost in the flesh.

The fenestra vestibularis of salamanders is closed only by a small cartilaginous operculum, which has no flalk, and is concealed by the flesh.

Muscles of the Officula.—Little is known about these in reptiles. It appears that serpernts, chameleons, and salamanders, are entirely deftitute of them, and that they are very inditinct in the teltulines. Comparetti has made some reeearches on this subject, but with no any clear or satisfactory results.

External Meatus, &c. — All parts of the ear, external to the membrana tympani, are wanting in reptiles. In the crocodile only is there any appearance of an external meatus, the skin forming a kind of lip or operculum above the membrana tympani: the latter is entirely concealed, except when this covering is removed. This must be the part mentioned by Herodotus as the external ear of the crocodile, to which the Egyptians attached rings.

Distribution of the Nerves. — In reptiles and fishes, but especially in the latter, we can observe, still better than in warm-blooded animals, the confanacy with which the branches of the auditory nerve proceed to the ampullse of the semi-circular canals. In reptiles it divides before it pales into the offese labyrinth, which it enters by several holes.

Organ of Touch and Integuments. — It does not seem clear that reptiles possess the sense of touch, that is, the power of recognizing, by any parts of their skin, the figure, hardnefs, or foftness, roughnefs or smoothnefs, of bodies. To the impressions of heat and cold, there is no doubt of their being fenible.

In no clafs do we observe so much variety in the nature of the integuments: the skin is different in almost every species. In many the structure is fo singular, that if we judged by this alone, we should form them into separate classes. What a contrall
REPTILES.

a contrast does the shell or bony cape of the tortoise form to the smooth skin of the tree-frog; how different are the annulated skin of the amphibia, the feamy covering of other serpents, and the integuments of the toad, rough and tuberculated.

Epidermis.—When we examine what parts of the body are covered with skin in the tortoise and turtle, we can recognize it at first sight only on the head, neck, limbs, and tail; the other parts exhibit to us merely an offaline box or exterior skeleton, including the body. But, if we examine more attentively, we shall find this skeleton covered by an extremely thin epidermis, which may be detached in transparent lamina, similar, in figure, to the horny plates, and varying in its constitution in the different species. It resembles a smooth and transparent parchment in the trench centra of Bofe (Daubin, t. ii. p. 153.) The epidermis covering other parts of these animals is a smooth thin layer, not essentially different from that of the frog and falamander, and detached in shreds several times in the year.

The epidermis of the falamander and frog is a soft thin membrane, covered with a mucous secretion; which answers a particular use in some kinds, as the rana calamita, enabled by its affluence to adhere to the smoothest bodies. This secretion, a simple and innocent mucus, is very different from another, which is found in many reptiles, possessing extremely powerful secrete properties; the latter is described under the head of peculiar secretions, in the latter part of this article.

The thin transparent cuticle of the frog, falamander, and newt, is very frequently changed, being detached in large portions. Blumenbach states that this change takes place in the summer months at least once a week. Specimen, p. 26.

The epidermis of lizards covers all their scales, and is detached in small dried portions, or in larger pieces. It forms also a thin continuous stratum in serpents, enveloping the whole surface, and spread over every scale and plate. It is detached annually, at a certain season, in a single piece, like a sheath. The ealt skin (flough, exuvia) is turned inside out, so that its exterior surface is the part previously in contact with the true skin. The animal escapes at the mouth, which is the only opening by which it can get out of the sheath. The part corresponding to the jaws is first detached, and turned back, so as to expose to us the snout, covered by a new skin. As the head passes out of its sheath, the latter goes backwards in the same proportion towards the tail, and is thus at last completely inverted. The transparent piece corresponding to the eye (i.e. an account of the eye) has its concavity backwards.

Ret expansive.—In all reptiles there is, under the epidermis, a mucous tissue, of which the colours vary very much. In the teudines, for instance, the skin which covers the feet and neck is not only differently coloured by the rete mucous, but the symmetrical spots, which we remark on the scales, are produced by the same substance. We discover by dissection. The thickness of the skin greatly diminishes as it approaches the breast-plate and the back-shell. It passes below the scales which cover those parts, and which are, themselves, covered by the epidermis and rete mucous; the variegated colours of which form the spots which we observe through the transparent parts. A rete mucous is equally found in the lizards, serpents, falamanders, frogs, &c. It is variously coloured in each species; and it presents often the most beautiful and charming tints. We find in this class almost all the known shades, even blue, bright red, orange, pearly, gold and silver.

Reptiles are remarkable for the changes of colour which they exhibit, according to the season or climate in which they live, or to temporary affections of various kinds. In this way the camelion has been most celebrated, and has afforded a very trite subject to poets and moralists. The changes are, in reality, very remarkable, and are particularly noticeable when the animal passes from the shade into the sun, or vice versa, when it is touched, or any thing placed round him, &c.

This property, however, is, by no means confined to the camelion. Brown long ago observed it in several species of lizards (Natural History of Jamaica, p. 462.) and it occurs also in reptiles of these climates. The green iguana, the agame, and the green lizard, are sometimes green, sometimes brownish in colour. The former is particularly observed in the copulating season; and is lost in the cold and rainy parts of the year. The common tree-frog of Europe exhibits various tints from the bright yellow emerald green to grey, blueish, violet, or brown. Other frogs and falamanders change their colours also, particularly about the copulating season.

The Papille.—Reptiles resemble birds with respect to the papille; we find none except under their feet; they are very thick, and projecting in several species of lizards, and particularly in the camelion. We cannot distinguish them in the sea tortoise, which have the feet in the form of fins. They do not exist in serpents, or at least not have the form of papillae.

Cutis.—Reptiles which have the body unfurnished with scales, or only partly covered by them, have a very compact and dense skin. We have an example in the tortoises, falamanders, frogs, and toads. In the two last genera, in particular, the cutis is rendered remarkable by not adhering to the body in all its points, as in the other animals, in which it is intimately united with the cellular substance. In those genera, however, it adheres only at the edges of the mouth, in the middle line of the body, the arm-pits and the groins. In all the other parts of the body it is free within the cutis, which incloses it like a girdle.

In lizards and serpents we find, as in fishes, a strong cutis under the scales, even adhering very closely to the muscles.

Cutaneous Muscles.—There is no cutaneous muscle on the trunk of frogs, because the skin does not adhere to that part of their body. Under the throat, however, we find some fibres, which are attached to the margin of the jaw, and inserted into the cellular substance that unites the skin to the origin of the breast.

