1819.
PUNISHMENT, a penalty imposed upon the commission of some crime or offence against the laws. It is essential to the nature of a law, that it import or decree a punishment to the transgressors of it.

Solon very justly alleged, that the two great stimulants of human action being hope and fear, a good government could not possibly exist without an equitable system of rewards and punishments.

The forms and manners of punishment are various in various countries and ages, and for various crimes; as treason, felony, adultery, parricide, &c.

There was a time, says Beccaria, when all punishments were pecuniary. The crimes of the subjects were the inheritance of the prince, so that an injury done to society was a favour to the crown, and the sovereign and magistrates, those guardians of the public security, were interested in the violation of the laws. Crimes were tried at that time in a court of exchequer, and the cause became a civil suit between the person accused and the crown. The magistrate then possessed powers that were not necessary for the public welfare, and the criminal suffered punishments different from those which the necessity of example required. The judge was rather a collector for the crown, an agent for the treasury, than a protector and minister of the laws.

Among the Romans, the pecuniary punishments were the muleta and confiscatio. The corporal punishments were capitio diminutio, aqua et ignis interdictio, proscriptio, deportatio, relegatio, furca, crux, carcer, culleus, equuleus, flagellation, damnatio ad gladium, ad metallum, flagellation, talio, &c. which fee deferred under their respective articles.

Among us the principal civil punishments are, fines, imprisonments, the stocks, pillory, burning in the hand, whipping, ducking, hanging, beheading, quartering, burning, transportation, &c.

The ecclesiastical punishments are, exsorciis, suspensions, deprivations, degradations, excommunications, anathema, penances, &c. The military punishments are, being shot, running the gantlet, riding the wooden horses, the bilboes, &c.

Among the Turks, &c. impaling, bastinadoes on the soles of the feet, &c. obtain. See Empalement, &c.

The right of punishing crimes against the law of nature, as murder and the like, is in a state of mere nature vested in every individual. Accordingly the first murderer, Cain, was so fearful of this, that we perceive him (Gen. iv. 14.) expressing his apprehensions, that whoever would find him would slay him. In a state of society, this right is transferred from individuals to the sovereign power; and thus men are prevented from being judges in their own cases, which is one of the evils that civil government was intended to remedy. The sword of justice is now vested by the consent of the whole community in the magistrate alone. Every punishment which does not arise from absolute necessity, lays the great Montesquieu, is tyrannical; and this proposition is rendered more general by Beccaria, who observes, that every act of authority of one man over another, for which there is not an absolute necessity, is tyrannical. Upon this principle, the sovereign's right to punish crimes is founded; that is, upon the necessity of defending the public liberty, entrusted to his care, from the usurpation of individuals; and punishments are just in proportion, as the liberty, preferred by the sovereign, is sacred and valuable. It was necessity that forced men to give up a part of their liberty, and it is certain, that every individual would chuse to put into the public stock the smallest portion possible; as much only as was sufficient to engage others to defend it. The aggregate of these, the smallest portions possible, forms the right of punishing; all that extends beyond this is abuse, and not justice. The laws only can determine the
Punishment.

The punishment of crimes; and the authority of making penal laws can only reside with the legislator, who represents the whole society, united by the social compact. No magistrate, therefore, as he is one of the society, can, with justice, inflict on any other member of the same society, punishment that is not ordained by the laws, nor increase the punishment already determined by the laws. To the sovereign representing the society itself, who makes general laws to bind the members, it does not belong to judge, whether any individual has violated the social compact, or incurred the criminal punishment. In this case, there are two parties, he represented by the sovereign, who inflicts upon the violation of the contract, and the other is the person accused, who denies it. It is necessary then, that there should be a third person to decide this contest; that is to say, a judge or magistrate, from whom determination there should be no appeal. Judges, in criminal cases, says Blackstone, have no right to interpret the penal laws, because they are not legislators. The lawful interpreter is the sovereign, that is, the representative of society, and not the judge, whose office is only to examine, if a man have, or have not committed an action contrary to the laws. Many evils arise from the erring inutility of arbitrary interpretation.

The lawfulness of punishing criminals, who are chargeable with offences against the laws of society, that are only "mala prohibita" and not "mala in se," is founded upon this principle, that the law by which they suffer was made by their own consent; it is a part of the original contract into which they entered, when first they engaged in society; it was calculated for, and has long contributed to, their own security. This right, conferred by universal consent, gives to the state exactly the same power, and no more, over all its members, as each individual had naturally over himself or others. Hence some have doubted how far a human legislature ought to inflict capital punishments for positive offences;—offences against the municipal law only, not against the law of nature; since no individual has, naturally, a power of inflicting death upon himself or others for actions in themselves indifferent.

With regard to offences "mala in se," capital punishments are in some instances inflicted by the immediate command of God himself to all mankind, as in the case of murder, by the precept delivered to Noah, their common ancestor and representative (Gen. ix. 6.), "whoso sheddeth man's blood, by man shall his blood be shed." In other instances they are inflicted after the example of the Creator, in his positive code of laws for the regulation of the Jewish republic, as in the case of the crime against nature. But they are sometimes inflicted without such express warrant or example, at the will and discretion of the human legislature, as for forgery, for theft, and sometimes for offences of a lighter kind. None of these crimes are offences against nature, but only against social rights. The practice of inflicting capital punishments, for offences of human institution, is thus justified by that great and good man, Sir Matthew Hale (1 Hal. P. C. 13.) "When offences grow enormous, frequent, and dangerous to a kingdom or state, destructive or highly pernicious to civil societies, and to the great injury and danger of the kingdom or its inhabitants, severe punishment and even death itself is necessary to be annexed to laws in many cases by the prudence of lawmakers." It is, therefore, as judge Blackstone observes, the enormity, or dangerous tendency of the crime, that alone can warrant any earthly legislature in putting him to death that commits it. It is not its frequency only, or the difficulty of otherwise preventing it, that will excuse our attempting to prevent it by a wanton effusion of human blood. For, though the end of punishment is to deter men from offending, it can never follow from this circumstance, that it is lawful to deter them at any rate, and by any means; since there may be unlawful methods of enforcing obedience even to the justest laws. Every humane legislator, as the learned judge remarks, will be therefore extremely cautious of establishing laws that inflict the penalty of death, especially for slight offences, or such as are merely positive. Nor will it avail to allege that no lighter penalty will be effectual, because experience has not taught us that capital punishments are more effectual. Was the vall territory of all the Ruffias, it may be asked, worse regulated under the empress Elizabeth, than under her more fanguinary predecessors? Or has it been fine, under Catharine II., less civilized, less focial, and less fevere? And yet we are assured, that neither of these illustrious princesses have, throughout their whole administration, inflicted the penalty of death; and the latter, upon full persifluation of its being useless, and even pernicious, forfudred for abolishing it entirely throughout her extensive dominions. But if capital punishments, says Blackstone, were proved by experience to be a sure and effectual remedy, which would not prove the necessity (upon which the justice and propriety depend) of inflicting upon all occasions, when other expediens fail. This reasoning would, as we may justly apprehend, extend much too far. Where the evil to be prevented is not adequate to the violence of the preventive, a sovereign that thinks seriously can never reconcile laws that inflict death to the dictates of conscience and humanity. To shed the blood of our fellow-citizens, says the learned and humane judge, is a matter that requires the great deliberation, and the fullest conviction of our own authority; for life is the immediate gift of God to man; which neither he can renounce, nor can it be taken from him, unless by the command or permission of him who gave it; either expressly revealed or collected from the laws of nature or society by clear and indubitable demonstration. Blackstone, however, would not be understood to deny the right of the legislature in any country to enforce its own laws by the death of the transgressors, though some persons of abilities have doubted it. To this class of persons we may refer the ingenuous writer already cited. The abuse of profination of punishments, which has sometimes been better, than indulged, Bcccaria to ensure the safety of society, that the punishment of death be really just or useful in a well-governed state? What right, he asks, have men to cut the throats of their fellow-citizens? Certainly not that on which the sovccignty and laws are founded. The laws are only the sum of the small parts of the private liberty of each individual, and represent the general will, which is the aggregate of that of each individual. Did any one ever give to others the right of taking away his life? Is it possible, that in the smallest portions of the liberty of each, factitious to the good of the public, can be contained the greatest of all good, life? If it were so, how shall it be reconciled to the maxim which tells us, that a man has no right to kill himself? Which be certainly must have, if he could give it away to another. The punishment of death is not authorized by any right, for no such right exists. The death of a citizen cannot be necessary, but in one case; when, though deprived of his liberty, he has such power and connections as may endanger the security of the nation; when his existence may produce a dangerous revolution in the established form of government. But even in this case, it can only be necessary when a nation is on the verge of recovering or losing its liberty; or in times of absolute anarchy, when the disorders themselves hold the place of laws.

If the experience of all ages be not sufficient to prove, that the punishment of death has never prevented determined
men from injuring society; if the example of the Romans; if twenty years reign of Elizabeth, empress of Russia, in which the gave the fathers of their country an example more illustrious than many conquests bought with blood; if, says Beccaria, all this be not sufficient to persuade mankind, who always suspect the voice of reason, and who choose rather to be led by authority, let us consult human nature in proof of this assertion.

It is not the intenleness of the pain that has the greatest effect on the mind, but its continuance; for its sensibility is more easily and more powerfully affected by weak but repeated impressions, than by a violent, but momentary, impulse. The power of habit is universal over every sensible being. As it is by that we learn to speak, to walk, and to satisfy our necessities, so the ideas of morality are stamped on our minds by repeated impressions. The death of a criminal is a terrible but momentary spectacle, and therefore a less efficacious method of deterring others, than the continued example of a man deprived of his liberty, condemned, as a beast of burden, to repair, by his labour, the injury he has done to society. "If I commit such a crime," says the Spectator to himself, "I shall be reduced to that miserable condition for the rest of my life." A much more powerful preventive than the fear of death, which men always behold in distant obscurity.

The terrors of death make so slight an impression, that it has not force enough to withstand the forgetfulness natural to mankind, even in the most essential things; especially when ascribed by the passions. Violent impressions surprise us, but their effect is momentary; they are fit to produce those revolutions which instantly transform a common man into a Lacedæmonian or a Perian; but in a free and quiet government, they ought to be rather frequent than strong.

The execution of a criminal is, to the multitude, a spectacle, which in some extases compasion mixed with indignation. Thse sentiments occupy the mind much more than that salutary terror which the laws endeavour to inspire; but in the contemplation of continued suffering, terror is the only, or at least predominant affection. The severity of a punishment should be just sufficient to excite compasion in the spectators, as it is intended more for them than for the criminal.

A punishment, to be just, should have only that degree of severity which is sufficient to deter others. Now there is no man, who, upon the least reflection, would put in competition the total and perpetual loss of his liberty, with the greatest advantages he could possibly obtain in consequence of a crime. Perpetual slavery, then, has in it all that is necessary to deter the most hardened and determined, as much as the punishment of death: it has even more. There are many who can look upon death with intrepidity and firmness; some through fanaticism, and others through vanity, which attends us even to the grave; others from a desperate resolution, either to get rid of their misery, or cease to live; but fanaticism and vanity forfake the criminal in invalidy, in chains and fetters, in an iron cage; and despair seems rather the beginning than the end of their misery. The mind, by collecting itself and uniting all its force, can, for a moment, repel afflicting grief; but its most vigorous efforts are insufficient to expel perpetual wretchedness.

In all nations, where death is used as a punishment, every example supposes a new crime committed. Whereas in perpetual slavery, every criminal affords a frequent and laeting example; and it is necessary that men should often be witnesses of the power of the laws, criminals should often be put to death; but this supposes a frequency of crimes; and from hence this punishment will cease to have its effect, so that it must be useful and effectual at the same time.

We shall be told, that perpetual slavery is as painful a punishment as death, and therefore as cruel. To which we answer, that if all the miserable moments in the life of a slave were collected into one point, it would be more cruel punishment than any other; but these are scattered through his whole life, whilst the pain of death exerts all its force in a moment. There is also another advantage in the punishment of slavery, which is, that it is more terrible to the spectator than to the sufferer himself; for the spectator considers the sum of all his wretched moments, whilst the sufferer, by the misery of the present, is prevented from thinking of the future. All evils are increased by the imagination, and the sufferer finds resources and consolations, of which the spectators are ignorant; who judge by their own sensibility of what passion in a mind, by habit grown callous to misfortune.

He who foresees that he must pass a great number of years, even his whole life, in pain and slavery; a slave to those laws by which he was protected; in fight of his fellow citizens, with whom he lives in freedom and society; makes an useful comparison between those evils, the uncertainty of his successes, and the shortness of the time in which he shall enjoy the fruits of his transgression. The example of those wretches continually before his eyes, makes a much greater impression on him than a punishment, which, instead of correcting, makes him more obdurate.

The punishment of death is pernicious to society, from the example of barbarity it affords. If the passions, or the necessity of war, have taught men to shed the blood of their fellow creatures, the laws, which are intended to moderate the ferocity of mankind, should not increase it by examples of barbarity, the more horrible, as this punishment is usually attended with formal pageantry. Is it not absurd, that the laws, which detest and punish homicide, should, in order to prevent murder, publicly commit murder themselves? What are the true and most useful laws? Those compact and conditions which all would propose and observe, in those moments when private interest is silent, or combined with that of the public. What are the natural sentiments of every person concerning the punishment of death? We may read them in the contempt and indignation with which every one looks on the executioner, who is nevertheless an innocent executor of the public will; a good citizen, who contributes to the advantage of society; the influence of the general security within, as good soldiers are without. What then is the origin of this contradiction? Why is this sentiment of mankind inedible, to the scandal of reason? It is, that in a secret corner of the mind, in which the original impressions of nature are still preserved, men discover a sentiment which tells them that their lives are not lawfully in the power of any one, but of that necessity only, which with its iron sceptre rules the universe.

What mull men think, when they see wise magistrates and grave ministers of justice, with indifference and tranquillity, dragging a criminal to death, and whilst a wretch trembles with agony, expecting the fatal stroke, the judge, who has condemned him, with the coldest insensibility, and perhaps with no small gratification from the exertion of his authority, quits his tribunal to enjoy the comforts and pleasures of life? They will say, 'Ah! those cruel formalities of justice are a cloak to tyranny, they are a secret language, a solemn veil, intended to conceal the sword by which we are sacrificed to the insatiable idol of despotic Murder, which they would reprentent to us as an horrible crime, we see practised by them without repugnance, or remorse. Let us follow their example.
ample. A violent death appeared terrible in their descriptions, but we see that it is the affair of a moment. It will be still less terrible to him, who, not expecting it, escapes almost all the pain. Such is the fatal, though absurd reasoning of men who are disposed to commit crimes; on whom, the abuse of religion has more influence than religion itself.

How happy were mankind, says this author, if laws were now to be formed; now that we see on the thrones of Europe, benevolent monarchs, friends to the virtues of peace, to the arts and sciences, fathers of their people, though crowned yet citizens; the increase of whole authority augments the happiness of their subjects, by destroying that intermediate delphatism, which intercepts the prayers of the people, to the throne. If these humane princes have suffered the old laws to subsist, it is doubtless because they are deterred by the numberless obstacles, which oppose the subversion of errors established by the function of many ages; and therefore every wise citizen will wish for the increase of their authority.

It has long since been observed, says Voltaire, to whom the commentary on Beccaria's effay is attributed, that a man after he is hanged is good for nothing, and that punishments invented for the good of society, ought to be useful to society. It is evident, that a score of stout robbers, condemned for life to some public work, would serve the rate in their punishment, and that hanging them is a benefit to nobody but the executioner.

There have been some judges, says this writer, who were passionately fond of spilling human blood; such was Jefferies in England, and Such in France was the man whom they called Coupe-tete. Nature never intended such men for magistrates, but for executioners.

As to the end, or final cause of human punishments, this is not to be considered as an atonement or expiation for the crime committed, but as a precaution against future offences of the same kind. This purpose is accomplished in three ways; either by the amendment of the offender himself, with a view to which all corporal punishments, fines, and temporary exile or imprisonment are inflicted; or by deterring others by the dread of his example, from committing similar offences, "ut pena (as Cicero expresses it, pro Cluentio, 45) ad paucos, maus ad omnes perveniat;" or, lastly, by depriving the party who offended and injures, of the power to do future mischief, which is effected by either putting him to death, or condemning him to perpetual confinement, slavery, or exile. The method of inflicting punishment, however, ought always to be proportioned to the particular purpose it is meant to serve, and by no means to exceed it; and therefore the pains of death, and perpetual disability by exile, slavery, or imprisonment, ought never to be inflicted, but when the offender appears incorrigible.

The majority of human punishments must be left to the arbitration of the legislature, which should inflict such penalties as are warranted by the laws of nature and society, and such as appear to be the best calculated to answer the end of precaution against future offences. Some have recommended, and highly extolled for its equity, the "lex talionis," or law of retaliation; but judge Blackstone observes, that this can never be in all cases an adequate or permanent rule of judgment. Although there cannot be any regular or determinate method of ascertaining the quantity of punishments for crimes, by any one uniform rule, applicable to all cases, and without ultimately referring to the will and discretion of the legislative power; yet there are some general principles, deduced from the nature and circumstances of the crime, that may afford some assiduous in allotting to it an adequate punishment. One circumstance that serves in some measure to determine the nature and degree of punishment regards the object of it; for the more dignified in respect of rank, character, and influence, the object of an injury is, so much greater care should be taken to prevent that injury, and of course under this aggravation the punishment should be more severe. Accordingly treason in conspiring the king's death, is by the English law punished with greater rigour than even actually killing any private subject. Moreover, the violence of passion, or temptation may, in some cases, alleviate a crime; such is theft in cafe of hunger, contradistinquished from the same crime committed through avarice, and to serve the purposes of luxury. Homicide, in consequence of sudden and violent resentment, is less penal than upon cool deliberate malice. The age, education, and character of the offender; the repetition (or otherwise) of the offence; the time, the place, the company in which it was committed: all these, and a thousand other incidents, may aggravate or extenuate the crime. Thus Democritus (in his oration against Midas) finely works up the aggravations of the insults he had received: "I was abused," says he, "by my enemy, in cold blood, out of malice, not by heat of wine, in the morning, publicly, before strangers as well as citizens; and that in the temple, whether the duty of my office called me."

Farther, as punishments are chiefly intended for the prevention of future crimes, those should be most severely punished, which are the most destructive of the public safety and happiness; and, among crimes of an equal malignity, those which a man has the most frequent and easy opportunity of committing, which cannot be so easily guarded against as others, and which, therefore, the offender has the strongest inducement to commit; according to Cicero's observation (Pro Sexto Rofcio, 40); "ea sunt animadverenda peccata maxima, que difficilimum praecaventur."

We may also observe, that punishments of unreasonable severity, especially when indiscriminately inflicted, have less effect in preventing crimes, and amending the manners of a people, than such as are more mild or merciful in general, and yet properly intermixted with due distinctions of severity. Crimes, says Beccaria, are more effectually prevented by the certainty than the severity of punishment. The certainty of a small punishment will make a stronger impression than the fear of one more severe, if attended with the hopes of escaping; for it is the nature of mankind to be terrified at the approach of the smallest inevitable evil, whilst hope, the best gift of heaven, hath the power of dispelling the apprehension of a greater; especially if supported by examples of impunity, which weakens or avarice too frequently afford.

If punishments be very severe, men are naturally led to the perpetration of other crimes, to avoid the punishment due to the first. The countries and times most notorious for severity of punishments, were always those in which the most bloody and inhuman actions and the most atrocious crimes were committed; for the hand of the legislator and the assailant were directed by the same spirit of ferocity; which, on the throne, dictated laws of iron to flames and savages, and, in private, infringed the subject to sacrifice one tyrant to make room for another.

In proportion as punishments become more cruel, the minds of men, as a fluid rises to the fame height with that which surrounds it, grow hardened and insensible; and the force of the passions still continuing, in the space of an hundred years, the abed terrifies no more than formerly the prisia. That a punishment may produce the effect required,
PUNISHMENT.

It is sufficient that the evil it occasions should exceed the good expected from the crime; including in the calculation the certainty of the punishment, and the privation of the expected advantage. All severity beyond this is superfluous, and therefore tyrannical.

There are yet two other consequences of cruel punishments, which contrast the purpose of their institution, which was, to prevent crimes. The first arises from the impossibility of establishing an exact proportion between the crime and punishment, for though ingenious cruelty hath greatly multiplied the variety of torments, yet the human frame can suffer only to a certain degree, beyond which it is impossible to proceed, be the enormity of the crime ever so great. The second consequence is impunity. Human nature is limited no less in evil than in good. Excessive barbarity cannot be more than temporary; it being impossible that it should be supported by a permanent system of legislation; for if the laws be too cruel they must be altered, or anarchy and impunity will succeed. The excessive severity of laws (says Montesquieu, Sp. of Laws, b. 6. c. 13.) hinders their execution; when the punishment surpasses all measure, the public will frequently, out of humanity, prefer impunity to it.

Thus also the statute 1 Mar. R. i. c. 1. recites in its preamble, "that the state of every king confi "fants more aff "rately in the love of the subject towards his prince, than in the dread of laws made with rigorous pains; and that laws made for the preservation of the commonwealth without great penalties, are more often obeyed and kept, than laws made with extreme punishments." Happy had it been for the nation, says judge Blackstone, if the subsequent practice of that deluded princes, in matters of religion, had been correspondent to those sentiments of herself and parliament, in matters of state and government. It may be further observed, that savage laws are a bad symptom of the distemper of any state, or at least of its weak constitution. The laws of the Roman kings, and the twelve tables of the decemvirs, were full of cruel punishments; the Porcian law, which exempted all citizens from sentence of death, solely abrogated them all. At this period the republic flourished; under the emperors severe punishments were revived; and then the empire fell.

We may further add, that it is absurd and impolitic to apply the same punishment to crimes of different malignity. Besides, a multitude of sanguinary laws (besides the doubt that may be entertained concerning the right of making them) proves likewise a manifef defect either in the wisdom of the legislative, or the strength of the executive power. Although it be much easier to extirpate than to amend mankind; yet that magistrate must be esteemed both a weak and a cruel surgeon, who cuts off every limb, which through ignorance or indolence he will not attempt to cure. Beccaria therefore proposes to form in every state a scale of crimes, with a corresponding scale of punishments, descending from the greatest to the least; but if this idea be deemed romantic, a wise legislator will at least mark the principal divisions, and not affix penalties of the first degree to offences of an inferior rank. When men fee no distinction made in the nature and gradations of punishment, the generality will be led to conclude, there is no distinction in the guilt. Much as we may be disposed to admire and extol the excellence of the English law in a variety of respects, yet none can otherwise than regret the frequency of its capital punishments; inflicted by a multitude of successive and independent statutes, upon crimes very different in their nature, and we cannot forbear paying our tribute of respect to Sir Samuel Romilly, whose talents and character far exceed our praise, and other legislators, who are laudably exerting themselves in simplifying and mitigating our penal code.

It is a melancholy truth, says judge Blackstone, that among the variety of actions, which men are daily liable to commit, no less than 160 have been declared by act of parliament to be felonies without benefit of clergy; or in other words, to be worthy of infanticide. So dreadful a list, instead of diminishing, increases the number of offenders. The injured, through compulsion will often forbear to prosecute; juries, through compulsion, will sometimes forget their oaths, and either acquit the guilty or mitigate the nature of the offence; and judges, through compulsion, will reprieve one half of the convicts, and recommend them to the royal mercy. Among all chances of escaping the ready and hardened offender overlooks the multitude that suffer; he boldly engages in some desperate attempt, to relieve his wants or supply his vices; and if, unexpectedly, the hand of justice overtakes him, he becomes himself peculiarly unfortunate, in falling at last a sacrifice to those laws, which long impunity has taught him to contempt.

Beccaria, whose excellent essay we have often cited in this article, observes, that the more immediately after the commission of a crime, a punishment is inflicted, the more just and useful it will be. It will be more just, because it spares the criminal the cruel and superfluous torment of uncertainty, which increases in proportion to the length of his imagination, and the feciile of his weakneds; and because the privation of liberty, being a punishment, ought to be inflicted before condemnation, but for as short a time as possible. Imprisonment, he says, being only the means of securing the person of the accused, until he be tried, condemned, or acquitted, ought not only to be of as short duration, but attended with as little severity as possible. The time should be determined by the necessary preparation for the trial, and the right of priority in the oldest prisoners. The confinement ought not to be cloister than is requisite to prevent his flight, or his concealing the proofs of the crime; and the trial should be conducted with all possible expedition. Can there be a more cruel contravention than that between the indolence of a judge, and the painful anxiety of the accused; the comforts and pleasures of an inflexible magistrate, and the filth and misery of the prisoner? In general, "The degree of the punishment, and the consequences of a crime, ought to be so contrived, as to have the greatest possible effect on others, with the least possible pain to the delinquent." If there be any society in which this is not a fundamental principle, it is an unlawful society; for mankind, by their union, originally intended to subject themselves to the least possible punishment.

An immediate punishment is more useful; because the smaller interval of time between the commission of the crime, and the punishment, the stronger and more lasting will be the association of the two ideas, crime and punishment; so that they may be considered, one as the cause, and the other as the unavoidable and necessary effect.

It is, then, of the greatest importance, that the punishment should succeed the crime as immediately as possible, if we intend, that in the rude minds of the multitude, the seducing picture of the advantage arising from the crime, should instantly awake the attendant idea of punishment. Delaying the punishment serves only to separate these two ideas; and thus affects the minds of the spectators rather as being a terrible fight, than the necessary consequence of a crime; the horror of which should contribute to heighten the idea of the punishment.
PUNISHMENT.

There is another excellent method of strengthening this important connection between the ideas of crime and punishment; that is, to make the punishment as analogous as possible to the nature of the crime; in order that the punishment may lead the mind to consider the crime in a different point of view, from that in which it was placed by the flattering idea of promised advantages. This ingenious writer cloths his essay with the following general theorem, as the result of his previous reasoning: 

"That a punishment may not be an act of violence, of one or of many against a private member of society, it should be public, immediate, and necessary; the least possible in the case given; proportioned to the crime, and determined by the laws." Montesq. Sp. of Laws. Boccaria's Essay on Crimes and Punishments. Blacklt. Com. vol. iv.

A valuable work, comprising the subject of this article, was prefixed to the public in the year 1811 by M. Dumont of Geneva. It was formed of detached materials, furnished by the papers of Mr. Jeremiah Bentham, and the whole is executed with such judgment in the arrangement of the matter, and so much livesiness and elegance as to the style of the composition, that M. Dumont appears more like an original author than an editor. This work would have afforded us many instructive and interesting extracts, if our limits had allowed our making that use of it, which it deserves. This, however, is the less necessary, as the reader may have access to the original treatise, viz. "Théorie des Pêines et des Rècompensées; par M. Jeremie Bentham, Jurisconsulte Anglois; redigée en Françoys d'apres les Manuferits, par M. Et. Dumont de Géneve," 2 vol. Svo. a Londres, 1811: or to the ample analysis of it in the Edinburgh Review, No 43. A brief account of its contents may, however, be gratifying to our readers. This work consists of two great parts or branches; the theory of penal legislation, and the theory of remunerative legislation. The first contains in a systematical form all the principles that serve to regulate the choice of different modes of punishment and the apportionment of punishments to crimes. In the second are exhibited the principles upon which the lawgiver ought to proceed, when he holds out inducements either alone or attended with correspondng penalties, to influence the conduct of his subjects. The first book explains the general principles of the system, and opens with definitions and classifications.

Punishment, in its most general sense, is the infliction of some evil upon an individual, with an intention that he should suffer this evil, and with a reference to some act done or omitted. Punishment, in its legal sense, is the infliction of some evil, according to judicial forms, upon an individual convicted of some act forbidden by law, and with the intention of preventing the recurrence of such acts. Punishments, as well as crimes, are divisible into four clases, as they affect the person, the property, the reputation, or the condition of those upon whom they are inflicted. Those which affect the person, or corporal punishments, are subdivided into various species; they may be simply or complexly affective, or restrictive, or active (e. g. compulsory labour) or capital. The other three clases are all private, affecting the delinquent with loss or degradation. Hence arises another general classification of punishments, by dividing them into corporal and private.

From this definition it appears, that the object of all punishment is the prevention of the offence in future, either by the same delinquent or by other persons in similar circumstances. The first end is accomplished in three ways; by taking from the offender the physical power of committing the offence; by taking away the desire; or by deterring him. The other, and principal object of the infliction, that of restraining others, can only be effected as far as the punishment is concerned, by the threat which it holds out of similar infliction. These objects, as they form the only just motives, constitute also the only justification of punishments. Although the direct and primary object of punishment is prevention, the civil magistrate, having provided for that object, has another duty to perform, which is to provide as far as possible for the reparation of the injury sustained through the crime committed.

The essence or effect of any punishment is, in the language of this system, the whole evil of every kind occasioned by it, including the suffering of the delinquent, the loss of his labour or life: to the state, the pecuniary cost of his punishment; and, in short, every thing endured, paid, or foregone, in order to obtain the double preventive which the punishment is intended to administer. The gain or profit of the punishment confina in this preventive, or in the tendency of the punishment to secure it. A punishment may be termed frugal or economical which produces the desired effect with as little suffering as possible; and it may be termed costly or prodigal, when the same effect might have been produced by a smaller degree of suffering. The real value is distinguished from the apparent value, of the suffering; the former being the actual amount of that which is inflicted; the latter, the portion of it which is exhibited, or otherwise made known to, and understood by the public. The expence of a punishment is equivalent to the real amount; the profit is in proportion to the apparent amount only; and hence are deduced these important maxims: 1. That, ceteris paribus, a punishment easily comprehended, is preferable to one of difficult apprehension: 2. That one which takes hold of the memory, is preferable to one easily forgotten; 3. That one which is as great or greater in apparent than in real amount, is preferable to one which is really greater than it appears to be:—the excess of real amount being in truth so much thrown away, so far as regards the principal object, of general example.

The next subject of discussion comprehends the principles that ought to regulate the extent of punishment, for the prevention of crimes. These are contained in the following propositions. These are contained in the following propositions. 1. The evil of the punishment must exceed the advantage arising from the crime; so that, generally speaking, the stronger the temptation to commit any crime, the more severe ought to be the punishment, subject to exceptions in extreme cases. 2. When the criminal act evidently indicates a habit or practice, the punishment should be proportioned, not to the gain derived from a single offence, but to the probable amount of profit flowing from a course of such conduct. 3. An addition must be made to the punishment, in order to compensate its want of certainty and proximity. 4. In cases where a temptation offers for the commission of different crimes, a more severe punishment should be denounced against the greater crime. 5. The more pernicious any crime is, the more safely may a severe punishment be ventured upon, for the chance of preventing it. 6. The nominal amount of punishment for the same crime, must often be varied: the discretion of the judge, according to the circumstances of the delinquent, in order to preserve the real amount of suffering.

The qualities of punishment, the consideration of which naturally succeeds that of the measure or quantity, are such as follow: it should be divisible; invariable, or certain or equal; commensurable with others; analogous to the crime; exemplary; economical; remissible; that it should restrain the offender from doing harm; conduce to his reformation; yield a profit, in the ordinary sense of the word; be simple in its description;
PUNISHMENT.

imposed are of two kinds: simple prohibitions, and restraints upon loco-motion. The former are to limited in their application, that we need not particularly specify them; but the latter are divided into five kinds: vis. imprisonment, in the ordinary sense of the word; quasi-imprisonment, or confinement within the district to which the offender belongs: relegation, or confinement to some other district within the dominions of the state: local interdiction, or banishment from a particular district: banishment from the territories of the state, either indefinitely, or to some specific foreign part.

Imprisonment, according to our author's statement, in order to be effectual, ought to place the offender, for a limited time, under the most complete restraint, instead of being long and flight. Mr. Benthain enlarges in the enumeration of the evils comprehended under this mode of suffering, of which some belong inseparably and necessarily to it; others such as are accessory, but most frequently accompany it; and others again such as arise from abuses of it. With imprisonment, he says, in certain cases, and always for a very limited time, may most advantageously be joined solitude, dungeons, and regimen. Our author, having exposed the absurd system of "prison-fees," infers from his general principles that there ought to be three kinds of prison, adapted to the several purposes of simple detention, penitentiary confinement, and perpetual imprisonment. The first being only applicable to the case of insolvent debtors guilty of imprudence or extravagance, and of accused persons kept for trial, should have no accompaniment whatever of rigour. The leading principle in distinguishing the two others is, that the subjects of the former are to enter again into society; while those of the latter, being for ever excluded from it, the exemplary nature of their sufferings should be the principal object of attention. The names of the three prisons, for these separate purposes, should be different, as well as their external appearance; and every thing which can seize hold of the imagination, without awakening sympathy, should be presented, both in the construction of the perpetual prison, and in the situation of its inhabitants.

The four classes of punishments comprehends those that are termed active or laborious. Punishments of this class, when examined by the rules already premised, are found to unite the greatest number of advantages with the fewest defects. In the discussion of this subject, the author directs our attention to what may be called the extreme case of mismanagement in this kind of punishments. Here he alludes to Botany Bay. The transportation of convicts to America, which preceded the present plan, with several disadvantages of great moment, was, upon the whole, infinitely preferable. It was grossly unequal, inasmuch as it became servitude with exile to the poor, while it was only simple relegation to those who could pay for their passage. It was defective too in preventive power, the opportunities of escape being necessarily great. In both these particulars, the deportation now practiced has the manifold advantage. All the convicts are equally under restraint, and their escape is much more difficult; but in every other point of view, it is either as bad, or a great deal worse. It is as little as possible exemplary: the disproportion between the real and apparent suffering,—the excess of the former,—is in truth a maximum. The community in this country see a convict sent on a long voyage, to a fertile country, living in a fine climate. This is the example. The reality is, that the miserable wretch, after rotting in the hulks for a year or two, is crammed with some hundreds of his fellows into a floating prison, or, it may be, a pill-house, in which, if he survives the risks of famine, pestilence, mutiny, fire, shipwreck, and explosion, he is conveyed, through the imprision...
The contractor infures the lives and safe custody of the convicts; he is allowed yearly a certain sum for the deaths, as calculated from the common tables, and he pays the same sum for each death which actually does happen, and for every escape which takes place. If we mistake not, Mr. Bentham, by his contract with government, further engaged to pay so much for each prisoner who, after his discharge, should afterwards be convicted of any offence. The entire publicity of his accounts was another condition, and one upon which he himself insisted. The Panopticon was to be open at all times to every magistrate, and at certain hours to the public generally.

The most striking points of the comparison between both systems, as they are presented to us by the anonymous author of the article on the subject in the Edinburgh Review, are such as follow. The punishment is in the highest degree exemplary; it is all seen and understood; it appears much greater than it really is; the comforts of the convicts, in their intercourse with each other according to their improvement, and in the state of industry, and cleanliness, and wholesome regimen, for which they have exchanged their ordinary habits, being, however real, by no means such as strike the multitude of spectators, who only see confinement, compulsory labour, and ignominy. The reforming effects of the plan are equally manifest: the labour, to which they are in part allured by a fixed allowance of profit; the perfect temperance in which they live; the facility afforded of separating them into classes, according to their habits and behaviour; the means of early instruction, both religious and other, which they give; all furnish as good a chance of reclaiming those unhappy persons who are not hardened in guilt, as from any such system can reasonably be expected. The preventive powers of the Panopticon are complete, while the convict remains in it; and although a relapse after liberation can only be guarded against by reformation, a contrivance is added to this establishment, admirably calculated to provide against the first dangers of the discharge: the convict is transferred to another place of mitigated confinement, where he is rather under inspection than in custody, and from whence he is gradually allowed wholly to withdraw. With respect to the cost of the plan, we may form some estimate of it from the terms of Mr. Bentham's contract. Each convict was to cost government 13l. 10s., including 11l. 10s. for the proportion of the expenses of building and ground. He was to provide a fund for indemnifying the parties injured; to allow the convicts one quarter of the profits of their labour; and, after the first trial, to make a reduction in the charge. Practical men, well versed in such matters, had no doubt that a very considerable reduction might have been speedily afforded; and that, in a few years, the profits would entirely defray the expenses of the establishment to the state. While all manner of delays and difficulties were thrown in the way of this experiment; while wis and jobbers, or, as they termed themselves, matter-of-fact men, averse to theories, and deprecating novelties, were employed in running it down; trials were made in America of penitentiary houses upon similar principles, though in a much less perfect shape, and without some of Mr. Bentham's chief improvements.

We have the most irrefragable testimony borne to their success, by the interesting narratives of the duc de Rochefoucault Liancourt and captain Turnbull: the one a person eminently skilled in the subject of prisons; the other a mere practical observer, imbued with no knowledge beyond that of the naval profession. Both these very different witnesses concur in their statement of the salutary conccquences of the plan; and if we wished to find a perfect contrast to the melancholy...
PUNISHMENT.

melancholy narratives of Mr. Collins, we could certainly nowhere to well be suited as in the descriptions which the French and English travellers have given us of the convicts in New York and Philadelphia.

5. Capital punishments compose the fifth class. This class consists either of simply inflicting death with the least possible degree of suffering, or in accompanying the destruction of life with torments. The latter method, at one period universally prevalent, and still known in most countries, is happily almost abolished in the two most civilized nations. In France, the Code Napoleon allowed it only in the cases of prattle, and attempts against the sovereign's life, where the addition made to the punishment of death is cutting off the right hand. In England, it is only in the case of high treason that such augmentations are allowed; the punishment of the law is no doubt barbarous in the extreme, but in practice it is always remitted. All such cruelties have the effect of inspiring pity in the spectators towards the criminal, and of rendering criminals more hardened and savage.

The ingenious author of the critique on Mr. Bentham's theory, to whose analysis of the work we are so much indebted in the compilation of this article, agrees with him in his objections to Boccares, who maintains that a punishment of longer duration is more terrible to the spectator. Clearly there is none so dreadful as death. M. Dumont adds, that its apparent suffering is greater than its real, which applies only to the pains of it. On the other hand, it exceeds all others in some material defects; not only is it expensive, and beginning to become unpopular, it is quite irremissible, and it is in the highest degree unequal, and incapable of division or apportionment. A very satisfactory statement is given under this head, of the evil tendency of frequent executions, of the kind of reafoning by which offenders at the moment of temptation get rid of the fear of death, and especially of the wide difference between the expectation of certain destruction, and yielding to impulses which may lead to it. The evils arising from its being irremissible are also ably expounded; yet we think the author has neglected to consider how much of its horror confisits in this quality. It is manifest that no other punishment can utterly exclude hope. In comparing capital with other punishments, our author is disposed to give the latter the preference, almost to the exclusion of the former; chiefly because, however exemplary the men in general the infliction of death may be, and how deep forever the impression it makes on their minds, it has not the same terrors for the class of men most likely to commit the worst offences, violent spirits and hardened delinquents. That its range should be extremely limited, we are willing to admit; but we differ from him in the position, that for this class of men, perpetual confinement or hard labour would have more terrors than death. The total extinction of life, without chance of escape, pardon, or mitigation, ought still to be denounced against all worst offences; and, by being confined to those, will unquestionably become doubly terrible. The evils arising, not directly from the abuse of this punishment, are so ably pointed out by Sir Samuel Romilly, that our author abrages, a part of the treatise before us, by referring to his tract.

The other great division of punishments in Mr. Bentham's theory, consists more peculiarly in privation. These may be arranged in three classes, as they impose a forfeiture of reputation, of property, or of condition. 1. Punishments which affect a man's reputation consist of appeals to public opinion, and are those measures which the lawgiver takes with respect to him, for directing that opinion against him. The lawgiver may inflict punishments of this kind, or rather may expose the offender to have them inflicted, either by simply denouncing, with the authority belonging to his functions, that certain acts shall be deemed infamous, or by treating the particular offender judiciously in a certain way. The latter is the mode used in modern times; and it is practiced in different ways; by publication of the offence; by judicial admonition; by inflicting punishments of the other classes, corporal as well as privative, the immediate object of which is not the destruction of reputation; by inflicting what may be termed quasi-corporal punishments, the sole object of which is infamy; by degradation, or depriving the offender of his rank, natural or conventional; by discrediting him, or preventing his testimony from being received. 2. The description of punishments affecting property consists of those which are pecuniary, and which are quasi-pecuniary, as confiscation of lands, &c. 3. The forfeiture of condition, or jure naturae, though a class of great extent, theoretically speaking, is in practice reduced within narrow limits. Marriage may be dissolved; children may be balladized; blood may be corrupted; the different kinds of trust may be taken away; a person may be reduced to slavery; a community may be deprived of its rights and privileges. Outlawry may also be referred to this head.

There are other kinds of infliction, which every found principle teaches us to avoid where it is possible, and to diminish as much as possible, where, from the defects of all human contrivances, they inevitably mingle themselves with the legitimate modes of punishment. Our author's system arranges them in two classes; those which are misplaced, or which fall upon other persons than the offender; and those which are complicated, or present neither to the legislator, the judge, the party, nor the public, any fixed and definite idea. Those punishments that are misplaced, in the proper use of the term, or which the legislator enacts with the intention of punishing another person than the offender, either along with him, or in his place, consist of four kinds; viz. vis. in no one, where the offender escapes; — transfère, where an innocent person is purposely punished which is connected with the offender; —collectore, where a body of innocent persons suffer, in the presumption of the guilty being among them; — fortuitous, where an innocent person suffers as well as the offender, though unconnected with him. The only instance of vis or vis is a punishment which is inflicted upon the families and creditors of suicides by the law of England. This, like all other absurd and unjust laws, is evaded, in almost every instance, by perjury, and the existence of invention in a sovereign. The example given of transfère punishment is the corruption of blood, the absurdity of which is ably exposed. The chief instances of collective punishments are those in which corporations are punished for the faults of certain individual corporations; a proceeding which can never be justified. The well-known examples of fortuitous punishments are taken from the law of England. The most notable is the forfeiture and sequestration of freehold property, in cases of attainder of treason and felony, where the confiscation relates back to the ammination of the offence, and all means of conveyance are avoided; so that a man may commit a secret crime, and sell his estate to an ignorant and innocent purchaser, in whose hands the crown, for the lord afterwards feizes the estate upon the vendor's attainder; and as his goods and chattels are forfeited upon conviction, the only fund of compensation is gone also. Deodands are another instance of similar injustice; and the punishment of incapacitating a perfon from giving evidence, is manifestly one which may
strike more injuriously at parties wholly unconnected with the offender, than at himself; besides, that it is by no means inflicted merely with the view of putting courts of justice on their guard against admitting a bad witness; for it is often the punishment of crimes which have no peculiar connection with violation of truth.

Among the evils of complicated punishments, we may reckon, besides outlawry and incapacitation of giving evidence, excommunication and felony. Some grofs abusés having occurred in the infliction of the punishment of excommunication, several distinguished persons have undertaken to substitute other procedure in its place; and Sir W. Scott brought a bill into parliament with this view, so that the evil is done away. The punishment of persons as felons, comprehends a number of inflictions very different from each other, so that our author considers the punishment as a felon to be a vague and indefinite term. This comprehends two descriptions of punishment; the one capital, with forfeiture of lands and chattels; the other not capital, but confining in forfeiture of chattels, and the form of burning in the hand; to which, by special enactment, imprisonment, transportation, or indeed any other punishment, may be superadded. It must be acknowledged, that a much simper and better manner of inflicting the punishment due to an offence would be, to tell at once what it is to be comprised; and instead of enacting that certain offences are felonies, which specifies nothing, to prohibit them, and state the precise inflictions which shall follow the commission of them. For the general character and high commendation of the work, which has furnished the preceding materials, we refer to the Edinb. Rev. N° 43, p. 1-31.

Penitent, in Theology. It has been disputed among divines, whether the punishment of the wicked in the future world be firitul eternal or not. For the arguments on both sides of the question, see HELL.

PUNITORY Interest, in the Civil Law, such interest of money, as is due for the delay of payment, breach of promise, &e.

PUN, in Natural History, the inward part of the excrement or exuberance of an oak. It is used by the Indians in Virginia for indiarubbing, as the East Indians use noxa. Phil. Traub. No. 454. sect. 1.

PUNN. See PEN.