In tortoises, the cutaneous collis is very visible, and seems to be formed of two parts; it is extended from within the concavity of the lower jaw to the bottom of the neck, at the anterior part of the breast-plate. A middle cellular line unites it with the muscle of the other side; it takes its origin from the transverse processes of the cervical vertebra. Being spread over all the muscles of the neck, it serves as a girdle to them; in its lower part it is perforated by the fermataleus, which, as we have already observed, arises from the lateral parts of the breast-plate.

Secretions of the Skin.—Among reptiles, those that have scales, as snakes and lizards, have the skin almost dry; but those with naked skins, as falamanders and frogs, have the surface of the body always copiously lubricated with viscid matter.

Toads and falamanders have even the power of augmenting the secretion of this liquor, and of making it exude, like a dew, through the pores of the skin.

The cutaneous glands are more visible in cold-blooded animals, than in the mammals.
REPTILES.

The salamanders have several glands ranged along the back, which form elevations or lumps on the skin. The toads have them scattered irregularly on the whole surface of the body; we observe, in particular, two which are very large, behind their ears; these glands produce an acrid humour, which is a poison to very small animals. In lizards, we observe a very regular row of small pores, which also yield a vicious humour.

Absorption of water by the skin of the frog.—Tawфон found that the frog, and tree-frog, when placed on a moistened paper, could absorb the moisture so rapidly, as nearly to double their weight in two hours, under certain circumstances. He states that they do not drink, but take in all their fluid in this way. (See his tracts and observations in natural history.) Daudin has verified the observation. He kept two frogs without any fluid for seven days, and then placed them in a bottle on moistened sheets of paper. In two hours they had nearly doubled their weight. Hill. Nat. des Reptiles, tom. i. p. 115.

Fingers.—The number of the fingers, and their flexibility, vary more in reptiles than in all the other classes. Common lizards have, in general, five fingers, of different lengths, well calculated to embrace objects in every direction. Some, as the crocodiles, have them palmented, at least in the posterior feet. Others, as the gekko, have them invected inferiorly with imbricated scales.

The camelieon has them united by the skin, as far as the nails, in two parts, which form the forceps. The skin of their inferior surface is furnished with febile papillae. The long lizards, called ceps and chalceids, have only three very small toes. The salamanders and frogs have them naked and definite of nails. In tree-frogs, the extremity of the toes is enlarged into a fpongy disk, capable of adhering with force to bodies. In toadlets, the toes are palmented. Lastly, the serpents are completely deprived of feet and toes.

The long separate toes of the batrachian order, and of several lizards, seem well enough calculated to serve as organs of touch; they might be applied to objects, and would surround them in various ways. They seem, however, to be employed merely as instruments of motion. It has been said of serpents (observes Blumenbach), with more ingenuity than truth, that their whole body is a hand; by which they gain just notions of the tangible properties of bodies. There is much more foundation for flating that the sense of touch, which is here meant, does not exist in any of the amphibia.” System of Comparative Anatomy, p. 319.

Among the reptiles the scales vary greatly, according to the genera. In tortoises they are plates of a horny substance, which are very hard and dense in the greater number. But in the turtle and crocuses, and several others, they are soft and flexible: sometimes these scales are imbricated, as in the hawk’s-bill turtle; and they are smooth, or channelled longitudinally; at others they form compartments of different figures: in the latter case they are more or less convex, and surrounded with furrows, or concentric channels, in the midst of which are points, which are either sebaceous, elevated, or blunt, as in the species named geometrica, greca, &c.

In the crocodile the scales are bony, arranged in transverse bands, and situated, in respect to each other, like the stones of a pavement. In the other lizards and serpents they consist of horny substance, and present almost every possible variety of form and arrangement.

Organ of Smelling.—This is left completely developed in the amphibians than in the two warm-blooded classes of vertebral animals. The sense of smelling is the most imperfect of the senses in this class, says Daudin, if we may judge by the structure of the nostrils. Reptiles do not seem to employ their snout in discovering or selecting their food, or for any of the purposes to which the faculty is subservient in other animals.

We find, however, in the whole class, nasal cavities opening on the snout in front, and on the palate behind, lined with a vascular pittutary membrane, on which olfactory and nasal nerves are distributed.

There are also different projecting laminae within the nose; but they consist of folds of the internal membrane, and are not lined with fleshy parts. The tortoise has three laminae, which divide the nasal cavity into several fossæ. The middle one corresponds to the external aperture of the nostrils; between it and the next there is an oblique canal, which leads to the posterior nares. We find only some tubercles in frogs, and other small species. It does not appear that any researches have been made respecting the parts in the crocodiles.

The olfactory nerve differs in reptiles little from that of birds, as to its origin and course; it differs less in its distribution, since it also divides, according to Scarpa, upon the septum, and the membranous fold corresponding to the superior turbinate bone, without proceeding farther.

The external nares of reptiles, more or less approximated, and susceptible of contraction and dilatation, are usually furnished with only some fleshy flaps, which dilate or contract their entrance. This is observable in the greater number of lizards, which differ from each other only as to the position of their external nares. They are cloeset to each other in the crocodiles. The tupinambis, the chelions, and the camels, have them more removed, and situated more laterally. In the salamanders they are exceedingly small. In frogs we observe a small tube, the motion of which is very apparent, because it is extremely useful in respiration, as we have already shewn. The tortoises have also two very small approximated nostrils. In the matamata, and one or two other species, they are situated at the end of a short cartilaginous proboscis. The external nase is also rather elongated in some serpents; for example, in the viper ammodytes, and the cobler naica. In the reptiles of this order there are small lateral nares, capable of flight extension. In the rattle-fake, and some others, there is a small blind hole, near the nase, on each side; we have described it under the head of peculiar organs. See Scarpa de Auditi et Olfacto, for a description and figures of the nase in the turtle and viper.

The Organ of Taste.—All reptiles possess a tongue, but whether they have the sense of taste is not so clear. As they all swallow their prey whole, there seems to be little room for the exercise of taste. We have already spoken of the tongue, in the account of the salivary glands; and have entered further into a consideration of its mechanism and moving power, in our description of the organs of mastication and deglutition.

Substance of the Tongue.—Reptiles vary greatly with respect to the tongue, as well as in many other circumstances. The tongue of toads and frogs is entirely fleshy, attached to the lower jaw, and, in a state of repose, inflected in the mouth.

In salamanders, it is attached as far as the point, which is not moveable, and the whole tongue is only free on its lateral parts. Crocodiles have it attached to the lower jaw, by both the edges and the point; and authors long supposed that this animal had no tongue. It is entirely fleshy in both these genera.

The chelions and the iguanas have a fleshy tongue, which poises nearly the same mobility as that of the mammalia.
The feinks and geckos differ only in having the tongue notched at the extremity; and in that respect it resembles the tongue of the bow-worms, to which, in general, the feinks are very much allied.

In common lizards, the tupinambis, or monitor, &c., the tongue is singularly extendible; it terminates in two long flexible points, though semi-cartilaginous; it completely rellies that of serpents, if we except the bow-worms and the amphibians, which cannot elongate their tongue, but which have it flat, and only eorked at the extremity.

The camelion has a cylindrical tongue, which may be considerably elongated by a mechanism analogous to that which takes place in wood-peckers.

**Structure of its Surface.**—The tongue of the tortoise is furnished superiormy with long, soft, close, conic papilk, which give it the appearance of velvet.

In the crocodile they are very short, and represent rather fleft rupe or papillae. They form, on the contrary, a very distinctly villous surface in the iguanas and the felions. The tongue of the camelion is furnished with deep, close, and very regular transverse rupe; in the lizards, with extendible and folded tongues; and in the serpents, that organ is singularly smooth, and as it were hoary towards its points.

The falamanders have, like the iguanas, a fine villous surface to the tongue; but in the frogs and toads the surface is perfectly smooth to the eye, and always mucous.

No reptile has two kinds of papilla, nor glands with a calyx.

**Peculiar Organs and Secretions.**—Many amphibians produce singular and specific odours, particularly when irritated. In the newt the smell has been compared to that of chopped parsley; in toads to garlic; in the crocodile there is a very strong smell of muck; and several tortoises have this muck-like smell. A singularly fetid odour is produced by the rattle-snake, when angry. May we suppose that this is a defence against hostile attacks, in the falamanders and water newts, as it seems to be in the viverre, and some frogs?

It may probably serve in spring, as Blumenbach suggests, as a means of venereal excitement. For if, after handling female toads for some time, the hand is plunged into water, where there are male toads, they flock instantly to the spot, and closely embrace the fingers. Specimen, p. 29.

The notion that this odour is employed by the rattle-snake to fullocate, fascinate, or in any way whatsoever, to act on the animals which form its prey, is entirely ungrounded, as we have already explained.

There are generally manifest organs for the secretion of the substances in which these properties reside. Small granulated tuberules are seen under the thighs of the lizards, the chalices, and the marbled iguana of Surinam, and near the anus of the amphibians, producing, particularly in the coupling season, a fluid, and smelling like dry hay.

**Musk Gland of the Crocodile.**—It lies under the skin of the lower jaw, on each side, about its middle. It is a small gland, of a homogeneous whitish tiffue, and covered by a tendinous sheath. It secretes an unctuous blackish-grey fluid, smelling most strongly of muck, and collected in a small bag, which opens externally by a large orifice.

**Anal Gland.**—It has also been observed in the crocodile and alligator, as well as in several serpents. They may be seen of considerable size in female colubres, under the tail behind the cloaca, in the part occupied by the poees of the males. They contain a thin yellow substance. Typhon has described them in the rattlesnake. Other snakes have been described as producing powerfully fetid odours from the mouth.

**Poisonous and Acid Secretions.**—There is a striking difference in this respect between warm-blooded animals and reptiles; none of the former produce any thing poisonous, unless we should make an exception concerning the liver of the urus artos, which is described by Ger. de Veer, one of the unfortunate sufferers, to have been nearly fatal when employed as food by Heemskerck and his companions, compelled to winter in Nova Zembla. Blumenbach's Specimen, p. 30.

Besides the terrible poison with which so many serpents are armed, already described in our account of the teeth, there are several more or less actively hurtful secretions in this class.

The glands or crypts under the skin, forming the cutaneous eminences in the falamander and toad, produce an irritating fluid, which they seem to have the power of excreting at pleasure. Blumenbach describes the acrimony of this fluid in the rana bombina, from his own experience of its effects. Having cut his hand while handling some of these animals, and applied it to his mouth to suck the wound, he found a caustic heat suddenly pervade the tongue and fauces, like what is produced by chewing the bark of the laurel; and it continued for several hours. P. 24.

It seems to be an analogous fluid in the falamander, by means of which this most innocent little animal, so unjustly deemed venomous, can extinguish a few coals when placed in them. But the contortions of the body sufficiently attest the pain produced by this cruel experiment, which is soon fatal, if prolonged. The fabulous notion of the ancients, that this little reptile can live in fire, is well known; and Benvenuto Cellini has ventured to affirm the truth of it, on the faith of his own experiments. See his Life.

The notion of the falamander being able to live in fire is the more extraordinary, when we contrive it with the fact, that it has been found in cakes of ice, and after remaining frozen for some days, recovered. So that it can actually survive congeulation.

Barton of Philadelphia has named an aquatic salamander, which he found near that city, salamandra venenosa, from the nature of the fluid which exudes from the tubercles of its back. Daudin, tom. viii. p. 229.

The gecko of Egypt produces a poisonous liquid of considerable activity. "It exudes (says Hafslequift) from the lobules of the toes; the gecko seeks for places and objects impregnated with marine salt, and passing several times over them, leaves its venom behind." I saw in 1750, two women and a girl, who nearly died in Cairo from eating cheeche which had been thus poisoned. I had another opportunity of noticing the acrimony of this fluid, in the production of red, inflamed, and itching pustules on the hand of a man, who endeavoured to catch the animal." The French naturalists, attached to the Egyptian expedition, confirm the report of Hafslequift. Daudin, tom. iv. p. 110, 111.