PUNO, in Geography, a town of Peru, now annexed to the viceroyalty of La Plata or Buenos Ayres, and capital of a district of the same name, called allo Paucaireolla (not Paucaireolla, as it is misprinted in that article). It is a rich and populous town, situated on the W. side of the lake Titicaca, and containing some illustrious families, as well as a beautiful church for the Spaniards, and another for the Indians, who weave great quantities of coarse cloth, with which they supply the neighbouring countries. S. lat. 16° 20'. W. long. 76° 26'.

PUNT, in Sea Language, a sort of oblong flat-bottomed boat, with a square head and stern, whose floor resembles the platform of a floating figure; and, used by shipwrights for breading, caulking, or repairing a ship's bottom. It is also used in some canals.

PUNTA, in Geography, a town of South America, in the audience of Quito, and jurisdiction of Guayaquil.

PUNTA Laguna, a town of Mexico, in the province of New Biscay; 40 miles N.N.E. of Durango.

Punta is also an epithet, distinguishing several capes, which are too numerous to be here recited; and this is the left necessary, as the principal of them occur under other appropriate titles.
found that the pupil not only dilated and contracted itself, when one of the eyes was shut, but also when both were open. F. Paul found, from repeated experiments, that the pupil not only of cats, but also of men, and other animals, always contracted itself when the eye was exposed to a bright light, and again dilated itself when the light was faint and languid. This he always observed, as well when both eyes were open, as when one of them was shut. The same remark had been made by Achillinus, in a treatise published in 1522; and the fact was known to the Arabians, Rhazes and Avicenna. That the pupil of the eye is enlarged, in order to view remote objects, and that it is contracted while we are viewing those that are near, is a fact with which Scheiner, in the beginning of the seventeenth century, was well acquainted, and which he proved by experiments, and illustrated by figures. When a needle, or any small object, is brought near to the eye of any person, who looks attentively at it, the pupil, he says, is plainly seen to contract; and it as constantly expands whenever it is withdrawn.

This alteration of the pupil is effected by certain muscular fibres on the outisde of the uvea, which arrive from nerves detached higher from the sclerotic. These fibres proceeding straight from their origin towards the centre, terminate in the orbicular limb or verge of the pupil, which consists of orbicular fibres, whereby the figure and space of the pupil are defined. The first, or longitudinal fibres, dilate the aperture of the pupilla; the latter, or orbicular ones, confine it.

Some authors, however, attribute the motions of the pupilla to the ligamentum ciliare; and others think, that both this, and the fibres of the uvea, concur herein. Dr. Durham adds, that while the pupil opens and shuts, the ligamentum ciliare dilates or compresse the crystalline, and brings it higher, or farther back, from the retina, as the object is more or less remote.

There is no doubht that the change to which the pupil is subject is the effect of light upon the eye. Dr. Hartley, Obf. on Man, vol. i. p. 219, supposes, that the light which enters at the pupil has great efficacy in contracting both the greater and less rings of the iris, as may be concluded, he says, from the immobility of the pupil in a gutta perforata; also because, on this supposition, the light which pusses in at the pupil, by contracting the less ring, becume a check and guard against its own too free admission, which is agreeable to the tenor of nature in like instances. The retina, he observes, extends to the greater ring, and may send some nervous fibres to it, and even to the iris.

Dr. Whytt also says, Elhay on vital and involuntary Motion, p. 112, that the contraction of the pupil is not performed by the action of light upon the iris, but upon the retina; since whatever intercepts the rays of light, so as to prevent their reaching the retina, causes a preternatural dilatation of the pupil; because in a cataract, where the crystalline humour, being considerably opaque, intercepts a great part of the rays, the pupil loses a good deal of its contractile power. This author also observes, that the wideness of the pupil in a syncope, apoplexy, and confirmed gutta perforata, shews that, in order to dilate the pupil to its largest size, no effort of the mind is necessary, but only the superior contractile power of the longitudinal fibres of the uvea, when its circular muscle is not excited into action by the stimulus of light on the retina. M. Mery informs us (Mem. Ac. Paris, for 1704) that, having plunged a cat in water, and exposing her eye to the strong light of the sun, the pupil was not at all contracted by it; whence he infers, that the contraction of the iris is not produced by the action of the light, but by some other circumstance. For he contends, that the eye in this situation receives more light than in the open air. M. de la Hire, in reply, endeavours to show, (Mem. Ac. Par. for 1709) that fewer rays enter the eye under water, and that, in those circumstances, it is not so liable to be affected by them. Besides, it is obvious to be remarked, that the cat must be in great terror in this situation; and being an animal that has a very great voluntary power over the muscles of the iris, and being now extremely attentive to every thing about her, she might have her eyes open, notwithstanding the action of the light upon it, and though it might be very painful to her.

The figure of the pupil, in various animals, is wonderfully adapted to their various circumstances and occasions in some, e. gr. in man, it is round, that form being fittest for the position of our eyes, and the various uses we make of them in all directions.

In others, it is elliptical or oblong; in some of which, e. gr. the horse, sheep, ox, &c. the ellipsis is transverse, and the fissure large, to enable them to see laterally, and even with a little light; and thereby both to gather their food the better in the night, and to avoid dangers on either side. In others, e. gr. the cat, the ellipsis is erect, and is also capable of opening very wide, and shutting very close; by means of the latter of which itates, that animal can exclude all, but, as it were, a single ray of light, and so avoid all the inconveniences of the bright sun; and by the former, it can take in all the faintest rays, and thus avoid the inconveniences of the night: an incomparable provision for these animals, which are to watch and way-lay their prey both by day and night, to see upwards and downwards, to climb, &c. See Eye and Vision.

Pupil, Closure of. A preternatural smallness of the pupil always renders the patient incapable of discerning objects well at night-time, and occasion a diminution of vision. The consequence of a complete closure of the pupil, a case termed simphalus, is total blindness. Both these affections only differ from each other in degree, and they originate from the same causes. The most frequent cause is a violent inflammation of the eyes, particularly when such disorder extends to the iris, and arises at a period when the anterior and posterior chambers of the aqueous humour contain none of this fluid. This case principally happens after the extraction of the cataract. Here the inflammation constantly affects the capsule of the crystalline lens, so as to make it opaque, and at the same time adheres behind the pupil to the iris; a circumstance which is well deserving attention. Not unfrequently, however, a closure of the pupil takes place during ophthalmy, notwithstanding both chambers of the eye are full of the aqueous humour. Wounds of the iris sometimes cause this unpleasant occurrence, especially when they continue open, and do not heal. It is observed to be most frequently produced by such wounds as divide the radiated fibres of the iris transversely. These wounds, however, do not invariably remain open; sometimes they close, and then the pupil undergoes no alteration. Even when such wounds do not unite, a closure of the pupil does not always follow. In these instances, the natural pupil has been remarked to become closed, and the preternatural aperture in the iris to be widened, when the eye was exposed to the light; and, on the contrary, immediately the light was diminished, the pupil became dilated, and the other opening was contracted and closed. - Wounds of the iris in the other direction, even when they remain diffimulated, often cause little or no diminution of the natural motion of the pupil.

It sometimes happens, that a greater or lesser portion of the iris is detached from the circumference of the cornea;
and, in this situation, an oval aperture is produced, through which the rays of light pass into the eye. A complete closure of the pupil is usually the consequence of such detachment of the iris. A blow on the eye, a kick of a horse, or some other external violence, attended with a violent concussion of the eye, is the common cause of this detachment of the iris. Once the eye has been it has brought on by a prolapse of the iris through an ulcerated opening in the cornea.

The iris was kept in a state of tension, and the patient was suffering constant pain in the eye; but, after a time, this pain suddenly ceased, when it was remarked, that the iris was torn from the upper edge of the cornea at five different points. The patient, who had been deprived of his sight by the closure of the pupil, now recovered it again. Through the aperture, formed by a separation of the iris from the cornea, patients commonly see distant objects tolerably well, notwithstanding the opening is immovable, and not in the centre of the eye; but, in general, they can see only a half of such objects as are near. In cases where the iris is thus detached, the pupil sometimes continues open. Janin once noticed an alternate motion in the pupil and the prettural opening. Between them the iris was thrown into folds, or wrinkles. Immediately a bright light entered the eye, the wrinkles diminished, the pupil contracted, and assumed a long narrow shape, while the pretural opening grew larger and wider. In dark places, the latter became smaller, the pupil larger, and the part of the iris situated between them more wrinkled.

Sometimes the pupil becomes closed, in consequence of a spasmodic contraction of the iris. At first, the pupil is merely Jeftened in diameter; the power of seeing decreases; and at length the eye is very feble of the light, though not at all inflamed. At last, the pupil is entirely closed. This case presents itself most frequently after operations for the cataract. The pupil occasionally undergoes a gradual diminution after such operations, and in the end is totally obliterated, without any particular cause, inflammation, or pain; and this event may happen several weeks, months, or years, after the time of those operations. It is remarked by surgical writers, that such persons as frequently read for a long while, and attentively look at shining, bright, strongly illuminated objects, run a risk of being attacked with this disorder. The pupil, which contracts itself very much during the inspection of these objects, at length becomes habituated to a state of contraction, and loses all power of expanding itself. Richter observes, that this form of the complaint is termed *fynizeis ex constructure*.

Infants are sometimes born without pupils. In this case, the situation of these openings is occupied by the membra pupillaris. By some this affection has been erroneously called *cataracta pupillaris*: as Richter observes, the term *fynizeis congenita* is much more applicable to it. A prolapse of the iris is commonly attended either with a diminution, or a total closure of the pupil. When the iris is reduced in time, the pupil generally expands again; but when the reduction is not effected till after a certain period, this opening remains closed, and this notwithstanding every portion of the iris be now replaced. A prolapse of the vitreous humour sometimes occurs, and leaves after it, a contracted state of the pupil. Every long continued deficiency of the aqueous, or considerable loss of the vitreous humour, by whatever cause produced, is accompanied with risk of a permanent diminution, or even a total closure of the pupil: hence it is often a symptom of *atrophia oculi*.

Sometimes, though the pupil is of proper dimensions, it is obstructed by extraneous matter. This case is termed *fynizeis fisuria*. The substance producing the obstruction is either a portion of coagulated blood, which is the consequence of an extravasation of this fluid in the anterior chamber; thick matter from a luppuration within the eye; or the remains of a diffused lens continuing after the operation of extracting the cataract. A white opaque membrane, like a clyl, is sometimes seen protruding through the pupil into the anterior chamber. The capsular cataract is occasionally so moveable, that, when the head is inclined forwards, it enters the pupil, and partly comes into the anterior chamber; but returns into its former position, as soon as the head is inclined backward again. Mauchart affiends, that he has seen a fungous excrecence growing from the edge of the iris, and filling up the pupil.

When the diminution or closure of the pupil is of long standing, it can never be relieved, except by an operation, whatever may be the nature of the cause from which it originates. When the pupil has been for a long while in a diminished or closed state, it loses entirely the power of expanding again, and continues lefrenched, or shut, notwithstanding the removal of the cause of the disorder. If the affection be congenital, or the consequence of inflammation, it can never be obviated except by an operation, however short the period of its duration may be. When it arises from irritation of the iris, or from intense observation of shining, bright objects, and has not existed a long time, it may be cured without an operation. Also, in cases where the operation is necessary, the mode of performing it differs according to circumstances.

Patients who become afflicted, in consequence of frequently observing bright, glittering objects, may obtain relief by a timely avoidance of every light that is too strong, wearing green spectacles, viewing objects with an opera glass, and frequently washing the eye with some warm emollient liquor, especially a decoction of mallows, hemlock, and poppy-heads. The peculiar virtue of the extract of belladonna, in making the pupil dilate, might here also be turned to great advantage. It is to be diluted and rubbed over the eye-lids and eye-brow, and allowed to remain applied a certain length of time every day. The same means are likewise proper in cafes, where the disorder depends upon irritation. Richter speaks favourably of the good effects of antimonial wine, and the extract of aconitum, as internal medicines, together with warm bathing and blisters. Here the outward application of the extract of belladonna unquestionably merits a careful trial.

There is a pretural contraction of the pupil, which alternately arises and then ceases again. This case sometimes lasts only a few hours; sometimes several days. During the attack, patients see more weakly than usual, or cannot see but very little, according as the pupil happens to be more or less diminished. In particular occasions, the attacks come on at fixed times, and the complaint is then periodical. During the disorder, the pupil seems to be affected with spasm. Occasionally, indeed, spasmodic complaints, says Richter, take place at the same time in other parts. Here the dilate is most commonly the consequence of irritation seated in the abdominal vasa, and requires aperient, and especially emetic medicines. When these means prove ineffectual, it is at length necessary to resort to the external and internal use of anodyne tonic remedies, valerian, bark, and small doses of ipecacuana. The outward application of the extract of belladonna to the eye-brow and eye-lids promises also, in such cafes, to be an useful auxiliary means. This sort of closure of the pupil has been observed as a symptom of hyphemia.

The eminent Mr. Chedden first made the proposal of perforating the iris, and also first put such an operation in execution.
execution. He introduced a slender knife, about one line from the margin of the cornea, through the coats of the eye, into the posterior chamber, and pulsed it through the iris in the situation of the closed pupil, so as to form in that membrane a small longitudinal incision. It is alleged that this operation of Cheifelden's has been repeatedly performed, and for the most part unsuccessfuil. According to the observations of Janin and Warner, the incision did not dilate, and became shut up again soon after it had been made. In one example, Janin was prevented from completing the operation with accuracy, in consequence of hemorrhage rendering the aqueous humour turbid. The plan of introducing the knife into the posterior, instead of the anterior chamber, seems also to be disadvantageous; for, in this last mode, the iris can be more easily got at, and nothing is injured except the inelastic cornea. On the other hand, in Cheifelden's method, all the coats of the eye, the lens and its capsule, and the ciliary processes, are all wounded. Besides, as the point of the knife is concealed behind the iris, one can never be certain that it is precisely opposite the place where the perforation of the iris ought to be made.

It was the opinion of Janin, that when the incision in the iris was made in a parallel direction to the radiated fibres of this membrane, it alwaye very soon closed again; and, on the contrary, that when it was made across these fibres, it not only dilated, but continued permanently open. He, therefore, used to operate as follows: he first divided the lower half of the cornea, as in the operation for the cataract; he then pulsed a finely pointed pair of scissors into the iris, about one line from the lower edge of the cornea, and the incision was made in a perpendicular direction on the inside of the pupil, without touching the pupil itself. The cut usually became dilated immediately, and remained open. But care must always be taken to make the wound in the iris on the side of the pupil next the inner canthus, as making it on the opposite side might occasion quinting. See Janin's Mémoires fur l'œil.

Wenzel's plan is more modern. The knife is introduced into the cornea in the manner usually done in the operation for the cataract; but when it has approached within half a linea of the place of the closed pupil, its point is to be deflected to the depth of half a line through the iris. Three-quarters of a line from this puncture, towards the inner canthus, the point is to be elevated again; and the incision of the cornea is then to be finished, as in operating for the cataract. In this way, a cut is made in the iris, resembling on a small scale the incision on the cornea; that is to say, it is of a semilunar shape, and forms a small flap; but it is rarely so smooth and even as that in the cornea. The flap is to be cut away with a small pair of scissors, so that a roundish aperture, which is sure to remain open, is produced in the iris. When the flap cannot be got hold of, so as to admit of being removed with scissors, a small piece of the iris is to be cut out.

The method which we have next to take notice of, is that proposed by the eminent Scarpa. He conceives, that the artificial pupil may be most easily made, by detaching a certain extent of the circumference of the iris, next the note, from the ciliary ligament, by means of a couching needle. Others object, however, that this mode is not only difficult, but that the aperture is hardly ever permanent.

The last way of operating, of which it remains for us to speak, is that recommended by Mr. Gibbon. This surgeon begins by making a puncture in the cornea, with a broad cornea knife, within a line of the sclerotica, to the extent of about three lines. All preflure is now to be removed from the eye-ball, and the cornea knife gently withdrawn. The consequence of this is, that a portion of the aqueous humour escapes, and the iris falls into contact with the opening in the cornea, and closes it, like a valve. A flight preflure must now be made upon the upper and inner part of the eye-ball, and be gently increased, or varied in direction, till the iris gradually protrudes, so as to present a bag of the size of a large pin's head. This protruded portion must be cut off with a pair of fine curved scissors, and, at the same time, all preflure is to be removed. The iris will then recede within the eye, and the piece that has been removed will leave an artificial pupil more or less circular.

When the centre of the cornea is to opaque, that the rays of light cannot enter the pupil, and the circumference of that membrane is transparent, vifion may be materially improved by removing a portion of the iris opposite the unripe part of the cornea.

There can be no doubt that, with respect to the comparative merit of the preceding modes of operating, Gibbon's plan ought in general to be preferred, as being nearer and safer than the others. Consult Sharp's Treatise on the Operations; Janin's Mem. fur l'œil; Wenzel on the Cataract; Scarpa sulle Malattie degli Occhi, capo 16; Richter's Anfanggründe, &c. band. 3. cap. 9.; Gibbon's Pract. Obs. on the Formation of an artificial Pupil, &c.

PUPIL. Preternatural Dilatation of. This affection, which is termed mydriasia, is usually a symptom of some other disease, and is hardly ever an original complaint. It occurs in very different degrees. Sometimes the pupil is considerably expanded, that the iris can just be discerned, like a small fold at the inner circumference of the margin of the cornea. In some cases, the pupil is totally immovable; in others, it retains a certain degree of motion. Not unfrequently, it has lost its round shape, and become of an oblong, or angular figure. In particular cases, the affection is only in one eye; in the majority of instances, it takes place in both. It is often accompanied with total blindness; occasionally, though less commonly, the patient retains the faculty of seeing. In the latter case, the patient has an aversion to the light, or is even quite blind in the day. He is also in constant danger of being totally deprived of vision in a gradual way by the gutta serena. (See Gutta, Serena.) To some patients of this description, all objects appear to be smaller and more diftant than they are in reality. The following are the difeases of which mydriasia is commonly a symptom. 1. Amaurosis, or the gutta serena. Of this complaint, however, it is not an inefcapable and constant symptom, the pupil sometimes retaining the power of motion, and being quite free from blemish; and in cases where it is dilated and motionless, it now and then recovers its natural size and movability, although the amaurosis continues unchanged. 2. The cataract. Here mydriasia happens under two different rales; namely, either when the cataract is adherent to the iris, or when the opaque crystalline lens is preternaturally thick and large. In the first case, it usually happens that the pupil is at the same time incapable of motion, and irregular; in the second, it sometimes can move in a certain degree, and the iris is convex and pressed forward toward the cornea. 3. Hydrophthalmitia, or dropy of the eye. Here the dilatation of the pupil arises immediately from the distended state of the eye-ball, and with this the disorder increases or subsides. (See Hydrophthalmitia.) 4. In patients who are troubled with worms; who are in fowus, who are afflicted with hydrocephalus, apoplexy, or any comatose disease, the pupils are in general preternaturally...
ternaturally dilated. In all such cases, the only indication is to endeavor to remove the original disease, of which the mydriasis is merely a symptom.

In the case where mydriasis is to be regarded as the only disorder, the complaint seems to depend upon a weakness or paralysis of the fibres which close the pupil. Here it is commonly the consequence of apoplexy, a blow on the eye, or a violent and sudden dilatation of the pupil, as, for example, sometimes happens in the extraction of a cataract. When the disease is of long standing, there is little hope of cure, whatever may be the cause from which the complaint arises. When it is recent, the pupil will sometimes regain the power of moving and contracting under the use of internal and external stimulants and tonic remedies. The chief means of this class are, blisters applied to the eye-brows, ethereal oil rubbed into the skin around the orbit, electricity, emetic medicines in small and full doses, and other similar remedies, which are usually preferred for the relief of paralytic affections of other parts. When these means prove unavailing, the practitioner must be content with recommending a palliative plan, which will be presently noticed.

As the pupil naturally dilates in the dark, it follows, that when a person is kept a long while away from the light, a mydriasis ev. conformatudine is produced, the pupil becoming habituated to the expanded state, and losing the power of contraction. In most instances, it gradually recovers its motion after the eye has been for a certain time exposed to the light again. The light, however, must be allowed to get to the eye only by degrees, or else its sudden operation on the eye, in the expanded state of the pupil, would be apt to impair, or even destroy vision altogether. When the pupil does not recover its power of motion, the patient must be satisfied with resorting to palliative means. It has been remarked, that mydriasis is sometimes a congenital defect. All attempts at a radical cure must here be attended with extreme difficulty. When the light cannot be endured without inconvenience, the palliative plan is necessary. A blow on the eye sometimes tears the pupil. The rent moily remains open, and the patient is in the same state as if affected with mydriasis. Here, as the laceration cannot be repaired, the indication is to prevent, by palliative means, vision from being hurt by the too great strength of the light.

Through a preternaturally dilated pupil the light enters the eye in such quantity, that the patient is blinded. He not only feels things very indistinctly in light places, but he also runs a risk of being gradually entirely deprived of vision, in consequence of the too strong action of the light upon the eye. The prevention of such mischief is the object of the palliative treatment. By it the light which falls upon the eye is to be diminished, so that the patient may be enabled to see not only plainly and without inconvenience in light places, but also without any danger of losing his sight altogether.

The usual means recommended for this purpose are, eye- and glass-frames, by which the light, coming principally from above, is kept from entering the eye; black veils over the face; green spectacles, which lessen the quantity of rays of light coming from objects which the patient is looking at; spectacles made with black cards, in the centre of which is left an opening of the size of the natural pupil. But the bell and most proper means is a pair of tubo-spectacles. This is a common pair of spectacles, which, instead of glass, has adapted to its two rings two conical tubes, the bases of which are to be put towards the eyes, and the narrower parts towards the objects which are looked at. These tubes ought to be made of black leather, and they should be three or four inches long. Their diameter at the base must be equal to that of the circumference of the orbit; but their outer ends need not be quite so wide. The edge of their bases is to be cut in such a way, that they will fit closely on the circumference of the orbit. The use of these tubes consists in their keeping off all the rays of light coming laterally, and only admitting thofe into the eye, which proceed from objects in the axis of vision. Every surgeon will be able, according to circumstances, to multiply and vary the contrivance here described. See Richter's Anfangli. der Wundarzneykunde, hand 3, kap. 10.

PUPILARIS MEMBRANA, in Anatomy, a circular membrane, by which the pupil is closed during the greater part of utero-gestation. See Eye.

PUPILLARITY, or PUPILLAGE, the state of a pupil, in opposition to pupilry.

PUPPET, in Natural History. See Aurelia.

PUPPISOS, a name given by some authors to the os frontis. The future in this bone is also called by many anatomists the futura pupils.

PUPPOLA, in Geography, a town of Sweden, in the government of Uleå; 45 miles S. of Uleå.

PUPULÆ, a name used by some to express the extremities of the fingers.

PUR, in Geography, a river of Rullia, which runs into the Tazorakain gulf. N. lat. 67° 40'. E. long. 78° 34'. Pur autre vic, in our Lacho-Books, is used where lands are held for the life of another. See Occupant, and Tenant.

PURA Eleemosyna, pura alms, denotes a tenure, whereby the churchmen hold lands in Scotland, somewhat on the footing of the primitive clergy.

Pura Halla. See Hasta.

PURALLA BAY, in Geography, a bay on the coast of Chilli. S. lat. 42° 16'.

PURANA, the common name of a series of poetical romances, considered among the Hindoes as sacred works, the offspring of inspired writers, communicated for the instruction and benefit of mankind. They are ascribed, in their present form, to a celebrated man in the literary history of the Hindoes, whom they call Vyafa. (See Vyasa.) He is suppos'd to have reduced an immense mass of inspired writings into eighteen works, and to have arranged them as they now appear. The following are the titles of these eighteen books, to which the common denomination of Purana is appended when spoken of or referred to. 1. Brah. or the Great One. 2. Padma, or the lotos. 3. Brhmanda. 4. Agni, or fire. 5. Vishnu. 6. Garuda. 7. The transformations of Brahma. 8. Siva. 9. Linga. 10. Nareda. 11. Skanda. 12. Markandeya, or the immortal man. 13. Bhavihita, or the prediction of futurity. 14. Matsya. 15. Varaha. 16. Kurma. 17. Vamana. 18. Bhagavata. Of these, the first four relate to cosmogony; the next nine to the attributes and powers of the Deity. The fifth is named after the vehicle or bird of Vishnu, called Supernus, as well as Garuda. (See Supernas.) See Linga, for the mystical symbol whence the ninth derives its name. Nareda, whose laws and history are detailed in the tenth, is a mythological son of Brahma. Skanda, the hero of the eleventh, is a name of Kartikeya; see that article. The fourteenth and three following relate the histories of four of the principal incarnations of Vishnu the preferer, called Matsyavatara, Varahavatara, Kurmaavatara, and Vamanaavatara. Under these articles respectively will be found a brief notice of the outline of their histories. The fourteenth, called Sri Bhagavata, is the life of Krishna, (see Krishna,)
with which the poet Vyasa is popularly imagined to have crowned the whole series; though some reasonably align them different compilers; and the series is differently arranged and named by other authorities. Every Purana treats of live subjects. 1. The creation of the universe. 2. Its progress, and the renovation of the worlds. 3. The genealogy of gods and heroes. 4. Chronology, according to a fabulous fable. 5. Heroic history, containing the achievements of demigods and heroes. Since each Purana contains a cosmogony, with mythological and heroic histories, they may, not unaptly, be compared to the Grecian theogonies.

A copy of, we believe, all the eighteen mythological poems, is preserved in the library of the East India house. It is estimated that the whole cannot consist of less than half a million of leaflets. Hitherto no translation of any of them, or of any considerable portion of either, hath been made from the original into any European language. They are, of course, written in the Sanscrit tongue. In some articles of this work a stanza, or a brief outline of some of the Puranic tales, elucidatory of the character or subject under discussion, is occasionally introduced, and may perhaps give some little idea of the style of these extravagant poems. The reader, in this view, may consult the following, in addition to the other articles herein and from the article referred to: Jam-bavanta, Kalpa, Karna-shagi, Kritika, Lellewara, Lotos, Mere, Muni, Nakshatra, Naramedha, Pava-ka, Pavana, Pikeswari, Pollear, Prithu, &c. &c.

As to these extravagant, and not always decent, tales of the Puranas, the probability is that physical or historical facts are thus connected under a veil of allegory, carried through a series of poetical narratives and adventures, related of the personified attributes of the Deity. The facts are either forgotten, or unknown to the vulgar; but the fables remain, and are generally and commonly alluded to in composition and conversion. Taken literally, as the transpositions of divine or holy persons, nothing (butting the invention, imagery, and other poetical merits) can be more contemptible than these Puranic romances; but if we desire to extract the grains of ore that the mists may probably contain, we must be content to examine them as they are; and in case of failure, many inquisitive researchers will deem their labour not lost, in the invention and other poetical beauties, astounding in these wild compositions.

We shall briefly give an abstract of the contents of two or three of the Puranas, whence a judgment may be formed of the others. The Agni Purana is leagued to have been delivered by Agni, or Pavaka, the god of fire. (See Pavaka.) It contains a great variety of subjects, and seems to have been intended as an epitome of Hindoo learning. The poem opens with a short account of the several incarnations of Vishnu, an enumeration of which, with a brief outline of their history, will be found in the article Vishnu of this work, and those thence referred to. It dwells, however, chiefly on the incarnations of Krishna and Rama. (See these articles.) Then follow a history of the creation; a tedious dissertations on the worship of the gods, with a description of their images, and directions for constructing and setting them up; a concise description of the earth, particularly of those places which are eloquently holy, with the forms of worship to be observed at them; a treatise of astronomy, or rather astrology; a variety of incantations, charms, and spells, for every occasion. One species of this is named mantra, under which article a sufficient account is given of them; computations of the periods called manvantara, kalpa, &c. (See Kalpa); a description of the several religious modes of life called dharma, and the duties to be performed in each; rules for penance (on this head see Tapas); feasts and fasts to be observed throughout the year; rules for bestowing charity; a dissertation on the great advantages to be derived from the mythic word OM (under which article of this work the reader will probably find sufficient of mysticism), with a hymn to Varun, of whom something occurs under that article. The next head relates to the office and duties of princes; under which are given rules for knowing the qualities of men and women; for choosing arms and reigns of royalty; for the choice of precious stones; and a treatise on the art of war. The next head treats of worldly transactions between man and man, as to buying and selling, borrowing and lending, giving and receiving, &c. &c. Then follow certain ordinances, according to the Veda, respecting security from misfortunes, &c. &c. and for the worship of the gods. Genealogies of the two races of solar and lunar kings, called Suryavanta and Chandravanta (see Surya) of the family of Ydhu and of Krishna, with a short history of the twelve years' war, described in the Mahabharat. (See Mahabharat.) A treatise on the art of healing, as applicable to man and beast, with rules for the management of elephants, horses, and cows; charms and spells for curing various disorders; and the modes of worshipping certain deities; on the letters of the Sanscrit alphabet; on the oraments of speech, as applicable to oratory, poetry, and the drama; on the mystic signification of the single letters of the Sanscrit alphabet; a grammar and short vocabulary of that language. The whole of this defunctory work is divided into 355 short chapters.

The Siva Purana is sometimes called alo, after one of the forms of his comfort, the Kalika Purana. (See Kal.) It is a mythological history of that god, including her adventures under various names and characters. Many of these names and characters are enumerated under the article Parvati, her more common name; and Mr. Moor has given an extract under Naramedha, which word means a man-facric, the rites and ceremonies of that horrid offering being minutely laid down in this Purana. It is a curious and entertaining work, including as episodes several beautiful allegories, particularly one founded on the motions of the moon. See Moor's Hindu Pantheon.

The Vayu Purana, as one of these poetical romances is variously called, but which we have not the means at this moment of ascertaining, is attributed to the regent of wind Vayu, otherwise and more commonly called Pavana (see Pavana); where the reason is furnished why the Purana is not called after that name. It contains, among a variety of other curious subjects, a circumstantial detail of the creation of all things, celestial and terrestrial, with the genealogy of the first inhabitants; chronological computations as to the grand periods manvantara, kalpa, &c. before spoken of; a description of the earth, as divided into islands, continents, &c. and its dimensions, and also of other planets and fixed stars, their distance, circumference of orbits, &c. &c. Under the article Pavana, an extract is given from the Matiya Purana, directing how images or pictures are to be made of the god of wind. Most of the Puranas contain directions of that sort.

A brief notice of one other of these inspired works will suffice. The Nareda Purana is believed to have been delivered by the inspired Nareda, a mythological son of Brahma. Under the article Noreda (see Hindu Pantheon) an account is given of him, with his genealogy, and the derivation of his name, from the Varaha Purana. Like the others, this poem opens with describing "how heaven and earth rose out of chaos," but it treats principally of the unity of God, and as it postscripturally is written with the Vaishnava bias (see Vaish-
of the Deity. On this point, see Sects of Hindous. It argues that all other gods are but emblems of the works of Maha Vishnu, and the female deities, or fakis, emblems or personifications of his powers. Other Hindoo fects lay the fame of the deity of their exclusive worship, as noticed under Krishna, Rama, Silva, &c. It states that the worship of the Trimurti, or either of the triad (see Trimurti), whether the creator, preserver, or regenerator, is in effect worshipping of Vishnu. This Purana concludes with rules for the several tribes in their spiritual and temporal conduct through life.

Their voluminous and certainly curious poems, are held in the general estimation of the Hindoos, as second only to the Veda, their immediate scripture. (See Veda.) Each of the Vedas are certain passages interpersed, relating chiefly to cosmogony, which are called Purana, but are wholly different from the eighteen mythological poems, the subject more especially of this article.

With respect to the age of the Puranas, orientalists differ widely. Sir W. Jones satisfied himself that they have been written about 2500 years. He does not state precisely the mode of reasoning, by which he arrived at this conclusion; he gives, however, the outline of the process, and asks the public to give him credit for a few very curious facts, which, although he feels, capable of strict proof, could then be only asserted. We are not aware that the proofs were ever submitted to the public; and whatever they were, they have not wrought conviction on the minds of all. Mr. Colebrooke, however, (Af. Ref. vol. vii.) leaves us to infer that he thought them very little inferior in point of antiquity to the age assigned them by his illustrious predecessor in the chair of the Asiatic Society. Mr. Wilford expressly says, that "the Puranas are certainly a modern compilation from valuable materials, that I am afraid no longer exist: an astronomical observation of the heliacal rising of Canopus, mentioned in two of the Puranas, puts this beyond doubt." (Af. Ref. vol. v.) Mr. Bentley, after giving various reasons and calculations for the foundation of his opinion, says, "It must be evident that none of the modern romances, commonly called the Puranas, at least in the form in which they now stand, are older than 684 (now 1813, about 695) years," that some of them are the compilations of full later times." (Ib. vol. viii.) As far, indeed, as the eighteenth Purana, called Sri Bhagavat, is concerned, Mr. Colebrooke countenances Mr. Bentley's opinion. "I am inclined," he says, "to adopt an opinion supported by many learned Hindoos, who consider the celebrated Sri Bhagavata as the work of a grammarian, supposed to have lived about 600 years ago." (Ib. See Sri Bhagavat.) Be this as it may, the orthodox Hindoos have implicit faith in, and great veneration for, those celebrated poems, or "sacred histories," as they call them; and it is authoritatively asserted, that "the Veda, the revealed system of medicine, the Puranas, and the code of Menu, are four works of supreme authority, which ought never to be shaken by arguments merely human. (See Menu.) Therefore, however, many individuals of all the four tribes of Hindoos, fewest certainly in that of Brahman, who correspond with the Levites of Israel, who deny the divine origin of the Puranas, looking upon them in nearly the same light as a rational critic of Europe may do.

Purangurah, in Geography, a town of Bengal; 20 miles S.E. of Isfamabad.

Purari, a name of the Hindoo deity Siva; which see.

Purarya, in Geography, a town of Hindooftan, in Oude; 32 miles N. Kairabad.

Purbach, George, in Biography, an eminent mathematician and astronomer in the 15th century, was born at Purbach, a town on the confines of Austria and Bavaria, in 1423. He was educated at Vienna, where he manifested great talents, and took his degree of M.A. with great applause. He directed his attention principally to mathematics, and advanced in that science with almost incredible rapidity. For farther improvement, he visited the most celebrated universities of Germany, France, and Italy. He found a particular friend and patron in cardinal Cusa, and he formed an intimacy with John Blanchini of Bologna, who admiring Purbach's extensive knowledge, and his ready method of communicating instruction, wished to prevail upon him to deliver lectures on astronomy at Ferrara; but Purbach preferred returning to Vienna, where he obtained the mathematical professorship in that university. About this time he received offers from Lodislaus, king of Hungary, to become his astronomer, accompanied with promises of liberal rewards and distinguished honours, which he declined.

The fame of Purbach, as a mathematical professor, was soon widely diffused, and brought numerous students to attend his lectures at Vienna. Among others was the celebrated Regiomontanus, who secured the efficacy of his method, and was chosen the almoner and companion of Purbach in his labours. From this time they maintained an union of studies, in their endeavours to improve the different branches of mathematical science, and more particularly astronomy. This science they would, no doubt, have materially improved by their joint labours, had Purbach's life been prolonged. His first essay was to amend the Latin translation of Ptolemy's Almagest. After this he wrote "An Introduction to Arithmetic," and proceeded to draw up another "On Gnomonics," or dialling, with tables suited to the difference of climates and latitudes. This was followed by a small tract "Concerning the Altitudes of the Sun," with a table, and "Astrolabic Canons." After this he made solid spheres, or celestial globes, and not only explained their construction and uses, but added to them a new table of fixed stars, with the longitude by which every star had increased, from the time of Ptolemy to the middle of the 15th century. He also invented various other instruments, among which was a "gnomon," or geometrical square, with canons, and a table for the use of it, which he sent to the archbishop Strigonia, who was himself a man of great erudition, and entertained a high opinion of Purbach. Our author made considerable improvements in trigonometry; prepared tables of the fixed stars, and undertook to reform those of the planets, and constructed some entirely new ones. When these tables were finiished, he drew up a kind of perpetual almanack, chiefly for the moon, answering to the periods of Meton and Calippus: also an almanack for the planets, or, as it was afterwards called, an Ephemeris for many years. He finished his "Theoria Nova Planetarum," (see Muller,) which was made a textbook in all the schools, and was commented upon by some of the most eminent mathematicians. Purbach died in the 33rd year of his age, in 1461.

Purbeck, in Geography, a district in the Blandford division of the county of Dorset, England, is bounded on the west by Luckford lake; on the south by the British channel; and on the other side by the river Frome, and the bay of Pool. It is improperly called an island, being in fact only a peninsula, as it may be entered from East Lulworth by an isthmus, between the head of Luckford lake and the sea. This district extends twelve miles in length, and varies from seven to ten in breadth.
It includes two hundreds, called Hazler and Rowbarrow, the former comprehending the eastern division of the isle, and the latter the western. These are subdivided into nine parishes, and contain one town, Corfe-castle, and several large villages and hamlets. The soil is everywhere calcareous; but the surface is much diversified by hill and dale. The quarries, shores, and cliffs, on the south side of the isle in particular, afford an inexhaustible fund of natural curiosities. Near Kingston, Worth, Langton, and Swanwick, are extensive quarries of freestone; and in many parts is a stone that rises thin, and is used for tiling; also a hard paving stone, much of which was used in rebuilding London after the fire, and in paving the streets and courts. At Swanwick is a white stone full of shells, which takes a high polish, and looks like alabaster; and near Dunhay is dug up marble of various colours, but chiefly a grey kind, formed by a congeries of shells, and anciently much used for grave stones and monuments. It was likewise very generally employed for small columns in the churches which were erected during the 13th century. The corona ammonis are frequently discovered here, some of them two or three feet in diameter.

In ancient times the whole of this isle was a forest, and was well flocked with red and fallow deer, and hogs, especially in the west parts; but these were almost entirely destroyed in the civil wars. James I. was the last of our kings who hunted there. The whole isle was till lately governed by a lord-lieutenant, who was admiral of the isle, and had power to raise and muster a militia; but this office ceased when the regular militia act was passed. Formerly there were many gentlemen's feats dispersed all over the isle; which were probably built for the reception and accommodation of the nobility and gentry who attended the royal hunts, as most of the owners of estates in this part of the country had their principal feats elsewhere, and only came hither in the hunting feasons. These are now almost, without exception, converted into farm-houses. For an account of the only town in Purbeck, see CORFE-CASTLE. Hutchins's History and Antiquities of the County of Dorset, 2d edit. by Gough. Beauties of England and Wales, vol. iv. by John Britton, and E. W. Braley.

Purbeck Stone, the fuscum ammonium Purbeckense of Da Costa, and pslvadum friabile albido fuscum of Hill, is an alkaline sandstone, which is hard and rough, of a disagreeable ash colour, very heavy, and moderately hard, of a texture not very compact, but somewhat porous, and is composed of an angular grit, cemented together by an earthy spar; it cuts freely, and with a tolerable even or smooth surface, but will not take a polih. It will not strike fire with a steel, and burns to a white colour. The quarries of this stone are in the island of Purbeck, in Dorsetshire, whence it is brought to London in great quantities, and used in building, and for pavements. Its specific gravity is 2.68. There is also another kind of Purbeck stone, the fuscum falco-albidum of Da Costa, and the symposium durissimum, splenditum albido-fuscum of Hill, which is alkaline, of a dull, disagreeable, pale, brownish, white colour, and is not capable of a polih, though it cuts to a very smooth surface: it is of a fine, close, compact texture, not quite delitigent of brightness, but full of sparcs of pure spar, and intimately mixed with small quantities of small pectinculus, which are often saturated and filled with the same substance; it is very heavy and hard, and water does not pervade its texture; it does not strike fire with steel, and when burnt, acquires a clear ash colour. This stone is brought from Purbeck, and used in building, pavements, &c. Hill informs us, that it is likewise found in many other parts of the kingdom, and that there are large strata of it in Yorkshire. Da Costa's Fossils, p. 128—152.

Purbutto, in Geography, a river of Hindooistan, which runs into the Chumbul; seven miles W. of Sulfor, in the country of Aghmare.

Purcarli, a town of European Turkey, in Beffaria, on the Dniepper; 4 miles S. E. of Bender.

Purcclain. See Porcelain.

Purcell, Henry, in Biography, an English musician of more extensive genius than perhaps our country can boast at any other period of time, was born in 1658. His father, Henry, and uncle, Thomas Purcell, were both musicians, and gentlemen of the chapel royal, at the restoration of King Charles II. There is a three-part song of Playford's "Musical Companion," by Henry Purcell, which, being printed in 1667, when our great musician was but nine years old, must have been the production of his father. There is likewise a chant in the first volume of Boyce's Collection, p. 289, No. 11, called the "burial chant," by Thomas Purcell, his uncle, who continued in the service of the chapel till the time of his death, in 1682. Though these compositions promise no great hereditary genius, they are mentioned here, as mankind is naturally curious concerning everything that is connected with eminent persons.

From whom Henry received his first instructions in music, cannot be very clearly ascertained. But his father dying in 1654, when he was no more than six years old, it is probable he was qualified for a chorister by Capt. Cook, who was master of the children from the restoration till the time of his death, in 1672. For, as Purcell was appointed organist of Westminster Abbey at eighteen years of age, he must have learned the elements of his art before his fourteenth year, at which time Pelham Humphrey, brought up in the royal chapel under Capt. Cook, was appointed his successor, as master of the boys. Purcell certainly continued to sing in the king's chapel, and to receive lessons from Humphrey till his voice broke, an accident which usually happens to youth at sixteen or seventeen years of age: after this, perhaps, he had a few lessons in composition from Dr. Blow, who were sufficient to cancel all the instructions he had received from other masters, and to occasion the boast inscribed on the tombstone of Blow, that he had been

"Master to the famous Mr. Henry Purcell."

But there is nothing more common than this petit larceny among musicians: if the first master has drugged eight or ten years with a pupil of genius, and it is thought necessary, in compliance with fashion or caprice, that he should receive a few lessons from a second, he instantly arrogates to himself the whole honour, both of the talents and cultivation of his new scholar, and the first and chief instructor is left to fling, "dic vos non vobis."

Purcell is said to have profited so much from his first lessons and close applications, as to have composed, during the time of his being a singing boy in the chapel, many of his anthems, which have been constantly sung in our cathedrals ever since. Eighteen was a very early age for his being appointed organist; that is, maestro di capella of Westminster Abbey, one of the first cathedrals in the kingdom for choral compositions and performance. It was not likely he would stop here: the world is, perhaps, more partial to promising youth than accomplished age: and at twenty-four, in 1672, he was advanced to one of the three places of organist of the chapel royal, on the death of Edward Lov, the successor of Dr. Christpher Gibbons, in the same station.
After this, he produced so many admirable compositions for the church and chapel of which he was organist, and where he was sure of having them better performed than elsewhere, that his fame was soon extended to the remotest parts of the kingdom.

From this time, his anthems were eagerly procured, and heard with pious rapture wherever they could be performed; nor was he himself long to devote himself totally to the service of the church. He was, very early in life, solicited to compose for the stage, and chamber, in both which undertakings he was so superior to all his predecessors, that his compositions seemed to speak a new language; yet, however different from that to which the public had been long accustomed, it was universally understood. His songs seem to contain whatever the ear could then wish, or heart could feel.

We have been assured by a very good judge of music, who was nineteen years of age when Purcell died, and remembered not only his person very well, but the effect which his songs had on himself and the public at that time, when many of them were first heard; and used to say, that "no other vocal music was listened to with pleasure, for near thirty years after Purcell's death; when they gave way only to the favourite opera songs of Handel."

The unlimited powers of this musician's genius embraced every species of composition that was then known, with equal felicity. In writing for the church, whether he adhered to the elaborate and learned style of his great predecessors Tallis, Bird, and Gibbons, in which no instrument is employed but the organ, and the several parts are constantly moving in fugue, imitation, or plain counterpoint; or, giving way to feeling and imagination, adopted the new and more expressive style of which he was himself one of the principal inventors, accompanying the voice-parts with instruments, to enrich the harmony, and enforce the melody and meaning of the words, he manifested equal abilities and resources. In compositions for the theatre, though the colouring and effects of an orchestra were then but little known, yet as he employed them more than his predecessors, and gave to the voice a melody more interesting and impassioned than, during the seventeenth century, had been heard in this country, or perhaps in Italy itself, he soon became the darling and delight of the nation. And in the several species of chamber music which he attempted, whether sonatas for instruments, or odes, cantatas, songs, ballads, and catches, for the voice, he so far paraped what our country had produced or imported before, that all other musical productions seem to have been instantly confinued to contempt or oblivion.

As many of his numerous compositions for the church, particularly those printed in the second and third volumes of Dr. Bayly's Collection, are still retained in the king's chapel, and in our cathedrals, we shall here acquaint the musical reader in what manner we have been affected by some of these productions, in a late attentive perusal of them.

It appears by Dr. Bayly's "Collection of the Words of Anthems of which his Majesty's Chapel Royal," that ten of Purcell's are still performed therein; and in the late Rev. Mr. Mason's "Copious Collection of the Words of such Anthems as are used in the Cathedral of York," that nearly twenty of his chorals compositions are still sung in that choir.

Purcell's four-part anthem, "O God, thou art my God," (Bayley's Collection, vol. ii. p. 148.) must certainly have been one of his juvenile productions, before he had sufficiently refined his ear, or exercised his judgment; as there are many crude harmonies, and false accents in it, which in riper years he would not have tolerated.

Of his six-part anthem, "O God thou hast called us out," the first movement, in which there are many bold harmonies, is extremely elaborate, yet spirited and pleasing. The verse, "O be thou our help," is not only full of new and fine effects, but touching. By those who object not to the confusion in the words which arises from fugue and imitation, while the several parts are singing different portions of the same sentence, at the same time, these words will appear perfectly well accented and expressed.

The first movement of his full anthem in eight parts, "O Lord God of hosts," is a noble composition, alla Pergolesiana, in which all the laws of fugue upon two, and sometimes four, subjects, are prefered inviolable; the harmony, though bold, is, in general, chaste, and the effect of the whole spirited and majestic. The second movement is extremely pathetic and expressive; but, both in that and the last movement, he seems trying experiments in harmony; and, in hazarding new combinations, he seems now and then to give the ear more pain than pleasure.

The two-part anthem, "Thy way, O God, is holy," continues to be excellent music still, in the slow movements; the quick, however, seems somewhat antiquated, and the melody to these words, "the air thundered," &c. seem too light and dramatic for the church at any period.

The three-part anthem, "Be merciful unto me, O God," is admirable throughout. Indeed, to our conceptions, there seems no better music existing, of the kind, than the opening of this anthem, in which the words, "I will praise God," and the last movement, in C natural, are in melody, harmony, and modulation, truly divine music.

The complete service of Purcell, in B flat, printed by Bayley, is a most agreeable and excellent piece of counterpoint, of which the modulation frequently simulates attention by unexpected transitions, yet of so sober a kind as never to give the ear the least uneasiness, till we come to the bottom of p. 110, and then the same crudities of the sharp 3d and flat 5th, and flat 3d, 4th, and 5th, which we have already cenured in the works of Dr. Blow, occur; which we hope, in spite of our partiality for Purcell, the organists of our cathedrals scruple not to change for better harmony.

These two or three combinations, like some words and phrases which Shakespeare tried unsuccessfully to render current, have been rejected by politeness; and it is in vain to attempt at forcing them upon the public by the mere weight of authority. The ear will patiently bear very rough usage from an artist who in general makes it such ample amends; however, there are limits, beyond which it is unsafe to exercise cruelty of all kinds; and the auricular senses will be deadened, disfigured, or rendered indifferent to music's powers, by too harsh treatment.

The "Benedictus," as well as "Te Deum," and all the rest of the service, must be extremely pleasing, in all other respects, to every ear sensible to harmony. The words are, in general, accented with great accuracy (except the contracting highfl into a monosyllable, to which only one note is given); and the few points of imitation are fragments of agreeable melody. In p. 121 of Bayley, the A and E, at the word benefit, in the Kyrie, are peculiarly beautiful, as are the 7th with the 9th at "before all worlds," in the credo, and the close at "by whom all things were made." The point at "throughout all generations," in the Magnificat, is what the Italians call bel tirato, well-worked. In the last line, however, of page 132, so many exceptionable combinations
nations occur, that we cannot pass them over without a stigma. Yet, upon the whole, the abilities of Purcell, as a profound contrapuntist, appear perhaps more in the course of this service than elsewhere; as he has manifested deep study and meditation in a species of writing to which it was not likely that his creative and impecunious genius would submit, having had the patience, as well as abilities, to enrich it with no less than four different canons, of the most difficult construction, as of two, three, and four in one, by inversion.

The superior genius of Purcell can be fairly estimated only by those who make themselves acquainted with the state of music previous to the time in which he flourished; compared with which, his productions for the church, if not more learned, will be found infinitely more varied and expressive; and his peculiar compositions appear to have descended from another more happy region, with which neither his predecessors nor contemporaries had any communication.

Besides the whole service, with three full, and six verse anthems, in Dr. Boyce’s Collection, there are nine verse and full anthems, wholly different, still sung in the cathedral at York. And in Dr. Tudway’s Collection, British Museum, there are, besides a whole service in B flat, different from that in Boyce, eight full and verse anthems, different from all the rest, four of which were composed for the chapel royal of Charles II., and are accompanied with instruments. And still, exclusive of these and the hymns printed in the two books of “Harmonia Sacra,” in a manuscript bequeathed to Christ-church college, Oxon. by Dr. Aldrich, there are two motets, and a “Gloria Patri” for four and five voices, in Latin, with seven psalms and hymns for three and four voices, by our fertile and diligent composer, that have all their peculiar merit, but of which some may, without hyperbole, be said to reach the true sublimity of sacred music.

To enter into a minute examination of these, and his admirable Te Deum and Jubilate, composed for St. Cecilia’s day, 1691, would extend this article to too great a length; though they merit much praise as well as critical remark; for, on the Te Deum we refer our readers to the ample account of him and his works, in Burney’s History of Music, vol. iii.

Purcell’s theatrical compositions, if we recollect the number and excellencies of his productions for the church, and the shortness of his life, will surprize by their multiplicity as well as singular merit. Of those dramas which are called operas, and of which music and decorations were the principal allurements held out to the public, a detailed account is given in speaking of the origin and progress of the musical drama in England, previous to the use of the Italian language, music, and performers on our lyric stage. (See Masques, and Matthew Locke.) And of Purcell’s detached and incidental songs, dialogues, and scenes, that were performed at our national theatre, or playhouse, the principal will be mentioned in speaking of his “Orpheus Britannicus,” or posthumous collection of his miscellaneous compositions. But before we enter on an examination of this work, it seems necessary to acquaint the reader, that the chief part of his instrumental music for the playhouse is included in a publication that appeared two years after his decease, under the title of “A Collection of Ayres composed for the Theatre, and on other Occasions, by the late Mr. Henry Purcell. London, printed for Frances Purcell, Executrix of the Author, 1697.” These airs are in four parts, for two violins, tenor and bass, and were played as overtures and aét-tunes in our own memory, till they were superceded by Handel’s hautbois concertos, and thence, by his overtures, while Boyce’s fantasies, and Arne’s compositions, served as aét-tunes. In process of time these were supplanted by Martini’s concertos and fantasies, which were thrown aside for the symphonies of Van Maldere, and fantasies of the elder Stamitz. About this time, the trios of Campioni, Zanetti, and Abel, came into play, and then the symphonies of Stamitz, Canabich, Holtzbauser, and other Germans, with those of Bach, Abel, and Giardini; which, having done their duty many years very pleasantly, “left their families;” and at present give way to Vanhal, Boccherini, Haydn, and Pleyel. “Sic transit gloria mundi!”

Purcell seems to have composed introductory and aét-tunes to most of the plays that were brought on the stage during his time. The publication of these, in four parts, contains his music to the following dramas:

“Abelazar,” 1677. The music of this consists of an overture, and eight airs or tunes.
““The Virtuous Wife,” 1680. Overture and seven airs.
“Indian Queen.” The first movement of this overture is equal to any of Handel’s. There are likewise two or three trumpet-tunes, well calculated for the instrument, and a rondéau at the end, which would now seem new, if played in a concert by a good band.
“Dioclesian, or the Prophetes,” 1690. The instrumental music of this English opera given here, consists of an overture of two movements, the first excellent in the style of Lulli, and afterwards of Handel, with better fugues; preludio, accompaniment to a song, trumpet-tune, air, hornpipe, country-dance, and canaries.
“Amphitrite,” 1691. Overture and eight tunes.
“Gordian Knot untied,” 1691. Overture and seven tunes.
“Distracted Innocence, or the Princes of Persia,” 1691. Overture and seven tunes, all proofs of the author’s original genius.
“The Fairy Queen,” 1692. Two overtures and sixteen tunes of different kinds. No. 12, an air, in 2, is a very curious canon on two subjects: the first treble and bass performing one, and the second and tenor the other. There is as much accent and spirit in this composition, as if it were in free counterpoint.
“The Old Bachelor,” 1693. Overture and eight tunes.
“The Married Bawbee,” 1694. Overture and eight tunes, among which is a very agreeable air for the trumpet, a march, and a hornpipe, that are characteristical. This last is very much in the style of a Spanish folkdance.
“The Double Dealer,” 1694. Overture and ten tunes. No. 6 and 9, pretty and curious.
“Bondoza,” 1695. Overture and eight tunes, including “Britons Strike Home,” and “To Arms,” in four parts.
These are the contents of this posthumous publication; but besides the music for these dramas, he composed overtures, aét-tunes, and songs, for “Timon of Athens,” 1678; for “Theodorus, or the Force of Love,” 1680; for Dryden’s “Tempest,” 1692; and for “Don Quixote,” 1694.
But few of Purcell’s stage songs seem to have been printed during his life. He published the music to a masque sung in the tragedy of “Oedipus,” when it was revived in 1692. And of a musical entertainment, performed Nov. 22, 1683, on St. Cecilia’s day, printed in score by John Playford, with a dedication to the gentlemen of the musical society, and particularly the freemasons, written by Henry Purcell, composer of the music.”
There are several of his songs in Playford's Collection, called "The Theatre of Music," 1687, fourth and last Book; and though these are not in his best manner, they are more original and interesting than the rest. Among these, p. 56, "A new song to a Scotch tune," by our author, seems to us more pleasing and less florid than any furious Scotch tune, or imitation of the national melody of the northern inhabitants of this island, that has been since produced.

Page 62 of the same Collection, there is an admirable piece of recitative, in a truly grand style: "Amidst the shades," &c. But the collection of his secular vocal music, which did him the greatest honour, and long rendered his name dear to the British nation, was published by his widow two years after his decease, by the title of "Orpheus Britannicus." Here were treasured up the songs from which the natives of this island received their first great delight and impression from the vocal music of a single voice. Before that period we had cultivated madrigals, and songs in parts, with diligence and success; but in all single songs, till those of Purcell appeared, the chief effects were produced from the words, not the melody. For the airs, till that time, were as unformed and mis-shapen, as if they had been made of notes scattered about by chance, instead of being cast in an elegant mould. Exclusive admirers of modern symmetry and elegance, may call Purcell's taste barbarous; yet in spite of superior cultivation and refinement, in spite of all the vicissitudes of fashion, through all his rudest and barbarism, original genius, feeling, and passion, are, and ever will be, discoverable in his works, by candid and competent judges of the art.

To this admirable collection are prefixed seven copies of verses to his memory, at the head of which is an ode, written on his death, by Dryden, which was set by Dr. Blow, and performed at the concert in York Buildings.

There are few songs in the "Orpheus Britannicus" but what contain some characteristic marks of the author's great and original genius. The melody, however, will at first seem to many at present uncouth and antiquated; but by a little allowance and examination, any one piffled of a great love for music, and a knowledge of our language, will feel, at certain places of almost every song, his superior felicity and passion in expressing the poet's sentiments which he had to translate into melody.

The favourite songs with Purcell's admirers in our youth, were the following; and upon a late attentive perusal of the book, they seem to have merited particular distinction. "Celia has a thousand charms!" the first movement of this, like many of Purcell's songs, seems only recitative graced, or embellished with the fashionable volutes, or flourishes of the times, which are now as antiquated as the curls of his own periwig, or the turbans and flounces of queen Elizabeth. The second movement, however, of this song, is plaintive and graceful; and at "I should my wretched, wretched, fate deplore," is still new and pathetic.

"You twice ten hundred detties," opens with what seems to us the best piece of recitative in our language. The words are admirably expressed throughout this song, by modulation as well as melody. And there is a propriety in the changes of movement, which does honour to Purcell's judgment, as much as the whole composition to his genius. The change of style and sluggish motion given to the notes at these words, "from thy sleeping mansion rife," is a model of musical imitation and expression. The modulation is still so excellent, that the best modern masters are obliged to adopt it on almost all great occasions.

Of the music to "King Arthur" we shall say but little, as it has been lately revived, well performed, and printed. If ever it could be said with truth of a composer, that he has devancé son siècle, outstrip his age, Purcell is entitled to that praise; as there are movements in many of his works which a century has not injured, particularly the duet in King Arthur, "Two daughters of this aged dream," and "Farrell liles all Ilies excelling," which contain not a single passage that the best composers of the present times, if it presented itself to their imagination, would reject. The dialogue in the "Prophefies," "Tell me why, my charming fair," is the most pleasing and ingenious of all the compositions of the kind which the rage of fashion produced during fifty years. The first part of "O lead me to some peaceful gloom," is truly elegant and pathetic.

"From rofe bow'er's," is said to have been "set in his last sicknefs," at which time he seems to have realized the poetical fable of the swan, and to have sung more sweetly as he approached nearer his dissolution; for it seems to us as if no one of his productions was so elevated, so pleasing, so expressive, and throughout so perfect, as this. The variety of movement, the artful, yet touching modulation, and, above all, the exquisite expression of the words, render it one of the most affecting compositions extant to every Englishman who regards music not merely as an agreeable arrangement and combination of sounds, but as the vehicle of sentiment, and voice of passion.

There is more elegant melody, more elaborate harmony, more ingenious contrivance, in the motion and contexture of the several parts than in the works of many great composers; but to the natives of England, who know the full power of our language, and feel the force, spirit, and shades of meaning, which every word bears according to its place in a sentence, and the situation of the speaker, or finger, we must again repeat it, this composition will have charms and effects, which, perhaps, Purcell's music only can produce.

"When Mira fings," is a duet that will ever be captivating, as long as the words remain intelligible; of which he has augmented the force, particularly at the end, by notes the most refined and expressive that the musical scale can furnish.

"Loft is my quiet," another duet, which still lives. And "Celebrate this festival," a birth-day song for queen Mary, which is graceful and pleasing through all its old-fashioned thoughts and embellishments. "I'll fail upon the dog-star," has all the fire of Handel's prime.

"Mad Befs" is a song, or rather a cantata fo celebrated, that it needs no panegyric, or renewal of public attention, as every captivating English singer in our memory has revived its favour. The first Mrs. Sheridan and Mrs. Bates never gave more exquisite delight by their admirable performance, than when they regaled their friends with this song. Beard, forty years ago, used to acquire great applause by singing Purcell's "Rofy Bowlers," and Frassi, by her performance of "Mad Befs," in the concerts at Hickford's rooms, the Castle, and Swan concerts, where Stanley was justly admired for his ingenious and masterly manner of accompanying them. "The Nature's Voice," is an imaginative song, seemingly on music, in which Purcell has crowded all the fashionable passages of taste and vocal difficulties of the times. Indeed, he seems to have anticipated many fantastical feats of execution and articulation in which great performers have since rivalled; and this is the more wonderful, as the Italian opera was not exhibited, or even attempted here, during the life of Purcell; whose decease preceded the arrival of Valentini and Nicolini, the first great fingers imported from Italy, at least ten years.

"Blow,
"Blow, Boreas, blow," was in great favour, during our youth, among the early admirers of Purcell; but this seems now more superannuated than any of his popular songs.

"Let Cæsar and Urania live," was a "ditty in a birthday ode, during the reign of king William and queen Mary, which continued to long in favour, not only while those love-reigns jointly wielded the sceptre, but even when George II. had lost his royal comfort, and there ceased to be a queen, or Urania, for whom to offer up prayers, that Dr. Green, and afterwards Dr. Blow, used frequently to introduce it into their own and the laureate's new odes. This duet, like many other productions of Purcell, was built on a ground-bafe of only two bars, which are invariably repeated to different passages of the voice-parts that are in harmony with it, throughout the movement. The latter part of this duet is extremely beautiful, and does not seem to all at have suffered from the voluntary restraint under which the composer laboured.

The composing fongs on a ground-bafe, was an exercise of ingenuity, in which Purcell seems to have much delighted; but though it was as much a fashion in his time, as the composing male on the subjects of old times in the days of Jaffin and variations upon those tunes in the days of Bird and Dr. Bull, in which they all manifest superior abilities, yet the practice was Gothic, and an unworthy employment for men possessed of such genius and original resources. The Italians started this, as well as most other musical fashions; for it appears by the works of Tranquillo Merula, published 1635, that writing upon a ground-bafe was a favourite occupation with that capricious composer, as well as our ingenious countryman.

Judges of musical design, modulation, and expression, will meet with many places to admire in fongs that have never been popular, yet have local beauties, and mark the superior powers of the composer, particularly in the "Sighs for the death of king Charles II." In the "Dialogue in tyrannic Love," p. 158, there is a passage upon which the late Mr. Bach has constructed a favourite movement in one of his Quartetti concertati.

"I attempt from love's sicknse," is an elegant little ballad, which, though it has been many years dead, would soon be recalled into existence and fashion, by the voice of some favourite singer, who should think it worth animation.

"Let the dreadful engines," this is the last song in the first volume of the "Orpheus Britannicus," of which, though both the words and music of the first movement are wild and bombast, yet the second and last discover a genius for the graceful comic, as well as the tender and sad style of composition; and there are several passages in this cantata sufficiently gay and new for a modern burletta.

In 1702, a second, and more correct, edition, of the first volume of this work was published, with more than thirty songs that were not in the first impression; but, in order to make room for which, some of the former were excluded.

The same year was likewise published a second volume of "Orpheus Britannicus," by Henry Playford, which he dedicated to the earl of Halifax. The song of this second volume, p. 4, beginning "Ah! cruel nymph!" has great ingenuity in the first movement, and grace in the second. And the third, "Crown the altar," from the most pleasing of any that he has composed on a ground-bafe. "May the god of wit inspire," for three voices, is natural and pleasing, and the echoes in the second part are very ingeniously contrived.

"Thus the gloomy world," accompanied with the trumpet, and violin alternately, is masterly, and well designed to display the truest and most brilliant tones of the trumpet, though but little is given to the violin, which so much better deserves employment, than an inlustrum of such false intonation as the trumpet.

Thore that can relish good music of every age and country, and have no exclusive partiality to individuals of either, will find amusement in the performance or perusal of Purcell's "Four Seasons," in the "Fairy Queen," which comprehend merit of various kinds.

"To arms, to arms," is an admirable military song, accompanied by a trumpet, which is so confined an instrument, that nearly the same passages must be used in all ages, so that this time has robbed this song of but little of its novelty. Indeed, the divisions of this air have been revived of late years, and are now as fashionable, in frivolous and unmeaning melody, as ever.

There are many excellent songs in this volume; however, these and their peculiar beauties we must pass over, or our commentary will encroach too much on the limits of our biographical articles, as well as on the time and patience of those readers to whom the name and productions of our British Orpheus are alike unknown or indifferent. Yet we must observe, that there is a composition in Purcell's "Bonduca," in which he has attempted a species of dramatic music, which has been thought of late invention; the words are "Hear ye gods of Britain!" which he has set in an accompanied recitative, a tempo, or aria parlante, the beginning, however, with the bafe a pedale, has the true characteristic of recitative. Afterwards, when the base is put in motion, the whole has the properties of an air, ingeniously and profitably accompanied by two violins and a base. Besides the true dramatic call of this composition, there are new harmonies hazarded, which we do not recollect having seen in anterior contrapuntists, at least of our own country.

We dare proceed no further in analyzing the works of our illustrious countryman, though it would afford us great pleasure, as we never look at them without feeling a merit very superior to that of any of his contemporaries out of Italy, and even there, only the vocal compositions of Carissimi and Stradella seem to surpass them in grace and elegance. Carissimi appears to have been his model in his best recitatives, and Lolli in the work; and it is manifest that he was fond of Stradella's manner of writing, though he never pillaged his passages.

We must not quit his vocal music without an honourable and grateful memorial of his catches, rounds, and glees, of which the humour, ingenuity, and melody, were so congenial with the national taste, as to render them almost the sole productions of the factious kind that were in general use for near four score years. And though the countenance and premiums bestowed of late years upon this species of composition, as well as modern refinements in melody and performance, have given birth to many glees, of a more elegant, graceful, and exalted kind, than any which Purcell produced; yet he seems hardly ever to have been equalled in the wit, pleasantry, and contrivance of his catches.

Of fifteen anthems, with symphonies and instrumental parts, with innumerable odes and miscellanies, we have room to lay nothing, though much praise is due to many of them.

An abyss of music prevailed in Purcell's time, which he carried to greater exults, perhaps, than any other composer, of repeating a word of one or two syllables an unlimited number of times, for the sake of the melody, and sometimes before the whole sentence has been heard. Such as no, no, no, all, all, all—pretty, pretty, pretty, &c. ad infinitum. But there is equal redundancy and obscurity in the tite which the Italians make at present of si, si, nit, and no, no, no, in their fongs.

Purcell
Purcell was so little acquainted with the unlimited power of the violin, that we have scarcely ever seen a becoming passage for that instrument in any one of his works; the symphonies and ritornels to his anthems and songs being equally deficient in force, inventi6n, and effect. And though his fantasias contain many ingenious, and, at the time they were composed, new traits of melody and modulation, if they are compared with the productions of his contemporary, Corelli, they will be called barbarous. But Corelli wrote for an instrument of which he was a great master: and who ever entirely succeeded in composing for one of which he was ignorant? When a great performer on keyed instruments confederes to compose for the violin, upon which he has never been a good player, or the voice, without knowing in what good finging conflicts, the passages all come from the head, and none from the hand, except the hand of a harpsichord player, which is ever unlit to fingered ideas either for a voice, or for any other instrument than his own. Such a composer for the violin must inevitably embarrass the player with perpetual awkwardness and difficulties without effect, which discover an utter ignorance of the finger-board.

If Purcell, by travelling, or by living longer at home, had heard the great instrumental performers, as well as great fingers, that arrived in this country soon after his decease, and had such to compose for, his productions would have been more regular, elegant, and graceful; and he would certainly have felt English words better than it was possible for any foreigner to do, for our feelings, however great his genius, or excellent, in other respects, his productions. But Purcell, like his successor, Arne, and others who have composed for the playhouse, had always an inferior band to the Italian opera composers, as well as inferior fingers, and an inferior audience to write for.

The diligent and candid Walther, by not having alligned to Purcell a niche in his Musical Dictionary, seems never to have heard of his exellence; but Purcell was so truly a national composer, that his name was not likely to be wafted to the continent; and the narrow limits of his fame may be fairly ascribed, not only to the paucity and poverty of his compositions for instruments, for which the musical productions are an intelligible language to every country, but to his vocal compositions being solely adapted to English words, which render it unlikely for their influence to extend beyond the fence that produced them.

We should, however, have known as little of Lulli, as the French or Italians of Purcell, but for the partiality which Charles II. acquired, by his long residence on the continent, for the arts and amusements of France. The first attempts at operas here, after the Reformation, were either in French, or on the model of those that were then in high favour at Versailles. And whoever is equally acquainted with the recitative, we had almost said the general melody of Lulli and Purcell, must perceive a strong resemblance.

Purcell, however, having infinitely more fancy, and, indeed, harmonical resources, than the Frenchified Tufcan, his productions now afford far greater pleasure and amusement to a liberal lover of music, than can be found, not only in the productions of Cambert and Grubu, whom Charles II. and to flatter his majesty, Dryden, patronized in preference to Purcell, but in all the noisy monotony of the rhapsodiih of Quinaut.

Let those who shall think Purcell has sacrificed the national honour by conferring his reverence for the productions of Italy, compare the peculiar productions of English musicians, from the death of queen Elizabeth to the year 1683, with those of Carissimi, Cetti, Stradella, and innumerable others of great abilities, and if they do not equally hate music and truth, they will admire Purcell's probity, as well as his genius.

Indeed, music was manifestly on the decline, in England, during the seventeenth century, till it was revived and invigorated by Purcell, whose genius, though less cultivated and polished, was equal to that of the greatest masters on the continent. And though his dramatic style and recitative were formed in a great measure on French models, there is a latent power and force in his expression of English words, whatever be the subject, that will make an unprejudiced native of this island feel, more than all the elegance, grace, and refinement of modern musick, lefts happily applied, can do. And this pleasure is communicated to us, not by the symmetry or rhythm of modern melody, but by his having fortified, lengthened, and tuned, the true accents of our mother-tongue; those notes of passion, which an inhabitant of this island would breathe, in such situations as the words he has to set describes. And these indigenous expreissions of passion Purcell had the power to enforce by the energy of modulation, which, on some occasions, was bold, affecting, and sublime.

These remarks are addressed to none but Englishmen: for the expression of words can be felt only by the natives of any country, who seldom extend their admiration of foreign vocal music, farther than to the general effect of its melody and harmony on the ear; nor has it any other advantage over instrumental, than that of being executed by the human voice, like falleggi. And if the Italians themselves did not come hither to give us the true expression of their foigs, we should never discover it by study and practice.

It has been extremely unfortunate for our national taste and our national honour, that Orlando Gibbons, Pelham Humphrey, and Henry Purcell, our three best composers during the last century, were not blest with sufficient longevity for their genius to expand in all its branches, or to form a school, which would have enabled us to proceed in the cultivation of musick without foreign assistance.

Orlando Gibbons died 1625, at forty-four.

Pelham Humphrey died 1674, at twenty-seven.

And Henry Purcell died 1695, at thirty-seven.

If these admirable composers had been blest with long life, we might have had a musick of our own, at least as good as that of France or Germany; which, without the assistance of the Italians, has long been admired and preferred to all others by the natives at large, though their princes have usually foreigners in their service. As it is, we have no school for composition, no well-digested method of study, nor, indeed, models of our own. Instrumental musick, therefore, has never gained much by our own abilities; for though some natives of England have had hands sufficient to execute the productions of the greatest masters on the continent, they have produced but little of their own that has been much esteemed. Handel's compositions for the organ and harpsichord, with those of Scarlatti and Alberti, were our chief practice and delight for more than fifty years; while those of Corelli, Geminiani, Albinoni, Vivaldi, Taffarni, Vercini, and Tartini, till the arrival of Giardini, supplied all our wants on the violin, during a still longer period. And as for the hautbois, Martini and Fisher, with their scholars and imitators, are all that we have listened to with pleasure.

If a parallel were to be drawn between Purcell and any popular composer of a different country, reasons might be adduced for supposing him superior to every great and favourite contemporary musician in Europe.

Carissimi and Stradella, if more polished in their style, were certainly less varied, and knew still less of instruments, than
than our countryman. They had both, perhaps, more grace and regularity, but infinitely less passion and fire. The elder Scarlatti was more ricercè and learned, but never fo natural and effecting.

In Germany, if Keffer, during an active and much longer life, surpassed him in the number and excellence of his dramatic compositions, his productions for the church, could they be found, would, we believe, bear no comparison.

Lulli, blest likewise with superior longevity, composed also more operas than Purcell, and was the idol of the nation for which he laboured; but though his overtures long served as models, even to Purcell, as well as to the composers of all the rest of Europe, and his music was performed by better fingers, and a more numerous band, supported by the patronage of a court, and all the splendour of ingenious and costly exhibition; it is easy to see that even his theatrical works are more manières, monotonous, and uninteresting in themselves, than those of Purcell; but in relinquishing the stage, and stepping on holy ground, we should have found, even in France, during all his glory, and the enthusiasm he raised, none of his votaries who would attempt to put his sacred music in comparison with that of our countryman.

Rameau, the successor of Lulli in court and popular favour, and who had more learning and theoretical knowledge in the art, than perhaps any practical musician of modern times; yet, in passions and expression of words and the passions, he was Purcell's inferior, even upon the stage; and in the church, he had no claim to celebrity.

Handel, who flourished in a less barbarous age for his art, has been acknowledged his superior in many particulars; but in none more than the art and grandeur of his choruses, the harmony and texture of his organ fugues, as well as his great style of playing that instrument; the majesty of his harpsichord and grand concertos, the ingenuity of the accompaniments to his songs and choruses, and even in the general melody of the airs themselves; yet in the accent, passion, and expression of English words, the vocal music of Purcell is, sometimes to our feelings, as inferior to Handel's as an original poem to a translation.

PURCHAS, SAMUEL, was born at Thaxted, in Essex, in 1577. He was educated at Cambridge, and was presented to a vicarage in his native county. This cure he resigned to his brother, and came to live in London, for the purpose of conducting the great work he had undertaken. The first volume folio appeared in 1613, under the title of "Purchas his Pilgrimage, or Relations of the World and the Religions observed in All Ages and Places discovered from the Creation unto this Present;" the other four volumes were published in 1625. To thefe the general title is " Hakluytus Posthumus, or Purchas his Pilgrims: containing a History of the World in Sea-voyages and Land-travels by Englishmen and others." The name of Hakluyt is introduced, because Purchas became possessed of the papers which he left behind him. This great work, of which the object is to connect ancient and modern history, was well received, but probably involved the author in debt. He had been collated to the rectory of St. Martin's Ludgate, and was chaplain to Abbot, archbishop of Canterbury. He died about the year 1628, at the age of fifty-one. Biog.-Brit.

PURCHASE, in Law, in its largest and most extensive sense, is defined by Littleton to be the possessio of lands and tenements, which a man hath by his own act or agreement, and not by de
cision from any of his ancestors or kindred. In this sense, it is contradistinguished from acquisition by right of blood, and includes every other method of coming to an estate, but merely that by inheritance; in which the title is vested in a person, not by his own act or agreement, but by the single operation of law. (Co. Litt. 18.) Purchase, in its vulgar and confined acceptation, is applied only to the acquisition of goods, lands, tenements, or the like, by means of money, or some other valuable consideration.

What we call purchase, perquisitia, the feudists call conquest, conqu默契, or conquest, (see Conquest;) both denoting any means of acquiring an estate out of the common course of inheritance; and this is still the proper phrase in the law of Scotland. The difference, in effect, between the acquisition of an estate by defent and by purchase, consists principally in these two points. 1. That by purchase the estate acquired is a new inheritable quality, and is defensible to the owner's blood in general, and not the blood only of some particular ancestor. 2. An estate taken by purchase will not make the heir answerable for the acts of the ancestor, as an estate by defent will. According to this legal signification of the word perquisitia, or purchase, it includes the five following methods of acquiring a title to estates, viz. fequest, occupancy, pre
dscription, forfeiture, and alienation, conveyance, or purchase, in its limited sense: under which latter head may be comprised any method in which estates are voluntarily resigned by one man, and accepted by another: whether that be effected by sale, gift, marriage-settlement, devise, or other transmutation of property, by the mutual consent of the parties. See the several articles, and Title.

Natural per

sons, incorporate persons, sole or aggregate, dead, dumb, and blind persons, minors, and all reclaimable creatures, may purchase, except in some cases; but some have capacity to purchase, and not to hold, as aliens, felons, &c.; and others have ability to hold or not to hold upon a purchase, at the election of themselves or others, as infants, and even coverts. 1 Init. 2, 3. 11 Rep. 77. 7 Rep. 17.

PURCHASE AND VALUE OF LAND. See Valuation of Land, and Political Economy. Pur

CHASE OF WITS. See Wit.

PURCHASE, in the Sea Language, has the same signification with draw in, at land. Thus, they say, the captain purchases apace, i.e., draws in the cable apace; and when they cannot draw or hold any thing in with the tackle, they say, the tackle will not purchase.

PURCHASE is also a name given by sailors to any mechanical power employed in raising or removing heavy bodies, or in fixing or extending the ship's rigging. Such are the tackles, windlasses, capstans, screws, and handspikes.

PURCHASE-BOOK, among Traders, is the name given to a book, which is a kind of journal, containing an account of all the purchases made, or things bought in the day.

PURCHASER, FIRST, Purchasius, in Law, denotes the person who first acquired an estate to his family, whether the name was transferred to him by sale or by gift, or by any other method, except only that of defent. See DESCENT.

PURCHASING OF ESTATES, in Agriculture, the business of buying landed property. In order to perform this act of bargain with propriety, and to the best advantage, attention is necessary to be had to a great variety of circumstances of different kinds, which respect the nature, quality, situation, condition, value, and conveniences of the property. See Valuation of Land.

But it is probably best done, when to any extent, by a surveyor or other person who is perfectly conversant with the nature of the business, and fully acquainted with the real
real value of landed property in the district where the purchase may be situate or meet with.

It has been observed by Mr. Marshall, that there are two methods of making bargains of this kind, the one by public biddings, the other by private treaty or contract: in either of which, a certain degree of caution is common prudence. In the former, however, the conditions being fixed, an accurate valuation is the best safeguard; and, in the latter, among honest men little more is required.

In purchasing by private contract, the particulars which may be previously required to be furnished by the seller, are the quantities of the several pieces of the lands which are on sale, together with the maps, or rough drafts, of the same; the tenure under which they are held; some assurance as to the title of the seller; and his right of alienation; the tenancy under which the several farms are let; and, if on lives, the ages of the nominees; if for a term of years, the number which are unexpired; if at will, the notices with which the tenants have been served, if any have been given.

An abstract of the covenants under which they are let; particularly of those which relate to taxes and repairs, to the expenditure of produce, to the ploughing of grass-lands, &c. &c.

The existing rents and profits receivable; whether for tenanted lands, appurtenances, or abstract rights; with the estimated value of the demesne, and the woodlands in hand; together with the estimated value of the timber growing upon the estate on sale; as well as of the minerals and foils which it may contain.

The outgoings to which the estate is liable; the proposed time of the delivery of possession; the price and the mode of payment which are expected.

And next, it will be proper to let down the particulars of the instructions to be given to a surveyor, or other valuer, of the estate to be purchased. It will be right, however, to promise, that much, in this respect, depends on the probability of purchasing; and on the time which is allowed for making the estimate. In cafes of sale by public auction, when there can be no certainty as to purchase, and where the time for valuation is limited, a rough estimate of each farm, and a general idea of the value of the timber and other appurtenances, may be all that can be prudently ascertained. But in a sale by private contract, where the refusal of an estate is granted, and time allowed for deliberate survey, a more minute investigation may be proper; especially where there is every reason to believe that a bargain will take place. For the same report will not only serve as a guide to the purchaser, but will become a valuable foundation, on which to ground the future management of the estate. And for these and other reasons, a purchase by private contract is most to be desired by one who is not in the habit of personally attending public sales, and is unacquainted with the business of an auction room.

It may be noticed, that the particulars to be required from a surveyor, or surveyors, in these cases, are principally the: the rental value of each field or parcel of land, with the rate in which it lies, as to arable, meadow, pasture, or woodland; the value of the timber and other appurtenances; the character of, and the state of management of each farm or tenement, with the eligibility of the occupier; together with the state of repair of buildings, gates, fences, water-courses, and roads, the amount of the encumbrances and outgoings. And, lastly, the probable value of the improvements of which the estate may appear to be capable; whether by the several means that are commonly practised, or by new regulations and improved modes of agricultural management, that may admit of being introduced.

It is added, that these several particulars of information being procured, the subjects of treaty are few. The two statements having being duly compared, so that no misunderstanding can take place between the parties, the price, and the times and mode of payment, are the principal matters of agreement. A clear understanding respecting the custody of title deeds and the expenses of conveyance, require, however, to be enumerated among the preliminaries of purchase.

In these transactions, it is also supposed, the business of negotiation is best carried on by letters; which become vouchers of facts. Whatever is done by interview, requires to be reduced to writing, and to be read by or to the parties before they separate, that no possibility of misconception may arise. And, added to these precautions, it is proper in large purchases, and when abstractions of intricate title deeds are to be made out, and examined, that a legal contract or memorandum of agreement should be entered into, for the mutual satisfaction and surety of the parties. This contract and the deed of conveyance, which is the instrument which is legally to transfer the property from the seller to the purchaser, may be said to conclude and ratify the business of purchase. And in this part of it, legal affinity is essentially necessary; to examine existing deeds, and see that the seller has a legal right and clear title to the land, and a legal power to dispose of it; as well as to draw up or examine the fresh deed of conveyance, and see that it is sufficient to transfer the property legally and adequately to the purchaser.

PURCHENA, in Geography, a town of Spain, in the province of Grenada; 62 miles E. of Grenada. N. lat. 37° 10'. W. long. 2° 30'.

PURE, something free from any admixture of foreign or heterogenous matters.

Pure Fire. See Fire.

Pure Hyperbola, in Conics, is a hyperbola without any oval, node, spike, or conjugate point. See Curve.

Pure Mathematics. See Mathematics.

Pure Proposition. See Proposition.

Pure Quadratics. See Quadratic.

Pure Resignation. See Resignation.

Pure Villenage. See Villenage.

PUREA, or PURAN, in Geography, a town of Chile; 80 miles S.S.E. of La Conception.

PUREWAR, a town of Hindooftan, in Oude; 10 miles N. of Bahraitich.

PUREG, anciently Pura, once the capital of Gedrofia (Mekran), and termination of the toilfome march of Alexander towards the frontiers of Caramania, is now a mean village.

PURENDERA, in Mythology, a name of Indra, the Hindoo regent of the firmament. (See Indra.) The word is said to mean destroyor of towns, the Indian Jupiter having, in revenge for sacrificial flights or negligences, frequently, according to the Hindoo books, assumed that character. The ancient city of Ouegen, the capital of Malwa, was, according to tradition, destroyed by Indra. See OUEGEN.

PURESIL, in Geography, a town of Hindooftan, in the cissar of Ciccocol; 40 miles N.W. of Viziaagram.

PURETTA, a name given by some writers to the common flowering black fand, used to flew over writing, and erroneously called by some fleet-dufti.

It is a natural mineral substance, found on the shores near Genoa, and in other places.
PUR

PURFLED, ornamental work, whether in stone or other materials, representing embroidery or lace work.

PURFEW, a term in Heraldry, expressing ermines, panes, or any of the furs, when they compose a border round a coat of arms.

Thus they say, he beareth gules a border, purlew, vairy; meaning, that the border is vairy.

PURG, or Forg, in Geography, a town of Persia, in the province of Laristan; 60 miles N.E. of Lar. N. lat. 28° 30'. F. long. 54° 40'.

PURGATION, PURGATiO, the act of purging, scouring, or purifying any thing, by separating and carrying off any impurities found therein.

Purification is also used, in Chemistry, for several preparations of metals and minerals, intended to clear them of their impurities; more usually called purification and refining.

The ordinary purgation of mercury is performed, by passing it through a chamois skin. (See Mercury.) Gold is purged by the coppel, cementation, &c. See Gold, Copper, &c.

Purgation, in Medicine, is the evacuation of the alimentary canal of its fecal contents, by means of substances which stimulate its fibers, and excite them to a more active peristaltic motion. Purgation is also sometimes carried farther, and, by causing a copious discharge of fluids from the exhalent vesicles of the inner surface of the bowels, produces a considerable evacuation from the bowels at large. For an elucidation of the doctrine of purgation, see Cathartik.

Purgation, in Law, is the clearing one's self of a crime, whereof publicly suspected or accused before a judge, called also judicium Dei.

Of these purgations there was anciently much use in England, especially touching matters of felony charged on clergies; and there is something of them still retained in the ecclesiastical court on suspicion of incon tinency, &c. Purgation is either canonical or vulgar.

Purgation, Canonical, is that prescribed in the canon law, the form of which, obtained in the spiritual court, is, that the party suspected shall take his oath that he is clear of the fact objected against him; and bring so many of his honest neighbours, not above twelve, as the court shall assign him, to swear, on their confidences, that they believe he swears truly.

The canonical doctrine of purgation, whereby the parties were obliged to answer upon oath to any matter, however criminal, that might be objected against them, continued till the middle of the 17th century to be upheld by the spiritual courts; when the legislature was obliged to interpose, to teach them a lesson of similar moderation. By the statute of 12 Car. II. cap. 12, it is enacted, that it shall not be lawful for any bishop, or ecclesiastical judge, to tender or administer to any person whatsoever, the oath usually called the oath ex officio, or any other oath whereby he may be compelled to confess, accuse, or purge himself of any criminal matter or thing, whereby he may be liable to any censure or punishment. But this does not extend to oaths in a civil suit; and, therefore, it is still the practice both in the spiritual courts, and in equity, to demand the personal answer of the party himself upon oath. Yet if in the bill any question be put, that tends to the discovery of any crime, the defendant may thereupon demur, and refuse to answer. Anciently, upon the allowance of the benefit of clergy, the person accused was delivered to the ordinary, to make his purgation, which was to be before a jury of twelve clerks, by his own oath affirming his innocence, and the oaths of twelve compurgators as to their belief of it. But now, by the Statute 18 Eliz. cap. 7, this kind of purgation is also taken away; and the person admitted to his clergy shall not be delivered to the ordinary.

Purgation, Vulgar, being the most ancient manner, was by fire, or water, or combat; used by infidels, and by Christians also, till abolished by the canon law. See Ordinal, and Concord.

Combat, though now disused, may yet be still practised by the laws of the realm, in cases where evidence is wanting, and where the defendant rather chooses combat than any other trial. See Combat.

Terrar bonus, &c. redhibendi post Purgationem. See Terre.

Purgation, in Rhetoric, is used for that kind of defence which takes place when the accused person owns the fact, but denies that he did it with design, or with any bad intention.

Purgation, in Tragedy, is a term which Aristotle uses for the effect of tragedy on the mind.

That philosopher observes, that tragedy, by means of the terror and compunction which it excites, purges passions out of the soul.

Indeed, Corneille adds, that tragedy frequently creates passions, instead of purging them; so that he takes Aristotle's purgation to be no more than a chimera.

Purgations, Menstrual, the catamenia or menstes of women.

Purgative, or Purging-Medicine, a medicament, which evacuates the contents of the bowels by stool. See Cathartik.

Purgatory, Purgatorium, in the Romish church, a place where the just are suppos'd to suffer the pains due to their sins, for which they have not satisfied in this world. It is by the mercy of God, the indulgences of the church, and the prayers of the faithful, that people are suppos'd to be delivered out of purgatory.

This doctrine of purgatory, which some derive from the Platonic fancies of Origen, the Montanists of Tertullian, pretended visions, and pagan Itories, rhetorical flourishes, and doubtful expressions of the later fathers, and in which we may discern an obvious resemblance to the famous pagan doctrine, concerning the purification of departed souls by means of a certain kind of fire, was partly introduced, at least in the spirit of it, towards the close of the fifth century, and by Gregory the Great in the sixth century; but it was not, however, positively affirmed till about the year 1140, nor made an article of faith till the council of Trent. See Purgation and Purgatory.

In Ireland is a place called St. Patrick's purgatory, where, as the legend has it, at the prayers of St. Patrick, bishop of the place, there was made a visible representation of the pains which the wicked undergo after death, in order to deter sinners, &c.

Purgative, or Purgating-Medicine, a term frequently used for some purgative medicine.

Purging, in Geography, a town of Hindoostan, in the circum of Ciccacole; 40 miles N.W. of Vizianiagram.

Purging, in Medicine, a term frequently used for a dose of some purgative medicine.

Purging Ale, Butler's. See Ale.

Purging Grain, Oily, in Botany. See Sesamum.

Purging Nut, in Botany. See Jatropha.

Purging Thorn. See Buckthorn.
PURGLITZ, or KRAZIOKIAD, in Geography, a citadel of Bohemia, in the circle of Rakonitz, where the royal treasures were anciently kept, and state prisoners confined; seven miles S.E. of Rakonitz.

PURGOT, a town of Hindooftan, in Coimbatore; 35 miles W. of Ardenelle.

PURGOW, a town of Hindooftan, in Baghlan; 25 miles E.N.E. of Bafieen.

PURGSTALL, a town of Austria; four miles N. of Scheibs.

PURIFICATION, in Chemistry, &c. the act of purifying or refining natural bodies; or of separating the faces and impurities from them.

For the methods of purifying metals, gold, silver, iron, copper, tin, &c. see GOLD, SILVER, &c. and REFINING.

For the purification of semi-metals, minerals, and other matters, as antimony, sulphur, camphor, saltpetre, &c. see ANTINOY, SULPHUR, CAMPHOR, &c.

PURIFICATION, in Pharmacy. See TRYING.