**Rattle of the Genus Croelclus.**—This singular organ conveys in many pieces, from one to thirty, or more, perfectly similar, not only in form, but often also in size, composed of a brittle, semi-transparent, horny substance, similar to that of scales. The piece immediately connected to the body forms a small sheath, moulded on the last vertebra of the tail, which it enfolds, and from which it is separated only by a thin membrane. Its surface presents three circular rings, corresponding to three elevations of the vertebra: the first, or nearest to the animal's tail, is the largest, and the two others decrease successively. All the pieces are encafed one in the other, the posterior two-thirds of each being enveloped by the following. Of the three rings or rings on each piece, the anterior only is visible, the two post-
terior being concealed by the following piece. The half, or
extreme portion, has all its three rings visible; and the or-
gan conflits, externally, of this piece, and the third rings of
all the others. The two half rings of each piece, included
in the two half of the succeeding, retain it in its place;
but, as the diameter of the former is less than that of the
latter, each piece is quite loose, and plays freely about that
which it envelops. None, except the first, is united to the
skin of the animal, or connected by any muscle, nerve, or
vein; it is, therefore, merely an exterior covering, moved,
as any foreign body would be, when the end of the tail is
agitated.

The different pieces of the organ are formed successively
on the skin of the tail, receiving from it the materials nec-

cary for its development, and adhering to it until its
growth is complete. A second piece, entirely similar to the
first, is formed under it, and detaches it from the end of the
tail. It is pushed backwards, leaving between its edge and
the skin of the tail an interval occupied by the first ring of
the new piece, of which the second and third rings are cov-
ered by the first piece. The latter is retained by this con-
nection, but plays freely round the first piece. A third
piece is formed under the second, as that was under the first;
pushing the second backwards, but retaining it by its two
posterior rings being included in the cavity of the second
piece.

If the vertebrae of the tail continue of uniform diameter,
all the pieces will be of the same size, and the rattle, conse-

quently, is of one breadth throughout. On the contrary,
it the vertebra grow while the rattle is being formed, the
pieces increase in size, and thus the rattle tapers to its end.

It is evident, from the preceding description, that one
piece only can be formed at each partial mounting of the end
of the tail; but as we do not know whether these mountings coincide with the general separation of the epider-

sms from the body, nor the periods of their recurrence, the
number of pieces not only affords no proof of specific
differences, but also indicates nothing about the age of the
animal. Lacépède, Hist. Nat. des Serpens, 12mo. t. 2.

Horns, &c. of other Serpents and Reptiles.—The Egyptian
ceratides is foamed, from its two moveable, pyramidal, four-
sided, curved horns, about two lines in length, placed above
the eyes. They consist of succedaneous strata, of which the
external separates like an epidermis, exhibiting always four
grooved sides. The external stratum separates thus with
the animal's skin, like the epidermis of the scales, which
this resembles entirely in its texture. Lacépède, ubi supra,
t. 1. p. 256.

In the babratic order, the horned frog has a conical
horny elevation above each eye; and the rana margaritifera
a peculiar hard crita on each side of the head.

The cecilia ibiara has two small tentacula or ciri, scarcely
visible near the nostrils; and the serpent, which Lacépède
has named erpeton tentaculé (Annales du Muséum, t. 2.
p. 280.) has two febyth appendages, covered with scales, ex-
tending from the end of the finot horizontally forwards. Is
there any probability that these parts in the cecilia and
erpeton are organs of touch?

Facial Pouches of Serpents.—A small bag has been ob-
served in the rattlesnake, in sixteen colubres, and three box,
between the eye and the nostril; it has a rounded form,
relying in a hollow of the bone, in shape not unlike the or-
bit. A small orifice behind the nostril leads to it. These
bags, which are lined with cuticle, have their covering col-
with the rest of the animal's skin. The cavities in question
were noticed in the rattlesnake by Tylor, Phil. Trans.
v. 13. p. 26; and they have been since described and deli-
gated by Dr. Ruffel and Sir Everard Hume. (Phil. Trans.
1804. p. 70.) The latter anatomist discovered nothing like
a secretory apparatus about them, nor anything that could
lead to conjectures concerning their office. They appear
not analogous, in situation and structure, to the small bags
of the deer and antelope, called by the French famiers.

We conclude our review of the struture and physiology
of reptiles with the summary of the principal differences
between their economy and that of the warm-blooded
clauses, which terminates the excellent " Specimen" of Blun-
menbach.

" Et calidis quidem animalibus a prima inde formationis
origine ad ultimum nique vitae halitum phlogisticus ut hodie
audit procursus. Mammalium factui plantae adminiculo,
zeque factae phlogisitn materne elemento igneo commutat.

ut per utrunque organismum nature regnum conflat—longe
magis opportuna, quam quae alioris ordinis facultatibus,
sufficiens, et compate conspirationes subtilitate vigor.

P. 36.

Anatomical Description of the Protozoa Anguis, and Siren
Lacertina.—See Cuvier, Récherches fur quelques Reptiles
douteux, infentes in Humboldt's Requell d'Oberservations de
Zoologie et d'Anatomie comparée faites dans fon
Voyage, t. 1.

By the word amphibious, applied to animals, naturalists
have meant to designate the power of living, and particular
of breathing, equally well in water and in air. In this fend
it cannot be applied, with propriety, to any of the animals
who have received the appellation from the ancients, and
most modern naturalists. Without speaking of the otters
and hippopotami, which are true aerial quadrupeds, visit-
ing the water merely in search of food, the seals and cetacean

5 F 2

animals,
animals, compelled by their organs of motion to pafs the whole, or nearly the whole of their life in water, can absolutely breathe air only.

All the reptiles to whom Linneus subfquently transferred this name of amphibious animals, are similarly circumftanced in their adult state; they can only breathe air, whether they live constantly in this element, as the lizard kind, or betake themselves, for a longer or shorter period, to the water, as the frogs and salamanders. On the other hand, the cartilaginous fishes, which this fame naturalist had joined to the reptiles, like all other fishes, can only breathe by the intervention of water; they have only gills; and it is by having reprefented as lungs the forked swimming bladder of fame of them, that Dr. Garden confided the fiftake of Linneus.

The larve or tadpoles of the batrachian reptiles only, that is to fay, of the salamanders and frogs, the tree-frogs and toads, have both branchiae and lungs; breathe, at leat for a certain time, both the air in its eflatic flate, and that which is contained in water; consequently participate equally the nature of aerial and aquatic animals; and may, therefore, without impropriety, bear the name of amphibious in its mean ftrict accception. But with thefe it is only a tranffitory, and with some perhaps only a momentary flate. As their lungs are developed, their branchiae are obliterated, and they entirely fole the latter, often even before reaching their full fize, and particularly before they are capable of reproduction. Such, at leat, is the refult of obfervations on all the tadpoles of these climates, on all which it is possible to follow in their various developeements.

But naturalifts have obferved three other animals, unifying, like our tadpoles, the two kinds of respiratory organs, not appearing to fole any of them at any epoch of their lives, and of their form and fize, that it is laid in the countries which they inhabit, no perfect reptile is known, of which they could be the larve. Are thefe creatures perfect animals—true permanent amphibia? Should they be confidered an intermediate clafs between reptiles and fihes? We proceed to examine this qufion, obferving, in the firfl place, that the structure of the circulating organs in the common tadpoles, which has been defcribed in a former part of this article, must be kept in view as a point of comparison.

Anatomy of the Siren Lacertina.—This animal is common in the rivers and marfhes of South Carolina, and is remark-able for poffefling only the fore feet. Dr. Garden fent an individual to Linneus, accompanied with a defcription, in which he mentioned the fimultaneous eflistence of branchiae and lungs, and declared that there is no salamander in Caro-lina large enough to have been produced from the firen. Hence Linneus determined to efablifh for it a particular order of reptiles, the amphibia meantes. Nearly at the fame time it was defcribed in the Philosophical Tramfactions by Ellis, whose defcription was accompanied with an anatomy of the animal by Mr. J. Huxter. Yet several naturalifts contested the refult of their examinations. Pallas, Hermann, Schneider, and others, confidered that it might be a larve. Camper, on the faith of an imperfect specimen, in which no lung could be found, concluded it was a fih, (Kleine Schriften, tom. iii. pl. 1. p. 20.); and Gmelin, on his authority, deflided it among the eels.

Cuvier has had an opportunity of diffefting and defcribing it. His account, which fettles the difputes fatisfactorily, is contained in the Recherche already quoted, and has furnifhed the materials of the following defcription. The facts are represented in the 18th and 19th plates of the firft volume of Humboldt's Recueil d'Obfervations de Zoologie et d'Anatomie compareé. The length was half a metre, but it reaches fometimes between 30 and 40 inches. The body is much like that of an eel. The anus is at 15 centimetres from the posterior extremity. The head is not feparated from the body by a neck; it is rounded, and terminated by an obtufe flout. The mouth is small, and the lips, which are not confiderable, are not fupported by any bones, as they fometimes are in fihes. The nostrils are two small holes near the edge of the upper lip. The eyes are placed above the angle of the mouth; they are round, small, without eye-lids, and only visible becaufe the skin, in pafing over them, becomes transparent. You may flin the head, like that of an eel, without injuring the eye-ball.

The openings of the fihes are three vertical filver placed in fuccifion behind the head; through them the water from the mouth is discharged. But there are no gills within, as in the lamprey for example; although Garden, Ellis, and Camper fuppofed it. The only branchiae are three tufts or fingers, attached to the superior angle of the flite, to which Ellis and Garden gave the name of opercula, but of which Linneus recognized the true nature. There are surely only three on each fide, of which the firft is the smallest, and the third the largeft. The different statements concerning their number, which embarrassd M. Schneider, arife from the name having been given to different parts. For example, Linneus, who rightly deemed the tufts to be branchiae, reckons three, without opercula (branchia ad latera colli unire tibia, expetra); but Gard n, who conceived that the branchiae were connected to the arches, fays there are four, with three opercula, or one operculum of three lobes.

Each of the tufts consists of a large fleftly and conical pedicle, of which the inferior edge is divided into two rows of appendices, which are themselves again divided in the fame manner. The animal must have the power of moving thefe branchiae in every direction; the net-work of branchial vesfels is expanded on their ramifications.

The fore feet, short and flender, are placed a little behind the branchial apertures. There are four fingers, of which the laft phalanges are pointed, but not furnished with nails. There is not the fmalleft appearance of scales on the skin.

Osteology.—Although the individual examined by Cuvier had not reached its full fize, ossification was considerably advanced. The cranium, lower jaw, and spine, were perfectly ossified. On the large bones of the arms there were epiphyses, and the ilacpa was almost entirely cartilaginous.

The latter bone remains contantly in this flate in the salamanders. The branchial arches were entirely cartilaginous, and probably continue fo, as no point of ossification could be obferved, although the os hyoide and its branches were already almost completely hardened.

From the head to the end of the tail there are ninety vertebræ; the anus is opposite to the forty-fifth, yet it is far from being opposite to the middle of the body, becaufe the vertebrae of the tail, particularly towards its end, are much smaller than the others. The land salamander has thirty-eight, and the aquatic about forty. The pelvis is suspended opposite to the fifteenth or sixteenth, in the former; to the fourteenth or fifteenth, in the latter. There is not the smallest veftige of pelvis or hind leg in the firen; there is not even any germ of these parts, although they exif in the tadpole at all ages. It is, therefore, very certainly never defigned to have hind legs. There is a kind of imperfect pelvis, even in the ophiuros (anguis vertebralis; glais-fmake), a true ferpent, though analogous to the lizards in fome points, but never poffefling hind legs.

Eight vertebrae only of the firen, from the fecond to the
ninth, support small ribs, or rather very short false ribs. In the land salamander there are twelve or thirteen, and in the aquatic eleven. These small ribs, bolt among the mucocele, are only observed in the genus of serpents called ceclia, where they exist in great number.

The individual vertebrae are very differently shaped from those of salamanders, frogs, and ceclia. The body is terminated behind and before by a hollow cone filled with cartilage, which gives it to the adjoining bones, as in fishes. There is a small longitudinal prominence below; and above, a cribs holding the place of the spinous processes, and bifurcated behind. The four angles of the superior surface are occupied by the articular apophyses, of which the anterior have their articular faces turned upwards, and the posterior downwards. The transverse processes are formed of two triangular plates: one, interior and horizontal, comes off from the whole side of the body of the vertebra; the other flints backwards, and reaches from the anterior articular processes to the posterior edge of the preceding. At the extreme point of their union we find the surface to which the rudiment of rib is articulated, in those vertebrae which have ribs.

None of the allied genera resemble the furn in the form of the vertebrae; and their singular shape would alone be sufficient to authorize us in constituting a separate genus for this animal. The head leads equally to the fame conclusion, being entirely different from that of the salamander, and other reptiles. The nitis, lightly excavated at the sides of the front, do not penetrate into the mouth: neither the orbit nor the temporal fossa is closed below. Hence the upper jaw-bone does not form a complete bony circle; its anterior part only is formed by the intermaxillary bones, and has no teeth. Thus the front has only palatine teeth attached to the two plates, and not implanted in the palate. The prominence, having the surface for the articulation of the lower jaw, is much shorter than in the salamander. The lower is articulated with it by a convex surface, shaped like the segment of a sphere: its concave parts is very short; each of its branches is composed of three pieces at least. The teeth are attached to their internal surface, and not implanted in their edges. The head is articulated to the neck by means of two syr salades.