PURIFICATION, in Matters of Religion, denotes an offering made the priest by women riding out of child-bed, before they are re-admitted into the church.

By the law of Moses, a woman, after bringing forth a male child, was unclean forty days; after a female, eighty days; during which time, she was not to touch any thing holy, nor to go near the temple, but was to continue within doors, separate from all company, and commerce of others.

This term expired, she was to present herself at the temple, and at the door of the tabernacle, to offer a lamb, as an holocaust, and a pigeon or turtle; which the priest taking, offered to God, and prayed for her, that she might be purified.

This ceremony, which consisted of two things, an holocaust, and a sacrifice of expiation, was called ἁρματικὸν ἐλαυνόν, purificatio, purgatio.

The holy Virgin, though, according to the fathers, exempt from the terms of the law, yet complied with it, and, at the time prescribed, went to the temple, and accomplished the law; in commemoration of which the church yearly commemorates the feast of the Purification of the Virgin, on the second of February; called also the Feast of Candlemas.

Purification, The Feast of the, seems to be very ancient. It is ordinarily said to have been instituted in the time of Justinian, in the year 542, and this on occasion of a mortality, which that year diffpeopled almost the whole city of Constantinople. Yet there are some, who imagine it to have been observed before, though in another manner, and on a different day from that fixed by Justinian; viz. between the Circumcision and Epiphany. See CANDLEMAS.

The same day is the presentation of our Saviour in the temple.

PURIFICATION, in Geography, a town of Mexico, in the province of Xalisco; eight miles S. of Compostella Nuova. N. lat. 19° 58'. W. long. 106° 40'.

PURIM, a solemn feast held among the Jews on the fourteenth and fifteenth of March, in memory of their deliverance from the conspiracy of Haman by Esther. See ESTHER.

This feast, which derives its name from the Persian word purim, q. d. lot, because it was by the casting of lots that Haman determined this time for the destruction of the Jews, is the Bacehans of these people, which they celebrate with all manner of rejoicing, mirth, and jollity; indulging themselves with every kind of luxury, especially in drinking wine even to drunkenness, which they consider as part of the duty of the solemnity; because it was by means of the wine banquet (they say) that Esther made the king's heart merry, and brought him into that good humour, which inclined him to grant the request presented by her for their deliverance; and, therefore, they think they ought also to make their hearts merry, when they celebrate the commemoration of it. During this festival the book of Esther is solemnly read in all their synagogues from the beginning to the end, at which they are all to be present, men, women, children, and servants, because all shared in the benefit of the deliverance which Esther obtained for them. And as often as the name of Haman occurs in the reading of this book, the custom is for all to clap with their hands, and laugh with their feet, and cry out, Let his memory perish. Prideaux's Conn. vol. ii. p. 456.

PURITANS, in Ecclesiastical History. See CATHARI and NOVATIANS.

PURITANS is also a term anciently used for the Calvinists of Great Britain, from their professing to follow the pure word of God, in opposition to all traditions, human constitutions, and other authorities.

The separation, whence this distinguishing appellation took its rise, commenced on the following occasion. Upon the accession of Queen Mary, it is well known that popery revived in this kingdom; the statutes of King Edward were repealed, and the penal laws against heretics were put in execution against the reformers. Many suffered at home; and others escaped the fury of persecution by seeking refuge in foreign countries. Some went into France and Flanders; some into those parts of Germany and Switzerland, where the reformation had taken place, and where the magistrates received them with great humanity, and allowed them places for public worship. The exiles were most numerous at Frankfort; and there that conti and division began, which gave rise to the Puritans, and to that separation from the church of England, which continues to this day. In the year 1554, some of the English fugitives settled in this city; and agreed to conduct their worship, without answering aloud after the minister, and without using the liturgy and surplice; to begin the public service with a general confession of sins, then to sing a psalm, after which the minister prayed for the divine assistance, and next proceeded to the sermon; after sermon, a general prayer for all elates, and particularly for England, at the end of which was subjoined the Lord's prayer, and a re-earful of the articles of belief; then the people were to sing another psalm, and the minister to dismiss them with a blessing. Such was the order which they had unanimously adopted; and having chosen a minister and deacons, they invited their dispersed brethren to join with them. In the year 1556, Dr. Cox, afterwards bishop of Ely, came to settle at Frankfort with several of his friends; who interrupting the public service by answering aloud after the minister, and reading the whole litany, in violation of the agreement upon which the congregation was formed, overpowered the first settlers; and obtaining leave of the magistrates for the free use of King Edward's service-book, performed divine worship according to the rites that had been authorized by that prince; while others, who preferred the Genevan method of worship, as more pure and simple, left the city of Frankfort, and removed to Basel and Geneva. Thus commenced the distinction of Puritans and Conformists, by which the two parties were afterwards known. The former were called Conformists, on account of their compliance with the ecclesiastical laws enacted by Edw. VI., and the denominations of Nonconformists and Puritans were given to the latter, from their inflicting upon a form of worship, more exempt from superstitition, and of a purer kind...
than the liturgy of Edward seemed to them to be. Upon the accession of queen Elizabeth, the exiles returned to England, where each party strove to advance the reformation according to their own standard. The queen, with those who had weathered the storm at home, were only for restoring king Edward's liturgy; but the majority of the exiles were for the worship and discipline of the foreign churches, and refused to comply with the old establishment, declaring loudly against the popish habits and ceremonies. However, the queen's party prevailed; and in 1559 a committee of divines was appointed to review king Edward's liturgy, which were instructed to strike out all offensive passages against the pope, and to make people easy about the belief of the corporal presence of Christ in the sacrament. But no alterations were made in favour of those who now began to be called Puritans, from their attempting a purer form of worship and discipline than had yet been established; and whole sentiments in many points were agreeable to those maintained by John Wickhike, the first reformer. For they agreed with him in opinion, that in the sacrament of orders there ought to be but two degrees, prebendary or bishop, and deacons; that all human traditions are superfluous and finful; that we must practice and teach only the laws of Christ; that mystical and significant ceremonies in religious worship are unlawful; and that to refrain men to a prescribed form of prayer is contrary to the liberty granted them by God. The old festivals, with their eyes and the popish habits, were continued as they were in the second year of King Edward VI. In 1558 the act of supremacy was passed, in which there is a remarkable clause, that gave rise to the court of high-commission, which proved afterwards so oppressive; and in 1559 was passed an act for the uniformity of common prayer, and service in the church, and administration of the sacraments. The Puritans denounced against these proceedings, and complained, that the gross superstitions of popery, which they had looked upon as abrogated and abolished, were now revived, and even imposed by authority. Some required nothing less than that the church of England should be exactly modelled after that of Geneva; others only desired liberty of conscience, with the privilege of celebrating divine worship in their own way; but neither party obtained the object of their wishes. The queen, intent upon the suppression of this troublesome sect (as she was used to call it), permitted its enemies to employ for that purpose all the resources of artifice, and all the severity of the laws. The court reformers pleaded, that every prince had authority to correct all abuses of doctrine and worship within his own territories; the Puritans, on the other hand, whilst they disdained all foreign authority and jurisdiction over the church, could not admit of that extensive power which the crown claimed by the supremacy; apprehending it unreasonable, that the religion of a whole nation should be at the disposal of a single lay person. However, they took the oath, with the queen's stipulation in her injunctions, as rendering her majesty only to the ancient and natural rights of sovereign princes over their subjects.

Farther, the court reformers allowed, that the church of Rome was a true church, though corrupt in some points of doctrine and government; that all her ministrations were valid, and that the pope was true bishop of Rome, though not of the universal church. But the Puritans affirmed the pope to be antichrist, the church of Rome to be no true church, and all her ministrations to be superfluous and idolatrous; they denounced her communion, and durst not supposeth the validity of their ordinations upon an uninterrupted line of succession from the apostles through her hands. Moreover, it was agreed by all, that the holy scriptures were a perfect rule of faith; but the bishops and court reformers did not allow them to be the standard of discipline or church government; affirming that our Saviour and his apostles left it to the discretion of the civil magistrate, in those places where Christianity should obtain, to accommodate the government of the church to the policy of the state. But the Puritans apprehended the holy scriptures to be a standard of church discipline as well as of doctrine; at least that nothing should be imposed as necessary but what was expressly contained in, or derived from them by necessary consequence, and, besides, they maintained that the discretionary power was not lodged with the civil magistrate, but with the spiritual officers of the church. Further, the court reformers maintained, that the practice of the primitive church for the first four or five centuries was a proper standard of church government and discipline, and in some respects a better than that of the apostles, which (according to them) was only accommodated to the infant state of the church while it was under persecution, whereas theirs was suited to the grandeur of a national establishment. Whereas the Puritans were for adhering to the bible in the main principles of church government, and for admitting no church officers or ordinances, but such as are herein mentioned; and they apprehended, that the appointment of the bishop, in establishing the first Christian church on the aristocratical plan then observed in the Jewish synagogues, designed it as an unchangeable model to be followed in all times and places. The court reformers also maintained, that things indifferent in their own nature, which are neither forbidden nor commanded in the holy scriptures, such as rites, ceremonies, habits, &c., might be settled, determined, and made necessary by the command of the civil magistrate, and that in such cases it was his insuperable duty of all subjects to observe. But the Puritans insisted, that those things which Christ had left indifferent, ought not to be made necessary by any human laws, and that such rites and ceremonies as had been abud of idolatry, and had a manifest tendency to lead men back to popery and superstition, were no longer indifferent, but should be rejected as unlawful. Nevertheless, both parties agreed to well in ascertaining the necessity of an uniformity of public worship, and of calling in the sword of the magistrate for the support and defence of their several principles; which they made an ill use of in their turns, as they could grasp the power into their hands. The standard of uniformity, according to the bishops, was the queen's supremacy, and the law of the land; according to the Puritans, the decrees of provincial and national synods, allowed and enforced by the civil magistrate; but neither party was for admitting that liberty of conscience, and freedom of profession, which is every man's right, as far as is consistent with the peace of the government under which he lives.

In the year 1564, upon a report that the habits, enjoined upon the clergy, were generally neglected, and also of intent to other imposed forms, the queen directed the ecclesiastical commissioners to consult some proper methods to reduce them to an exact uniformity; upon which they agreed on certain advertisements (as they were called), partly for due order in preaching and administering the sacraments, and partly for the appearance of ecclesiastical persons. To these advertisements certain protestations were annexed, to be made, promised, and subscribed by such as should hereafter be admitted to any office or cure in the church. The queen, though she would give no authority to the advertisements, which had occasioned much remonstrance and complaint, issued out a proclamation in 1565, peremptorily re-
inquiring uniformity in the habits, upon pain of prohibition
from preaching, and deprivation. Parker, the archbishop
of Canterbury, was violent and unrelenting; and by various
methods of severity, harassed, silenced, and deprived many
of those who scrupled the use of the habits. The turgid
ministers, finding that renewed applications to the queen
and her commissions were ineffectual, published, in 1566, a
small tract in vindication of their conduct; in which they
allege, that neither the prophets of the Old Testament, nor
the apostles of the New, were distinguished by their gar-
ments; that a distinction of garments in the Christian church
did not generally obtain till long after the rising of anti-
christ; that the garments against which they objected, had
been abused to idolatry, forcery, and all kinds of conjura-
tions; that they were an offence to weak Christians, an
encouragement to ignorant and obtinate papists, and the
use of them an affrontation of returning to their communion;
that at best they were only human appointments, subject
to the apostle's reproof, Col. ii. 20—22; that allowing them
to be indifferent (which they did not grant), yet they ought
not to be impeded, because it was an infringement of the
liberty with which Christ had made them free; and finally
they urged the suffrage of foreign divines, who all condemned
the habits, though they were not willing to hazard the re-
formation in its infancy, on account of them.

If, at this time, the habits and a few ceremonies had been
left indifferent, both ministers and people would have ac-
quiesced; but it was the compelling of these things by law
that made them separate from the established church. Ac-
ccordingly, in 1566, they came to a resolution, alleging it
to be their duty, in their present circumstances, to break off
from the public churches, and to assemble, as they had op-
portunity, in private houses, or elsewhere, to worship God
in a manner that might not offend against the light of their
consciences; and it was debated among them, whether they
should use as much of the common prayer and service of the
church as was not offensive, or resolve at once, since they
were cut off from the church of England, to set up the
pure and belted form of worship, most consonant to the holy
Scriptures, and to the practice of the foreign reformers.
The latter of these measures was concluded upon; and
accordingly they laid aside the English liturgy, and made
use of the Geneva service-book. However, it is necessary
to observe, that though all the Puritans of these times would
have remained in the church, if they might have been in-
dulged in the habits and a few ceremonies, yet they were far
from being satisfied with the hierarchy. They had other
objections besides those for which they were deprived; of
which we shall here subjoin a summary. They complained
of the bishops affecting to be thought a superior order to
preachers, and claiming the sole right of ordination, and the
use of the keys; and affuming, in connection with their
office, temporal dignities, titles, and employments. As
long, however, as the English bishops pretended to derive
their dignity and authority from no other fource than the
laws of their country, and pleaded a right, merely human,
to the rank they held in the church, and state, the controversy
was carried on without excessive animosity and zeal; but
the flame broke out with redoubled fury in the year 1588, when
 Bancroft, afterwards archbishop of Canterbury, ventured
to affirm that the order of bishops was superior to the body
of preachers, not in consequence of any human institution,
but jure divina, or by the express appointment of God him-
self. Further, the Puritans excepted against the titles and
offices of archdeacons, deans, chapters, and other officials,
belonging to cathedrals, as having no foundation in Scripture,
or primitive antiquity, and intruding upon the

privileges of the prebendaries in the several dioceses. They
complained of the exorbitant power and jurisdiction of the
bishops and their chancellors in their spiritual courts, as de-

drived from the canon law of the pope, and not from the
word of God, or the statute law of the land. They
lamented the want of a godly discipline, and were uneasy at
the promiscuous and general access of all persons to the
Lord's Table. Though they did not dispute the lawfulness of
giving forms of prayer, provided a due liberty was allowed
for prayers of their own composition before and after sermon,
yet they disliked the frequent repetition of the Lord's
prayer in the liturgy, the interposition of the prayers by the
frequent repetitions of the people, some palliages in the office
of marriage, as With my body I thee worship, and in that of
burial, as In sure and certain hope of the resurrection to eternal
life, pronounced over the word of men, if not excommunicated,
&c. They also objected against the reading of the
apocryphal books in the church, while some parts of
canonical scripture were omitted; and though they did not
dislike the homilies, they thought that no man should be
ordained a minister in the church who was not capable of
preaching and expounding the holy scriptures. They dis-
approved of several of the church festivals or holidays, as
having no foundation in scripture, or primitive antiquity;
and they disallowed of the cathedral mode of worship; nor
did they approve of musical instruments in the church
service. Finally, they enforced conformity to certain rites
and ceremonies, which were enjoined by the rubric, or the
queen's injunctions; as the sign of the cross in baptism,
baptism by midwives, or other women, in cases of sickness,
and the mode of dressing women; the use of god-fathers and
god-mothers, to the exclusion of parents from being fureties
for the education of their own children; the custom of con-
firming children, as soon as they could repeat the Lord's
prayer and their catechism, by which they had a right to
come to the sacrament, without any other qualification, and
the imposition of hands, as a sign of the divine favour,
which seemed to them to imply a sacramental efficacy in
this ceremony; kneeling at the sacrament of the Lord's
fupper, whilst they considered that Christ gave it to his dis-
ciples rather in a posture of fealing than of adoration; that
it had no foundation in antiquity; that it had been grossly
abused by the papists to idolatry in their adoration of the
holy; and that, if the posture were indifferent, it ought not
to be impeded as a necessary term of communion; nor did
they approve of administering either of the sacraments in
private, even in cases of danger; bowing at the name of
Jesus; giving the ring in marriage, which they considered
as derived from the papists, who made marriage a sacrament,
and the ring a sort of sacred sign or symbol; the prohibition
of marriage during certain times of the year, and the heeding
it for money; and, lastly, the wearing of the surplice, and
other vestments to be used in divine service.

In points of doctrine there was, at this time, no difference
between the Puritans and Conformists; and if we add one
article more to the preceding, we shall have the principal
heads of controversy between the church of England and
the Protestant Dissenters, at this day; viz., the natural
right which every man has to judge for himself, and make
prophesies of that religion he apprehends most agreeable to
truth; as far as it does not affect the peace and safety of the
government under which he lives; without being determined
by the prejudices of education, the laws of the civil magis-
trate, or the decrees of councils, churches, or synods. See
Protestant Dissenters.

Towards the latter end of queen Elizabeth's reign, there
arose a party, which were first for softening, and then for

overthrowing,
overthrowing, the received opinions concerning predetermination, perseverance, free-will, effectual grace, and the extent of Christ's redemption. The clergy of the episcopal church began to lean towards the notions concerning these intricate points, which Arminius propagated some time after this; while on the other hand, the Puritans adhered rigorously to the system of Calvin. Several episcopal doctors remained attached to the same system in the reign of James I. &c. and all these abettors of Calvinism, whether episcopal or presbyterian, were called doctrinal Puritans. At length, according to Mr. Fuller, (Church Hist. book ix. p. 97, book x. p. 100.) the name was extended to dignify all those who endeavoured in their devotions to accompany the minister with a pure heart, and who were remarkably holy in their conversation; so that a Puritan was a man of severe morals, a Calvinist in doctrine, and a Non-conformist to the ceremonies and discipline of the church, though he did not totally separate from it.

Queen Elizabeth was violent in her opposition to the Puritans through the whole course of her reign; and besides the ordinary courts of the bishops, the erected, as we have already observed, a new tribunal, called the court of high-communion, which suspended and deprived men of their livings, not by the verdict of twelve men upon oath, but by the solemn determination of three commissioners of her own nomination, founded not upon the statute law of the realm, but upon the canon law; and instead of producing witnesses in open court to prove the charge, they allowed a power of administering an oath ex officio, by which the prisoner was obliged to answer all questions the court should put to him, though never to prejudicial to his own defence. If he refused to swear, he was imprisoned for contempt; and if he took the oath, he was convicted upon his own confession.

During the reign of James I. from whom the Puritans expected more indulgent treatment, they were treated with great severity, and many of them were obliged to leave the kingdom, and retire to Holland; and from thence considerable numbers migrated to America in the year 1620. All were Puritans, in the estimation of King James, who adhered to the laws of the land in opposition to his arbitrary government, though otherwise ever so good churchmen. These were called Puritans in the large; and those who were accursed to the ceremonies, and adhered to the doctrines of Calvin, were Church Puritans, who, though comparatively few, yet being joined by those of the other class, became the majority of the nation. The success that attended the first emigrants, who settled in that part of America afterwards called New Plymouth, engaged great numbers of Puritans, who groaned under the oppression of the bishops, and the severity of a court, by which this oppression was authorized, to follow the fortunes of these religious adventurers; and this produced a second emigration in the year 1629, which gave birth to the second grand colony, commonly known by the name of the Massachusetts Bay. The colony of Connecticut was formed by emigrants of the same class in 1636, and that of New Haven in 1637, who fled from the persecution of Laud, and the oppressions of the star-chamber and high-communion courts. Afterwards, when the Puritans were not allowed to transport themselves to New England, many of them removed, with their families, into the Low Countries.

After the restoration of Charles II. in the year 1662, the name of Puritans, says bishop Burnet, was changed into that of Protestant Non-conformists, who were subdivided into Presbyterians, Independents, Anabaptists, and Quakers. At this time a public law, called the Act of Uniformity, was enacted, by which all who refused to observe the rites, and subscribe the doctrines of the church of England, were entirely excluded from its communion. From this period until the reign of William III. the Non-conformists were in a precarious and changing situation, sometimes involved in calamity and trouble, and at other times enjoying some intervals of tranquillity and certain gleams of hope, according to the varying spirit of the court and ministry, but never entirely free from perplexities and fears. But in the year 1689, their affairs took a favourable turn, when a bill for the toleration of all Protestant Differents from the church of England, except the Socinians, passed in parliament, almost without opposition, and delivered those who could comply with the conditions it imposed, from the penal laws to which they had been subjected by the act of uniformity, and other acts passed under the house of Stuart. For the present state of the toleration, see TOLERATION. See also Corporation Act and Test. Neal's Hist. of the Puritans, in 4 vols. 8vo. passim.

PURITY, in Oratory, is one of the constituent parts of elegance, and denotes the choice of such words and phrases as are fit and agreeable to the use of the language in which we speak. Grammarians reduce the faults which they oppose to it to two sorts, which they call barbarism and solecism; the former of which respects single words, and is an offence against etymology, and the reproach of it is incurred by the use of words entirely obsolete, by the use of words entirely new, or by new formations and compositions, from simple and primitive words in present use. The latter respects the construction of words, and is an offence against syntax: to which Dr. Campbell adds a third class of faults, under the denomination of impropriety, which is an offence against lexicography, the business of which is to assign to every word of the language the precise meaning or meanings which use hath assigned to it. This impropriety occurs both in single words and in phrases. Dr. Ward recounts the principal things that vitiate the purity of language. It often happens, he says, that such words and forms of speaking, as were introduced by the learned, are afterwards dropped by them, as mean and fordid, from a seeming bafeness contracted from vulgar use; and it is common to language, with all other human productions, that it is in its own nature liable to a confiant change. (Hor. Art. Poet. v. 68.) We must, therefore, as he observes, be apt to conceive an obsolete, or obsoletely words and phrases, than from fordid ones. On the other hand, we should refrain from new ones, or such, whose use has not been yet sufficiently establishted at last among those of the best taste. Besides, any mistake in the sense of words or their construction, is opposed to purity; for to speak purely is to speak correctly. And further, a distinction ought to be made between a poetic diction, and that of prose writers; for poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words: so that what is a beauty in them, would often appear unnatural and affected in prose. Ward's Or. vol. i. p. 368, &c. Campbell's Phil. of Rhet. vol. i. p. 409, &c.

PURKI, in Geography, a town of Hindooslan, in Bahar; 33 miles N. of Ramgur.

PURLIEU. See Purlieu.

PURLIEU-Woods, such as formerly constituted parts of the royal forests, but of which the owners have obtained grants from the crown, and permission to disforest them, and which not being now subject to any of the laws or regulations by which different interests in forest woods are conducted, may, Mr. Donaldson says, be to all intents and purposes considered as private property. And, he adds, that
that the manner in which these woodlands are occupied is exactly the same as that of many of the royal forests, with the exception of the right of pasturage, and for that reason much more productive and beneficial. See Woods and Royal Forests.

PURLINS, in Building, those pieces of timber that lie across the rafters on the infide, to keep them from finking in the middle of their length.

PURLUE, Purlieus, or Pourallee, formed from the French pur, pure, and lieu, place, is all that ground near any forest, which, being added to the ancient forest by our kings, was, by perambulation, granted by fome of their succf celors, fierved again from the fame, and made purlieu, i.e. pure and free from the laws and obedience of the forest.

A purlieu, or pourallee, is defined a circuit of ground adjoining to the forest, and circumscribed with immovable boundaries, known only by matter of record; which com padds of ground was once forest, and afterwards was diffafforefted by the perambulations made for fevering the new forest from the old.

Purlieus, or pourallees, commenced after the manner following. King Henry I. at his accession to the crown in 1154, took so much delight in the forests of this kingdom, that, not being contented with those he found here, though many and large, he began to enlarge divers of them, and to afforeft the lands of his subj ects nearly adjoining to the fame.

His succf celors, Henry II. and Richard I., far from re trenching or restoring any thing, made still farther encroachments; and thus did the lands continue till the 17th year of king John; at which time, the grievance being grown notorious, and generally felt by all degrees of people, divers noblemen and gentlemen befought the king to grant, that they might have all those new afforeftations made by his predecessors afo re f aid, and by himself, diffafforefted again; and the king, after much folicitation, was at length prevailed on to fub feribe and fcel fuch articles concerning the liberties of the forest, as they then demanded; being, for the most part, fuch as are now contained in the Charter of the Forest.

Hereupon choice was made of divers noblemen, &c. to the number of twenty-five, who were sworn, with others their aff iliants, to fee the faid liberties, fo granted and confirmed by the king, to be in every point observed.

But, before any thing was done to the pufpofe, king John died; and king Henry III. fucceding, ftrengthen folicitations were made to him; who, for the better accomplifhing of the faid diffafforeftation, ordered inquisitions to be taken, by fubf tantial juries, for ferving all the new forests from the old: upon which, two commiffioners were fent to take thofe inquisitions; in virtue whereof, many great woods and lands were not only diffafforefted, but were improved to arable lands by the owners thereof. After this charter was made and confirmed, fome of thofe new afforeftations were perambulated, and proper inquisitions taken, and the certainty was determined by matter of record, which were the old, and which the new: though it appears, that the greatest part of the new afforeftations were ftil remaining during the life of king Henry III.

Under Edward I. ftrengthen petitions and folicitations being fent on foot, three bishops, three earls, and three barons, were at length appointed to fee thofe perambulations performed and continued; who caufed them to be made accordingly, and inquisitions to be taken thereupon, and returned into the court of chancery; and all thofe that were ancient forest to be meared, and bounded with irremovable boundaries, to be known by matter of record for ever.

Those woods and lands, that had been newly afforefted, the king likewise caufed to be seperated from the old, and to be returned into the chancery by marks, meres, and bounds, to be known in like manner by matter of record for ever.

Thus it appears how the purlieus, or pourallees, had their fift beginning; for all fuch woods and lands as were afforefted by Henry II. Richard I. or king John, and, by perambulations, farer from the ancient forests, were, and yet are, called pourallee, g. d. woods and lands farer from the old forests, and defafforefted by perambulation; pourallee: being the fame as perambulation, in Latin.

But, notwithstanding fuch new afforeftations were difafforefted by perambulation, whereby the fame became pourallee, or purlieus, yet they were not thereby difafforefted as to every man, but that they do, in fome fence, continue forest till as to others. For, by the words of Charta de Forestia, if the king has afforefted any woods or lands of his subje ts, to the damage of the proprietors, they fhould forthwith be defafforefted again; that is, only as to thofe perfon s whole woods and lands they were: who, as the proper owners thereof, might fell and cut down their woods at their own pleafure, without any licence from the king; as also convert their meadows and patures into tillage, or otherwife improve their ground to the def advantage. So alfo they might hunt, and chafe the wild beafts of the forest towards the fame, &c. But no other perfon fhould claim fuch benefit of hunting in the pourallee, besides the proper owner of the foil thereof, who is left at liberty to fuffer the pourallee to remain forest till, as fome, in effeft, have thought moft expedient, becaufe hereby entitled to the benefit of the common within the forest, which otherwife they were excluded from. Hence, if the beafts chance to wander out of the forest into the pourallee, the king hath a property in them till, againft every man, but the owner of the ground wherein they are, who hath a fpecial property in them, ratios fell; yet fo as he may only take them by hunting, or chafing with his greyhounds or dogs, without any forereftalling or forereftating them in their cure again towards the forest.

Befide what hitherto has been faid of the difference between forest and purlieu, or pourallee, there is this farther divery, that all the woods and lands within the regard of the forest are absolutely within the bondage or charge of the forest, as well in repect to the owners thereof, as of any other perfon; for no one may cut down his own woods, or improve his own lands, within the regard of the forest, without licence from the king or his chief justice in eyre of the forest. Neither shall any perfon hunt, chafe, or molest the wild beafts of the forest in his ground, within the regard of the forest, without licence or warrant from the king, or his chief justice of the forest fo to do.

But thofe, whose grounds are within the pourallees, are not subject to thofe reftrictions. Yet are not the woods and lands in the pourallees absolutely freed from the bondage of the forest, in repect of the wild beafts having their haunts therein, when they happen to ftray out of the forest; as but as they were once absolutely forest, fo they are still conditionally fo.

Purlieu-Man, or Purlieu-man, or Pourallez-man, is one who has land within the purlieu; and is allowed or qualified to hunt or cource within the fame, though under certain reftrictions.

By fl. 13 Ric. II. he who may lawfully hunt in any pourallee, ought to have woods or lands of freehold within the pourallee, to the yearly value of 40l. By fl. Jac. 1. he ought to have lands of inheritance of the yearly value of 10/. or lands of freehold of the yearly value of 30/. or have
have goods worth 200l. or be the son of a knight or baron, or perfon of a higher degree, or son and heir apparent of an esquire. But, by a later aél. Car. II. no man may keep greyhounds within the pourallec, or elsewhere, within England or Wales, unless he have a free warren, or be lord of a manor, or such a freetholder as is feised, in his own right, or in right of his wife, of lands, tenements, or hereditaments of the clear yearly value of 40l. over and above all charges and reprises of such estate of inheritance; or of lands, tenements, or hereditaments, in his own right, or in right of his wife, for term of life or lives, of the yearly value of 80l. over and above all charges and reprises, or that is worth in goods or chattels 400l.

The pourallec, or purlicue, then, is said to be for him that is so qualified; others, not qualified, and therefore not purlicue-men, yet having land in the pourallec, may, if they find any wild beasts of the forest in their own grounds within the pourallec, chase them thereout with little dogs; but not with greyhounds, or other dogs.

Nor is the purlicue-man left at large to hunt at his own discretion; but he is tied down to several rules; as,

1. That he always begins his chase in his own ground; and, that, though he finds such wild beasts in his own pourallecs, and in respect thereof, hath a property in them, rationes soli, against all persons, but the king; yet such his property is only on this condition, that he can stay them with his dogs in chase, without forestalling them, before they can recover the forest. If they be within the lift of the forest, before the dogs fallen on them, they are the king's, or other owner of the forest.

2. But if the pourallec-man first make his chase in his own freehold, he may pursue the same through every man's ground within the pourallec, and his dogs fallen on a wild beast, before he can get within the bounds of the forest, and the beast draws the dogs into the forest, and is there slain by them; here the pourallec-man shall not enter into the forest, nor take the beast so killed, because his course was irregular from the beginning, as he could claim no property in the beast, ratione soli.

3. A pourallec-man may hunt in his own pourallec with no more company than his own servants; neither may he appoint, licence, or warrant any other person, except his servants, to hunt by his commandment in his pourallec.

4. Every pourallec-man is forbidden, by the laws of the forest, to hunt in his own grounds within the pourallec every day, or oftener than three days in any one week, Sunday excepted.

5. Nor is any man to disturb, or make a course after any deer found in his pourallec, within forty days after the king hath made a general hunting in the forest adjoining thereunto; because then the wild beasts of the forest come not into the pouralleces of their own accord, but as they are forced into the same by the hunters, with clamours, and blowing of horns, so that they fly thither for refuge.

6. No man shall hunt within seven miles of the borders of the forest, or in his own pourallec, within forty days next before the king hath illused out his proclamation, declaring his royal will and pleasure to make a general hunting in that forest.

Inasmuch as the pouralleces were once, and in some few still are forest, it was necessary to have officers to attend, and take on them the charge of the preservation of the game that may happen to wander out of the forest into the pouralleces; since otherwise the laws of the pouralleces could not be executed, but the forest itself would soon be destroyed by the pourallec-men.

For this reason, rangers were first appointed, who, though not officers in the forest, yet appertain thereto; for all officers in the forest have charge of the vert and venison of the forest; but a ranger hath no charge of the vert, but only of venison coming out of the forest, into the pouralleces, his place of charge; from whence his office is to conduct the same back again into the forest.

This officer is appointed by the king, or his chief justice in eyre, and is made by patent, with a fee commonly of twenty, thirty, or forty pounds, or more, by the year, payable out of the exchequer, as also certain fees-deer, both red and fallow, to be taken annually, at proper feasons, out of the forest.

The substance of his oath is, to rechase, and with his hounds drive back, the wild beasts of the forest; as often as they range out of the same into the pouralleces; to prevent all unlawful hunting and hunters of wild beasts of venery and chase, as well within the pouralleces, as within the forest; and to prevent those and other offences, at the next court of attachments or swainmeet, which shall first happen.

Rangers, it is to be observed, belong only to such pouralleces as were once the woods and lands of the subjéct, and were afterwards disafforested again, and so became pouralleces. Hence, as there are some forests in England, which never had any enlargement by new affercations, and therefore have no pouralleces at this day, there can be no rangers belonging to them. Manwood's Forest Laws, part 2. c. 20. 4. 1 John's Rep. 278. 7. 206. 987.

PURMALL, in Geography, a town of Hindoostan; 15 miles W.S.W. of Allahabad.

PURMERENT, a town of North Holland, on a brook of the same name, governed by a council, bailiff, and burgomasters. The town had a voice in the assembly of the states; 10 miles N. of Amsterdam. N. lat. 52° 33'. E. long. 4° 46'.—Also, a small island near the coast of Java, on which lies a hospital for the diseased poor of Batavia.—Also, a small island in a large bay on the N. coast of New Guinea. S. lat. 2° 16'. E. long. 153° 12'.

Purna. See Pannah.

Purneah, a circar of Bengal, bounded on the N. by Morung, on the E. by Dinagepour, on the S. by Rajmal, and on the W. by Bahar; about 80 miles long from N.E. to S.W., and 70 from N.W. to S.E. The capital of the same name is situated on a river which runs into the Ganges; 200 miles N. of Calcutta. N. lat. 25° 48'. E. long. 87° 40'.

Purnitz, a town of Moravia, in the circle of Iglau; 7 miles S.E. of Iglau.

Purparty (Fr. pour part, i.e. pro parte) is that part or share of an estate, first held in common by parencens, which is by partition allotted to any of them. To make purparty is to divide and fever the lands that fall to parencens, which till partition they held jointly, and pro indiviso. Old Nat. Br. 11.

Purple, Purpura, πορπορ, a red colour, bordering on violet; now dyed chiefly with cochineal.

Purple was much esteemed among the ancients; especially the Tyrian purple, which underwent more dye than the rest, and which was almost peculiar to the emperors and kings. Yet this purple did not exceed that now in use. The chief reasons why the ancient purple dye has been diffused are, that the latter is both cheaper and finer.

The ancient purple was tinged or given with the blood or juice of a precious turbinated tettaeous sea-fish, called by the Greeks πορπορ, and by the Latins purpura; of which we have descriptions in several authors, and fleins in most of the cabinets of the curious. See Purple-Fish.
PUR

The method of obtaining the colour, Mr. Cole (see Purple-Fib/3) describes thus:

The shell, which is very hard, being broken, (with the mouth of thefish downwards, so as not to crush the body,) and the broken pieces being picked off, there appears a white vein lying transversely in a little furrow or cleft next the head of the fish.

In this vein is the purple matter lodged; some of which, being laid on linen, appears at first of a light green colour; and, if exposed to the sun, soon changes into a deep green, and in a few minutes, into a pea-green, and, in a few more, into a blue; whence it soon becomes of a purplish-red, and, in an hour more, of a deep purple red.

And here the fun's action terminates; but by washing in sealding water and soap, and drying it, the colour ripens to a mottl bright and beautiful crimson, which will bear washing admirably without the addition of any dyptic. While the cloth marked with this colour lies in the fun, it will yield a very strong and factid smell, as if garlic and atla facetids were mixed together.

The juice which gives this beautiful purple colour is, says M. du Hamel, while it remains in the body of the animal, and while that is in health, wholly white; but no sooner is it exposed to the sun, than it begins to change colour, and in less than five minutes goes through the several changes of pale green, yellowish, and a beautiful emerald green; after this it becomes of a deeper and duller green, then blueish, reddish, and, finally, a deep and very beautiful purple. Sometimes the juice is found naturally green in the animal: this is probably from the creature's being in a diseased state. But when it is naturally thus, it immediately becomes red, and afterwards purple, on being exposed to the fun; its several preceding changes seeming to have been made already in the body of the animal.

If a piece of linen be rubbed over with this juice, and part of it exposed to the fun, part not, that only will turn red which is exposed to the sun, the other remaining green without any alteration; and it is observed, that the stronger the sun shines, the quicker the change appears, and probably the colour is in proportion also the more beautiful and lively. And it is very remarkable, that if a needle, or any other opaque body, be laid upon the linen which is yet green, and is to become red on being exposed to the fun; after such an exposure, the whole shall be changed red or purple, excepting only that small spot which is covered by the needle, which will still remain green.

A plate of glass, though it be three inches thick, will not prevent the colour from changing purple by being laid over it; but the thinnest piece of metal will keep it wholly green. The one being opaque, and the other pellucid, are evidently the only reasons for this difference.

If the coloured linen be successively covered by three pieces of paper, the one blacked with ink, the other in its natural state, and the third rubbed over with oil, it will change colour on being exposed to the fun in different degrees; and that exactly in proportion to the degree of transparency in each of the papers: most of all in that which was covered with the oiled paper; something less in that covered by the paper in its natural state; and least of all in that which was covered with the blacked paper, as that is least transparent.

The common heat of a fire, or that of a red-hot iron, produces no change at all in the colour when green. The vapour of burning sulphur produces a little; but the green, which had not changed to purple by these experiments, immediately changed to it on being exposed to the rays of the sun.

These experiments were all made in the months of January and February, by M. du Hamel, in Provence; and the fun having power to change the colour so speedily there in these cold months, probably in a warmer climate or season the air would have been sufficient for the purpose, without the open fun; since it seems, from experiment, that both the solar rays, and the light alone in a cloudy day, can act upon this colour. The light and heat of the fun bat act on this colour: light is always sufficient to produce the effect, but the heat may easily be too great or too little; and to do the whole in perfection, it must be at a certain middle degree.

This beautiful purple, if it can ever be brought into use in dyeing, will have one very great advantage from its volatility. The pieces of cloth that had been stained by it retained their colour, in spite of several boilings in different liquors, which M. du Hamel made them pass through; and the colour, on examination, was found not to be superficial, but penetrated the whole body of the stuff, which was tinged by it. There are many inconveniences which must naturally attend the use of this substance as a dye, but they may, perhaps, all be got over by care and application. It is very certain, that it is of too vile a nature easily to penetrate many substances; but it is also certain, that this might be obviated by diffusing it in some proper liquor. It appears very plainly, that the ancients had a method of thus dissolving their purple; but we neither know what was their purple, nor what its diluent; nor, which would be of much more consequence to us at present, what is the proper diluent for our own. Mem. Acad. Scien. Par. 1736.

M. Reanumar has also discovered another very different kind of purple. This is produced in oval grains about a quarter of an inch long, full of white liquor bordering on yellow, which cover certain Roues or hands, about which the bussca of Poitou usualy assemble.

By the experiments M. Reanumar has made, it appears that these grains are neither the eggs of the bussca, nor the seeds of any tea-plants, nor any riling plants, but the eggs of some other unknown fish.

These grains, being bruised on a white linen, at first only tinge it yellow, and that insensibly; but in three or four minutes they give it a very beautiful purple red, provided the linen be exposed to the open air; for the air of a room, even though the windows be open, will not do. This colour fades, however, a little by repeated waisings.

M. Reanumar concludes, from some experiments he made, that the effect of the air on the liquor does not consist in its taking away any particles of it, nor in giving it any new ones, but only in its agitating it, and changing the arrangement of the parts that compose it. He adds, that the liquor of the bussca, and that of the grains, seem to be nearly of the same nature; except that the latter is more watery, and only fatine; whereas the other is hot, and pungent.

P. Labat gives us the description of another purple dye, produced by a tree growing in the Antilles. The juice of this tree, when cut standing, is of a blood-red, and communicates the same colour to cloths; though, like the former, it loses much in often waising.

PURPLE, Dyeing. See Dying.

PURPLE GOLD. See Gold Precipitate, &c.

PURPLE, in Medicine, an epithet applied to every disease, in which eruptions of purple spots, or petechias, appear, and these being usually the accompaniments of fevers of every kind in their worst and most dangerous forms, so purple fever.
fever was nearly synonymous with purrid, or malignant fever. See Petechia, and Purpura.

Purple Apple, in Botany. See Annona.

Purple Fiih, Purpura, in Natural History, the name of a genus of shell-fish, the characters of which are these: it is an univalve shell, jagged and befit from head to tail with fringes, tubercles, umbo, or fomite. The mouth is small and roundish; the tail is short, and usually the base runs out into a long beak. See Drying.

It has been usual with most authors to confound together the genera of the purpura and purpura, and to use the words as synonymous: but though there is some external resemblance between many of the shells of the two genera, yet they are cally distinguished by this, that the mouth of the purpura is long, and is left dentated and slaked than that of the murex. The body and the head of the shells of this genus are not so elevated as those of the murex kind, and are not covered with points or buttons at the mouth. If a shell is therefore found to have a small, smooth, and round mouth, and a body covered with undulated leaves, as it were, like those of favor or enidine, and sometimes with long points, and its tail, whether long or short, be hollowed and somewhat bent, this may be called a purpura, and not a murex. Linnaeus makes the purpura a species of the murex.

The ancients distinguished three kinds of purpura; one which had a long and crooked tail, made hollow like a tube or pipe; a second which had either no tail at all, or at the most a very short one; and a third which had no spiral head, or, as we should express it, no clavicle.

On examining the whole family of the purpurae, we may distinguish four remarkable specific differences among them. The first of these comprehends those purpura which have the body of the shell garnished with a fort of undulated foliage in clouded ridges, and have a short and crooked tail. The second comprehends those which have the body of the shell covered with acute points, and have a long tail. The third comprehends those which have as long a tail as the former, but have a smooth body, or at the utmost have only a few slight protuberances and wrinkles on it. And the fourth takes in those which are small, and have an elevated clavicle, a short crooked tail, and the body of which is covered either with flender fringes or hairs.

This species of fish, as well as the murex, served among the ancients to dye the fine purple colour which they were so fond of, and some of the buccina (e.g. the lapillus of Linnaeus) have been of late found to have the same juice. The purpura and murex are both filled up in great plenty in the gulf of Tarentum; but the small quantity of the coloured juice which each fish contains, and the necessity of using it before the animal dies, makes it impossible to bring it to any regular article of traffic. The ancients used this colour only on cotton and woollen stuffs; whereas our cochineal, which was unknown to the ancients, frikes equally well on silks and stuffs. These shells are also found in various parts of the Mediterranean.

In the seas of the Spanish West Indies about Nicoya, is found a shell-fish, which perfectly resembles the ancient purpura, and, in all probability, is the very same. This fish, Gage tells us, usually lives seven years; it hides itself a little before the dog days, and continues to disappear for three hundred days running.

They are gathered plentifully in the spring, and, by rubbing one against another, they yield a kind of salvia or thick glitter, resembling lost wax: but the purple dye is in the throat of the fish, and the finest part is lodged in a little white vein; the rest of the body is of no use. He adds, that the chief riches of Nicoya consist in this fish. Cloth of Segovia, dyed with it, is sold for twenty crowns the ell; and some but the greatest Spanish lords use it.

There are also found upon the coasts of the South-sea, near the equator, in the neighbourhood of point St. Helena, in the province of Guayaquil, certain sea-fish, as Don Antonio de Ulloa calls them, flicking to the flones, and covered by the sea at high water, about the size of small nuts, which contain a liquor or juice that has the true colour of purple. The colour is very bright, and so durable that washing rather increaseth than diminisheth its lustre, nor does it fade or decay by use and wearing. Woven stuffs are not dyed with it, but only cotton threads. As soon as a sufficient quantity of the liquor is squeezed from the fish, the cotton thread is drawn through it, and it takes and retains the tinture without any farther trouble; but the purple colour is not discovered till the thread is dry. The juice being of a milky colour at first, but it soon changes into green, and at last settles in a purple.

Besides the Indian purple fishes, we have others much nearer home. In the Philosoph. Transact. abr. vol. ii. p. 283, we have an account of purple fish discovered in 1684, by Mr. W. Cole, on the coasts of Someretshire, South Wales, &c. where it is found in great abundance. The modern purple fish, M. Reaumur observes, is a kind of buccina, a name given by the ancients to all fishes whose shell bears any resemblance to a hunting-horn; and it appears from Pliny, that part of the ancient purple was taken from this kind of shell-fish: so that this may be esteemed a recovery of what had been suppos'd entirely lost. See Drying.

The fish, he observes, is good; and adds, that there are several kinds of it differing in size and shell, and also in the colour of the tinging liquor. There are some found on the coasts of Poitou.

The Caribbea islands have likewise their purple fish. This is called purgan, being of the size of the end of the finger, and resembling our periwinkles; its shell is of a brownish azure, its flesh white, its intelettes of a very bright red, the colour of which appears through the body; and it is this that dyes the froth, which it casts forth when taken, and which is at first of a violet hue, bordering on blue.