The bone apparatus of the branchial resembles that of fishes, with a few slight differences. A longitudinal bony piece bears, at each of its extremities, a pair of transverse portions. Each of these anterior portions is joined to a cartilage, which ascends behind the head, suspended by a strong ligament to the sides of the occiput: it is analogous to the piece which supports the radii of the branchial membrane in fishes. But here there are no radii; and there is even no sensation of continuity between this piece and the first arch of the branchia. This first arch, the largest of all, is joined to the posterior transverse piece mentioned above. The three others are joined to a third bony piece, similar to the preceding, but suspended behind it, and not articulated to the longitudinal piece. These four arches are simply cartilaginous. Their superior extremity is suspended to the second rib by a ligament, but not articulated to it. Their edges exhibit a series of small fine denticuli, which border the three branchial apertures: the anterior edge of the first arch, and the posterior of the last, not concurring in the formation of any opening, have none of these denticuli. The skin is immediately attached to these arches, and these support nothing, as we have already said, analogous to the branchial of fishes. The tufts, which have no bone in their interior, are the only branchia.

The osteology of the legs is the same as in the salamander: it comprises a slender scapula, terminated above by a cartilaginous dilatation; a large cartilaginous plate, which may be regarded as a double clavicle, analogous to that of the frog, the ufe of which is to protect the front of the chest, a humerus; two bones of the forearm; a carpus, of which the bones were too small and soft to be reckoned; a metacarpus and phalanges.

**Organs of Sense.**—The ear is the only one which Cuvier could observe accurately; it seemed to resemble that of the salamander. In the outer side of the bone inclosing the labyrinth, is an oval aperture, simply cleft by a cartilaginous plate, covered by soft parts.

**Organs of Circulation and Respiration.**—There is a single auricle of considerable size, with its circumference denticulated, receiving all the blood of the body, and the lung; two large valves are placed at the mouth of the vena cava. This auricle communicates with the ventricle by a single orifice; and the blood departs from the latter by the aorta only. The heart is therefore exactly the same as that of the frog, the salamander, and of fishes.

The trunk of the aorta, or rather of the vessel, which in fishes is called the branchial artery, is furnished with fleshy and thick sides, and its basis has three strong valves. It divides into three branches on each side for the three branchial tufts, and no branch goes from it to any other part. These arterial branches become attached to the three cartilaginous arches in their way to the branchia; but they form no plexus on them, which proves that branchiae are not attached to these arches as in fishes, and as Garden, Ellis, and Camper imagined in the heart.

Arriving at the branchial tufts, the arteries ramify over all their subdivisions, and the veins bring back the blood in a contrary direction. The same circumstances may be seen in the branchia of young aquatic salamanders, in which perhaps the circulation of the blood can be more easily observed with the microscope, than in any other animal organ.

Having quitted the tufts, the branchial veins assume the texture of arteries, and join together, towards the spine, to form the ascending aorta; but they produce, before their union, the branches which in other animals arise from the ascending aorta, that is, those of the head, arms, and lungs; these latter come from the third of these branchial veins converted into arteries.

The lungs are two long cylindrical bags, extending to the posterior end of the abdomen, and then bent forwards. The veins and arteries form a loose network on their membrane. Air enters them through a larynx placed on the os hyoides, and opening between two small rounded margins placed vertically. A very slight cartilaginous prominence is observable on each side in its interior, and the glottis is below these; but there is no chorda vocalis with a sharp edge. Yet it does not follow that the observers, who have ascribed a voice to the firen, are inexact; for the approximation of the two prominences just mentioned would be sufficient for its production.

The trachea is a simple membranous, white, and thick canal, without any perceivable cartilaginous rings.

**Organs of Digestion.**—We have already mentioned the jaws and teeth. The tongue is not fleshy, nor movable; it is supported, as in fishes, by the anterior extremity of the os hyoides. It does not resemble that of the salamander, and much less that of the frog, both of which are more free behind than in front, and have a very glandular surface.

The oesophagus is folded longitudinally. The coats of the stomach are moderately thick; it first swells a little, then
then becomes muscular and contracted, and is narrower than the duodenum. The latter is the widest part of the intestine, which becomes smaller towards the anus. Although longer than the abdominal canal, and consequently forming several flights, it exhibits no great folds. There is no cecum, nor any remarkable change of structure to point out the distinctions of different kinds of intestine. The pylorus has no valve; the mucous membrane of the stomach is smooth; that of the intestine has papillae like small scales.

The canal is supported by two parallel mesenteries, of which the right adheres to the whole length of the liver. There is no omentum.

The liver is black, elongated, and occupies more than three-fourths of the length of the abdomen. The gall-bladder is lodged in a deep groove towards its middle, and furnishes a single canal, opening into the intestine a little beyond the pylorus. No duct could be perceived coming directly from the liver, but such a one might have been confounded with the numerous mesenteric vessels.

A slender and very long spleen is attached to the mesentery of the left side, and occupies more than three-fourths of the length of the abdomen.

Organ of Generation.—The individual examined by Cuvier was a female. The ovaries were considerably developed, about one-fourth of the length of the abdomen, oblong, composed of lobes, filled with very visible ova, although so scattered that they probably did not approach to the size which they would have reached in the season of reproduction. A short and straightoviduct was closely connected to the kidney; this part was very different from the long tortuous tubes of the frog and salamander, and approached to the structure of fishes.

Organ of Secretion.—The kidneys were small, well supplied with blood-vessels, and situated at the sides of the rectum. The bladder elongated, and not divided as in frogs.

The conclusions drawn by Cuvier from the preceding account are; 1. That the fin, into whatever flate it may pass, is a distinct animal, different in all the details of its organization from the salamanders and their larvae, which are articulated with to the branchies, 2. That it is very certainly not defined to parallel hind feet, and consequently is a biped reptile.

There is no reason to suppose that it ever loses its branchies, since it is found to posses them at the largest size to which we know of its reaching, and the unanimous testimony of those, who have seen the animal in its native country, proves that no individual has ever been seen without them.

That it is essentially different from fishes in its osteological structure, and even in the organization of the branchies.

That it therefore constitutes a particular genus of batracian reptiles, preserving always the double respiratory organs; and may be considered as a permanent larva of that family.

Anatomy of the Proteus Anguinus.—This animal was first noticed in the Synopsis Reptilium of Laurenti, in 1768. Scopoli gave a more minute account of it in 1772, in his Annus quintus Hillor. Nat. p. 75. Naturalists were divided in opinion, whether it should be regarded as a perfect animal, or only as the larva of some reptile. An excellent description of it, both as to its external characters and structure, was published in the Philosophical Transactions for 1801, pt. 2, by Dr. Schrebers of Vienna, in a paper entitled, "An historical and anatomical Description of a doubtful amphibious Animal of Germany, called by Laurenti Proteus Anguinus. Cuvier has since described it in his Recherches sur quelques Reptiles douteux.

The individual examined by Cuvier was 0.25 of a metre in length, and of the size of the little finger: Mr. Schrebers saw one of 0.33, or 13 English inches. The body is slightly compressed, and grooved at the sides, like the firen. The tail is more flattened, and furnished at its edges and end with a fin, which does not reach either above or below farther than the anus. The feet are slender; the knee and elbow being about their middle, and directed as in the salamanders: the fore-feet are terminated by three equal toes without nails, the hind-feet by two only; a combination, which is hitherto unique in the animal kingdom.

The head has some resemblance to that of an eel; the opening of the mouth is of moderate size, and furnished with thin lips. The nostrils are a longitudinal slit on each side, parallel to the side of the upper lip. No eye is perceptible externally; but when the animal is skinned, it is seen under the integuments as a black point, about the thirteenth of a line in breadth.

Is the depression produced by the muscles at the sides of the cranium are seen the openings of the branchies. They are three, covered in some degree by a prominence of the skin, supported by a muscular flatum. The branchies are three small appendages, of a red-blood colour in the living animal.

The skin is whitish, soft, smooth, and presents some small prominences when examined with a magnifying glass.

Osteology.—When the muscles, that swell the cranium externally, are removed, it appears flat, and quite on a level with the face; the latter terminates in a point in front. The middle of the cranium has its sides parallel; the posterior part swells out in the situation of the prominences to which the lower jaw is articulated, which are directed forwards. Behind, the occiput has two lateral eftites for the muscles. The head is articulated with the atlas by two condyles; the upper surface of the cranium is very flat.

There is no distinct zygomatic arch, orbit, or temporal fossa.

All round the upper jaw is a row of small pointed and vertical teeth; and in front only a small additional row before the others. The inferior jaw has a single row of teeth. Its two branches are nearly rectilinear, and make an angle of about 45°. It has no ascending branch, and the corono id process is inconspicuous. All these parts are well ossified and firm; and, although the future are still visible, we cannot fail to see that the bones belong to an animal very near the adult flate.

The bony apparatus of the gills is much more firm than in the firen or axolotl, and somewhat differently composed. The hyoideal branches are flender, and suspended to the sides of the cranium behind the articulation of the lower jaw. The os hyoide is short and thick, and supports behind two pieces equally short and thick, which diverge a little. The first arch of each side, which is the largest, is articulated to the extremity of one of these pieces, and has the two other arches attached to its posterior edge.

There are fifty-six vertebrae: the pelvis is attached to the thirty-first; and the twenty-five following belong to the tail. Six only of these vertebrae, beginning with the second, support rudiments of ribs, still smaller than those of the salamander and the firen.

All the vertebrae, excepting the last of the tail, are perfectly ossified: their form is peculiar to this species.

Organ of Digestion.—The tongue is short, with little power of motion in front, and supported by the anterior extremity.
extremity of the os hyoides. The intestinal canal extends readily in a straight line through the abdomen. The cephalus is folded longitudinally; and the stomach is only a rather larger portion of the canal, not marked by any constriction. There is neither caecum nor large intestine. An oblong liver, pointed at the two ends, of a blackish-grey colour, with two notches in its left edge, occupies about two-thirds of the length of the animal. A large gal-bladder, attached to the internal surface of the liver, pours the bile into the intestine by a short canal. The pancreas is small and narrow, and attached to the intestine opposite to the gall-bladder. An oblong narrow sphen is attached to the mesentery, and is about one-fourth of the length of the liver. The mesentery is simple, and has the usual vessels. There is no omentum.

The Organs of Circulation are the same as in the firen, except that the branchial veins unite together, to form the defeding artery; rather lower down.

Organs of Respiration.—The branchiae are moved, as in the axolotl, the firen, &c.: but no reptile has so small a proportion of lung as the protes. There is no larynx, properly so called, only a small opening at the bottom of the pharynx, which is the entrance of a common crescent-shaped cavity, the angles of which are prolonged to form the lungs. The latter are merely two very thin membranous canals, terminated by a flight dilatation, precipitating in their interior no division into cells, and exhibiting very few blood-vessels on their parietes. When we confider how little difference there is between such lungs and the forked air-bladders of some cartilaginous fishes, we can hardly help concluding that there is some analogy between the two organs.

Organs of Generation.—In the female dissected by Cuvier, oblong lobed ovaries, full of very distinct small ova, were situated towards the lower part of the abdomen, at the sides of the rectum. Very long oviducts, making several turns, like those of the falamander, ascend to the anterior third part of the cavity.

Organs of Secretion.—There are kidneis and a bladder, as in the falamanders: the former are very long, and pafs high up in the abdomen.

All these observations, and particularly those concerning the osteology, make it clear that the protes is a particular animal, different from all hitherto known: they also make it very probable that it is an adult animal, not defined to undergo any further change of fiate.

A protes taken alive threw up from its stomac many shells of the genus helix, but it would not take these shells or any other food, and became daily more languid and weak. It seemed, when alive, very torpid, and moved but seldom; it swam, however, sometimes, with the help of its broad tail, very swiftly, in every direction. The first days it crept slowly on the bottom, and seemed to look for food; it often took a shell into its mouth, but gave it out again, swallowing none. Several times it rote to the surface, fretched its head out of the water, and took in air, but returned directly to the bottom. It uses its feet in creeping on the bottom, and in ascending along the sides of the vessel, if of wood. It creeps very slowly or deliberately, insomuch that this motion seemed quite characteristic of the animal.

It often produces a hissing kind of noise, pretty loud, more so than one should expect from the size of the animal, and resembling that produced by drawing the piton of a syringe.