To oblige them to yield the greater quantity of froth, they lay them on a plate, and shake and beat them against one another; upon which the plate is immediately covered with the froth, which is received on a linen cloth, and becomes purple in proportion as it dries.

P. Labat observes, that if this be the real Tyrian purple, the secret of preparing and fixing it is lost; this colour being found to dwindle and dilipate, in proportion as the linen dyed with it is washed.

The purpurae lives on other fish. It usually hides itself at a small depth in the sand, sometimes even in fresh-water rivers, and as it lies hid, it thrusts up a pointed tongue, which wounds and kills any thing that comes over it. We frequently find sea-shells with round holes bored through them, as regularly as if made with a boring instrument; these are generally allowed to be made by the tongue of the purpura, in order to its feeding on the fish within.

The purpura has two horns like that of a snail; and Fabius Columna says, that they have eyes in these, not placed at the ends, as in the snail, but in the middle of each horn.

The purpura is a shell-fish very well known, and has been known also in almost all times to afford a purple liquor; but as there has been no method discovered of bringing this li-

PURPURA, Persiun, the fame with the Persian shell, a species of delium.

Purpura, in Medicine, the nomenclature of cutaneous difeases propounded by Dr. Willan, signifies an eruption of purple specks and patches, that is of petechia, ecbymonata, and velicis, accompanied with general debility, but not always with fever.

Under this limitation, the purpura is fynonimous with the "petechia fine febræ" of fome medical writers, (see Romberg, Ephem. Natur. Curiof. dec. iii. ann. 9 and 10, ob. 108 ; and Dr. Graaf, Diff. Inaug. de Petechiis fine Febre, Gott. 1775 ;) with the "hemorrhæa petechialis" (see Dr. Adair, Diff. Inaug. Edin. 1780, and Dr. Bateman, Diff. Inaug. Ibid. 1801 ;) with the "land-februy," &c. of others. Riverius, Diemerbroeck, Sauvages, Cullon, and one or two others, appropriated the term purpura in like manner to petechial spots only, and rightly excluded from this appellation all other eruptions of a character essentially different.

In thus limiting the acceptation of the term, however, it is proper to mention, that in the writings of many physicians it is applied to various other eruptive diseases, which have no affinity with petechial blotches, and very little with each other. Thus, under the name of purpura, the redd gum, or flrophulus, is described by Ettmuller,—the scarlet fever by Schultz and Juncker,—the meafles by Hafenrefler and Morton,—the nettle-rash, military vehicles, and lichen, by Hoffmann and others. See Willan on Cutan. Diff. P. 452.

The purpura occurs under various degrees of violence, which induced Dr. Willan to make two fpecies, which he denominated simplex and hemorrhagica, according as the eruption occurred alone, or with difcharges of blood. It is imposible, however, to draw a fubftantive line, where nature presents no clear difference. We can only state that, in the milder degrees, there is an eruption of petechie only, chiefly appearing on the extremities and breath, and seldom affecting the face. The complexion is generally pallid or fallow, and there is a confiderable degree of debility and languor, and sometimes pains in the limbs.

In the more severe cafes of the difeafe, the failure of strength is considerably greater, and often precedes, for some time, the appearance of the eruption. The spots commonly appear firit on the legs, where they are ufually the largelft and moft numerous, and are often accompanied with anaefhetic swellings. When they firit appear, they are of a bright red hue, but they gradually become purple or livid, and when about to disappear, they change to a brown or yellowish hue; fo that in the progres of the difeafe, as the spots appear and fade in succession, the skin presents a confiderably variegated appearance. In the more severe forms, the petechiae are intermixed with ecbymofes and velicis, or livid patches and flripes, reftembling the effects of a bruise, or of the strokes of a whip. In this flate, sometimes, when these patches do not appear fpontaneously, the gentleft pressure on the skin, fuch as is applied in feeling the pulse, will produce a purple blotch, like that which follows a fharp blow.

When the difeafe is still more severe, in addition to these effusions of blood under the cuticle, condfiderable difcharges of blood take place from fome parts which are defended by a very delicate cuticle; whence thofe hemorrhages originate particularly from the internal passages and organs, and are occasionally very profufe, endangering, and occasionally destroying life. Most frequently, however, the bleeding is flow, and in small quantity, fometimes almoft a conflant oozing, and fometimes returning at intervals. These hemorrhages take place from the gums, noftiles, throat, the inside of the cheeks, the tongue, and lips; fometimes from the lining membrane of the eye-lobes, the ufehera, and the external ear; and fometimes from the internal cavities, the lungs, flomach, bowels, kidneys, uterus, and bladder. There is great variety, however, in the periods of the difeafe at which these hemorrhages commence and ceafe, and as to the proportion which they bear to the cutaneous affifrence.

This fingular difeafe occasionally appears suddenly, in the midft of good health, attacking during the night. It is always accompanied by great faeblenefs and defpiration of fpirits; and fometimes by pains in the chelf, loins, or abdomen, by irregularity of bowels, or by cough; and the pulse is fometimes flichtly quickened and very fbleeble, as in a moderate hectic. But in fome cafes thefe functions are not perceptibly defurbed. The duration of the difeafe is equally uncertain; in fome infances it has terminated in a few days, while in others it has continued not only many months, but years. When it terminates fatally, it is conffamment in confequence of a copious hemorrhage, either suddenly from fome important organ, or more slowly from feveral parts at the fame time.

The caufes of this difeafe are not clearly afferted, nor its pathology well understood. It occurs at every period of life, and in both fexes; but most frequently in women, and in boys before the age of puberty, particularly in thofe who are of a delicate habit, who live in close and crowded situations, and on poor diet, or are employed in feditious occupations, and fubjeft to grief, anxiety, fatigue, and want of fleep. It has likewife attacked thofe who are left in a flate of debility by previous acute and chronic difeafes, as after meafles or small-pox, or during confinement in the puerperal flate, or after a violent faliivation from mercury. On the other hand, however, the difeafe appears occasionally in its moft severe and fatal form, where none of these circumstances had previously existed: for infance, in young perions living in the country, and fuffering no privation of any of the comforts of life, and previously enjoying good health. This fect tends greatly to obscure the pathology of the difeafe: for it renders the operation of these alleged caufes extremely questionable, and feems to efftablifh an effential diftinction between purpura and februy, in the origin and nature of the morbid actions which constitute the difeafe. In februy (by which we mean the febr-buta, or true februy, formerly prevalent among fefmen in long voyages, and among peopls in befieged towns, and other situations, when living upon putrid, falted, dried, or otherwife indigefible food, yielding imperfect nutriment,) the reftoration of the proper nourifhment, with the ufe of fresh vegetables and acids, invariably removes the symptoms, and they never commence where fuch diet can be obtained: while, in many cafes of purpura, this diet has been taken abundantly, without the smallest alleviation of the complaint, and the difeafe has come on, where there had been no deficiency. "On the other hand, the rapidity of
the attack, the acetuness of the pains in the internal cavities, the actual inflammatory symptoms that sometimes supervene, the occasional removal of the disease by spontaneous hemorrhage, the frequent relief derived from artificial discharges of blood, (see two cases of purpura by Dr. Parry, Edinburgh Med. and Surg. Journ. for Jan. 1809), and from purging, all tend to excite a suspicion that some local vesicular congestion or obstruction is the cause of the symptoms in different instances. " (Bateman's Practical Synopsis of Cutan. Dis. p. 110.) Several facts in proof of these observations are related in the work just quoted; but a sufficient number has not yet been collected to afford any general inference respecting the nature of the disease.

The cure of purpura is, therefore, not established upon any clear principle, and there has been considerable difference of opinion upon the subject. Dr. Willan has given a very imperfect view of this point. All that he says relative to the cure of the wound form purpura, is comprised in these few lines. "In the treatment of this disease, we should recommend moderate exercise in the open air, a generous diet, and the free use of wine, Peruvian bark, vitriolic acid, &c. Without air, exercise, and an easy state of mind, the effect of medicines is very uncertain."

(On Cutan. Diæeses, p. 461.) Of this, indeed, he has given an ample proof in the next sentence, where he tells us that a patient "took for two or three months Peruvian bark in considerable quantities, the vitriolic and marine acid, and wine, without much advantage." In truth, the cure of purpura is, we believe, not to be effected by these means. In the lighter degrees of the disease, occurring in children who are ill fed and nursed, and excluded from the air and from all exercise, these toxins may seem to do good, when combined with air and exercise. "But," as Dr. Bateman observes, "when it occurs in adults, especially in those already enjoying the benefits of exercise in the air of the country, and who have suffered no privation in respect to diet; or when it appears in persons previously stout, or even plethoric; when it is accompanied with a white and loaded tongue, a quick and somewhat sharp, though small, pulse, occasional chills and heats, and other symptoms of feverishness, however moderate;—symptoms which may be presumed to indicate the existence of some local congestion; —then the administration of tonic medicines, particularly of wine, cinchona, and other warmer tonics, will be found efficacious, if not decidedly injurious. In such cases, free and repeated evacuations of the bowels, by medicines containing some portion of the muriate of mercury, will be found most beneficial. The continuance or repetition of these evacuations must, of course, be regulated by their effects on the symptoms of the complaint, or on the general constitution, and by the appearance of the excretions from the intestines. If the pains are severe and fixed, and if the marks of febrile irritation are considerable, and the spontaneous hemorrhage not profuse, local or general blood-letting may doubtless be employed with great benefit, especially in robust adults." Præç. Synopsis, before quoted, p. 114.

The importance of free purgation in purpura has been clearly flated in a short but valuable communication from Dr. Harty, of Dublin, published in the Edinburgh Medical and Surgical Journal, for April, 1813: in more than a dozen cases treated in this manner by Dr. Harty, the hemorrhages ceased, and the purple spots disappeared, after a few doses of calomel and jalap had been taken. In the two cases related in the same useful journal by Dr. Parry, of Bath, before alluded to, and which were speedily cured by two bleedings from the arm, the blood drawn exhibited a tenacious contracted coagulum, covered with a thick coat of lymph, as in diseases of an inflammatory nature. The patients were a lady and an officer, the latter of whom was accustomed to free living: in both cases some degree of feverishness accompanied the purpura.

There is one variety of the disease, which Dr. Willan distinguishes as a third species, by the title of purpura urticans, because the eruption commences in the form of rounded and reddish elevations of the cuticle, resembling the wheels of nettles-rash; but they are not accompanied by the same sensations, tingling and itching, which belong to the nettles-rash. These little tumours gradually dilate; but within one or two days they subside to the level of the surrounding cuticle, and at the same time their hue becomes darker and at length livid, or purple. As these spots are not permanent, but appear in succession in different places, they are commonly seen of different hues; the freshest and elevated ones being of a brighter red, while the level spots exhibit different degrees of lividity, and become brown as they disappear. They are most common on the legs, where they are frequently mixed with petechiae; but they sometimes appear on other parts of the body.

The duration of the purpura urticans is various, from three to five weeks, in the course of which time the hands and ankles are affected with oedematous swellings: there is also a distressing degree of languor and debility, and a loss of appetite, but seldom hemorrhage. It generally appears in summer and autumn, affecting those who are exposed to fatigue, and live on poor diet, and delicate young women of indolent and luxurious habits. The same precautions, as to treatment, are applicable to this as to the other varieties of purpura.

When purple spots occur as symptomatique of bad fevers, they require no peculiar treatment. They are much less frequent concomitants of fevers than they were formerly; a circumstance which is probably to be ascribed partly to the more liberal use of purgatives at present in all febrile diseases, and partly to the more free admissin of fresh air, to the superior cleanliness, &c. now observed in these matters. The appearance of these spots has been occasionally noticed by various authors in agues, remittent fevers, pallsies, dropy, and atrophy. Dr. Willan observes, that in the last stage of pulmonary consumption they sometimes occur as the immediate forerunners of death. (See Pett. Histo.) For histories and cafes of purpura, see Duncain's Med. Comment., vol. xiv. and xx. and Med. Cæses, vol. p. 90. Annals of Medicine, vol. ii. Memoirs of the Med. Society of London, vol. iii. art. 20.; and vol. iv. art. 17. Medical Tracts and Obs. vol. ii. Willan's Reports on the Diæeses of London.

PURPURATI, in our Ancient Historians, denote the sons of emperors and kings.

PURPURE, Pourpir, or Purple, in Heraldry, according to some, is one of the five colours of armories, mixed or compounded of gules and azure, bordering on violet; and, according to others, of a little black and much red colour. It is, by the heralds, supposed a symbol of temperance, liberality, dignity, authority, faith, and piety. Most authors in heraldry, as Favy, Geliot, Monet, and Meunier, do not allow purple for a colour, in regard it is not simple, but composed of a mixture of other colours. They rather esteem it a kind of intermediate tincture, sometimes metal, and sometimes colour: hence the Spaniards call it una misma; so that one cannot lay it on metal and colour without falsifying the arms.

Add, that many take the purple, as it is accounted, on many ancient bearings, by which some of the moderns would evince
evidence the regularity and legitimacy of this colour in armory, to be no other than silver tarnished.

Spelman, however, in his Apologia, allows purple the preference before all other colours, as having been an enunt of royalty for many ages; yet even he allows it to have been excluded, by the ancient heralds, as only an imperfect colour.

It is represented in engraving, by diagonal lines drawn from the finiter chief to the dexter base point. In the coats of noblemen it is called amethyst; and in those of princes, Mercury.

PURPURINA, a name used by Caneparius, and some other authors, for the aurum mofiacum, or aurum mufivum of the flops, the present preparation of which differs from that of that author only in the proportions of the ingredients.

PURPURISSUS, in the Ancient Writers, both Greek and Roman, the name of a compound colour or focus of a fine purplish red, used to paint women's cheeks.

It seems by the composition to have been somewhat like our rose pink, as it is called by the colourmen. It was made of the creta argentaria, or fine white kind of chalk, diffolved in a strong purple tincture of some of the roots of wood which dyed red; and when the coarser part was subdued to the bottom of the vessel, the liquor, while yet thick, was poured off into another vessel; and what subdued from this, which was as fine as flour, was of a beautiful pale purple, and was the purpurius faved for use.

PURREL, anno 35 Eliz. cap. 10, a lift ordained to be made at the ends of kerfeyes, to prevent deceit in diminishing their length.

PURRONGUR, in Geography, a town of Hindoostan, in the circuit of Bilsa; 20 miles S.E. of Bilsa.

PURROWNAD, a town of Hindoostan, in Oude; 33 miles E. of Gooracourp. N. lat. 26° 57'. E. long. 84° 17'.

PURRUAD, a small circuit of Bengal, about 16 miles in circumference; N. of Maulda. —Also, a town of Bengal, and chief town of the said circuit; 26 miles E.S.E. of Burdwan. N. lat. 23° 4'. E. long. 88° 25'.

PURSAH, a town of Hindoostan, in Bahar; 18 miles N.W. of Churup.

PURSAUMMAH, a town of Hindoostan, in Bahar; 35 miles E. of Durbangh.

PURSE, a manner of accounting; or, as some call it, a species of money of account, much used in the Levant, particularly at Constantinople, where it is 500 aperas; three aperas being equal to a para, and forty paras equal to a piaffe, called by the Turks gronche, and by the English dollar. By the regulations of 1780, the purfe of 500 piaffees was to weigh 2812½ Turkish drams. A single piaffe weighed 5½ drams; or 277 English grains; and the other pieces in proportion. Their standard of fine silver was reduced at the same time to 50 carats (or hundredth parts) of fine silver, and 50 of alloy; which gave the value of the piaffe at 19½ d. sterling, and the other silver coins in proportion. But since that period the Turkish coins have undergone a deterioration; so that a piaffe of the latest coinage being weighed and affayed by the king's alay master of the Mint, appeared to be in weight 8 dw. 6 gr.; in fineness, 5 oz. 6 dw. worse than the English standard. This gives its fineness 47 carats 2 grains Turkish, and its value, in sterling, 13½ d. Kelly's Un. Cambilt.

This money of account is called purses, because all the grand vignet's treasure in the fagagio is kept in leather bags of this value.

In this, however, there is some difference; for the purse in Egypt is 25,000 medinis, or 75,000 aperas; and in other parts of Turkey it is only 20,000.

This method of accounting the Turks derive from the Greeks, and they from the Romans; the emperors of which brought it to Constantinople, as appears from a letter of Constance to Cecilian, bishop of Carthage, quoted by Eusebius and Nicephorus. See FOLIS.

Purse-Net, in Rural Economy, a net used for taking both hares and rabbits at certain times; and three or four dozen of them are sufficient to lay over their holes: they are to be fastened, by tying lirings to sticks thrust into the earth, otherwise when the rabbits bolt away, they will run away and get out of the nets; but when the nets are fixed, and all things are in order, there must be one or two perons to lie close, to see what game comes home; while, in the mean time, you beat the bushes, to force them homewards. But another way to take rabbits with these nets, is, at their coming out of their parraces: and they should be secrcted in this manner. First hunt them up and down, to force them all in, then put in a ferret, with a bell about her neck, which gives the rabbit notice of her coming, who, in endeavouring to avoid the ferret, runs into the net.

PURSER, an officer who leads a man of war, appointed by the lords of the admiralty, who receives her victuals from the victualler; and is to take care that it be in good condition, and well laid up and flowed. He is also to see that they are carefully distributed to the officers and crew, according to the instructions which he has received from the commissioners of the navy for that purpose. To him also belongs the distribution of flops, &c.

He is also to keep a list of the men and boys belonging to the ship, and to let down, exactly, the day of each man's admittance into pay; that the paymaster or treasurer of the navy may issue out his disbursements, and pay off the men according to the muster-book.

Pursiveness, or Pursiness, among Farriers, thickness of wind, a name common to all those diseases in horses which arise from obstructions in the passageways of the lungs.

Pursiveness, sometimes also called broken wind, may proceed from an ulcer, or some inward walling of the lungs, in which the small vessels are worn or abraded by the sharpness or acrimony of the common discharge.

The like disorder may also arise from a flagination, hindering the air from penetrating so as to lift up the lungs in the act of respiration; or from some tough and mucilaginous matter separated in the branches of the wind-pipe.

The usual occasions are cold, surfeits, and other diseases not thoroughly carried off. Purse disorders may also arise from wholesome food, bad air, and hard riding when a horse is full. The signs are commonly a heaving and beating of the flanks; a wheezing and rattle; sometimes the kernels about the throat will swell, and there will be a glandulous running at the nose, which is the utmost stage of the disease, and usually reputed desperate.

Purslane, in Botany. See Portulaca.

Purslane, Herbe. See Triainthesma.

Purslane, Sot. See Atriplex.

Purslane Tree. See Portulacária.

Purslane, Water. See Peplis.

Pursottumpour, in Geography, a town of Hindoostan, in Bahar; 35 miles W.S.W. of Arrah.

Pursoah, a town of Hindoostan, in Bahar; 25 miles W.S.W. of Gayah.

Pursuyant. See Pursuyant.

Pursur, in Geography, a town of Hindoostan, in Oude; 13 miles N. of Mahondu.

Purver, anthony, in Biography, was born at Up.
Hurborn, in Hampshire, about the beginning of the 18th century. His education was extremely limited, but he exhibited a striking proof of his capacity for learning while he was very young; for, being prevented by ill-health from attending school almost six weeks, he applied, by himself, during that time, with such diligence and success to the study of arithmetic, that upon his return to school he was able to explain the problems of evolution to his master, whose attainments had not carried him so far. At this time of life he exhibited great powers of memory, by committing to it twelve of the longest chapters in the Bible in as many hours. He was put apprentice to a shoe-maker, who was also a dealer in sheep, and employed Anthony a good deal in looking after his flock. This was not by any means an irksome business, as it afforded him an opportunity for reading the scriptures, to which he was particularly attached. As he advanced in years, he found that his favourite book contained doctrines that were very differently interpreted by different persons, and he was resolved to study the Old and New Testament in their original languages. Having renounced the occupation for which he was originally intended when he was about twenty years of age, he commenced teacher in a school, but afterwards removed to London, for the sake of more easily acquiring the means of prosecuting his studies. Here he probably resided in 1727, when he published his work, entitled 'The Youth's Delight.' While at London he became a Quaker, and officiated among the friends in the character of a minister. He returned to Hurborn, and refumped his school in 1727, and probably continued it for some time, during which he began to transcribe the books of the Old Testament, from the original Hebrew. While thus employed, he felt it his duty to become a missionary, and travelled through several counties of the kingdom, till he came to Stambrook, near Bristol, towards the latter part of the year 1738. Here he resided at the house of a maltster, where his industry continued in a classical learning, while he devoted his leisure to his favourite employment of translating the scriptures. In 1740 he made an attempt to publish his translation of the Old Testament in numbers; but for want of encouragement he did not proceed beyond two or three numbers. When he had completed the translation of the whole Bible, he could find no bookseller who would embark in the publication. Thus was the labour of thirty years likely to be lost, till Dr. Fothergill made him a present of 1000l. for the copy, and took upon himself the expense of printing the work. Under his auspices, it made its appearance in the year 1764, with the title of 'A new and literal Translation of all the Books of the Old and New Testament, with Notes critical and explanatory,' in 2 vols. folio. It was the author's intention to have published a second edition, with various corrections and alterations, but he did not live to accomplish the design. He died in 1777, about the age of 75. Purser was described by Dr. Fothergill as 'a man of great simplicity of manners, regular conduct, and a modest reserve: he is steadily attentive to truth, hates falsehood, and has an unconquerable aversion to vice; and to crown the portrait, he is not only greatly benevolent to mankind, but has a lively sense of the divine attributes, and a profound reverence of, and submission to, the Supreme Being.'

Purveyance. See Purveyance.
Purveyor. See Purveyor.
Purview, from the French, purvau, a gift, grant, provision, &c. a term frequently used, by Sir Edward Coke, for the body of an act of parliament, or that part which begins with Be it enacted, &c. as contradistinguished from the preamble.

The statute of 3 Hen. VII. stands upon a preamble and a purview. 12 Rep.

Purulent, Purulentus, in Medicine, something mixed with, or partaking of, pus or matter.

Phthahical people frequently spit a purulent matter. In a dyentery, the fluids are purulent when there is an ulcer in the reins or bladder, the urine is purulent.

Purusha, in Mythology. See Purusha.

Puruz, in Geography, a river of La Plata, which rises about S. lat. 17° 25', taking the name of 'Rio Beni,' and afterwards called 'Amaru-Mayu,' or 'The Serpent;' from S. lat. 12° its course is not ascertained till it comes to S. lat. 6°, after which it affumes the name of Puruz, and runs into the river of the Amazons, or Maranon, S. lat. 3° 44'. W. long. 45° 6'. Its whole course is northerly about 800 miles.

Purwar, a town of Hindoostan, in Lahore; 14 miles S. of Seacold.

Purysburg, a handsome town of South Carolina, in Beaufort district, which district contains 25,887 inhabitants, on the E. side of Savannah river, 37 miles from the ocean, and 20 from Savannah. It derives its name from a Swiss, John Peter Purry, who settled a colony of his countrymen here about the year 1735, with a view to the cultivation of silk. The mulberry-trees are still standing, and some attention is paid to the raising of silk. The town contains between 40 and 50 dwelling-houses, and an episcopal church; 64 miles W.S.W. of Charleston. N. lat. 32° 23'. W. long. 81° 12'.

Pus, from pust, matter, the fluid contained in abscesses, and discharged from ulcerated surfaces, and sometimes from membranous surfaces which are merely inflamed, and quite free from ulceration, as is illustrated in cases of gonorrhoea, empyema, &c. Pus is formed by a peculiar process, which is termed suppuration, of which we shall have occasion to speak in a future volume of this work.

In the present place, we shall content ourselves with inserting a few observations on the qualities and uses of pus, chiefly taken from the writings of Mr. Hunter.

True pus has certain properties, which, when taken singly, may belong to other secretions, but which, conjointly, form the peculiar character of this fluid, viz. globules swimming in a fluid, which is coagulable by a solution of salt ammoniac, which no other animal secretion is, and, at the same time, a consequence of inflammation.

The colour and the consistence of pus are the two qualities which first attract the notice of every, the most superficial, observer. The colour arises from the largest portion of this fluid being composed of very small round bodies, very much like those little globules which, swimming in a fluid, make cream. The fluid in which the globules of pus swim, we might at first suppose to be the serum of the blood, for it coagulates with heat, like the latter fluid. Pus is also probably mixed with a small quantity of coagulating lymph; as it partly coagulates after it is secreted.

The fluid part of pus, however, is known to have properties which serum has not. There being a similarity between pus and milk, experiments have been made to ascertain whether the fluid of pus could be coagulated with the gastric juice of animals; but no coagulation could be effected in this manner: a solution of salt ammoniac made the fluid part of pus coagulate; but not any other secretion,
or natural fluid; and hence it was concluded, that whenever globules were found swimming in a fluid, coagulable by sal ammoniac, the matter was to be considered as pus.

The proportion which the white globules bear to the other parts of pus, depends on the health of the parts producing the discharge. When the globules are very abundant, the matter is thicker and whiter, and is called healthy pus; the meaning of which is, that the fluids, which produced it, are in good health; for these appearances in the matter are no more than the result of certain salutary processes going on in the fluids, the effect of which precedes to produce the disposition, on which both suppuration and granulation depend.

Pus is specifically heavier than water, and is probably about as heavy as blood.

Besides the above properties, pus has a sweetish mawkish taste, very different from that of most other secretions, and the same taste takes place, whether it is pus from a sore, or an irritated inflamed surface.

Pus has a smell in some degree peculiar to itself; but this differs in different cases. Some discharges, it is said, may be known by the smell, as, for instance, a gonorrhoea.

Pus finds in water; mucus floats. Pus communicates to water an uniformly troubled white colour; mucus gives the appearance of stringy portions floating in it. Mucus is said to be more readily dissolved by sulphuric acid than pus is. It has also been asserted, that if water be added to such solutions, the pus is precipitated to the bottom of the vessel; while the mucus, instead of being completely precipitated, forms swimming flakes. A solution of caustic alkali differentiates both pus and mucus; but when water is added, the pus is said to become separated, but not the mucus.

Though solutions in chemical menstrua and precipitations have been thought a test of the distinction between these two fluids; yet the method has been thought absurd and unphilosophical. It has been conceived, that all animal substances whatever, when in solution, either in acids or alkalies, would be in the same state, and therefore, that the precipitation would be the same in all. Calcareous earth, when dissolved in muriatic acid, is in that acid in the same state, whether it has been dissolved from chalk, limestone, marble, or calcareous spar, and precipitations from all are the same. Hence experiments were made on organic animal matter, such as muscle, tendon, cartilage, liver, and brain; and on inorganic, such as pus and the white of an egg. All these substances were dissolved in sulphuric acid, and precipitated with the vegetable alkali. Each precipitation was examined with such magnifiers as plainly showed the forms of the precipitates, all which appeared to be flaky substances. The precipitate by the volatile alkali had exactly the same appearance. The same appearances were seen when the above kinds of animal matter were dissolved in the vegetable caustic alkali, and precipitated with the muriatic acid. A flaky substance, void of any regular form, composed each precipitate.

Pus does not irritate the particular surface which secretes it, though it may be irritating to any other. Hence no suppuring surface, of any specific kind, can be kept up by its own matter. If this had not been the case, no foreign matter of a specific quality, or producing matter of an irritating kind, could ever have been healed. This is similar to every foreign secretion of stimulating fluids, as the bile, tears, &c. which fluids do not stimulate their own glands or ducts, but are capable of stimulating any other part of the body.

Whenever a real disease attacks either the suppuring surface or the constitution, the production of true pus ceases, and the fluid becomes changed in some measure, in proportion to these morbid alterations. In general it becomes thinner and more transparent, and it partakes more of the nature of the blood, as is the case in most other secretions under similar circumstances. Sanies is the term usually applied by surgeons to pus in this degenerated state. This unhealthy putrid matter has more of the ferum, and frequently more of the coagulating lymph in it, and is the combination, which renders it coagulable by a solution of sal ammoniac. It has also a greater proportion of the extraneous parts of the blood, which are soluble in water, such as salts; and it has a greater tendency to true pus to become putrid. Such unhealthy matter may even be irritating to the surface which produces it.

The discharge, when of an irritating fort, is more stimulating to the adjoining parts with which it comes in contact, than to its own secreting surface. In this manner it frequently produces excoriations of the skin and ulceration. Thus the tears excoriate the skin of the cheek, in consequence of the quantity of salts which they contain. From this effect, matter has been called corrosive, a quality which it has not; the only property which it possesses being that of irritating the parts which it touches, so as to cause their absorption.

When the vessels thus lose the power of producing good pus, they also lose more or less the power of forming granulations. This may depend on some deviation from the due structure and action which such vesseis should possess, in order to be qualified for the performance of these two operations.

Pus, from several circumstances, would appear in general to have a greater tendency to putrefaction than the natural juices have; but, perhaps, this is not the case with pure pus, which, when first discharged from an abscess, is commonly perfectly sweet. There are, however, some exceptions to this, but these depend on circumstances entirely foreign to the nature of pus itself. Thus, if the abscess had any communication with the air, while the matter was confined in it; or if the collection has been too near the colon, or rectum, as to have been infected by the feces, then we cannot wonder that the matter should become putrid. When blood is blended with pus; when sloughs are mixed with it; when the parts forming the seat of the abscess are in a gangrenous state from an erysipelas afflication; the matter has a greater tendency to putrefy than the pure pus discharged from sound abscesses, or healing sores. Pure matter, though easily rendered susceptible of change by extraneous additions, is in its own nature tolerably uniform and immutable. It appears so unchangeable, that we find it retained in an abscess for weeks, without having undergone any alteration. These qualities, however, only belong to perf. pus.

In the preceding paragraph it is stated, that matter remains very often unchanged in abscesses for weeks. This expressio of Hunter's is not strictly correct; for it is well known, that the surfaces of the cavities of abscesses are always absorbing, as well as secreting ones; consequently there must be a continual mutation going on in the contained matter.

When there are diseased bones, or other extraneous bodies, exciting irritation, sometimes even to so great a degree as to make the vessels bleed, and often wounding the vessels of the part, the matter is always found to be very offensive. This state of the discharge is one mark of a diseased bone.

The
The discharge of an unhealthy fore blackens silver probes, and preparations of lead. This effect is imputed by Dr. Crawford to the sulphurated hydrogen gas generated in the matter. Phil. Trans, vol. lxxx. for the year 1790. p. 391, &c.

Use of Pus. — By some it is supposed to carry off humours from the constitution. Suppuration is sometimes regarded as a constitutional disease, changed into a local one, which constitutional malady is discharged, or thrown out of the body, either in the form of pus, or together with this fluid. Critical abscesses have been thought to be cases of this sort. Suppuration has also been imagined to carry off local complaints from other parts of the body, on the old principle of derivation or revulsion. For this reason, fores or issues are made in, found parts before allowing other fores to be dried up. Suppuration is sometimes excited with a view of making parts, such as indurated swellings, dillofse into pus; but we have endeavoured to shew that no dillofication of the solids is concerned in the production of pus.

A secretion of pus is looked upon as a general prevention of many, or of all, the caufes of disease. Hence issues are made to keep off both universal as well as local diseases. However, the use of pus is perhaps unknown; for it is formed most perfectly from healthy fores, and in healthy constitutions; and large discharges from parts not very essential to life, produce very little change in the constitution, and as little upon being healed up, whatever some may appone to the contrary.

This is certainly the cafe with many old ulcers, the suppuration from which seems to have little or no effect in impairing the health. Nor is there any real reason to be afraid of healing such fores, when possible, lest a worse disease should follow from the ftoppage of the discharge, to which the fylem is supposed to be habituated to much, that the continuance of such discharge is essential to health.

Every one knows, that when there is no interference of air, that is, when the surface of a fore is left uncovered, the thin part of the matter evaporates, and the thick part forms a fcafb. Nature, therefore, seems to have designed, that one use of pus should be to make a cover and protection for ulcerated surfaces.

Among the fecondary uses of suppuration may be mentioned, opening a communication between a disease and the external surface of the body; forming a pallage for the exit of extraneous bodies, &c.

Pusa, in Geography, a town of Hindoostan, in Bahr; 16 miles E. of Hajnpur.

Pusbach, a town of Germany, in the principality of Alsbach; 12 miles S. of Culmbach.

Puschenga, a river of Russia, which rises in lake rus, in the government of Archangel, and runs into the sea near Kevrol.

Puschiano, a town of Switzerland, in the Grifons, on which is derived the name of one of the jurisdictions held by the duke of Milan, in the year 1436. The greater number of the inhabitants contain the Roman Catholics. The town lies three miles N. of a lake of the same name, abounding in fish, and distant 14 miles S.W. of Bormio, and is situated 17 miles W.S.W. of the fame vn, and 20 miles E. of Chiavenna.

Puschima, a town of Russia, in the government of Tver; 40 miles N.N.E. of Bie佐erikt.

Pushan, in Mythology, a name for Surya, a personification of the sun, among the Hindoos, and a name also to their god Siva.

Pusheng, in Geography. See Kooshineee.
exaggerated by the eastern dialect, that there is not much to be expected from them.

PUSULA, in Geography, a town of Sweden, in the province of Nyland; 37 miles N.N.W. of Hellingfors.

PUT, in the Manager, called in French matière, is used for the breaking or managing of a horse; thus,

To put a horse to corsets, or caprioles, is to teach him those parts of the manage.

To put a horse upon his haunches, called in French afferus, is to make him bend them handomely in galloping in the manage, or upon a flop. See HAUNCHES.

To put a horse to the walk, trot, or gallop, is to make him walk, trot, or gallop.

To put a horse under the button, see BUTTON.

PUTAGE, PUTAGIUM, in our old Law Books, denotes whoredom or fornication on the part of a woman.

The word is formed from the French paitte, whore; put-agiun, q. d. putam aperer. "Quod autum generaliter follet dici, patagium harredate nam adimit; illud intelligendum est de putaggio matris; quia filius haeres legitimus est, quem nuptia demonstrat." Glov. lib. vi. cap. 12.

PUTALA, in Geography. See PATI.

PUTALLOM, a town on the coast of Ceylon, near Calpenteen, remarkable for its falt-pans. This place, before the arrival of Europeans on the island, supplied the natives with salt; and on account of its convenient situation, was pitched upon by the Dutch for the manufacture of the salt with which they supplied the king of Candy's dominions, according to the articles of their treaty with him. The salt-pans are formed by an arm of the sea which overflows part of the country between Putallob and Calpenteen. A very large quantity of salt was manufactured here by the Dutch; they looked upon it as of the highest importance to their interests in the island, and the most formidable weapon which it was in their power to employ against the native king, as it was impossible for him to procure any but through their means. Since the British have obtained possession of the island, this manufacture has been almost entirely neglected. It is capable, however, of being rendered very profitable, as it is the only one of this kind on the side of the island, and the most conveniently situated for supplying the king of Candy's dominions. The Dutch enacted very severe laws to prevent individuals from manufacturing or trading in this article; the government taking upon itself the self-maintenance of the works, and the care of supplying both its own subjects and the Cadians. In order to keep a constant check on the latter, the Dutch were careful not to allow them too great a quantity at once; and whatever remained at Putallob, after supplying the demands of each year, they destroyed, that it might not be seized upon by usurpation.

PUTANGES, a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentan; nine miles N.W. of Argentan. The place contains 502, and the canton 110,934 inhabitants, on a territory of 212½ square kilometres, in 31 communes.

PUTANISM, PUTANISMO, an Italian term, naturalized by some English writers, signifying whoredom, or the life or condition of a courtesan.

The word we borrow immediately from the French, putaison; and they from the Italian putana, whore; of putta, girl.

PUTAO, in Geography, a town on the S. coast of the island of Luzon. S. lat. 13° 6'. E. long. 123° 28'.

PUTATIVE, SUPPOSITIVE, something reputed to be what it really is not.

The word is feldom used but in the phrase putative father.

Thus we say, Joseph was the putative father of Jesus Christ.

PUTEVERI, in Biography, a native of Otaheite, brought into France by the circumnavigator Bougainville; of whom a gentleman, who had resided in the island for some time, and was an excellent judge of music, assured us that the effects of French music, when fairly tried upon him immediately upon his arrival, were not those of rapture, but ridicule. He danced to it, indeed, as we should to a marked measure beat on a drum or a table; for as soon as he returned from the great opera, whether he was carried, he mimicked what he had heard and seen in the most natural and ridiculous manner possible; giving the company a specimen of the French opera, which was the most admirable parody imaginable of French singing, or rather of the screams and howlings at the Académie Royale de la Muque in the time of Louis XV. Our friend wished to try the effects of Italian music upon this demi-savage native of Otaheite; but there was no opportunity, for how could it be properly executed at Paris? However, according to the late lord marshal, the experiment had been fairly made on another occasion.

A young Greek lady being brought from her own country to Paris, some years since, was, soon after her arrival in that city, carried to the opera by some French ladies, supposing, as she had never heard cultivated music, that she would be in raptures at it; but, contrary to their expectations, she declared that the singing only reminded her of the hideous howlings of the Calamus Tartars, and as to the machinery, which it was thought would afford her great amusement, she proclaimed her dislike of many parts of it, and was particularly shocked by what she called the impious and wicked imitation of God's thunder. Soon after this experiment she went to Venice, where another trial was made on her unprejudiced ears, at an Italian opera, in which the famous Gazzelli sung, at whole performance she was quite dissolved in pleasure, and was ever after passionately fond of Italian music.

PUTAWATAMES, or POOTOOITAMES, in Geography, Indians who inhabit between St. Joseph's and Detroit in North America, and can furnish about 500 warriors. There are two tribes of this name, the one of the river St. Joseph, and the other of Huron. At the treaty of Greenville, August 3d, 1795, they ceded lands to the United States, who paid them a sum of money, and engaged to give them goods to the value of 1000 dollars per annum, for ever.

PUTBUS, a town and fort of the island of Rugen; five miles S. of Bergen.

PUTCABARY, a town of Hindoostan, in Bengal 45 miles S.E. of Moorshedabad.

PUTEA, in Ancient Geography, a town of Africa pro pria, S. of Adrametum, between Campa and Caraga, according to Ptolemy. — Alfo, a town of Syria, in the Palm rene, between Oriza and Abada. Ptol.

PUTEAL, among the Romans, a small kind of edifice raised in the place where a thunder-bolt had fallen. See BIDENTAL.

PUTEKAW, in Geography, a town of Prussia, in the province of Ermeland; five miles S.W. of Frauw burg.

PUTEMAHRY, a town of Hindoostan, in Bengal 16 miles N. of Kifhenagur.

PUTEOLANUS PVULIS. See POZZOLANA.

PUTIONELO, or PUTUS, in Geography, a town in the duchy of Hulrin; four miles N.W. of Oldenburg.

PUTI, or POTI, a town of the principality of Gurî.
at the mouth of the Rione, on the Black sea; 30 miles W.S.W. of Cottariti. N. lat. 42°. E. long. 41° 28'.

PUTICULI, among the Romans, ditches or holes in the earth, a little without the Equinute gate, in which the poorer sort of people were buried.

PUTIGNANO, in Geography, a town of Naples, in the province of Bari; 33 miles S.E. of Bari.

PUTIVLI, a town of Rufa, in the government of Kurik, on the 5em; 72 miles W.S.W. of Kurik. N. lat. 51° 20'. E. long. 34° 14'.

PUTTACH, a town of Bavaria, in the bishopric of Bamberg; five miles E. of Gollweinwein.

PUTTLITZ, or Puttlitz, a town of Brandenburg, in the Mark of Pregnitz; 10 miles N. of Perleberg. N. lat. 53° 10'. E. long. 13° 3'.

PUTLOGS, or Putlocks, in Building, short pieces of timber, about seven feet long, used in building fields. They lie at right angles to the wall, with one of their ends bearing upon it, and the other upon the ledges or poles which stand parallel to the side of the wall of the building.

PUTNA, in Geography, a town of Moldavia; 32 miles W. of Suceava.—Alla, a river of Moldavia, which runs into the Miuncow, to Tocofi.

PUTNAM, a county of America, in the southern district of Georgia, containing 6899 free persons, and 3320 slaves. Its chief town is Eatonston.

PUTNEY, a town of America, in Windham county, and state of Vermont, containing 1667 inhabitants.

Putney, a village and parish, on the west half hundred of Brixton, and county of Surrey, England, is situated on the south bank of the river Thames, at the distance of four miles from Hyde Park corner, London. The parish contains 1630 acres, of which the greater proportion is an open common or heath. In the time of the civil wars it was the scene of some very interesting transactions. The parliamentary army lay at Putney, for a considerable time, in the year 1747; and here the general officers, after long debates in the church, completed their propositions for the future government of the kingdom, and sent them to the king at Hampton Court. Here also were born two celebrated traitors, Nicholas Wilm, bishop of Ely, and Thomas Cromwell, earl of Ely, the protege of Wolsey, and the successor to his power and misfortunes. In this parish are many agreeable villas; in one of which the late illustrious William Pitt breathed his last. The church was originally built as a chapel of ease to Wimbledon, not long after the conquest; but was, in a great measure, re-erected in the reign of Henry VII. It is a small edifice, with a stone tower at the west end. A little chapel at the easter extremity of the south aisle, built by bishop Wilt, is, however, its chief ornament. Monuments and inscriptions are numerous, but few of them deserve notice. Over the Thames, in this parish, is a wooden bridge, constructed in the year 1729, at the expense of £23,975; and yielding a revenue, by tolls, to the proprietors, of above 3000l. per annum. A fishery here was posessed by the lord of the manor, previous to the conquest; and is now rented for a considerable sum. All hurgers and porpoises are claimed by the lord mayor of London, but the fishermen receive 13s. for each of the former, and a guinea for each of the latter, when delivered to the water bailiff. On the common stands an obelisk, erected, in 1766, in memory of Hartley's invention for securing buildings against fire.

PUTNOK, a town of Hungary; 36 miles W.N.W. of Tokay.

PUTORIUS, in Zoology, the Pole-cat, a species of Myosel; which see. See also Pole-cat.

PUTORIUS STRIPENS, a name given by some to that species of serpent called by others Dryas.

PUTREFACTION, or PUTRIFICATION, in Chemistry, is a species of fermentation (which see); being the last stage of the fermentatory process, and consisting not merely in the decomposition and transposition of the particles of putrefying substances, whether animal or vegetable, by which new combinations are produced, but also in the extraction and expulsion of some of the constituent parts of these substances.

This decomposition or derangement of the constituent parts of vegetable substances is usually called fermentation, and that of animal bodies, is denominated putrefaction. The agents that produce both kinds of decomposition, and the circumstances that attend them are, in various respects, very similar, and the chief difference of the products that are obtained from both depends upon the diversity of their constituent parts. The processes of putrefaction, and its effect in dissolving the combination of the constituent parts of bodies, are sufficiently obvious to denote; but the rationale of the process, and the mode in which gaseous and volatile compounds are separated from bodies that are disorganized and afterwards form new combinations, are still involved in considerable obscurity; and different writers have disagreed in their explication of them. Several facts, however, are universally acknowledged; and of these we shall give a brief account in the sequel of this article, together with a detail of some of those principles and theories that have been adopted for explaining them. Becher long ago observed, in his "Phys. Subst. I. § 5": "that air is the principal agent of decomposition, but that water and heat very much facilitate its action. Thus he says, "Fermentation ergo definitur quod fit corporis desinitor rarefactio, particularurnque abseraturn interpositione; ex quo conclusur debere in aeris fieri nec minimum frigidum, nec rarefactio impediatur; nec minimum calido, ne partis raribiles expediantur."

An animal substance may be preferred from putrefaction by depriving it of the contact of the air; and this process may be accelerated or retarded by varying or modifying the purity of the same fluid. When we observe putrefaction occurring without the access of atmospheric air, the effect is produced by the water which impregnates the animal substance; becomes decomposed, and affords the element and the agent of putrefaction. Hence it appears, that moisture is an indispensable requisite to facilitate putrefaction. A moderate degree of heat is also a condition favourable to animal decomposition.

Dr. Hales, it is well known, ascribed the cohesion and solidity of bodies to the air, which exerts in them a fixed form, and forms, as he expresses it, the cement or bond of union between their several constituent particles. To this purpose he observes, that air abounds much more in solid bodies than in liquid bodies; and that solid bodies being generally denser than water, the attraction of the air of those solid bodies in a fixed state, and its repulsion when in an elastic state, are greater than the attraction and repulsion of the lighter watery particles in a fixed and in an elastic state; and hence the particles of air are fitter to be the principal bond of union in solid bodies, than the particles of water. This opinion was afterwards adopted by baron de Haller, who maintains, that air is the vinculum elementorum primarium, or the true cement which binds together the earthly particles.
PUTREFACTION.

particles of bodies. Mr. Macbride, as we have elsewhere shewn, has taken occasion, by a variety of experiments, to illustrate and establish this opinion; and in support of it he alleges, that the preservation of firmness and soundness in bodies depends on restraining the escape of that principle, since known by the name of fixed air, and which he supposes to be the immediate cause of cohesion: for the moment it flies off and refurnishes its elasticity, the other constituent particles, viz. the earthy, the saline, the oily or inflammable, and the aqueous, being thereby put in motion, immediately begin to exert their several peculiar attractive and repulsive powers, and run into new combinations, which first change, and at length altogether destroy the texture of the substance they formerly composed; provided that this substance contained in itself a sufficient quantity of water to allow of the intellel motion, by giving the proper degree of fluidity; for without fluidity there can be no intellel motion; and without intellel motion there can be no change of combination: because we fee that such animal and vegetable bodies as are suddenly deprived of their water, or naturally contain very little, are almost as durable and unchangeable in their texture as minerals. Hence Acosta observes, that in Peru, and others have observed the fame in Egypt, where it very rarely rains, every thing will continue a long time uncorruptible; unless we should rather ascribe this effect to the abundance of nitrous falt in the air of those places, which is known to refil putrepaion. Indeed all putrefactions, both of animal and vegetable bodies, are affirmed by the learned Boerhave to be performed by means of water alone. Take, fays he, a pound of fresh flesh, and keep it in a heat like that of our body, and, in a few days the putrepaion will be completed; but if you dry it out, or exhale, all the watery part from the fame chemical vessel, though the falt and oil remain, the flesh will harden like a fcone, and may be kept for ages without putrepaion. Though when thus hardened, water poured on it, or even the common dew, will soon set it a putrepaing. Thus Villaris and Cazalet of Bourdeaux, as Chapital informs us, dried meat by means of floves, which was preferred for several years without contracting any bad flavour.

By fuch means, bread, flefh, or the like foods, may be preferred for many ages; provided regard be had to the place. Hence it is that in dry countries, as Egypt, dead carafes never putrepe, but dry and harden uncorruptible; as weufe also in the mumfies found buried under the sand.

The sands and light porous earths preferv human bodies by exhausting their juices and drying the folid parts. Hence it is, that entire carafes have been devourfed in Arabia, confifting of men and camels, preferved in the sands under which the impetuous winds have buried them. In the library of Trinity college, Cambridge, a human body may be seen in a perfect flate, which was found under the sand in the illand of Teneriff. Hence putrefacciones putrepe much more flowly when exposed to a drying wind, than in a feltered place.

Nevertheless, too much humidity impedes putrepaion. To this purpofe Bofher observes: "Nimia quoque humi-ditas a putrefactione impedit, prout nimius calor; nam corpora in aqua potius gradatim confumi quam putrefecerent, fi novalemper al fuus flatus, experientia docet; unde longo tempore intepra interdum subnumerar perfusius a putrefactione immumia vidimus; adco ut nobis aliquando peculitio occurreret, tracentando tali modo cadaveras anatomiae subspicienda, quo diutius a fatora et putrefactione immumia forint." Accordingly it is neceffary, that in order to a body's putrepaion by moifure, that the water fhouid impregnate but not inundate it. It is also neceffary, that it fhoulde remain in the texture of the animal body, without being renewed; for thus the lymph is difolved, and the molt putrefiable substance is prefered to the air with the greateft extent of surface; and the water itself is decomposed, and by this means affords the putrepaive principle.

Even human blood, which, naturally, is fo prone to putrepaion, if you deprive it of its watery part, may be kept for fifty years. Goat's blood, we actually find kept fo long in the shops, without corrupting; though, if you diflove it in water, and expofe it to a gentle warmth, it will putrepe immediately. Blood is paid to be the molt putrefacient animal substance that is known; and this property is ascribed partly to its fluidity and partly to the large quantity of fibrin and unconfonned albumen, which it contains, and efcpecially to the former. See Blood.

We fhall here add, that animal substances feem to be (cæteris paribus) more putrepaient in proportion to the number of confonnt parts which they contain. The substances either absolutely or nearly imputrefacible are bone and confonned albumen, the latter being fuch as exifits in cuticle, nail, hair, &c. which long remain unaltered in the midle of putrepaing substances. Animal oil also putrefies with great dificulty, and hence the people that live in the molt northern parts of America, the Equinoxus and others, prefere fift and meat to a certain degree from putrepaion by immersion in fift-oil.

In putrepaion there is a great intellel motion, which, when carried to an extreme, and when the putrefying substance is much compressed, is accompanied with heat and fmoke, and fometimes flame. However, M. Beaume affirms, that putrepaion is not attended with any fensible heat: when, indeed, it proceeds slowly, and the quantity of putrepaing matter is but fmall, the heat, if any, is very little. That putrefactione substances emit light, is an unquaffionable fact; and on this principle philosophers account for the luminoufnes of the sea, the ignis fatus, &c. To this purpofe M. Ant. Martin (Swed. Abhaf. vol. xxvii. p. 225, cited by Dr. Priefley, in his History of Light, &c. p. 576.) observes, that human bodies have fometimes emitted light about the time they begin to putrepe; and that the walls and roof of a place in which dead bodies had often been exposed, had a kind of dew or clammines upon them, which was fometimes luminous. And he imagines, that the lights which are faid to be seen in burying grounds may be owing to this caufe. It has been obferved, that heat extinguifhes the light of putrefacient substances; Mr. Canton, attending to this circumstance in fome experiments for alcertaining the caufe of the luminoufnes of the sea, remarks, that though the greatefl fummer heat is well known to promote putrepaion, yet twenty degrees more than that of the human blood feems to hinder it; for putting a small piece of luminous fish into a thin glafs ball, he found that water of the heat of one hundred and eighteen degrees would extinguifhe its light in less than half a minute; but that on taking it out of the water, it would begin to recover its light in about ten fconds: but it was never afterwards fo bright as before. See Light.

It has been obferved, that a temperature from about forty degrees to the highest natural heat is favourable to the putrepaion of animal matter, whereas a freezing temperature is known to flop putrepaion, as it is the cullom in cold countries to bring victuals frozen to market, and in this flate they are kept for any length of time without any other preparation; and besides, bodies of men or of other animals remain unaltered under ice for many weeks. We might
PUTREFACITION.

might allege many other circumstances of a similar nature. On the other hand, a search for heat also prevents putrefaction; probably by expelling the moisture which is essential to the process, because by a lower degree of heat putrefaction is promoted. The influence of temperature on animal putrefaction is thus stated by Becher: "Aer calidus et humidus maxime et putrefactionem facit—corpora frigida et seca difficult; imo aliquae profusio non putrefavit; quae ab imperitis proinde pro sanitatis habita fuerat; ita aer frigidus et secus, imprimit calidus et seco, a putrefactione quoque prefererat; quod in Hispania videmus, et locis aliis calido, hec, caldo acro praeepiit, ubi corpora non putrefuerunt et refolventur; nam cadaevra in oriente in arena, ino apud nos arte in funus, ficcari, et sic ad finem mundi ulque ut putredine praeferratur, certum est; intentione quoque frigus ut putredine praeferrare: unde corpora Stockholmiae tota hyeme in patibulo suspensa fine putredine animadversuramus." From the facts already stated, we may deduce the most effectual means of preventing, and increasing putrefaction, and also of modifying it at pleasure. A body may be preferred from putrefaction by depriving it of the contact of atmospheric air: for this purpose nothing more is required than to place the body in a vacuum, or to envelope it in a covering, which may defend it from the immediate action of air; or also to envelope it in an atmosphere of some gaseous substancc, which does not contain vital air. Putrefaction may also be favoured by keeping bodies at a suitable temperature. A degree of heat from between sixty-five and ninety degrees diminishes the adhesion of the parts, and favours the action of the air; but if the heat be greater, says Chaptal, it volatilizes the aqueous principle, dries the solids, and retards the putrefaction. Hence it is inferred, that for the decomposition of an animal substancc, it is necessary that it should have the contact of atmospheric air, and that the purer the air is, the more speedy will be the putrefaction: that it be exposed to a moderate degree of heat: and that its texture be impregnated with humidity.

The most sudden and remarkable changes produced upon a body by putrefaction, are upon its colour, smell, and taste. Flesh beginning to putrefy, is well known to exhale very soon after a penetrating fetid smell, its colour becomes pale, then inclining to blue, and afterwards livid and black, and its taste nauseous. Transpant liquor, as urine and broth, during putrefaction, becomes also turbid: as the putrefaction advances, the smell becomes more and more fetid, and it also acquires great pungency, which is caused by a large quantity of volatile alkali, difengaged from those substancces that are completely putrefied. Solid bodies, whilst they are putrefying, swell, become soft, lose the cohesion of their parts, and are liable to a very disagreeable putrid pulpiness: the fluids become turbid, and the effluvia are loathsome and sickening, and after a time a putrid gas is difengaged in a slow but fenible effervescence. A foul and brown humour then sweats out from the pulpiness, and about this time the effluvium is very fenibly ammoniacal, which is indicated by its effects on the eyes and throat, and by forming a white vapour with muriatic acid gas. For some time a large part of the putrid substancc is evaporated, and carried off in the putrid gas and difperscd in the atmosphere, after which the extreme factor substanccs; and finally the process of putrefaction ceases, and leaves a kind of fat fetid earthy matter. All the gases certainly known to be produced by putrefaction, are carbonic acid, carbuiretted hydrogen, fulphuretted and phosphuretted hydrogen, and ammonia; but either of these, or some of these, must be considerably changed by the solution of the animal matter; or some compound not yet examined, must be produced in that state of putrefaction, when the gas evolved occasions such dreadful effects upon those that have the misfortune to fall in the way of it, even when diluted considerablcly with common air. This is said to be the case when the abdomen of a large animal is first burst, after some days or perhaps weeks of putrefaction; the gas from which causes incontinent fainting, and sometimes death, and even when the person exposed to it receives the first shock, it leaves excessive debility and other alarming symptoms for a considerable time.

The most detestable gas that is known is, perhaps, carburetted hydrogen, but the effects of this, as obtained by chemical means, are far short of those above-mentioned, when equally diluted. The generation of ammonia has been satisfactorily accounted for, since the discovery of the constituent parts of the volatile alkali, by the new combination formed between the azote of the animal matter, and the hydrogen, of which latter there are many sources, and particularly that of the decomposition of water. As ammonia is always produced during putrefaction, it seems rational to suppose, that one important purpose of the moifure necessary to the process, is to afford, by its decomposition, the hydrogen of the volatile alkali. The nitrous acid is also an undoubted product of putrefaction; but farther experiments and facts are necessary for explaining the reason, why in some cases the azote tends to unite with oxygen to form this acid, and in others with hydrogen to form ammonia. For an account of the peculiar changes which animal flesh undergoes, by which it is converted into a fpermaceti-like substancc, instead of passing through the usual process of putrid decomposition, we refer to the article Adipocere.

Sir John Pringle has observed, that, as all the humours of all animal bodies become thinner by putrefaction, so the solid or fibrous parts are thereby relaxed, and rendered more tender: and hence the extraordinary bulk of the heart, liver, and spleen, incident to persons labouring under putrid diseases, may be accounted for. It is remarkable, that in defections of persons who die of the plague, the heart is almost always found of an uncommon magnitude; and as to the fcurvy, the liver and spleen are sometimes enlarged to such a degree, that the tumour may be seen outwardly.

From matters completely putrefied may be obtained by distillation volatile alkali, some liquid and some solid; a pungent fetid oil, which at first is thin, and afterwards becomes more thick; and a residuum of coal, not easily reducible to ashes. Some writers on this subject have apprehended, that putrid substancces are not to be regarded as alkaline. Sir John Pringle, finding from the experiments which he made in the year 1750, that syrup of violets was not changed into a green colour by the fermen of putrid blood; that this fermen did not make any effervescence, when spirit of vitriol was poured upon it; that water, in which corrupted flesh had been for some time intimated, neither effervesced nor changed the colour of the syrup; and that alkaline salts, both fixed and volatile, powerfully oppose putrefaction; was led to adopt this opinion. But when he became acquainted with the experiments made by M. J. Bapt, Gaber of Turin (Acta Taurinene, vol. i. p. 78, &c.) he embraced with the liberality of a true philologist, the first opportunity of acknowledging his mistake. M. Gaber, having poured a drop or two of aqua fortis upon bile, taken out of the gall-bladder of a person who had died of an invertebrate jaundice without a fever, and whose body had lain about twenty-four hours in a cold place in winter, found, that the mixture immediately effervesced, became fenibly warm, and that several air-bubbles rose to the surface. He also exposed the remainder of this bile in three open glass
to the thirty-fifth, twenty-fifth, and tenth degrees of heat, indicated by Reaumur's thermometer, and at the end of twenty-four hours mixed them with acids; and he found, that the bile which had been placed in a degree of heat answering to thirty-five, was most diluted, and gave very slight indications of effervescence; that which had been in twenty-five was also diluted, and the acid produced a more sensible effervescence, but still very slight; and the bile which had been exposed only to the temperament of the air, varying from feno to ten, preferred its tenacity, and fermented as much as that in his first experiment. Having mixed some blood, taken out of a vein of the dead body at the same time, and which appeared to be of the yellowish-red, with spirit of nitre, the mixture effervesced, but in a much less degree than the bile: this mixture, being left to digest for some hours, a yellow serum separated from the blood, and covered its whole surface; and the blood, being subjected to the same heat as the bile, and for the same time, appeared more diffused to effervescence than the bile, though this disposition afterwards gradually diminished. From these experiments the ingenious writer infers, that in digested bodies the humours may become so alkalefcent as to effervesc with acids; that a very slight degree of putrefaction and factor, which is not sufficient to produce alkalefcence out of the body, will produce it in the body; that alkali formed in the body, and contained in the bile, is extremely volatile, since the heat of twenty-five degrees made a great part of it evaporate; and that the same alkali contained in the blood, being a little more entangled with other elements, is consequent ly less volatile, since the same degree of heat continued for the same time, diffused but a very inconsiderable part of it; and, therefore, that the different phenomena taken notice of by those who have professed experiments of this kind, some of whom affirm that they have been undoubted proofs of the presence of an alkali; and others that they have scarcely discovered any such indications at all, are the effects of different degrees of heat, the fineness of the substance exposed to the heat, or the different volatility of the alkali arising from its coaction with other principles. Having made similar experiments upon healthy bile, blood, and serum, and submitted them to the action of mineral acids, he found the bile most diffused to effervescence; that human bile was more diffused to effervescence than the bile of an ox; that corrupt blood ferments with acids still slower; and that serum ferments slower than blood. He also observed, that putrefac tive humours not only effervesc with mineral acids, but with very weak distilled vinegar; and that those humours that have been exposed to artificial heat, become more volatile and effervescence foetid, and foetid arrive at the last stage of fermentation; in which case the fermentation ceases, though the heat is continued; and the smell, which till then is intolerably foetid, becomes more or less inoffensive. The factor, he says, manifests itself sooner and laris longer than the alkalefcence.

M. Guiber further observes, in relation to the experiments of sir John Pringle, that at the degree of heat to which he exposed putrefactive substances, and which was equal to the hundredth degree of Fahrenheit, corresponding nearly to the thirtieth degree of Reaumur, animal humours very soon become putrid; but that they as soon lose the alkalefcent quality which they derive from putrefaction, if this degree of heat is continued; so that as the corrupting humours manifest their alkalefcent quality only for a very short time, it might easily happen that no signs of alkalefcence appeared in his experiment, if it was not made in the critical moment, i.e. if he examined the putrefactive humours a little before the alkali was formed, or a little after it had evaporated. And he, therefore, apprehends, that if Sir John Pringle's experiments were made with a degree of heat just equal to his own, the refuit, ceteris paribus, must have been the same.

From other experiments this writer infers, that blood received from the arm, agitated and left to putrefy, does not putrefy fo soon, nor so soon manifest signs of alkalefcence, as the red part separated from the serum, because the serum putrefies more slowly than any other animal humour; and that the alkali, which evaporates with a degree of heat from twenty-five to twenty-eight of Reaumur, being collected in a receiver, will effervescence, and that the residuum is a mass extremely foetid, wholly delittle of alkali, and, consequently, that no effervescence is to be expected by pouring acids upon it. Having kept some blood in a glass vessel close stopped, he found that it retained its alkalefcence a long time, though exposed to a degree of heat equal to twenty-five; but upon unstop ping the vessel, it flew off with great violence, in an extremely foetid vapour. These experiments he attributes to the expansion of the air, in consequence of the putrefaction; and hence he deduces the reason, why the humours that are contained in the vessels of a human body become alkalefcent while they are yet scarcely foetid, although when drawn from the body, and kept in open vessels, they become foetid, before they give signs of alkalefcence. As soon as they begin to form alkali in the vessels, the alkali is retained; but as it exhales from vessels exposed to the air, a greater quantity must be formed than exhalates before it can become sensible. Having collected the distilled liquor of blood in such a state of putrefaction as to effervesc with acids, and exposed it to the action of various acids, a violent effervescence ensued; and when poured upon purpuro of violets, it produced as fine a green as spirits of hartshorn; and this tinture, having been changed into a red by the effusion of a few drops of aqua fortis, became again blue, upon pouring into it some more of the distilled liquor; whence he concludes, that putrefactive humours form a true alkali, which exhales with a very slight heat.

From other experiments he infers, that the alkali of putrefactive substances is not the productive cause of their factor, because the latter remains when the former is departed. But as both appear in the same degree of heat, when long continued, it appears, he says, that this factor is produced by the effusion of parts extremely volatile, but different from volatile alkali, which, though sooner produced, are more slowly diffipated. Alkalefcence, however, may be sometimes connected with a flight factor; and, on the contrary, extreme factor may fabil without alkalefcence. And this fact confirms the observation of sir John Pringle, who found a difference between the foetid and alkaline particles; since the exhalations of fresh urine are not pernicious, though they contain more alkali than any substance in a state of putrefaction, the odour of which is pernicious in the highest degree; and, therefore, putrid effluvia are of a different nature from alkaline falks. M. Guiber further adds, by way of inference from this fact, that a volatile alkali is not a necessary product of putrefaction, and that the degree of alkalefcence is not equal to that of putrefaction. Dr. Croll, professor of chemistry at Brunswick, has objected to this doctrine, as not conformable to the phenomena (Phil. Tran. vol. ixi. part i. art. 3); for he supposes, that as all falk depend upon a saline matter joined with phlogiston, and the saline matter producing the putrid fench was very probably not an acid, it must be a volatile alkali, which, involved in phlogistic matter, might fly off before the alkali was developed. From some experiments made with a view of ascertaining this fact, he infers that the volatile alkali is present as long, at least, as the putrid smell continues, and that this volatile alkali is the basis of it; because, as this was
distilled over in his experiments, the residuum, being still in intelline motion, required only the herbaceous smell. The reason why the volatile alkali has been distinctly observed at a certain period of putrefaction, and not in the other, he apprehends to be this: the volatile alkali has, it seems, a tendency to diftangle itself, by intelline motion, of all such matter as it is involved with; but if it is not combined with such fixed matter as retains it till it has gone through all its evolutions, it is, being itself volatile, carried off by the still more volatile phlogistic matter with which it is commonly joined. For this reason, he supposes the putrefyng matter flows in its beginning no signs of volatile alkali, because its smell depends only on those particles which have been on the surface, without any strong cohesion with the substance. In the latter progress of putrefaction, the matter involving the alkali, or forming it, is intermixed, and in cohesion with the solid particles of the substance, and is by these means retained till the alkali is come to its purer state. Towards the end of putrefaction, the cohesion of the particles being almost entirely taken off, the volatile alkali is carried off before it can go through all its rates.

Dr. Macbride made several experiments with putrid blood and putrid bile, which ascertain the fact, that as soon as an animal substance begins to putrefy, it begins to dislodge an alkaline quality; and this volatile matter, now produced in it, may be separated by distillation in a very gentle warmth; but he observes, that the volatile alkali obtained from putrid substanctes is not exactly similar to that obtained by violent heat from animal substances not putrid. It differs remarkably in the flavour, which is nauseous and disagreeable, is not so pungent, and is much weaker than the common volatile alkali; and this latter is capable of dissipulating the putrid alkali, and of driving it off from any body to which it has been united. But to return from this digression. As to the cause and progress of putrefaction, it has been generally believed, that the contact of atmospherical air is necessary for this purpose, and that bodies become putrid, because the air communicates somewhat to them: accordingly it has been alleged, that bodies buried deep under the earth, or in water, out of the reach of any air, have remained entire for ages; which, when exposed to the open air, have soon rotted and mouldered away. It is also well known, that bodies are preferred from putrefaction by covering them with wax, flax, &c.; and Mr. Boyle relates, that he has preserved lemons, oranges, and other fruits, from putrefaction, during several years, by including them in an exhausted receiver. Experiments of the same kind have been lately made by M. Eller of Berlin, which shewed that substanctes, even of the most putrefaction (such as blood) may be kept found in vacuo for many years. But Dr. Macbride has urged a variety of facts and considerations to prove, that putrefaction enues in consequence of the loss of some principle, which cemented the constituent particles of bodies, and that, when this is disengaged from them, they separate, and are difunct. This principle he discovered to be air, which, in putrefaction and fermentation, is extracted and thrown off, from a fixed and non-elastic state, into one that is volatile and elastic; but which immediately, upon meeting with a proper recipient, returns again to its former nature. Thus he found, that caustic alkali and quicklime may be rendered mild by absorbing this air, extracted from putrefying and fermenting substanctes; that without the extircation of this air no putrefaction can happen; and that even by absorption of it, putrefted substanctes may be corrected and rendered sweet. To the same purpose Dr. Alexander has endeavoured to prove, that putrid matter will preserve other substanctes from putrefaction; which is not improbable, be-

cause, being already saturated with the putrid effluvium, they cannot readily take any more. Dr. Macbride, having exposed putrid matter to the vapours arising from fermenting mixtures, or from alkaline substanctes effervescing with acids, found that the putrid quality was destroyed; and hence he considers the fixed air as powerfully antiseptic. And it appears also from the experiments of Dr. Priestly, that fixed air corrects and renders wholesome air tainted with respiration or putrefaction. Hence he infers, that lime-kilns, which discharge great quantities of this air, may be wholesome in the neighbourhood of populous towns, the atmosphere of which must abound with putrid effluvia. Sir William Lee, in a hot feast, contrived, by impregnating water with fixed air, in the manner described under Pyrmon's water, and washing meat with it two or three times a-day, not only to prevent it as perfectly sweet and good to the extent of ten days, as at the first killing, but also to recover some meat that had begun to change. And it is farther well known, that fixed air, or carbonic acid, has been lately introduced into the materia medica, and administered with success in a variety of putrid cases. Dr. Macbride has also proved, that putrefaction is accelerated by taking off the preffure of the atmosphere; and from some experiments he has led to conclude, that it will take place sooner in vacuo than in the open air; but making a more complete vacuum by means of two brafs hemispheres joined together, he found that the observation of Mr. Boyle and others was agreeable to fact. It appeared also, by inflooding flesh in condenfed air, that increasing the preffure of the surrounding air, retarded putrefaction; and hence he deduces, what he deems to be a demonstrative proof, that bodies do not putrefy, because the air adds somewhat to them; for if they did, then a piece of flesh which lay in condenfed air ought to have putrefied the soonest, because it had the greatest quantity of air applied to its surface. But the reason why, according to his fystem, condenfed air prevents putrefaction, is, that the preflure of every fide muff force the confluent particles closer together, thus increafe their cofection, and prevent the intelline motion; and without intelline motion there can be no change of combination. However, it is observed by Sir John Pringle, that the putrefaction of meat and other substanctes, advances quicker in a confined than free air; for as the moft putrid parts are also the moft fugitive, they fucceffively infue from a corruptible substancte, and difperfe with the wind; but in a stagnation of air they remain about the body, and in the nature of a ferment excite its corruption.

It has been long observed, that putrefaction generates air. Hence, though fresh, as well as blood, be particularly heavier than water, yet dead bodies are found to float, after lying some time at the bottom, from air generated in the bowels by putrefaction. And since it has been found by experiments, that the blood and other animal substanctes begin to emit air before they are so far corrupted, as they frequently are in putrid diseasles, it is probable that several of the symptoms in deep furfeits may be owing to the action of the confined air. As dead bodies become putrid from the los of their fixed air, according to Dr. Macbride's theory, he conjectures, that the immediate cause of putrefaction in living bodies may be the detachment of too large a proportion of their fixed air. This fact he endeavours to evince by an enumeration of the symptoms that occur in the feburvy, and other highly putrid diseasles, which shew that the air is actually detached from the blood in such cases; as well as from an examination of the principal and prevailing causses of such disorders. And since the air tainted with animal or vegetable putrefaction is the same with air rendered noxious by animal respiration; since both equally extinguish flame, are
are equally noxious to animals, are equally and in the same way offensive to the smell, equally precipitate lime in lime water, and are restored by the same means. Dr. Priestley suggests, that one afe of the lungs is to carry off the putrid effluvia, without which, perhaps, a living body might putrefy as soon as a dead one. See Blood and Respiration.

We shall here observe, that putrifying and fermenting substances have been found, by the experiments of Mr. Cavendish, Dr. Priestley, &c. to yield not only fixed but inflammable air. From an experiment of Dr. Priestley, intended to determine the proportion of each of the kinds of air in the different stages of the putrefactive process, it appears that a piece of mutton weighing four pennyweights fix grains, yielded in $2\frac{1}{4}$ measures of air, of which $2\frac{7}{10}$ was fixed, and the rest inflammable; and that all the inflammable part was exhausted a considerable time before the fixed air. The fame ingenious writer has observed, that the diminution of common air, by means of putrefaction, amounts to a complete fourth part of the whole, notwithstanding the production of some permanent air from the putrifying substance, and that in all respects, the appearance of being produced solely by the precipitation of fixed air. It must come to every reader, in any way acquainted with this subject, if the phlogistic theory be admitted, (which indeed is now generally discarded,) that if inflammable air be the same with phlogiston, as Dr. Priestley seemed to have discovered, many of the phenomena of putrefaction, depending on this principle, such as the smell, colour, light, &c. will probably from hence admit of an easy explication.

We shall here subjoin some observations with respect to the decomposition of animal bodies that are interred in burying-grounds. In this situation, the decomposition is four times as slow as when the putrifying animal is exposed to the air. It is not perfectly ended, according to Mr. Petit, till three years after the body has been interred, at the depth of four feet; and it is flower in proportion as the body is buried at a greater depth. These facts agree with the principles which we have already established for bodies buried in the earth, and subjected to laws of decomposition very different from those which take place in bodies exposed to the open air. In this case, the decomposition is favoured by the waters which filter through the earth, and dilute and carry with them the animal juices. It is also favoured by the earth, which absorbs the juices with more or less facility. Meffrs. Lemery, Geoffroy, and Hunaud, have proved that argillaceous earths exert a very slow action upon bodies; but when the earths are porous and light, the bodies then dry very speedily. The several principles of bodies absorbed by the earth, or carried by the vapours, are dispersed through a great space, imbibed by the roots of vegetables, and gradually decomposed. This is what paffes in burying-grounds in the open air; but it is very far from being applicable to the sepulchres which are made in churches and covered places. Here is neither water nor vegetation; and consequently no cause which can carry away, dilute, or change the nature of the animal fluids: and we cannot but applaud the wisdom of government, which has prohibited the burying in churches; a practice which was once a subject of horror and infection.

The accidents which have happened at the opening of graves and vaults are but too numerous, to render any apology necessary for our speaking a few words respecting the method of preventing them.

The decomposition of a body in the bowels of the earth can never be dangerous, provided it be buried at a sufficient depth, and that the grave be not opened before its entire and complete decomposition. The depth of the grave ought to be such that the external air cannot penetrate it; that the juices, with which the earth is impregnated, may be conveyed to its surface; and that the exhalations, vapours, or gases, which are developed or formed by decomposition, should not be capable of forcing the earthy covering which detains them. The nature of the earth in which the grave is dug, influences all its effects. If the stratum which covers the body be argillaceous, the depth of the grave may be less, as this earth difficultly affords a passage to gas and vapour; but in general it is admitted to be necessary that bodies should be buried at the depth of five feet, to prevent all these unhappy accidents. It is likewise necessary to attend to the circumstance, that a grave ought not to be opened before the complete decomposition of the body.

This decomposition, according to Mr. Petit, is not perfect until the expiration of three years, in graves of four feet depth; or four years, when they are six feet deep. This term affords many varieties, according to the nature of the earth, and the constitution of the subjects buried in it; but we may consider it as a medium. The pernicious sultan, which allows a single grain of air to favours more or less numerous, ought therefore to be suppressed; for, in this case, the grave may be opened before the time, here described. These are abuses which ought to occupy the attention of government; and it is time that the vanity of individuals should be sacrificed to the public safety. It is likewise necessary to prohibit burying in vaults, and even in coffins. In the first case, the principles of the bodies are spread into the air, and infect it; in the second, their decomposition is slower and less perfect.

If these precautions be neglected; if the dead bodies be heaped together in too confined a space; if the earth be not proper to absorb the juices, and decompose them; if the grave be opened before the entire decomposition of the body; unhappy accidents will no doubt be produced; and these accidents are but too common in great towns, where every wise precaution is neglected. An instance of this happened, when the ground of the church of St. Benoit at Paris was dug up a few years ago; a nauseous vapour was emitted, and several of the neighbours were affected by it. The earth which was taken out of this grave was nauseous, viscid, and emitted an infectious smell. Meffrs. Maret and Navier have left us several similar observations. Chaplet's Elem. of Chem. vol. iii.

Putrefaction is one of the instruments in nature by which many great changes are brought about. In the processes of vegetable putrefaction, if we throw together any of the tender, green, and succulent parts of recent vegetables, whether acid or alkaline, in a large heap, in the warm open air, and press them down with an additional weight, if their own be inconsiderable; the middle part of the heap will, in a little time, spontaneously conceive a small degree of heat, and pass successively through the other degrees, till it arrive at a state of ebullition, and be perfectly putrefied.

In the space of three days, from the first putting them together, they will yield a heat, perceivable by the hand, equal to that of a human body in a healthy state; by the fifth, the heat will be too great for the hand to bear without pain; and, lastly, by the sixth, seventh, or eighth day, the juices will generally appear ready to boil; and sometimes the matter will even blaze, and burn away.

By this spontaneous operation, the vegetable acquires an abominably putrid, atercorganous, or cadaverous, taint and odour; and turns entirely into one soft, similar, pulpy mass, or morsiflamentum, greatly resembling festid human excrements in the fecund, and putrefied flesh in the tafte.
PUTREFAC TION.

If now this solid matter, thus obtained, be directly, whilst it remains in its solid state, committed to a glass retort, and distilled with proper degrees of fire, there will come over, 1. A water impregnated with an urinous spirit, perfectly like that obtainable from animal subjects, and separable by a fresh distillation flowly made in a tall glass, into elementary water, and a large quantity of pure, white, volatile, dry, alkaline, falt, not to be distinguished from animal farts. 2. A volatile, alkaline, oily falt, that flows into globes. 3. An exceedingly volatile and thick fettid oil, both which are entirely like those of animals. And, lastly, the remainder, being calcined in an open fire, affords not the least particle of fixed falt; just as if the subject had really been of the animal, and not of the vegetable kingdom.

This process is truly universal, and holds equally in all kinds of vegetables, though ever so different in their nature and virtue.

Experiments have been made in the coldest and moft succulent, or watery, plants; such as purilue, foxtle, &c. as well as with the hottest or most acrimonious, such as the fupers, &c. and it was always found to succeed; but that the sooner, as the vegetable employed contained the greater quantity of oil, though with the fame phenomena.

It will likewise succeed with dry vegetables, provided they be moistened with water before they are thrown into heaps; and thus we sometimes fee, that stacks of hay will spontaneously take fire, and burn away; especially if the hay was not well dried in the making.

The conditions necessary for the putrefaction of vegetables are similar to those required in the putrefaction of animal substances. It is necessary that the organization be impregnated with water; the contact of air is necessary, as is also a certain degree of heat; and for the due effect of this kind of decomposition, the vegetables should be kept together, and their juices be abundant. In these circumstances, the phenomena of decomposition are as follow: the colour of the vegetable is changed; the green leaves become yellow; the texture becomes lax, and the parts less coherent; the colour of the vegetable itself changes to black or brown; the mafs rifes, and perceptibly swells up; the heat becomes more intense, and is perceived on approaching the heap; and the fumes which arise already a smell, which sometimes is not disagreeable; at the same time bubbles arise, and break at the surface of the liquid, when the vegetables are reduced to a magma. This gas is a mixture of nitrogen, hydrogene, and carbonic acid. At this epocha, likewise, an ammonical gas is emitted, which is formed in these circumstances; and, in proportion as these appearances diminish, the strong and offensive odour is succeeded by another which is fainter and milder, and the mafs becomes dry. The internal part still exhibits the vegetable structure, when the item is solid, and the fibrous matter has been the predominating principle; and it then constitutes manure or soil. Hence it arises that the herbaceous plants of a boole texture, and abounding in juices, are not capable of forming manure by their decomposition, but are reduced into a brown mafs of little confluence, in which neither fibre nor texture are observed; and this is what, for the most part, forms vegetable mould.

Vegetable mould usually constitutes the first covering or stratum of our globe; and in such cases wherein it is discovered at a depth in the earth, there is no doubt but it has been buried by some revolution.

When a vegetable is converted into earth by this tumultuous fermentation, it still retains the remains of the vegetable, mixed and confounded with the other solid earths and metallic products; and by distillation it affords oil, nitrogen gas, and often hydrogen. It may, therefore, be considered as an intermediate substance between crude and organic bodies, which participate of the inertia of the one, and the activity of the other; and which in this state is still subject to an infensible fermentation, that changes its nature still more, and deprives it of all its organic contents. These remains of vegetables, still contained in vegetable earth, serve as food for other plants that may grow in it. The infensible progress of fermentation, and the fucction of vegetables, impoverishes the vegetable earth, deprive it of all its organic matter, and there remain only the earths and metallic residue which form the till poor soils, and oehres when the fermenting principle is very abundant.

As this muddy earth is a mixture of all the primitive earths, and some of the metals which are the product of vegetation, as well as the oils, the farts, and other products we meet with in it; we may consider it as the residue of vegetable decomposition, as the great agent and means by which nature repairs the continual loss of the mineral kingdom undergone. In this mixture of all the principles the materials of all compounds exit; and these materials are so much the more disposed to enter into combinations, as they are in a more divided and disengaged state. It is in these earths that we find diamonds, quartz crystals, fars, gypsum, &c. It is in this matrix that the bog ores, or ochreous ores of iron, are formed; and it appears that nature has reserved the impoverished residue of vegetables for the reproduction or reparation of the earthly and metallic substances of the globe, while the organic remains are made to serve as nourishment for the growth of other succeeding vegetables.

Some have taken occasion to apply the proces of putrefaction to that of digestion, or the change which the aliment suffers in the human body. (See Digestion.) For the change our vegetable foods undergo in the body, being such as brings them to be of the same nature, and to afford the same principles, with the change induced by putrefaction, is a presumption, that digestion is nothing else. Besides, as we know that neither animal nor vegetable substances can become aliment, without undergoing some degree of putrefaction, many illtemperments must proceed from a deficiency of this action; the crisis of fevers seems to depend upon it; and even animal heat, according to Dr. Stevenson, does the same.

Now, that the concoction of the humours is nothing else but putrefaction, seems probable from hence, that whenever they are in that state, they are always more fluid, and fitter to pass through the smaller vesseles, where they stagnated before. Again, the offensiveness of the sweats, or other excrements consequent on a crisis, is likewise a sure sign of a high degree of corruption. The time of resolution or putrefaction depends on the degree of heat, the habit of the patient, and on the part obstructed. Resolution is the putrefaction of the impacted humour only, but suppuration implies a corruption of the vessels also. This manner of speaking, indeed, has been disused, from the prejudice that nothing was putrid but what was offensively so; whereas, in fact, every fibre becoming more tender, and humour thinner, may be considered as putrid in some degree, whether the change tends to the better health, or to the destruction of the person, or whether it becomes grateful or offensive to the senses.

Mr. Boyle has used the words fermentation and putrefaction of the blood promiscuously, in his Treatise on the Human Blood. Stahl and other celebrated chemists likewise use the term putrid ferment; which fe.
PUTREFACTION.

It is, therefore, truly observed by lord Bacon (Nat. Hist. cent. iv.) that an enquiry into the means of preventing or slaying putrefaction is of excellent use in phylic. Sir John Pringle has made many curious experiments with a view of determining the power of certain substances to promote or to prevent putrefaction, together with remarks on this subject, which are published in the Phil. Trans. vol. xlvi. p. 480. 525. 550, and by way of appendix to his Observations on the Diseases of the Army. From the experiments of this learned and judicious physician, it appears, that fats of every kind, whether acid, alkaline, or neutral, fixed or volatile, as well as the astringent and gummy-teninous part of vegetables, all of them will produce and most of them correct putrefaction; and he pursued this branch of inquiry so far as to enable him to form a table shewing the comparative anti-septic power of the several substances, that of tea-fall being the standard. See this table under the article Antiseptic.

Of all retenious substances, he found that camphor or fixed putrefaction most powerfully; its anti-septic power being three hundred times greater than that of tea-fall.

Decocctions of wheat, barley, and other farinaceous grains, checked putrefaction, by becoming four. He also made experiments to discover the effects of mixing vegetable with animal matters.

Two drams of raw beef, as much bread, and an ounce of water, being kept to the confidence of pap, and exposed to 90° of heat, according to Fahrenheit's thermometer, began to ferment in a few hours, and continued in a fermentation two days. When it began to ferment and swell, the putrefaction had begun; and in a few hours afterwards the smell was offensive. Next day the putrid smell ceased, and an acid taste and smell succeeded. Fresh alimentary vegetables, as spinach, asparagus, fcurvy-grass, produced similar effects as bread on flesh, but in a weaker degree. From several other experiments, he found that animal substances excite the fermentation of vegetable substances; and that the latter substances correct the putrefacncy of the former.

By adding salvia to a similar mixture of flesh, bread, and water, the fermentation was retarded, moderated, but rendered of twice the usual duration, and the acid produced at last was weaker than when no salvia was used.

By adding an oily substance to the common mixture of flesh, bread, and water, a stronger fermentation was produced, which could not be moderated by the quantity of salvia used in the former experiment, till some fixed alkaline salt was added, which salt was found, without salvia, to stop suddenly very high fermentations.

He did not find that small quantities of the following salts, salt ammoniac, nitre, virolated tartar, sal durresicus, salt of hartthorn, salt of wormwood, were feptic, as small quantities of tea-fall were.

Sugar was found to refit putrefaction at first, as other salts do, and also to check the putrefaction after it had begun by its own fermentative quality, like bread and other fermentative vegetables.

Lime-water made some small reflection to putrefaction.

Port-wine, small beer, infusions of bitter vegetables, of bark, and the juice of antiscorbutic plants, retarded the fermentation of mixtures of flesh and bread. But an untrained decoction of bark considerably increased that fermentation.

Lime-water neither retarded nor hastened the fermentation of such a mixture; but when the fermentation ceased, the liquor was neither putrid nor acid, but smell agreeably.

Flesh pounded in a mortar was found to ferment sooner than that which had not been bruised.

The tough inflammatory crust of blood was found to be most putrificent, next to which the effalamentum, or red coagulated mafs, and laftly the serum.

Charcoal is a powerful antiseptic; hence all sorts of glas-wefels and other utensils may be purified from long retained smells of every kind, in the easiest and most perfect manner, by ringing them out well with charcoal powder, after the groffer impurities have been scooped off with sand and potash. Rubbing the teeth and washing out the mouth with fine charcoal powder will render the teeth beautifully white, and the breath perfectly sweet, when an offensive breath has been owing to a furonelic disposition of the gums. (Crelle's Journal, vol. ii.) Meat also, which is a little taint with putridity, may at once be made sweet by charcoal; and it has been said, that common raw spirits agitated with charcoal will be deprived of their bad flavour, but they are apt to resume their old flavour, if kept in the cork only a few weeks.

The experiments of the author of the "Effai pour servir a l'Histoire de la Putrefaction," shew that metallic salts, retenious powders, extracts of bark and opium, are very powerfully antiseptic, and that fats with earthy bases are less antiseptic than any other fats.

The famous ingenious physician made some attempts towards the sweetening of corrupted flesh by means of mild substances. For this purpose he put a piece of putrid flesh into an infusion of chamomile flowers, which was renewed twice or thrice in as many days, and its sweetnes and firm texture were recovered. Several pieces of putrid flesh were also sweetened by repeated infusions of a strong decoction of the bark; and he constantly observed, that not only the corrupted smell was removed, but a firmness restored to the fibres. The corrupt yolk of an egg, diluted with water, was sweetened by mixing it with a strong infusion of chamomile flowers. He found also that decoctions of wormwood, of the bark, and infusions of chamomile flowers, and of snake-root, preserved yolks of eggs for a longer time than water, even with the addition of a considerable quantity of tea-fall; and that they were preferred better by salt of hartthorn than by four times the weight of tea-fall. Ox-gall was kept for some time from putrefaction by small quantities of lees of tartar, spirit of hartthorn, crude salt ammoniac, and the Julian mixture; and still longer by a decoction of wormwood, infusion of chamomile flowers and of snake-root, and by solutions of myrrh, camphor, and salt of amber. The infusion of human blood was preferred for a decoction of the bark, and an infusion of snake-root, as effectually as flesh. See Antiseptic.

For an account of sir John Pringle's experiments and observations with respect to those subjects that halten or promote putrefaction, see Septics.

Dr. Macbride's experiments confirm many of those above related, especially those which shew that the fermentation of vegetable substances is increased by a mixture of animal or putrificent matter, that the putrefaction of the latter is corrected by the fermentative quality of the former; and that the putrefaction and fermentation of mixtures of animal and vegetable substances were accelerated by additions of absorbent earths and of Peruvian bark. He also found, that although unburnt calcareous earths were feptic, quicklime and lime-water prevented putrefaction, but that they destroyed or dissolved the texture of flesh.

From his experiments we learn also, that acids, even when greatly lowered, have a strong degree of power to refit putrefaction, and also to correct it; but that they destroy the texture of the substance whose foundness they were supposed to restore; that fats in general, by a property which is common to them all as fats, have the same power,
power, but that they exceed the acids in their efficacy for correcting putrefaction; that fermenting and effervescent mixtures are the most powerful of all known antiseptics; and, in general, that whatsoever hath a power to restrain the escape of the fixed air, or hinder the intelline motion, must of course prevent putrefaction; and that fixed air, when transferred from a found body to one that is putrid, appears to restore to that body the principle which has been destroyed or lost.

Dr. Macbride objects against the administration of acids in putrid diseases, for the following reasons; because, if they came unaltered to the absorbent vessels, they would not admit of them, and if they did, they would be dangerous, and they are quite changed before they leave the primary use. Dr. Crel [Phil. Tranf. vol. xxxi. part i. p. 346.] has replied to this reasoning, and proposed experiments to prove, that acids, though changed in the alimentary canal so far as not to effervescce with alkalis, may, notwithstanding, check putrefaction, and, therefore, that their use is of great consequence, and ought not to be omitted in putrid diseases.