All the habits of the protes designate a sluggish and weak-minded, agreeing very well with the excessive smallness of its pulmonary organs, and the very mean and considerable extent of their surface.

It is a very rare animal, having been hitherto found, and that in very small numbers, only in those lakes of Carniola, which are celebrated on account of their subterranean communications and the singular phenomena which result from thence. That of Cirknitz is the most famous, and is regarded as the source of all the others. According to Laurent, the first protes, was found in this: but Schreiber assures us that it only inhabits the lake called Sitichier See, communicating with the Cirknitz; and that it is thrown out in the overflownings, which occur once or twice a-year.

Cuvier thinks it probable that its natural abode is in the subterranean communications extending from one lake to the other. It has, in fact, all the characters of a subterranean, as well as of an aquatic, animal. Its small eyes, concealed and rendered useless by an opaque skin, recall to us the blind rat (zerni, mus, or palax typhlus) which lives under ground, and has exactly the same organization.

In a letter to Cuvier, Schreiber informed him that, since the publication of his paper in 1801, he has met with several individuals, all perfectly alike, among which he had in vain sought for one without the branchie. That he himself has found, which have been two years in his possession, alive and well, although they have taken no food the whole time.

For the external figure and anatomy of this animal, see the plates subjoined to Dr. Schreiber's paper in the Phil. Trans. and pl. 13 of the Recueil d'Obf. de Zool. et d'Anat. Comparée de Humboldt, v. 1.

Another of these doubtful animals has been figured in the Annales du Musee, v. 10. p. 250. pl. 17. under the name of protea, or salmander tetrastyle, by Lacépède, who has there described its external conformation. It poifilles branchial appendages, eyes covered by the epidermis, and two rows of fine teeth. As only the specimen described in the above quoted work is known (without any information about the quarter whence it came), its anatomical structure has not been examined. All the appearances lead us to expect an internal organization like those of the proteus and firen.

Reptiles are likewise used, abusively, for plants which creep on the earth, or on other plants, as wanting strength of stalk to sustain themselves.
REPTON, in Geography, a considerable town in the hundred of Repton and Gresley, and county of Derby, England, is situated near the banks of the river Trent, at the distance of eight miles S.W. from the town of Derby, and four N.E. from Burton-upon-Trent in Staffordshire. Among antiquaries it is celebrated as the site of the capital of the Mercian monarchy, and the burial-place of several of its sovereigns. At that period it was called Hroopendune; and is conjectured by some to have risen upon the ruins of the Roman station Repandum; and the town is called Reppendune in ancient deeds. In the Saxon annals Repton is said to have been noted for a noble monastery of men and women, established, under the government of an abbot, previous to the year 660. This abbey was destroyed by the Danes in the reign of Guthred, the last king of Mercia, and remained in a desolated state till the year 1172, when it was refounded as a priory by Matilda, widow of Ranulph, second earl of Chester, who bestowed upon the monks the tithes of Repton, and considerable estates in the neighbourhood, besides Bartlow in Est., and lands at Graniden, in Huntingdonshire. At the dissolution its revenues were estimated at £571. 18s. 2d. In the original structure were deposited the remains of several of the Mercian kings; as were likewise those of Rychnardus, brother to Sigebert, king of the West Saxons. Some portions of the later buildings are yet in existence, being converted into a school house and apartments for the master and usher. The school-room, as appears from the windows and other traces, was either the refectory, or the hall, of the priory. It is supported by a row of strong round columns, with pointed arches. At the northern extremity of this room was the dormitory; and on the east side were situated the cloisters, the area of which is now a garden. Adjoining the cloisters stood the church which Fuller, in his “Church History,” describes as an elegant and spacious structure, supported in the interior by pillars of alabaster, fragments of which have been occasionally laid open. Foundations of other buildings, besides those mentioned, may still be plainly traced in various directions; and on the site of the prior’s lodging is a mansion called Old Trent, built about a century ago, which displays, towards the water, a curious brick tower with an ornamental cornice, part of a former building, erected by Prior Overton in the reign of Henry VI.

Repton confits chiefly of one street of scattered houses, extending about a mile in length, and watered by a fine stream, which discharges itself into the Trent. At the lower end of the town stands the parish church, a large, handsome edifice, ornamented with a fine spire two hundred feet high. Tradition affirms that the present is the third church, which has occupied the same site; and there can be no doubt that parts of it are of different and distant dates. The nave and side aisles seem to be of the reign of Edward III.; but the chancel is probably more ancient, as its columns are massive, and its arches semicircular. Beneath this part of the church is a crypt, bearing a strong resemblance, in form and ornaments, to the crypt under Canterbury cathedral, and also to that under St. Peter’s in the East, at Oxford. In the interior of this building are several handsome monuments to the memory of the Thacker family. Within a close behind the church, a labourer some years ago discovered a cemetery, which contained among many other human skeletons, one of an extraordinary size, measuring nine feet in length. This discovery is noticed by Dr. Pegge in the Philosophical Transactions for the year 1734. An old Roman cross, consisting of a single shaft, placed upon eight octagonal shafts, stands in the area fronting the church. The parish of Repton, according to the parliamentary returns of 1811, contains 326 houses, and 1648 inhabitants, who are chiefly engaged in pursuits connected with agriculture.

At a short distance from Repton is Sudbury, the seat and property of the family of Vernon, which is of great antiquity, deriving its descent from Richard de Vernon, a Norman lord, who accompanied the Conqueror to England; and was one of the seven barons created by Hugh Lupus, the great earl of Chester. Sir Ralph de Vernon, who was alive in the reign of Edward I., is said to have reached the extraordinary age of 150 years. Sudbury church, an ancient fabric, standing in the garden near the house, is decorated with many sepulchral tombs to members of this family. One, in commemoration of Catharine, daughter to the late lord Vernon, is remarkable for the beauty of the epitaph, which was written by William Whitehead, poet-laureat.

At Egginton, on the banks of the river Dove, west of Repton, is a seat of Sir Henry Every, whose family was originally seated in Somersetshire. Part of the old mansion here was destroyed by fire in the year 1736, and the present house then erected on its site.

Bretyl park, the seat of the Earl of Chesterfield, is about three miles S.W. of Repton. About three miles E. of Bretyl is Calke hall, the seat of Sir Henry Harpur, bart. The house is a spacious quadrangular edifice, seated in a park surrounded by eminences. Beauties of England and Wales, vol. iii. by John Britton and E. W. Brayley, 1802.