With regard to the exhibition of alkalis, Dr. Macbride observes, that the point is not yet satisfactorily settled. There can be no doubt of their power to resist and correct putrefaction in dead bodies; but whether, upon the pre-2

sumption of this virtue, they can be given with propriety as antiseptics, he adds, is not so clear. Dr. Crel affirms, that they can never be used in living bodies as antiseptics; for, laying aside their stimulating quality, which must prevent their use in most of the putrid diseases, they would, he apprehends, increase the morbid matter, by being intimately mixed by circulation with phlogistic matter, which they find abundantly in such bodies. Altrigents, says Dr. Macbride, prevent putrefaction very powerfully, but they have not the least degree of efficacy in correcting it; and as antiseptics, they can be of importance only in those cases where, from extreme relaxation and resolution of the solids, the diffused fluids are suffered to transude, and either form spots of different hues, or run off by actual hemorrhage; and he apprehends, that acids act in those cases where they have been administered with succefs, merely as altrigents. The antiseptic virtue of the gummy-refinous vegetables, judging of their effect by that of the bark, appears to depend on their fermenting in the body, and parting with fixed air in the course of their fermentation, and throwing a great quantity of it into the blood; and attending to the things that prevent putrefaction in living bodies, we shall find that the dependence is on the quantity of air. Thus, vegetable food prevents the putrefactive diathesis; and to the frequent use of fresh vegetables and sugar, in the diet of the European nations, it is owing that putrid diseases or plagues are now so uncommon. And what proves almost to a demonstration the antiseptic power of the fermentable substances, is the cure of the fea-IV.

Dr. Crel disagrees with the opinion of Dr. Macbride, that putrid diseases may be cured with fermentable substances only; nor is he convinced that putrefaction depends only on the loss of fixed air. Thus, he apprehends, is an effect rather than the cause of putrefaction. We shall here only add, that Dr. Macbride recommends, in the putrid yellow fever of the West Indies, to give the patient repeated doses of the alkaline fluids, in fresh lime-juice, or the like, and to let it be swallowed during the effervescence; and to order the patient's drink to be somewhat of the highly fermentable kind; such as the juice of the green sugar-cane, diluted and acidulated with some of the recent four juices. The natives on the coast of Africa give in fevers of this kind, with good succesf, a drink prepared by macerating in water a fruit of the plum kind, that grows there in great plenty. He adds, that by throwing in such a quantity of antiseptic vapour as would be furnished from this kind of materials, the putrefactive acrimony, which at first seems chiefly to affect the biliary system, might be corrected and satureted. See on the subject of this article Dr. Macbride's Essays, 1776, paffim.

Putrefaction, in Phvology, the spontaneous changes which animal substances undergo, when deprived of life. See Death.

Putrefaction, in Agriculture. It is by means of putrefaction, as flated under its appropriate article, that various substances and bodies are decomposed, reduced, and brought into the slate proper for being applied to lands for the support of crops; but this is more fully explained, in speaking of the nature of the different materials that are capable of being made ufe of in ameliorating land for the growth of crops. See Management.

Putrefaction of Water. It is said to be the peculiar quality of the Thames water, that it will flink and yet be wholesome; and after this will recover itself again. Many sailors have been obliged to drink it flinking, so that they held their noses while they poured it down their throats, yet no sicknefs ensued from it. It generates a fpirit alo in this flinking slate, which will take fire at the approach of a lighted candle, as if spirit of wine were touched by the flame.

It appears from the article Putrefaction, that though a volatile alkali may be obtained from putrid substances by distillation, such substances must not be flurred to remain too long before they are distilled, unless they are kept in close vessels; because the volatile alkali, which is the offspring of putrefaction, is diluted as fast as it is generated, inasmuch that, at length, nothing is left behind but an infipid water, or a solid matter, being an earth familiar to common mould. It is in this way, says Dr. Macbride, that flinking water, after some time, becomes sweet: the volatile alkali, generated by the putrefaction of the animal and vegetable substances at first contained in the water, being, after a while, entirely diluted, leaves the remainder without any disagreeable smell.

Putrid water is immediately deprived of its offensive smell by charcoal. If putrid water be agitated with a small quantity of magnesia, it will lose its bad taste and smell in a few minutes. See Crell's Journal, and Proufl, Journal de Phy-5

A method of preserving water free from putrefaction was some years since propofed by Dr. Allfon. It conifted in adding a quantity of lime to every cask of water; and as lime is known to have a strong antiseptic property, water, as long as it retains the impregnation of lime, never putrefies. In order to free the water, at the time of using it, from the lime, Dr. Allfon proposes the precipitation of the latter by throwing a quantity of magnesia alba, on this principle, that as lime-dope is rendered soluble in water by the deprivation of its fixed air, and has a greater affinity with that air than magnesia has, the particles of quicklime diffolved in the water would attract the air from the magnesia, and thereby becoming no longer soluble, would fall to the bottom, and leave the water tasteless and fit for economical ufe. See Lime-water and Magnesia.

The expence, however, attending this process prevented the execution of the proposal. Mr. Henry has not long ago sug-gested a cheap and easily practicable method of precipitating the lime, and thus of reftoring the water to its original taste. The following is a short sketcf of the author's procels. To

preferve
prefer the water from putrefaction, two pounds of good quicklime are directed to be added to each cask of water of a hundred and twenty gallons. To free the water afterwards from the lime with which it has been impregnated, it is to be drawn off into a strong cask, containing about sixty gallons, with an aperture at one end large enough to admit a vessel, which is to be let down into it by means of rings, and which contains a proper quantity of effervescent materials, that is, of marble or chalk, and vitriolic acid. Eight ounces of mild calcareous earth, and six ounces of strong vitriolic acid, will be sufficient for sixty gallons of lime-water. The mouth of this last vessel is to be flapped with a tubulated flapper, through which the fixed air, let loose from the marble, passes up through the body of the water. The lime is thus rendered infusable, and is soon precipitated in the form of an impalpable powder of chalk; the water being thus restored to the same state of purity as when it was first tipped on board; or, as Mr. Henry believes, to a state of still greater purity; several hard waters having, in consequence of this process, been rendered as soft as rain water, and freed from different impregnation. For farther particulars, and the description and drawing of an apparatus for this operation, see Henry's Account of a Method of preserving Water at Sea, &c. p. 10, &c. 1781.

PUTRESCENT MATTERS in Agriculture, such substances as are in a state of putridity. Various materials of this kind are capable of being made use of by the farmer. It has been lately suggested by Dr. Hunter, of York, in a paper in the third volume of the Farmer's Magazine, that different materials of this nature may form a substitute for the folding of sheep.

The trouble and expense of keeping a flock of sheep for the purpose of folding, may probably be avoided by forming large ponds, so constructed as to receive and hold water. Into these ponds let drains from the stables, cow-houses, ox-stalls, pigeon and wath-houses be directed; and, in order to enrich the water, let all kinds of vegetable and animal substances be thrown in, particularly the contents of the cellars and slaughter-houses. It is presumed, that this putrid water, when put upon the land by means of water-carts, will prove as beneficial as a flock of sheep kept for the express purpose of folding; and where no sheep are kept for that purpose, such will prove an excellent manure for meadow laid. A pond of sixty feet diameter, by six feet deep, which will contain upwards of 700 hogheads of water and putrescent bodies, may be equal in its effects to a considerable fold of sheep. The putrefaction of the water may be greatly increased, by occasionally supplying the ponds with the refuse of fish, and sea-weed, where they can be conveniently procured; and in all places within a reasonable distance of sea-ports, where ships are employed in the Greenland fisheries, the farmer will find a seasonable supply of putrescent matter by the purchase of the whale blubber, after the oil has been taken from it. Such is the strength of the last named substance, that it is well worth the farmer's while to be at the expense of carrying it in casks to a considerable distance, for the purpose of giving vigour to his compost dunghills. The ancients were particularly nice in the formation of their dunghills; and it is a reproach to the present race of farmers, that so material a branch of their business should, at this day, be so imperfectly known or attended to. And in many large cities, and especially Edinburgh, it would be a great improvement, if a well-constructed reservoir was made to receive the excrementsitious matter, the bowen being occasionally replenished with earth and small rabbit. In this manner, many thousands of loads of rich manure might be made from the sea, to which place the excrementitious matters are upon their passage.

PUTRID, PUTRIDUS, something rotten, or putrified. See PUTREFACTION.

Thus we say, putrid flesh; a putrid humour: putrid limbs, i.e. mortified ones, are to be cut off.

PUTRID DISCHARGE. See PUTRID FEVER, &c.

PUTRID FERMENT. See FERMENT.

PUTRID FEVER, &c. in Medicine, an epithet originating in the chemical school of physis, in which the true operations and phenomena of life were mistaken for the fermentations and decompositions of the laboratory. This mistake was probably the result of the offensive smell, and actual putrefactive odour of some of the discharges from the living body, in the last stages of fever fevers; but further observation has demonstrated that, however the excrements may undergo the process of putrefaction after they are thrown out of the living system, no degree of putreception can exist for a moment in the circulating blood, without occasioning instant death.

The symptoms which were formerly ascribed to putrefaction, but which are now believed to originate from a great deficiency of the vital or nervous power derived from the brain and nervous system, are such as occur in typhus gravior, the hospital and gaol fever, and in the worst cases of delirium, and small-pox; among which are a black tongue and mouth, extreme prostration of strength, festid evacuations from the bowels, those, and bladder, hemorrhages, petechiae, and purple blanches, &c. See Fever, and Typhus.

PUTRID ULCER. See Ulcer.

PUTRINE, in Geography, a town of Prussia, in Oberland; six miles W. of Paffenhain.

PUTT, in Rural Economy, a provincial word, applied commonly in some districts to the mole-hill. Also, sometimes to animals which put or thrust with their horns.

PUTT, or PINE, in Geography, a town of Anterior Pomerania; eight miles S.W. of Stralsund.

PUTTAN-SUMNAUT, a town of Hindoostan, in Gujarat; near which was a famous pagoda, much venerated and frequented by devotees from all parts of the country. In the year 1002 this town and temple were taken by Mahommed, king of Ghizni, and plundered of their great wealth. In the temple was found a statue, in which, on being broken, was found a vast quantity of precious stones. The Hindoos believed that the souls of deceased persons came to this place to be transferred to other bodies; 80 miles S. of Noangur. N. lat. 21°1'. E. long. 69°40'.

PUTTEN, VAN DER, HENRY, in Biography, was born at Vanlode in 1574; after studying at the universities of the Low Countries, he visited Italy, and for a considerable time was professor of rhetoric at Milan, where he took the degree of doctor of laws. He was nominated historiographer to his Catholic majesty, and received the honour of citizenship at Rome. In 1626 he was invited to the chair of Lipsius, who had been his tutor. He was also made a counsellor to the archduke Albert, and entrusted with the government of the citadel of Louvain. When a truce was negotiating between the Dutch and the King of Spain, in 1633, he published a work, entitled "Statera Belgii et Pacis," in which he shewed how important a peace would be to the Spanish Netherlands. This work gave great offence, and the author had nearly experienced the usual fate of those who counsellied pacific measures, at a time when passion, prejudice, and interest, urge the continuance of war. He died at Louvain in 1646, age 72. Besides his "Statera," mentioned above, he published "Historia Infusbrica," and "Orchestra.
PUW

"Orchestra Burgundica;" "Theatrum Historiae Imperatorum;" "Comus, feu de Luxu;" "De usu Bibliothecae," with a catalogue of the Ambrobian library; besides several tracts relative to classical antiquities, printed among the collections of Graevius and Groenovius. Moreri.

Putten, in Geography, a small island of Holland, in the Meuse, E. of Zierikzee.

PUTTERAHET, a town of Hindoostan, in the circur of Gohud; 27 miles E.N.E. of Gohud.

PUTTOCKS, or Puttock-Shrouds, otherwise called putock or foot-book shrouds, in a Ship, are small shrouds which go from the throds of the main-mast, fore-mast, and mizen-mast, to the top-mast shrouds; and if there be any top-gallant mast, there are puttocks to go from the top-mast shrouds to these. These puttocks are at the bottom fixed to a staff, or to some rope which is fixed to a plate of iron, or to a dead-man's eye, to which the laniards of the fore-mast shrouds come. See Shrouds.

PUTTY sometimes denotes a white powder of lead and tin calcined together, in the proportion of two parts of lead to one of tin; used in polishes, and giving the last gloss to works of iron, steel, copper, and glass. This is also the basis of white enamels, and glazings for earthen-ware.

Putty is also used to denote spodumine.

Putty, in its popular sense, denotes a kind of paste, composed of whitening, with or without a little white lead, and linseed oil, beaten together to the consistence of a tough dough; used by glaziers for fattening the squares of glass in sash-windows, &c. and by painters, to flop up the crevices and clefts in timber and wainscot, to prevent the wet from getting in, and ruining the work.

PUTTYRAM, in Geography, a town of Hindoostan, in Bengal; 18 miles E.S.E. of Dimgapour.

PUTUAY, a small island on the coast of Bengal. N. lat. 22° 41'. E. long. 89° 28'.

PUTUMAYO, a river of South America, which rises about 80 miles S. of Popayan, pursues an easterly course, inclining to the south, about 300 miles, and after being joined by a branch of the Caquet, takes the name of Ica, and running S.E. about 200 miles, joins the river of the Amazons in S. lat. 3° 10'. W. long. 50° 12'.—Also, a town of South America, in the government of Popayan, on a river of the same name; 50 miles E. of Pasto.

PUTURA, a cullum claimed by the keepers of forests, and sometimes by bailiffs of hundreds, to take man's meat, horse's meat, and dog's meat, of the tenants and inhabitants, gratis, within the perambulation of the forest, hundred, &c.

"Johannes clamat unam putaram in prorata de Penevoffham, qui est quidam cella abbreviata de Eveham, pro fe & mini-tris, equis, & garcibionibus suis, per suum diem & duas noctes, de tribus feptimannis, in tres feptimannis, varia de vehiculibus, ut & eceulentis & potulentis, ad collas proratas predicit indebites." Placit. apud Praetion. 17 Edw. III.

This custom, within the liberty of Knaresburg, was long since turned into the payment of four-pence, pro putura.

The land subject to this service is called terra putatura. The learned Sonner has erred in his exposition of this word.

PUTYAJURY, in Geography, a town of Bengal; 30 miles S.S.W. of Silhet.

PUTZIG. See PAUZ.

PUVIGLIO, a town of the duchy of Parma; nine miles N.E. of Parma.

PUWAKHAGA, in Botany, the name by which some authors call the faufel-tree, of whose fruit the expressed juice called terra Japonica, or Japan earth, is made.

PUXUANAIRO, in Geography, a town of Mexico, in the province of Mechoscan; 25 miles N.W. of Mechoscan.

PUY, Peter de, in Biography, the third son of Claude du Puy, a magistrat in the parliament of Paris, was born in that city in 1582, and was educated with great care under his father. While a youth, he made extraordinary proficiency in literature, and still further improved himself by a journey to Holland, whither he accompanied the French ambassador. After his return he laboured with great alacrity in ascertaining the rights of the crown of France over some of the neighbouring districts, and for that purpose was indefatigable in his examination of ancient charters, and thereby acquired a profound knowledge of French history. The reward of this, and other labours of the same sort, were the places of king's counsellor, and keeper of the royal library, in both of which he was distinguished by his patriotic and love of letters. His works were numerous and valuable. In almost all of them he aims at reproducing the ecclesiastical authority, and the claims of the see of Rome; hence they were not well received at the papal court. They are, however, said to contain a rich treasure of facts relative to all the matters on which he treats. He died at Paris in 1651, at the age of 69, and his life was written by his intimate friend Nicholas Rigault. Some of his writings are as follows: "Preuex des Liberto de l'Eglise Galligale;" "Histoire Veritable de la Condamnation de l'Ordre des Templiers;" "Traite de la Loi Saliq;" "Du Concordat de Bologne entre le Pape Léon X., et le Roi Francis I.;" "Apoloigie de l'Histoire de M. le Prefident de Thou." He had a brother, James, prior of St. Sauveur, who became keeper of the king's library after the death of Peter, whom he abridged in all his works, of the greater part of which he was the publisher. He died in 1656, leaving behind him a high character for learning and probity.

Another brother, Christoffer du Puy, was prothonotary to the cardinal of Joyeuse, and by his remonstrances he prevented the congregation of the Index from putting the first of de Thou's history in the list of heretical books. He was king's almoner, and, while attached to cardinal du Perroux, he made a collection entitled "Perroniana." He became a Carthusian, and died at Rome in 1554, proctor-general of his order.

Puy, Louis de, a man of letters, was born at Clarey, in Burgundy, in 1709; he studied in the college of Lyons, and came to Paris in 1732. He was for a considerable time principal editor of the Journal des Scavans, and during thirty years enriched this collection with a great number of critical dissertations. He was well versed in the learned languages, and in the mathematics, and acquired an extensive knowledge of history and antiquities. The prince of Soubise entrusted him with the management of his library, and by his care it was rendered one of the most valuable in the metropolis. In 1753 he was nominated secretary to the Academy of Inscriptions, in which situation he pronounced the catalogues of twelve of his acquaintances, and edited from the 36th to the 41st vols. of its memoirs. He died in 1795. He was author of "Observations on infinitely small Quantities, and the metaphorical Principles of Geometry," inserted in the Journal des Scavans for 1759; "A Translation of four Tragedies of Sophocles," 1762; "A Translation of the Greek Fragments of Anthemius on mechanical Paradoxes, with Notes;" some memoirs on the Roman coin, the silver denier of Charlemagne, and other antiquarian and literary subjects. Du Puy was highly esteemed for strict probity,
sincerity, and an obliging disposition, which displayed itself in useful advice and information to those who consulted him on literary topics.

Puy, Mademoiselle du, a celebrated performer on the harp, who had acquired a considerable fortune by the exercise of her talents in different parts of Europe. She died at Paris in 1777, and made a will that seemed dictated by infatuation. Among other articles, she ordered that no blind, lame, or deformed person should attend her funeral. She ordered that her house should be let to none but nobility. She left a large piece of ground to be formed into a public garden, upon condition that no flunted trees should be allowed a place in it. And lastly, she bequeathed an annuity for the maintenance of cats, of which she was fond, and for a person to look after them. But the annuity depended wholly on the life of the cats. The harp upon which she had acquired her pollefions, was left to a blind harper in the Hospita of Quinze Vingts, who played tolerably well on many different instruments. Great pains were taken to set this will at nile, but without effect. It was declared valid by law, and obliged to be executed. Laborde.

Puy, Le, in Geography, a town of France, and principal place of a district, in the department of the Upper Loire, and capital of the department, situated on a small river near the Loire; before the revolution, the see of a bishop; a place of considerable trade, especially in lace; 38 miles S.W. of Lyons. The place contains 15,015 inhabitants, in two cantons, the one containing 13,396, and the other 14,100, on an extent of 185 kilometres, in 16 communes. N. lat. 45° 1'. E. long. 3° 57'.

Puy-Laurens, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavaur; 12 miles S.E. of Lavaur. This place contains 5648, and the canton 9817 inhabitants, on a territory of 125 kilometres, in 9 communes.

Puy-L'Evêque, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 14 miles W. of Cahors. The place contains 2082, and the canton 12,127 inhabitants, on a territory of 285 kilometres, in 11 communes.

Puy-Mirolo, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen. The place contains 1263, and the canton 8072 inhabitants, on a territory of 125 kilometres, in 11 communes.

Puy de Bellard, a town of France, in the department of La Vendée; 18 miles N.W. of Fontenay le Comte.

Puy Laguerre, a town of France, in the department of the Gers; nine miles N.E. of Auch.

Puy de Dome, a mountain of France, near Clermont en Ferrand, 810 toises in height.

Puy de Dome is also the name of one of the nine departments of the central region of France, so called from the mountain that is situated in it; it is bounded on the N. by the department of the Allier, on the E. by that of the Rhône and Loire, on the S. by the departments of the Cantal and Upper Loire, and on the W. by those of the Corrèze and Creuse; formerly Lower Auvergne, in N. lat. 45° 40', containing 8450 kilometres, or about 52 French leagues in length, and 22 in breadth, or 447 square leagues, and 561,444 inhabitants; divided into five districts, viz. Riom, including 126,640; Thiers, 61,530; Ambert, 73,535; Clermont, 158,449; and Libourne, 88,290 inhabitants; 50 cantons, and 438 communes. The circles, according to Haffenrater, are 8, the cantons 71, and the population 516,593. Its capital is Clermont. The general total of its contributions in the 11th year of the new French era, was estimated at 3,656,547 francs; and its expenses for administration, judiciary, and for public instruction, at 374,681 francs, 37 cents. The soil of this department, diversified with hills and plains, is remarkably fertile, producing abundantly grain, wine, fruits, hemp, and pastures. It has mines of silver and lead, mineral springs, &c.

Puy le Garde, a town of France, in the department of the Lot; 15 miles N.E. of Montauban.

Puy Guillaume, a town of France, in the department of the Puy de Dome; eight miles N.E. of Lezoux.

Puy Laurens, a town of France, in the department of the Aude; seven miles S.E. of Quillan.

Puy Marain, a town of France, in the department of the Upper Garonne; 17 miles N. of St. Gaudens.

Puy Miolans, a town of France, in the department of the Lot and Garonne; six miles E. of Marmande.

Puy Maissone, a town of France, in the department of the Lower Alps; 15 miles S. of Digne.

Puy Notre Dame, or Puy en Ayzon, a town of France, in the department of the Mayene and Loire; 10 miles S.W. of Saumur.

Puy de la Poise, a town of France, in the department of the Puy de Dome; 18 miles E. of Clermont.

Puy la Roque, a town of France, in the department of the Lot; 17 miles N.E. of Montauban.

Puy St. Martin, a town of France, in the department of the Drôme; 11 miles N.E. of Montelimar.

Puy Val d’Or, a town of France, in the department of the Eastern Pyrenees; 10 miles N.W. of Montlouis.

Puya, in Botany, the vulgar name, in Chili, of a plant, which is figured in Feuillee, v. 3. 50. t. 39, and adopted as a genus, after Molina, in Jullieu’s Genera 447, under the above barbarous appellation, with the following character.

Calyx in fix deep segments; the inner mottled large, and vaulted. Stamens 5, inserted into the lower part of the calyx; their filaments formed like a scale at the base, and bearing honey. Germin superius, triangular, & (style and stigma unknown). Capsule of three cells, with numerous minute seeds, (doubtful whether furnished with down.)

Feuillee’s description is to the following effect. The roots are fibrous, throwing up several stems, about nine feet high, as thick as a man’s body at the bottom, where they are clothed with the fealy imbricated velliges of old leaves, above which stand the numerous leaves of the present year. These are three or four feet long, and about two inches wide, resembling the foliage of the Pine-apple, their margins being fringed with very sharp hooked prickles, five lines long, and about an inch and half asunder; the surface of the leaves is smooth, shining, of a fine bright green. The Indians make use of these prickles as fish-hooks. The part of the stem above the leaves is round, two inches or more in thickness; of a blueish-green externally; white and watery within, clothed with very short, alternate, claspings leaves, or scales. The summit consists of a large pyramidal of flowering branches, or spikes, the lowestmost a foot long; all clothed with similar feales, or bracteas, each of which is accompanied by a sessile axillary flower. Each flower is composed of six leaves, three large and three small, in a double row. The latter are three quarters of an inch long, (Feuillee says, apparently by mistake, three inches,) and three lines and a half broad, covered with minute white down: the three larger are of a greenish-yellow, two inches and a half long, and nine lines broad, terminating like a Gothic arcade. The flowers roll up spirally as they fade. Six stamens spring from the bottom of each flower, surrounding a triangular pistil, which extends beyond them, and becomes a fruit
PW L

a fruit, of three cells, filled with an infinite number of seeds. T. seuillec met with several specimens of this plant in the kingdom of Chili. He refers it to his genus of *Rentalms*, the *Tillandsia* of Linnaeus. Juillef justly suspect its being the same genus with Mr. Herrier's *Ptycaurz*, see that article; of which therefore the plant in question may be preumed to constitute an additional species to the four we have described; agreeing most with *P. brachyata* in habit, size and colour, but differing in having more spinous leaves, as well as a more compound indument.

The reader will observe that Juille, according to the principles he had alluded to, calls the whole integument of the flower a calyx, while we follow other writers in taking the three inner parts for petals; a distinction, if we must not, by their habit, and mode of withering. The little differences respecting the scales or nectaries may easily be reconciled.

PUCYERDA, in Geography, a town of Spain, in Catalonia, and capital of the county of Cerdagne, surrounded with walls and bastions, and defended by a castle; 19 miles E.N.E. of Urgel. N. lat. 42° 39'. E. long. 1° 48'.

PUYO, a town of France, in the department of the Landes; nine miles S.W. of Aire.

PUYs, a term used for the poles with which the keels on the Tyne river are towed along.

Puysegur, James de Chatenet, Lord of, in Biography, lieutenant-general under Lewis XIII. and XIV., was born in 1600. He entered the army at the age of seventeen, and served, without intermission, during forty-three years. He was present at above thirty battles, and one hundred and twenty sieges, without ever having been sick or received a wound, but he had not the good fortune to rise in his profession, being too zealous for the king's service, than complaisant to the ministers. He drew up "Momeirs," comprising the period from 1617 to 1658, in which are contained various remarkable particulars relative to the campaigns in which he served, with useful military instructions. They were printed at Paris and Amsterdam in 1690, 2 vols. 12mo., under the inspection of Du Chesne, bibliographer of France, and they have the character of narrating with freedom and fidelity. He died at his country seat in 1682.

Moreri.

Puysegur, James de Chatelet, Marquis de, was son of the preceding, born at Paris in 1655, and entered into the army under his father, and gradually rose to the post of commander-in-chief in the French Netherlands, and finally, to the still more important one of a marshal of France in 1734. He died at Paris in the year 1743, at the age of 88. He was author of a work "On the Art-Military," published by his only son the marquis of Puysegur. Moreri.

Puzzalo, in Geography, a town of the island of Sicily, in the valley of Noto, near the coast of the island; 12 miles S.W. of Noto.

Puzzling Bay, a bay in the Frisians of Magellan, on the coast of Patagonia. N. lat. 53° 35'. W. long. 74° 28'.

Puzzolana. See Pozzolana, and Calcium Cen-

Puzzoloni, in Geography. See Pozzoluni.

PWLLHELI, a borough, market, and sea-port town in the parish of Denio, commened of Cannologion, cantref of Lleyn, now called the hundred of Gyfflogion, county of Caernarvon, South Wales, is situated on the south side of the promontory of Lleyn, in St. George's Channel, at the distance of 27 miles S.S.W. from Caernarvon, and 243 miles W.N.W. from London. This town consists chiefly of a single street, running parallel to the shore. It was constituted a free borough by Edward the Black Prince, at the request of Nigel de Loharyn, and had its privileges confirmed by King Edward III. The government is vested in a mayor, recorder, and two bailiffs, who have the powers of justices. The market days are here are Wednesday and Saturday, weekly; and there are besides six annual fairs. This town has a considerable trade; and upwards of eighty ships, of different burthen, belong to it. Along the coast to Bardsea island, an extensive and valuable herring fishery has been lately established. The harbour is good, and well sheltered from the winds; and the bay, to which the town gives name, affords excellent anchorage ground. Pwllheli is one of the contributory boroughs with Caernarvon, in returning one member to parliament, and is likewise the seat of the petty feoffors for the district of Lleyn, which extends about twenty-two miles in length, and from three to ten in breadth, projecting into the sea in a manner similar to the county of Cornwall. According to the parliamentary returns of 1811, the parish contains 312 houses, and 1383 inhabitants, of which number, above one-half are resident in the town of Pwllheli.

At the distance of five miles from this town is Carn-

Madryn, a strong fortres, which formerly belonged to the sons of Owen Gwyned. The bottom, sides, and top are filled with cells, varying in size and shape, many of which are full nearly entire. Close to the sea-coast is an entrenched, called Dinns Dinille, which constitutes an object of great attraction from the road to Caernarvon by Caern Fawr, a neat romantic village, boating one of the largest and handsomest churches in Wales. Near it is the valley called Nant-y-Gwirtheyn, or the valley of Vortigern, where that prince is said to have concealed himself, to avoid the persecution of his subjects. It is bounded on two sides by flown heaps, only productive of heath and stunted gore, and on a third by a tremendous precipice. The only opening to this secluded spot is towards the sea, "a northern aspect, where chilling winds exert all their fury, and half freeze, during winter, its few inhabitants." Nichol son's Cambrian Traveller's Guide, 1813. Carlyle's Topographical Dictionary of Wales, 1811, 4to.

PYANEPSIA, *P. Lyne*, in Antiquity, a festival celebrated by the Athenians in the month Pyanepsis; which, according to the generality of the critics, corresponded to our September.

Plutarch refers the institution of this festa to Theocus; who, at his arrival from Crete, made a kind of sacrifice to Apollo of all the provisions remaining in his vefiel; putting them all into a kettle, boiling them together, and eating them with his fix companions; which custom was afterwards continued. The scholiast of Aristophanes says, this was done to acquit himself of a vow he made to Apollo in a temple.

M. Baudelot writes the word *Pyanepsis*, and takes it to be a festa instiiluted in memory of Theocus's return after killing the Minotaur.

The Greeks vary as to the origin and signification of the word Pyanepsis, whence the festa is denominated. Harpocrates calls it *Pyanepia*; he adds, that others call it *Pyanopfia*; because the fruits all appear to the eye. Hefychius writes *Pyanepfsia*; and derives it from *pya*, bean, and *punps*, couch, because in this festa the Athenians gathered their beans, and made a kind of broth of them.

Pyaneon, in *Atheneutics*., in the Athenian Chronology, a month of thirty days, in which the festival Pyanepsis was celebrated, and called by the Bocciati Damastrius.

Pyaour, in Geography, a town of Hindoostan, in Bahar; 13 miles E. of Bahar.

PYBO-
P Y C

PYBOLOWO, a town of Lithuania; 25 miles E. of Minsk.

PYCIFERT, in Botany, a name given by Hernandez, and some other authors, to a peculiar species of tobacco, distinguished by Mr. Tournefort by the name of nicotiana major lato et rotundo folio, the broad roundish-leaved great tobacco.

PYCANTHEMUM, a name contrived by Michaux, from πυκνός, dense, and άυτρόν, a flower, to express the dense inflorescence.—Michaux Boreali-Amer. v. 2. 7. Ait. Hort. Kew v. 3. 376. Pursh v. 2. 409. (Brachylytemum; Michaux Boreali-Amer. v. 2. 5.)—Claph and order, Didynamia Gymnosperm. Nat. Ord. Perticillate, Linn. Labiata, Juff.

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, flariated, crect, permanent, with five awl-shaped, acute, nearly equal teeth; the mouth naked. Car. of one petal, ringent; tube cylindrical, the length of the calyx; upper lip nearly erect, oblong, slightly convex, rounded, scarcely notched; lower lip much the largest, widely spreading, channelled, three-lobed; the lateral lobes semi-elliptical; the middle one longest. Stam. Filaments four, awl-shaped, dilant, various in length; two of them shorter than the rest; anthers with two parallel cells. Pfl. Germin superiour, four-crest; style bristle-shaped, rather shorter than the corolla; ligmas two, spreading, acute. Peric. none, except the permanent calyx. Seeds four, roundish.

Ell. Ch. Calyx five-crest. Middle segment of the lower lip of the corolla longer than the rest. Stamens distant. Anthers with parallel cells.

Obf. This genus seems to differ from Satureja principally in the form of its corolla. The species, as far as we know, are all American.

1. P. incanum. Hoary Tufted Savory. Michaux v. 2. 7. Pursh n. 1. Ait. n. 1. (Chinopodium incanum; Linn. Sp. Pl. 822. Willd. Sp. Pl. v. 3. 132. C. menthe folio, incanum et odoratum; Dill. Elliot. 87. t. 74. C. Serpentina dictum, &c.; Pluk. Mant. 51. t. 344. f. 1.)—Leaves oblong-ovate, aige, slightly ferrated, downy. Heads compound; the lateral ones flakled. Braegeae falcatae.—Found in low fields and copses, from Virginia to Carolina; flowering from July to October. It was cultivated in Sheard's garden at Eltham before the year 1732, but has scarcely been attended to by recent amateurs. The roots is perennial. Stem three feet high, erect, somewhat branched, leafy, bluntly quadrangular. Leaves about two inches long, on short flakles; their under side moat hoary or downy. Flowers white, tinged with red, in dense flaked hoary whorls, with a terminal head; their inner braeageae bristle-shaped. The whole herb is clothed with fine soft pubescence; the leaves marked with pellucid dots; their scent aromatic, partaking of the common, as well as sweet, Marjoram.

2. P. arifolatum. Brilly Tufted Savory. Michaux v. 2. 8. t. 33. Pursh n. 2. Ait. n. 2. (Nepeta virginica; Linn. Sp. Pl. 799. Willd. Sp. Pl. v. 3. 56. Chinopodium amaraci folio, flore albo; Pluk. Phyt. t. 85. f. 2.)—Leaves ovato-lanceolate, somewhat hoary, slightly ferrated. Heads ferrile. Braegeae and calyx avned.—Native of dry woods, on a limestone soil, from Maryland to Carolina, flowering in July and August. Miller appears to have cultivated this species in 1752. It is perennial, with altogether the herbage and aspect of an Originum. The leaves are not an inch long, nearly ferrile, dotted, veiny, thick-edged, very minutely, and scarcely perceptibly, hoary. Flowers white, small, in numerous, dense, terminal, hoary, compound heads. Braegeae lanceolate, entire, with long, rigid, awn-like points.

3. P. montanum. Mountain Tufted Savory. Michaux v. 2. 8. Pursh n. 3.—Leaves ovulo-lanceolate, ferrile. Heads ferrile. Calyxes crowded, erect, with short bristles.—Native of high mountains in Carolina; according to Michaux, the only person who appears to have gathered this plant. The flowers and part of the rest of the herb, are usually tinged with purple. We have seen neither specimen nor figure.

4. P. Monarda. Monarda Tufted Savory. Michaux v. 2. 8. t. 24. Pursh n. 4. (Origanum incanum; Walter Carol. 165.)—Somewhat hairy. Leaves ovate, taper-pointed, ferrated. Outer braeageae ovate, coloured, longer than the flowers; inner lanceolate, fringed. Calyx bearded. —Found on the mountains of Virginia and Carolina, but as yet a stranger to our gardens. It flowers from June to August, and is perennial. The habit of the plant, and its coloured braeageae, resemble Monarda filifolia. The flowers are small, and pale red, according to Mr. Pursh, on whom we depend for the synonym of Walter.

5. P. linifolium. Flax-leaved Tufted Savory. Pursh n. 5. Ait. n. 2. (Brachylytemum virginicum; Michaux v. 2. 6. B. linifolium; Wildl. Enum. 623. Thymus virginicus; Linn. Syll. Veg. ed. 13. 453. Wildl. Sp. Pl. v. 3. 145. Satureja virginiana; Linn. Sp. Pl. 753. Herm. Parad. 218. t. 218. Pulegium virginianum anguifolium, &c.; Pluk. Phyt. t. 54. f. 2.)—Stem erect, much branched, corymbose, roughish. Leaves lanceolate, entire. Heads crowded, nearly globular. Braeageae ovate, fringed.—Found in rather dry and mountainous meadows of North America, from New England to Carolina, flowering in July and August. Miller had it in cultivation in the year 1739, and it is still preferred in curious gardens, being a tolerably hardy, somewhat shrubby, perennial, of a bushy corymbose habit, about eighteen inches or two feet high. The whole plant smells strongly of Penny-royal. The flowers is square, pale, downy chiefly at the angles; its upper branches rising all nearly to a level, and forming a corymbus of numerous, globose or hemispherical, downy heads, of small white flowers. The braeageae are numerous, all ovate; the outer ones large, the inner very downy. Such is the plant intended by Linneus under the above synonym, and which is perhaps rather the P. lanceolatum of Pursh, than his linifolium. In the latter the flowers are longer than the corolla; in the former they are shorter; but this is evidently, as in Mints, a variable circumstance; and therefore the Pycanthemum and Brachylytemum of Michaux, are certainly one and the same genus. We are confident also that there is no specific difference between Pursh's and Wildenow's linifolium and lanceolatum.

Sect. 2. Stamens within the tube. Brachylytemum of Michaux.

6. P. muticum. Pointed Tufted Savory. Pursh n. 7. (Brachylytemum muticum; Michaux v. 2. 6. t. 32.)—Leaves ovate, pointed, smoothish, somewhat ferrate. Heads terminal, ferrile, solitary. Braegeae lanceolate, acid; aholiefs.—Gathered by Michaux in Upper Carolina. Mr. Pursh never found this species. The former writer is incorrect in his definition of the leaves, which are by no means "lanceolate-oval," nor are they "dentate," but truly ferrate, at least in his plate. The heads bear some resemblance to those of our fifth species, but are less globose.

7. P. verticillatum. Whorled Tufted Savory. Pursh n. 8. (Brachylytemum verticillatum; Michaux v. 2. 6. t. 31. Originum chinopodiodea; Walt. Carol. 165.)—Leaves ovate, pointed, entire. Flowers capitate and whorled. Braegeae lanceolate, pointed.—Native of mountains in North America, from Pennsylvania to Carolina, flowering
PYCNITE, in Mineralogy, is the mineral called schinite by Klaproth, leucolite by Daubenton, and schorlous beryl by Werner, who first classed it as a subspecies of beryl. It is now arranged with the topaz, to which it is constitutionally more related. It is commonly found in granite rocks. Small four-sided prisms may be obtained by a careful mechanical division from the large crystals; the bases of these are rhombic with angles of 120° and 60°. Bucholz considers this to be the primitive form of pycnite. The colour of this mineral is usually a light yellow, passing on one side from greyish and yellowish-white to straw-yellow, or from reddish-white to a pale brown and crimson red. Some specimens are marked with spots of violet blue. The crystals are translucent. The clefts are imperfectly foliated, the longitudinal imperfectly small conchoideal. It is harder than quartz, which it scratches, but it is readily broken in a direction perpendicular to the axis of the crystals. Its specific gravity is 3.61.

By the analysis of Vauquelin, pycnite contains:

Bucholz makes the proportion of fluoric acid 17 per cent.

There is no clear difference in the proportion of fluoric acid in different specimens of the topaz, as given by Klaproth and Vauquelin. See TOPAZ B.

PYCNON. See SPIRUS.

PYCNOTYL, *pynx*, formed from *pynx*, chest, and *-style*, a column in the Ancient Architecture, a building where the columns stand very close to one another; one diameter and a half of the column being allowed for the intercolumniation.

The pycnotyle is the smallest of all the intercolumniations mentioned by Vitruvius. Some make it the same with *fyllio*; others distinguish it by its allowing half a module more in the Corinthian intercolumniation.

The pycnotyle, Mr. Evelyn observes, chiefly belonged to the Composite order, and was used before the most magnificent buildings; as at present, in the peristyle of St. Peter's at Rome, consisting of near three hundred columns; and such as yet remain of the ancients among the late discovered sites of Palmyra.

PYCNOTICS, Ingrains, or medicines of an aqueous nature, which have the faculty of cooling and condensing, or thickening, the humours.

The word, in its original Greek, *pygonikon*, signifies something that has the power of thickening.

Purifane, the nemaphur or water-lily, *lotus, &c.* are ranked among pycnotics.

PYDNA, in Ancient Geography, a town of Macedon, in Pieria, on the coast of the Thermaean gulf, some miles N. of the river ALambda. It was near this town that the Romans gained over Perusus the battle which terminated the kingdom of Macedonia. Steph. Byz. calls it Cyno. - Allo, a town of the Rhodians. - Allo, a mountain of the island of Creta. - Allo, a town of Asia, in Phrygia, in the vicinity of Mount Ida.

PYF, in English Antiquity. See PICA

PYF, in Mechanics. See CRAB.

PYF, in Ornithology. See PICA.

PYF, Sea. See PICA MARINA.

Pye's Islands, in Geography, a cluster of small islands in the North Pacific ocean, near the W. coast of North America. The southerly forms in various appearances, E. long. 210° 21'.

PYGAIA, in the Materia Medica, a name by which some authors have called the isopenaun or nemaphor In- dian root.

PYGERGA, in Zoology, a species of *Antelope*; which see.

PYGARGITES, in Natural History, a name given by Pliny and some other of the old writers to the eagle-bone, when it was variegated with white, in the manner of the tail of the eagle, called *pygargus*.

PYGARGUS, in Ornithology, a species of eagle, called also by some authors *albicilla*, and *birundinaria*. Linnaeus has classed this bird among the vultures, calling it *volat albicilla*; because its bill is rather straighter than is usual in the eagle; but Mr. Pennant observes, that it has no claim to be ranked with that genus, because the pygargus is wholly feathered; whereas the characteristic mark of the vulture is, that the head and neck are either quite bare, or only covered with down.

It is a large and fierce bird, of the size of the common turkey; its beak is yellow, and covered with a yellow membrane at its base; it has large hazel-coloured eyes; its feet are yellow; and its claws extremely strong and sharp; the head is white, and there are no feathers, but some fine hairs between the eyes and nostrils; the upper part of the neck is of a reddish-brown, and the rump black; all the body above this is of an obscure, dull colour, and its wings are partly black, partly grey; its tail is long, and the upper half of it is white, and the rest black. It is from this white part that it has its name *albicilla*. The male is of a darker colour than the female. This bird inhabits Scotland and the Orkneys, and feeds on fish as well as on land animals.

Authors who have written on this subject seem not at all agreed to call the same bird by this name. The pygargus of Aldrovand seems different from this, and the pygargus prior of Bellonnus seems no other than the male of that kind of hawk, called in English the hen-barrow.

Mr. Willughby imagines his first pygargus, p. 61., to be only a variety of the white-tailed eagle, having the fame charac-
characteristic mark, and differing only in the pale colour of the head.

Pygargus Accipiter, a name by which many authors have called the fubhuteo, a bird of the hawk kind; the male of which is called in English the hen-harrier, and the female fupposed by some to be the ring-tail. See Falco.

Pygela, in Ancient Geography, a town of Afa Minor, in Ionia, where was a temple of Venus Manychian, according to Strabo and Steph. Byz.

Pygme, ρυγμης, the length, or extent, between the elbow, and extremity of the hand, the fill being shut; called also a cubit.

Pygmy, Pygmaeus, ρυγμαιος, formed of ρυγμης cubit, a dwarf, or perion of exceeding small stature, not exceeding a cubit in height. See Dwarf.

The appellation is given among the ancients to a fabulous nation, said to have inhabited Thrace; who generated and brought forth young at five years of age, and were old at eight; famous for the bloody wars they waged with the cranes.

Pygmy Apes, in Zoology. See Simia Sylvana.

Pyha, in Geography, a large lake of Sweden, in the province of Savolax, N.E. of lake Saima, and communicating with it.—Alfo, a river of Sweden, which runs into the gulf of Bothnia, at Brahefled.

Pyhajarvi, a town of Sweden, in the province of Nyland; 34 miles N.W. of Helsingfors.

Pyhajoki, a town of Sweden, in East Bothnia, near the sea coast; 10 miles S.S.W. of Brahefled.

Pyhamaa, a small island in the gulf of Bothnia, on a peninsular of the coast of Finland. N. lat. 69° 59'. E. long. 21° 12'.

Pykheus, a town of Bengal; 52 miles S.E. of Pucculoe.

Pyker, or Pykar, in our Writers, a small ship or herring boat.

Pyla, in Geography, a town of the duchy of Warsaw; 48 miles N. of Pofen.—Alfo, a river of England, in Monmouthshire, which runs into the Olwy; 2 miles N.E. of Ulk.

Pylandes, in Biography. See Bathylus, Hyla, Mime, and Pantomine.

Pylez Persides, in Ancient Geography, a famous ftrait in Asia, between the Perife and Sufiana, according to Diodorus Siculus. This ftrait is named Portæ Perife by Strabo, and Pyle Sufiades by Arrian.

Pylez Sarmatice. Sarmatia is bounded on the S. by mount Caucrus, which separates it from the neighbouring countries. Ptolemy speaks of two ftrifes or palfages in this famous mountain; one called Portæ Caucrus, which affords entrance into Siberia; the other named Pylez Albanize, and gives entrance into Albania.

Pylea, a town of Macedonia, in Trachinia, situated at the foot of mount Oeta, according to Philostratus. This gave name to the Pylican gulf, mentioned by Strabo.

Pylea, νολαια, in Antiquity, a name given to the affembly of the Amphiytions, as well when they met at Delphi as at Thermopyle. The concourse of people at these affembles was so great, that the term pylea came to be used for any very numerous affembly, or crowd of people. Mem. Acad. Infr. vol. iv. p. 287. 290.

Pylagore, Παλαγόρης, a name given to the Amphiytions, because they afsembled at Thermopyle, or Pyike.

Pylau, in Geography, a town of Prussia; 18 miles S. of Königsberg.

Pyle, Thomas, in Biography, was born at Stodey, near Holt, in Norfolk, in the year 1674. He received his academical education at Caius college, Cambridge, where he took his degrees, and became an excellent scholar. When inducted to the church, he discharged all the duties attaching to his situation as curate with the most conscientious integrity. His great aim was to amend and improve his hearers, and his discourses and urgent manner gained him the attention for which he was anxious. In early life he took part in the Bangorian controversy, and acquitted himself so much to the satisfaction of bishop Headly, that his lordship presented him with a prebend, and procured for him a redulatoryship in the cathedral church of Salisbury, and likewise made his two sons prebendaries of Winchellera. He died in his 84th year. He was greatly admired as a preacher, and no less so as a faithful friend, an agreeable companion, a man of the most liberal sentiments, and so free from all pride and conceit of his own abilities, that he was apt to pay a deference to the opinions of many persons much inferior to himself. Archbishop Herring speaks of him as a worthy man, but who had not at all times the proper government of his own temper. He was author of several works: as "A Paraphrase, with Notes, on the Acts of the Apostles, and Epistles," being a supplement to Dr. Clarke's Paraphrase on the Four Gospels: "The Scripture Preservative against Popery; being a Paraphrase, with Notes, on the Revelation of St. John." He published also, between the years 1715 and 1725, "A Paraphrase, with short and useful Notes, on the Books of the Old Testament." In 1773, his friends published two vols. of posthumous sermons, to which, in 1783, a third was added. Though these sermons want the care and polish of finished compositions, they are reckoned interesting and highly useful family discourses.

Pyle-Rudbar, in Geography, a town of Peria, in the province of Ghilan; 32 miles S. of Rehld.

Pyling the Ground for Foundations. See Foundation, and Pallification.

Pyloric Artery and Vein, in Anatomy, are blood vessels belonging to the stomach. See Stomach.

Pylorus, the circular ring by which the stomach communicates with the small intestine. See Stomach.

Pylstart, in Geography, an island in the South Pacific ocean, about six miles in circumference, discovered by Tasman in 1643. It presents to view two lofty hills, which seem separated from each other by a low valley; it is called by Maurelle "La Sola." S. lat. 22° 22', W. long. 175° 59'.

Pylus Melfinent, now Nauvarin, in Ancient Geography, was situated on the western coast of Melfenia, over-again the island of Asina.

Pylus (Lonchion), or Avarino Vecio, a town of Melfenia, upon the sea-coast, S.E. of Platamodes.

Pylus Alivanus, a town of Triphylia, N.W. of Onus, upon the Ladon.

Pymatuning, in Geography, a town of America, in Mercer county, Pennsylvania; 23 miles W.S.W. of Fort Franklin. It contains 376 inhabitants.

Pynaer, Adam, in Biography, a landscape painter, was born at the village of Pynaker, near Delft, in 1621. Whether his real name was that by which he is known or not, is not now to be ascertained. By an earneft study of the art, first in his native land, and afterwards at Rome, he acquired very considerable skill and celebrity. He generally exhibits brilliant effects of sunshine, in subjects not always happily felected, but executed with great fineness, purity, and taste. In his pictures we frequently see ruins of elegant and antique buildings, and figures well adapted to the scenery.
PYR

feenere. In general his pictures are of a small size, and are rather scarce. He died in 1673, at the age of 52.

PYNANG, in Botany, a name by which some authors call the faule, or area-coarse; a kind of palm, from the ex-
pressed juice of which the drug commonly, but improperly,

PYNY, in Geography, a town of Hindooftan, in Coim-

PYONY Water. See Water.

PYRACANTHA, in Botany, a name given by some
authors to the lyceum, or box-thorn.

PYRÆA, or PYRETHEA, among the Eastern Nations
of Antiquity, were great infidues uncored, and dedi-
cated to the sun, in which a perpetual fire was kept up in
honour of this luminary, which was worshipped by moil
of them. See CHAMAN.

PYRALIS, the fire-fly, a name given by authors to a
fupposed infect, which they say is produced in the violent
fires of the glafs and metal furnaces. Thin. lib. ii. c. xxxvi.

PYRAMID, ψωςως, in Geometry, a solid standing on a
square, triangular, or polygonal basis, and terminating at
top in a point; or a body whose base is a regular rectilinear
figure, and whose sides are plain triangles; their several ve-
tices meeting together in one point.

Euclid defines it a solid figure, confiding of three trian-
gles whose bases are all in the plane same, and have one
common vertex.

Wolfius defines it a solid, bounded by as many triangles,
A D C, D C B, and A D B, terminating in one point D,
as the base A B C has fides. Plate XI. Geometry, fig. 18.
The pyramid is faid to be triangular, quadrangular, quadra-
gonular, &c. according as the base is triangular, quadrangu-
lar, &c. The pyramid may be called a square, triangular,
&c. cone; or the cone a round pyramid.

PYRAMID, Properties of the. 1. All pyramids and cones
standing on the same base, and having the fame altitude, are
demonstrated to be equal.

2. A triangular pyramid is the third part of a prifm,
standing on the fame base, and of the fame altitude.

3. Hence, fince every multangular may be divided into
triangulars, every pyramid is the third part of a prifm,
standing on the fame basis, and of the fame altitude.

4. If a pyramid be cut by a plane, a b c, parallel to its base,
A B C, the former plane, or bafe, will be similar to the latter.

5. All pyramids, prifms, cylinders, &c. are in a ratio
compounded of their bases and altitudes: the bafes, there-
fore, being equal, they are in proportion to their altitudes;
and the altitudes being equal, they are in proportion to
their bafes.

6. Similar pyramids, prifms, cylinders, cones, &c. are in
a triplicate ratio of their homologous fides.

7. Equal pyramids, &c. reciprocate their bafes and alti-

dates; i.e. the altitude of the one is to that of the other,
as the bafe of this to the bafe of that.

8. A sphere is equal to a pyramid, whose bafe is equal
to the surface, and its height to the radius of the sphere.

PYRAMID, to measure the surface and solidity of. A. Find
the bolidy of a prifm that has the fame bafe and height
with the given pyramid. And divide this by three; the
quotient will be the bolidy of the pyramid. Or, multiply
the bafe by the perpendicular height; and one-third of the
product will be the content.

Suppofe, ι. gr. the bolidy of the prifm be found
6710328, the bolidy of the pyramid will be thus found
22336776.

PYR

The surface of a pyramid is had, by finding the areas,
both of a base, A B C, and of the lateral triangles, A C D,
B D, D B A. (See Triangles.) The sum of thefe is the
area of the pyramid.

The external surface of a right pyramid, standing on a
regular polygonal bafe, is equal to the altitude of one of
the triangles which compose it, multiplied by the whole
circumference of the bafe of the pyramid.

PYRAMID on a plane, to describe a. 1. Draw the bafe,
η. gr. the triangle A B C (if the pyramid required be tri-
gerangular); fo as that the fide A B, fupposed to be turned
behind, be not expreffed. 2. On A C and C B, confruct
the triangles A D C and C D B, meeting in any affumed
or determined point, η. gr. D; and draw A D, C D, B D;
then will A D B C be a triangular pyramid.

PYRAMID of pole-board, &c. to conftruct a. Suppofe,
in. gr. a triangular pyramid required. 1. With the radius
A B describe an arc BE (fig. 19.); and to this are apply
two equal chords, B C, C D, and D E. 2. On C D con-
fruct an equilaterial triangle, D F C, and draw the right
lines A D and A C. This pole-board, &c. being cut off
by the contour of the figure, what remains within will
turn up into a pyramid.

PYRAMID, Truncated. See Truncated.

PYRAMID, Frustum of a. See Frustum.

PYRAMID, in Architecture, denotes a solid, maffive edifice
which, from a square, triangular, or other bafe, rifes dimin-
ishing to a point, or vertex.

Some derive the word from ψωςος, wheat, and σως,
calling; pretending that the firft pyramids were built by the
patriarch Joseph, for granaries. But Villalpandus, with
much better reafon, derives the word from ψις, fire; be-
cause of their ending in a point like flame.

Wilkins, coventiant with the Coptic tongue, fuggefts
(Diff. de Ling. Copt.) another derivation from that lan-
guage, in which ψαυρος signifies a king, and ψαυς,
meaning; pretending that the firft pyramids were thus called,
becaufe they were erected to preferve the memories of the
Egyptian kings and their families; and that thofe who de-
scended from them had recourfe to thefe pillars in order to
prove their pedigree.

When they are very narrow at bottom, i. e. their bafe
very small, they are called obelisks, and needles.

Pyramids are fometimes erected to preferve the memory
of fingular events, and, fometimes, to tranfmit to posterity
the glory and magnificence of princes; but, as they are the
symbols of immortality, they are more commonly used
as funerar monuments.

Such is that of Cefius at Rome, the maufoloeum of this
fufliiered Roman, who was one of the seven officers
called Epulones, and is faid to have lived under Augustus,
repaired in 1673, by Alexander VII. and thofe other
celebrated ones of Egypt, as famous for their size as
their antiquity; and reckoned by the ancients among the
wonders of the world.

These laft are all fquare in their bases; and it is a thing
that has been frequently propofed, to eftablfh a fixed mea-
Sure from them, to be thereby tranfmitted to posterity.
See their defcriptions, meafures, &c. in Thevenot, Pietro
della Valle, Greaves, Pococke, Shaw, Perry, Mallet, Sa-
vary, &c. The pyramids of Egypt, comprehending the
great and small, are very numerous; of thefe there are about
twenty of the largest size. The moft remarkable are the
three pyramids of Memphis, or, as they are now called, of
Ghefsi, Geeza, or Gizé. The dimensions of thefe have been
differently flated both by ancient and

modern
PYRAMID.

modern writers. Herodotus (lib. ii.) makes the bafe of it to be 800 Grecian feet long; Diodorus (lib. i.) 700; Strabo (lib. xvii.) less than 600; and Pliny (lib. xxxvi. c. 12.) 883 feet. Among the moderns, Sсид found it to be 300 paces; Bellonius 324; Greaves 693 English feet; Le Brun 704 French feet, or 750 English feet; Prosper Alpinus 750 French feet; Thevenot 682; Niebuhr 710; Chazelles 704.80 English feet. In order to reconcile these differences, Dr. Shaw observes, that none of the sides of this pyramid are exactly upon a level; so that it is difficult to find a true horizontal bafe; besides, it is impossible to say how much the drifts of sand, to which it is exposed, may have been accumulated above the foundation of it; and, therefore, all calculations depending upon the time and circumstances of the situation, when they were made, must be exceedingly precarious. The perpendicular altitude of it, according to Greaves, is 499 feet; but its oblique height is equal to the breadth of the bafe, or 693 feet. The whole area of the bafe contains 480,449 square feet, or 11,553.77 English acres. The height, according to Herodotus, is 800 French feet; according to Strabo 623; according to Diodorus Siculus 600 and a fraction; as stated by Le Brun 616; by Prosper Alpinus 625; by Thevenot 520; by Niebuhr 440. The ascent to the top of the pyramid is by steps, the lowermost being near four feet high and three broad; the second of the bafe dimensions, but retiring inward from the birt near three feet; and in the same manner the third row is placed upon the second, and the rest in the same order to the top, which terminates in a small flat or square; and they are so disposed, that a line stretched from the bottom to the top would touch the angle of every step. These steps are called by Herodotus little altars, on account of the borm; and their number has been variously affigned; Greaves states them at 207; Maillet at 286; Pococke at 212; Belon at 250; Thevenot at 208, and Chazelles at 499,222 English feet. For a description of the bide of this pyramid, we must refer to Greaves, Savary, &c. ubi infra.

This pyramid, being that already described, is situated on a rocky hill, in the sandy desert of Libya, about one quarter of a mile from the plains of Egypt, above which the rock rises 1000 feet or more, with a gentle and easy ascent. Upon this advantageous elevation, and bold bases, the pyramid is erected; the height of the situation adding to the beauty of the work, and the solidity of the work affording it a durable support.

We may here observe, that the sides of this pyramid stand exactly facing the four quarters of the world, and consequently mark the true meridian of the place; which specific position could not have been well owing to chance, but was probably, the effect of design and art; and this is said to be confirmed by the position of the tomb itself, which lies within it. We may hence infer that the Egyptians had made an early progress in astronomy.

The second pyramid stands at about a bow-shot from the first, towards the south of this. Herodotus states, after having measured both, that it falls short of the other in magnitude; that it has no subterraneous chambers, and that the Nile is not conveyed into it by a channel, as into the former, but that it is of an equal altitude. Diodorus informs us, that it resembles the first in its architecture, but is inferior to it in magnitude; each side of the base containing a stadium, or 600 Grecian feet in length, so that by his computation each side is less than that of the former in length by 100 feet. Pliny makes it but 631 feet square. Strabo supposes these pyramids to be equal, and Greaves affures us, that the bafes of both are alike, and that the height is not inferior to that of the first. This pyramid has no entrance like the other, and is built of white stones, not far to so large, as those of the first: the sides do not rise with gradations, but are smooth and equal, and the whole fabric, except on the south side, is quite entire. On the N. and W. sides of this second pyramid are two very flatly and elaborate pieces of architecture, about 30 feet in depth, and about 1400 in length, cut out of the rock in a perpendicular direction and squared by a chisel; supposed to be designed for the lodgings of the Egyptian priests.

The third pyramid stands at about the distance of a furlong from the second, on an advantageous rising of the rock, so that at a distance it appears equal to the former, though it be much less and lower. Herodotus says that it is 350 feet on every side, and to the middle, built of Ethic marble. Diodorus gives the same dimensions of its bafe, and adds that the walls were raised fifteen stories with black stone, like Thebas marble, and the rest finished with such materials as the other pyramids are built with; that this piece of work, though it be exceeded by the two former in magnitude, yet far excels them in respect to the furniture, art, and magnificence of the marble; and that the side towards the north, the name of Mycerinus, the founder, is engraved; but the inscription has been defaced by time. Pliny writes to the same effect, except that he makes this pyramid 563 feet between the angles.

Dr. Shaw apprehends, that neither of these pyramids was ever finished, supposing that the steps already mentioned should have been filled up with prismatical stones, so that each side of the pyramid might be smooth and level, like that of Celsus at Rome.

But from the description of Maillet and Savary, the first pyramid appears to have been covered with a coating of marble, and thus finished on the outside, but clofed; and that it has been since forcibly opened, and the stones which but the passage and were of an enormous size have been removed. This passage was composed of marble, and the stones which form their four sides are of the finest white and hardest marble. For other particulars we refer to Greaves, Maillet, and Savary.

The ancients inform us, that the stones of the pyramids were brought from the mountains of Arabia, and Herodotus (lib. ii. c. 124.) has described the manner in which they were conveyed; but Dr. Shaw imagines, that they were taken from the spot where they were employed; and he observes, that the greater part of them, especially, is not an entire heap of hewn stones, because that portion of it, which lies below the horizontal section of the entrance, may probably be no more than an incrustation of the natural rock on which it is founded. Dr. Bryant conjectures, that, like the sphynx, which stands direfly in the front of the second pyramid, they were immense rocks which stood upon the brow of the mountain; that the Egyptians caused them over with large stones, and brought them by these means to a degree of symmetry and proportion. At the same time they filled up the unnecessary interfaces with rubbish and mortar, and made chambers and apartments, as the intervals in the rock allowed, being obliged to humour the indirect turns and openings in the original maps to execute what they proposed. This he infers from the narrowness and unnecessary sloping of the passages, which are often very close and deep, and also from the fewness of the rooms in a work of so immense a structure. That the pyramids were built upon a rock in the place where they
PYRAMID.

now stand, was suggested by Mr. Hooke. See Birch's Hist. Royal Society, vol. iv, p. 245.
It is very surprising that the pyramids, which have been reckoned among the wonders of the world, should not have preferred a more certain era, and tradition of the names of their founders. Pliny reckons a number of authors who have wrote concerning them; and all, he informs us, disaffire in their accounts of those who built them. Some modern writers maintain, that they were erected by the Egyptians, under the tyranny of the Pharaohs, and alleges to this purpose the testimony of Josephus, Antiq. lib. i., cap. 5.

According to the relations of Herodotus (lib. ii.), and Diodorus (lib. i.), the first pyramid was erected by Cheops, or Cheimarion, a king of Egypt, who is said to have employed three hundred and sixty thousand men for twenty years in the structure. Cepheres, brother and successor to the former king, is said to be the founder of the second pyramid; and the third is said to have been built by Mycerinus, the son of Chemmis, according to Diodorus, but according to Herodotus, of Cheops. However, Herodotus says, that some ascribed the fault to Rhodore, a courtier, and the other two to the shepherd Philission. The learned Greaves places the three kings who erected these pyramids in the twentieth dynasty; Cheops having begun his reign in the year 3448 of the Julian period, 460 years before the first olympiad, and 1266 years before the Christian era. He reigned fifty years, says Herodotus, and built this pyramid, as Diodorus observes, 1000 years before his time, or in the 180th olympiad; whereas, he might have died 1207. Cepheres, the builder of the second, reigned fifty-six years; and Mycerinus, the builder of the third, seven years.

Dr. Bryant gives a different account of the origin of these pyramids: he ascribes the structure to them of the Cuthites (see Dispersion of Mankind), or Arabian shepherds, who built Heliopolis, and who were the giants and Titans of the first age. These sons of Chus, according to this writer, seem to have come into Egypt immediately after their dispersion from Babel.

Many have considered these ancient structures with contempt, as being vast piles without any great symmetry, and have thought the labour idle, and the expense unnecessary. Thus Pliny (lib. xxxvi. cap. 12.) calls them regum pecunia attribuata ad fluenta orientalia, &c., built for ostentation, to keep an idle people employed, and to prevent commotion and rebellion. Aristotle (Polit. lib. iii.) calls them the work of tyranny.

The general opinion with regard to their intention and use is, that they were sepulchres and monuments of the dead, particularly of kings. This is expressly affirmed by Diodorus (lib. i.), and Strabo (lib. xvii.), and the opinion is confirmed by the writings of the Arabs. And the reason, says Greaves, of their erecting these magnificent structures is founded in the theology of the Egyptians, who, as Servius shews in his comment upon Virgil (Aeneid, lib. iii.), where he describes the funeral of Polydorus—Animamque sepulcro continuam—believed, that as long as the body endured, so long the soul continued with it; and this was also the opinion of the Stoics. Upon this principle, that the bodies might neither be reduced to dust by putrefaction, nor converted into ashes by fire, they embalmed them, and laid them up in these flately repositories, where they might continue free from the injury of time and of men. The reason of their building these sepulchres in the form of pyramids, was either from a notion that this was the most permanent form of structure, or because they hereby intended to represent some of their gods: particularly, as Greaves conjectures, Osiris, or the funer with many rays; for, under this form, the statues of the gods were frequently exhibited, and the gods themselves worshipped.

Among the Egyptians, the pyramid is said to have been a symbol of human life; the beginning of which is represented by the base, and the end by the apex; on which account it was that they used to erect them on sepulchres.

Herodotus.

Some, however, have objected to this design of the Egyptian pyramids, and are of opinion that they were originally intended for some nobler purpose. If Cheops, or any other person, says Dr. Shaw, who was the founder of the great pyramid, intended it only for his sepulchre, what occasion was there for such a narrow crooked entrance into it? for the well, as it is called, at the end of the entrance; for the lower chamber, with a large niche or hole in the eastern wall of it; for the long narrow cavities in the walls of the upper room; or, for the two antechambers and the lofty gallery, with benches on each side that introduce us into it.

As the whole of the Egyptian theology was clothed in mysterious emblems and figures, it seems reasonable to suppose, says this writer, that all these turnings, apartments, and secrets in architecture were designed for some purpose of religion, and that the Deity, which was typified in the outward form of this pile, was to be worshipped within. The square cell of granite marble, which is placed in the upper chamber of the great pyramid, may be supposed to have been rather intended for some religious use than for the coffin of Cheops. It might have served for one of their sacred chells, in which either the images of their deities, or their sacred vestments or utensils were kept, or it might have been a sepulchre or cistern, such as contained the holy water used in their ceremonies. Its length favours the opinion of its having been designed for a coffin, but its height and breadth far exceed the dimensions that were adhered to on such occasions; the Egyptian stone coffins were made of a different form, and inscribed with hieroglyphs. Nor is this cell placed according to the manner in which the Egyptians deposit their dead; for their mummies always stand upright, whereas this cell is laid flat upon the floor. If, therefore, this cell was not intended for a coffin, it is inferred that the pyramid itself could not have taken the name of a sepulchre from it. Cheops, indeed, and others might have been buried within the precinct of this or any other of the pyramids, and this was no more than was practised in other temples, and therefore could not destroy the principal use and design for which they were erected. Upon the whole, Dr. Shaw concludes, from the outward figure of these piles, the structure and contrivance of the several apartments in the inside of the greatest, together with the ample provision that was made on each side of it for the reception, as may be supposed, of the priests, that the Egyptians intended the latter for one of the places, as all of them were to be the objects, at least, of their worship and devotion.

Dr. Bryant has lately maintained, with considerable force of argument and reason, this opinion, that the pyramids were designed for high altars and temples, and were constructed in honour of the Deity. If the chief pyramid were designed for a place of burial, what occasion, says he, was there for a well, and for passages of communication, which led to other buildings? The apartments near the pyramids he supposes to have been designed for the reception of priests, and to be appendages not to a tomb, but to a temple of the Deity.
The stone coffin, he apprehends, was a trough or reservoir for water, which, by means of the well, they drew from the Nile. The priests of Egypt delighted in obscurity, and they probably came by the subterraneous passages of the building to the dark chambers within; where they performed their hallucinations, and other nocturnal rites. Many, he adds, of the ancient temples in this country were caverns in the rock, enlarged by art, and cut out into numberless dreary apartments; for no nation upon the earth was so addicted to gloom and melancholy as the Egyptians. From the top of the pyramids they observed the heavens, and marked the constellations; and upon the same eminence it is probable that they offered up vows and oblations. See on this article Graves's Works, vol. i. p. 1, &c. Shaw's Travels, fol. p. 413, &c. Pococke's Description of the East, vol. i. p. 41, &c. Perry's View of the Levant, p. 413, &c. Bryant's Anal. of Ancient Mythol. vol. iii. p. 523, &c. Farmer's Worship of Human Spirits, &c. p. 379, &c. Savary's Letters, vol. 1.

The tomb of Porfenna, king of Etruria, at Clusium in Italy, is an ancient monument of marble stone, each side of which is three hundred feet broad, and fifty feet high. Within the square base there is an inextricable labyrinth; upon this square there stand five pyramids, four in the angles and one in the middle, seventy-five feet broad at the bottom, and a hundred and fifty feet high, and terminating in a point; at top they are covered with a brass circle, which from are suspended bells, which are put in motion by the wind, so as that their sound may be heard at a great distance. Upon this circle there are four other pyramids, each a hundred feet high, above which, upon one plane, there are five other pyramids. Such is the account which Pliny gives from Varro, lib. xxxvi. cap. 13.

Pyramid, Optic. See Optic Pyramid.
Pyramidal Fountain. See Fountain.
Pyramidal Mirror. See Mirror.
Pyramidal Numbers are the sums of polygonal numbers, collected after the same manner as the polygonal numbers themselves are extracted from arithmetical progressions. See Numbers.

These are particularly called first pyramids. The sums of first pyramidals are called second pyramidals. And the sums of those third pyramidals; and so on, ad infinitum. Particularly, those arising from triangular numbers are called prime triangular pyramidals; those arising from pentagonal numbers are called prime pentagonal pyramidals, &c. The numbers 1, 4, 10, 20, 35, &c. formed by the addition of the triangular numbers 1, 3, 6, 10, &c. are actually called by the simple name of pyramidals; and the general formula for finding them is \( n \times \frac{n-1}{2} \times \frac{n-2}{3} \); i.e. the fourth pyramidal may be found by substituting 4 for \( n \); the fifth, by substituting 5 for \( n \), &c.

Pyramidalia Corpora, in Anatomy, two prominences in the medulla oblongata. See Brain, and Nervous System.

Pyramidalis Abdominis, one of the abdominal muscles. See Oblique.

Pyramidalis Nefi, a name given by some anatomists to that portion of muscular fibres which descend from the fronto-occipitals along the side of the nose. See Epigraанию.

Pyramidoïd, called also parabolic spindle, a solid figure, formed by the revolution of a semiparabola round one of its ordinates.

According to the method of indivisibles, this may be conceived to consist of an infinite series of circles, whose diameters are all parallel to the axis of the revolving parabola.

The parabolic spindle is equal to \( \pi \) times its circumference cylinder. See Spindle.

Pyramidoïd, Parabolic. See Parabolic Pyramidoïd.
Pyramids, in Geography, rocks in the East Indian sea, near the E. coast of the island of Myof. S. lat. \( 55° \); E. long. \( 130° 59' \).

Pyramids, Ghizhi, in Ancient Geography, a river of Asia, rising in the country of Cataonia, where it begins to be navigable, and traversing mount Taurus through the rocks, it enters the plain of Cilicia, palls by the foot of the mountain of Anazarbus, and leaving it to the right, throws itself into Mopluete, and at a length holes itself in the Mediterranean, at the point where was formerly situated the town of Megara.

Pyraulm, in Geography, a town of Bavaria, and capital of a lordship united to Salzburg; 13 miles S.E. of Nuremberg.

Pyreneus Promontorium, Cape de Creus, in Ancient Geography, a promontory of Hispasia Citerior, which terminates the Pyrenees to the sea, and projects into the sea.

Pyreneus Saltus, a name given by Cornelius Nepos and Livy to that part of the Pyrenean mountains which Hannibal traversed in his way to Italy, passing from Spain to Gaul.

Pyrene, a town of Gallia Celtica, near the place where the Danube rises, according to Herodotus.

Pyrene, in Natural History, the name of a stone found always in the shape of the stone of an olive. It is of the lapis Judaicus kind, being no other than the petrifed spine of some species of echinates.

Pyreneès, in Geography, a chain of mountains, celebrated since the time of Herodotus, forming the boundaries between France and Spain, and extending from the Mediterranean to the Atlantic, about 200 miles in length, and in its greatest breadth 100 miles. Its various branches are distinguished by different names, and may be considered as belonging either to France or Spain. The highest summits of these mountains, which are in the centre of the chain, have preferred to the research of the naturalist not only calamitous appearances, but even labyrinths. The highest elevation of the Pyrenees is Mount Perdú, for an account of which, we refer to that article. The Canigou was formerly reckoned the highest summit, though it does not exceed 8,444 English feet. Other noted heights are Tucarroay, Marbore, the pic de Midi, 9,300 feet high, the pic de los Reyes, 7,620 feet high, the pic d'Ollano, 11,700 feet in height, the pic d'Arni, the Niege Veille, the Vigne Mali, La Breche de Roland, &c. At a distance the Pyrenean chain appears like a shaggy ridge, presenting the segment of a circle fronting France, and defending at each extremity till it disappears in the ocean and Mediterranean. Thus, at St. Jean de Luz, only high hills appear, and in like manner on the coast beyond the summit Canigou, the elevations gradually diminish. The highest summits are covered with perpetual snow. Blocks of granite are intermixed with vertical bands, argillaceous and calcareous, the latter primitive or secondary, and supplying the marbles of Campan and Antin, of beautiful red spotted with white, though the general mountain mass is grey. To the S. and W. the Pyrenees present nothing but a dreariness, but oh the N. and E. the descent is more gradual, and affords frequent woods and pastures. Besides the dreadful fall of rocks,
rocks, undermined by the waters, they are exposed to Lavanges, or the impetuous defects of vall mallek of snow, called Avalanches in Switzerland, and have their glaciers and other terrific features of the Alps.

The opinion of Ramond, that the summit of mont Perdu (which; fee) must have been covered by the sea, is confirmed by Lapérouse. (Journ. des Mines, N. 46.) A circular feature of the Pyrenees consists of boules, as they are called, or walls disposed in a circular form. Near the summit of mont Perdu is a considerable lake, more than 9000 feet above the level of the sea, which throws its waters to the E. into the Spanish valley of Beonna; and that the travellers allege as a proof that mont Perdu really belongs to Spain, and that Tuccarro forms the boundary. Lapérouse suggests it as probable that the sole access to the summit of mont Perdu will be found on the side of Spain; there being three summits called by the Spaniards "las Tres Sorrellas," or the Three Sisters; the highest being to the N., and the lowest on the S., but separated by large glaciers. Hence it bears the exclaim of chains of mountains, in which bands of granite, porphyry, trap, hornblende, and petriflare, alternate very straight with primitive limestone, and are so intermingled as to prove a common origin. But in the Pyrenees these bands are surmounted by secondary limestones, replete with marine spoils, and containing several skeletons of animals, so that he concludes that the highest mountains of the chain must have yielded to the fury of the ocean, and that the secondary parts only now exist. Mr. Townend (Spain, i. 59.) observes, that the lime-stone and schistus feed the vegetation on the N. of the Pyrenees, while the S. is barren, and consists of granite; while, in fact, mountains are generally barren and precipitous on the S. and W., because the most violent rains and tempests come from those regions. Pinkerton's Geog. vol. i.

The pillars across these mountains from one country to another are five; the three principal of which are from St. Sebastián to St. Jean de Luz; from Pamplona to St. Jean de Luz; and from Juncqueira to Perpignan. These mountains afford quantities of timber for flinging, which are conveyed, by means of the Ebro and other streams to the sea, with abundance of pitch and tar. The Pyrenees give name to three of the French departments.

Pyrenees, Upper, a department of France, in the Garonne region, formerly Bigorre, in N. lat. 43° 40' formerly Roussillon, bounded by the departments of the Arrieve and the Aude, on the E. by the Mediterranean, on the S. and W. by Spain; about 38 miles from E. to W., and from 18 to 25 from N. to S., or 28 Fr. leagues in length, and 15 in breadth, containing 43372 kilometres or 212 square leagues, and 177644 inhabitants; it is divided into 3 districts, 17 cantons, and 249 communes. The three districts are Perpignan, including 11961 inhabitants, Cerbè, 24750, and Prades, 41953. According to Hallenfraz, the number of circles is 3, of cantons 52, and of inhabitants 114,178. The contributions in the 11th year of the French era amounted to 1505,530 fr. and the expenses for administration, education, &c. to 181,061 fr. 87 cents.

The capital is Perpignan. This department is fertile in corn, wine, oil, flax, hemp, fruits, and pastures. On the hills there is little wood, but variety of medicinal plants and herbs. There are several lofty mountains on the S. and W. boundaries, as Maffane, Canjou, &c.

Pyrenees, Lower, a department of France, in the S.W., or Garonne region, composed of Barre, Navarre, Baque-Francois, with a part of Chalosse and of Landes, in N. lat. 43° 10', and bounded on the N. by the departments of the Landes and Gers, on the E. by the department of the Upper Pyrenees, on the S. by Spain, and on the W. by the sea; 70 miles in length, and from 15 to 45 in breadth, or 16 Fr. leagues in length and 10 in breadth. It contains 58725 kilometres, or 388 square leagues, and 384030 inhabitants. It is divided into 5 districts, 40 cantons, and 660 communes. The districts or circles are, Pau, including 99,486 inhabitants, Oyon, 69,484, Manon, 64,447, Bayonne, 69,484, and Orchis, 80,127. According to Hallenfraz, its circles are 6, its cantons 44, and the number of its inhabitants 358,339. Its capital is Pau. Its contributions in the 11th year of the French era amounted to 1523,760 fr. and its expenses for administration, &c. to 209,740 fr. 66 cents. This department, bounded on one side by the Pyrenees, and on the other by the ocean, presents a great variety of soil and diversity of prospect. The mountains are crowned with woods; the hills are covered with vines; the valleys are rich and populous; the heaths are wild and uncultivated. The plains yield wheat, rye, barley, oats, millet, flax, fruits, and pastures. It has mines of silver, copper, iron, quarries of marble, granite, slate, and mineral springs.

Pyrenoïdes Processus, in Anatomy, a procus of the second vertebra of the neck; called also odontoides, and dentiformis, or the tooth-like procus.

The word Pyrenus, is formed of πυρενος, nucleus, kernel, or berry, and πυρος, fire, figure.

Pyrethrum, in Botany, an ancient Greek name, adopted by Haller, Gartner, and the writer of the present article, who are followed by Willdenow and Aiton, for the genus in question, on account of its resemblance to the graduation of Dictyonurus. The latter is, however, the Anthurias Pyrethrum of modern writers, or Pellitory of Spain; owing its Greek appellation to the fiery or pungent flavour of the root; whence it obtained the Latin name of Salvia, because it caufes so remarkable a flow of saliva. Our present Pyrethrum is made up of several Linjane species of Cheiranthum and Malartic, with some new ones.—Haller Helvet. v. i. 10. Sm. Fl. Brit. 920. Willd. Sp. Pl. v. 3. 2150. Alt. Hort. Kew. v. 5. 97. Pursh v. 2. 527. Gartn. t. 169.—Clafes and order, Synge-nesia Polyganiacum-superflus. Nat. Ord. Compositae distiques, Linn. Corymbiferae, Jull.

Gen. Ch. Common Calfy hemispherical, imbricated; the scales close-pressed, rather acute, membranous at the edges. Cor. compound, radiated. Florets of the disk perfect, numerous,
PYRETHRUM.

numerous, tubular, funnel-shaped, with five spreading segments; those of the radius more than 12, female, ligulate, elliptic-oblong, three-toothed. Stem in the perfect florets. Filaments five, capillary, very short; anthers united into a cylinder, hardly so long as the corolla. Pif. German, in all the florets; obovate; style thread-shaped, longer than the stamens; stigmas two, divaricated, abrupt. Pericarp none, the calyx remaining unaltered. Seeds nearly sike in all the florets, oblong, quadrangular, each crowned with an erect, membranous, more or less lobed border. 

Section 1. Radius albite; rarely reddish.

1. P. frutescens. Shrubby Feverfew. Willd. n. 1. (Chrysanthemum frutescens; Linn. Sp. Pl. 1251. Leucanthemum canariense, sapore pyrethri; Walth. Hort. 31. t. 24. Buphthalmum canariense leucanthemum; Pluk. Alm. 73. Phyt. t. 272, f. 6.)—Stem shrubby. Leaves fleshy, pinnatifid, linear, toothed; three-keeled at the extremities. Native of the Canary islands, from whence it was brought very early; flowering in the green-house half part of the year. The woody stem is much branched. The leaves are crowded about the ends of the branches, and in their fleshy texture, as well as linear forked figure, resemble those of a Cithaenum, or Artemisia. The flowers are terminal, solitary, on long naked stalks, and resemble a white daisy.

2. P. simplicifolium. Simple-leaved West Indian Feverfew. Willd. n. 2. (Matricaria? prostrata; Swartz Ind. Occ. v. 3. 1566.)—Leaves obovate; toothed at the extremity. Stalks axillary, single-flowered. Branches profuse. Gathered by Von Rohr in Curacao and the neighbouring islands. It has never been brought alive to Europe. Stem herbaceous, branched, decumbent, round, downy, especially the ends of the branches. Leaves alternate, nearly sessile, wedge-shaped, obovate, or roundish, half an inch long, downy, ribbed, notched or serrated; mostly accompanied by two minute leaves at the base. Stalks opposite to the leaves, thickish, an inch long, erect, downy, each bearing a yellowish-white, nearly globose, flower, whose disk is entirely yellow. Seeds crowned with a quadrangular minute border. Swartz.

3. P. ptarmicifolium. Goose-tongue Feverfew. Willd. n. 3. Ait. n. 2.—Leaves linear, finely serrated. Flowers corymbose. Native of north California. Sir Joseph Banks sent it to Kew in 1803. Willdenow describes this as perennial, with the habit of Achillea Ptarmica, only the flowers are twice as large. The stem is branched, either erect or decumbent. Leaves an inch long, very finely and sharply serrated. Corymbs terminal, simple, the stalks single-flowered. Radiant florets ovate. Crown half the length of the seed.

4. P. ferotinum. Creeping-rooted Feverfew. Willd. n. 4. Ait. n. 3. Pursh n. 1. (Chrysanthemum ferotinum; Linn. Sp. Pl. 1251. Jacq. Obl. falc. 4. t. 90. Belis americana, procer, ferotina, ramoza, flore amplimento; Pluk. Alm. 65. Phyt. t. 17, f. 2.)—Leaves lanceolate; the lower ones strongly serrated; the upper entire. Branches corymbose. Supposed to be a native of North America; but Michaux has it not, and Pursh merely saw a specimen in Mr. Lambert's herbarium, probably, like that of Linnaeus, from a garden. The plant was cultivated by Miller, and is a hardy perennial, flowering in October or later. Its stem is herbaceous, two or three feet high, much branched, leafy, furrowed and angular. Leaves alternate, filiform, two or three inches long, and half an inch wide, entire or sparingly serrated in the upper parts of the stem, but mostly furnished, in our specimens, with a sharp tooth on each side at the base, which we do not find mentioned by authors. The flowers are terminal, solitary, much like our common Chrysanthemum Leucanthemum, but rather smaller.

5. P. nigrosum. Bog Feverfew. Willd. n. 5. Waldst. et Kit. Hungary.—Leaves lanceolate, all deeply serrated. Stem erect, branched at the top.—Native of wet ground in Hungary and Spain. Perennial. Very nearly akin to the last, but different in having all the leaves deeply serrated throughout, and the stem branched at the top only. Willd.

6. P. Halleri. Hallerian Feverfew. Willd. n. 6. (P. n. 97; Hall. Helvet. v. 1. 41. Leucanthemum alpinum tenuifolium; Barred. Lc. 1. 458. f. 3.)—Stem-leaves lanceolate, deeply toothed; radical ones pinnatifid, on long stalks. Stem single-flowered.—Native of the Swifs Alps, in shady places. The roots are creeping, black, long and fleshy, with very long fibres. Stems solitary, simple, leafy, ascending, three or four inches high. Leaves smooth; the lowermost short, wedge-shaped, deeply pinnatifid, on long stalks; the uppermost sessile, deeply and sharply toothed, an inch or more in length. Flowers solitary, flalked, terminal, large; the calyx-seals bordered with black; the radiant florets broad and elliptical. The above figure of Barrell shows to accord better with our Swifs specimens than fig. 2, cited by Haller and his copyists, except that the upper leaves in fig. 3 are too narrow.

7. P. alpinum. Alpine Feverfew. Willd. n. 7. Ait. n. 4. (Chrysanthemum alpinum; Linn. Sp. Pl. 1253. Leucanthemum alpinum; Chf. Hill. v. 1. 335.)—Lower leaves wedge-shaped, pinnatifid; uppermost linear and entire. Stem single-flowered.—Native of the German, Swifs and Italian Alps. The creeping roots throw about many short tufted leafy stems, each bearing one long simple, flower-stalk, downy in its upper part, and furnished below with one, two, or more, alternate, simple, linear, entire floral leaves. The rest of the foliage is flalked, pinnatifid, somewhat cleft; the segments elliptical, entire, smooth, rather fleshy; each, with its flat stalk, an inch or more in length. The flower is large, much like the last.

8. P. Balsamita. Coltetary-leaved Feverfew. Willd. n. 8. Ait. n. 5. (Chrysanthemum Balsamita; Linn. Sp. Pl. 1252. Jacq. Obl. falc. 4. t. 89. Leucanthemum orientale, colli Hort us folio; Tourn. Cor. 37.)—Leaves ovate-oblong, serrated, auricled. Flowers corymbose.—Native of the Levant; rare in our gardens. Mr. Blackburne is said to have cultivated it in his celebrated collection at Orford about 35 years ago. The habit of this species is so much like Common Coltmary, Tanacetum Balsamita of Linnaeus, that one cannot help supposing they are mere varieties of each other. The preference of a radius, in the plant before us, is known, by the examples of Bident and Coreopsis, to be no infallible distinction. There is indeed the membranous crown of the seed, as Willdenow remarks, which makes this a Pyrethrum, not a Chrysanthemum; but such belongs to Tanacetum, and confirms our suspicion, or rather our belief, that the present is but a radiated variety of the Coltmary. The radius is about twice the length of the calyx, white, not yellow, as Linnaeus seems to describe it.

9. P. pallidus. Marsh Feverfew. Willd. n. 9. (Leucanthemum orientale, chrysanthe folio, tanaceti odor; Tourn. Cor. 37.)—Leaves smooth, filiform, lyra-pinnatifid. Stalks single-flowered, corymbose.—Native of marshy places in Armenia. Tournefort.—Stem erect, furrowed, smooth, two feet high. Leaves an inch or inch
and half long; their segments lanceolate, toothed at the outer margin, the lower ones deep, the upper gradually confluent into a large cut terminal lobe, and entire. Stalks single-flowered, leafy, alternate, five six or six at the top of the stem, composita a corymb. Flowers the size of Chrysanthemum Laneraeum. Willd.

10. P. pinatifidum. Pinnaflid Feverfew. Willd. n. 10. — "Leaves downy, glaucous, nearly fettile, lyrate-pinnaflid, unequally toothed. Flowers corrymbose." — Willdenow delibered this from living specimens, but did not know their native country. The stem is laid to be cleft, two feet high, branched, furrowed, slightly downy. Leaves downy on both sides; pinnate at the base; pinnaflid in the middle; cut at the end; their length two or three inches; their segments lanceolate, unequally toothed. Corymb simple, at the tips of the stem and branches. Flowers almoft like the common P. Parthenium.

11. P. macrophyllum. Large-leaved Feverfew. Willd. n. 11. Ait. n. 6. (Chrysanthemum macrophyllum; Willd. Sp. Pl. v. 3. 2444. Sims in Curt. Mag. t. 1080. Buphthalmum orientale, tanaceti folio ampliore, flore magno coccineo; Tourne. Cor. p. 37. Buxb. Cent. 2. 255. 1. 20.) — Leaves smooth, pinnate; leaflets once or twice pinnaflid, ferrate, acute, or pinnate. Stem erect, fingle-flowered. Gathered by Tournefort in Iberia. It is found also on mount Caucasus, from whence that diloggued cultivator Mr. Lodwig received seeds of this elegant species in 1803.

The plant proaves perennial and hardy, flowering in August or September. The stem is 12 or 18 inches high, more to less leafy, bearing one large handsome flower, whose disk is yellow, and the radius of a rich rose colour, or crimson, on its upper side; sometimes varying to white. The leaflets are from two to four inches long, falked, rigid, ferial beneath, pinnate, variously ferrate, cut or pinnaflid, all the points and ferratures very acute. Tournefort gathered plentiful pof this plant, and his original specimens are diflered through many collections.

12. P. corymbosum. Mountain Feverfew. Willd. n. 12. Ait. n. 8. (Chrysanthemum corymbosum; Jacq. Aufr. t. 379. Ch. corymbosum; Linn. Sp. Pl. 1251. Tanacetum non odorum; Ger. Em. 675.) — Leaves pinnate; leaflets lanceolate, pinnatifid, sharply ferrate; the upper ones confluent. Flower-flakes corymbose. Native of mountainous woods in Siberia, and many parts of Germany. Gerasde appears, by the catalogue of his garden, to have cultivated it in 1596. The root is perennial, woody, with long fibres. Stems erect, two or three feet high. Leaves somewhat like Tanly, but without fettite or taffe, except that after a while, according to Jacquin, they cause a heat or pungency in the mouth. The numerous large white flowers, each with a bright yellow disk, form an ample terminal corymbose.

—Native of cultivated or waste ground throughout Europe, springing up abundantly with us in neglected gardens or court-yards, flowering all summer long. The root appears to be rather biennial than perennial. The whole herb is bitter and aromatic, hoary or downy. Stem bulky. Leaves falked, flat and dilated. Flowers numerous, each about the size of a common daily, but with a large yellow disk, and short white radius. Sometimes the latter is wanting; and more frequently the flowers are double, the disk becoming white and ligulate, like the radius, but each fvel of a smaller proportion. The receptacle is flat.

14. P. parthenifolium. Narrow Hoary Feverfew. Willd. n. 14. — "Leaves pinnate; leaflets oblong, obtute, pinnatifid, toothed. Stem wand-like. Flowers corrymbose. Radius three the length of the calyx. Seed-crown entire." — Willdenow described this from a garden, without knowing whence it came. He says it is very like the last, but has a taller wand-like stem, narrower leaves, a f Falk bur half no large, though the radius is larger, and an entire, not toothed, margin to the seed. A plant, now become a weed in Kew garden, and said to have been imported from China; answers precisely to this description in every point, except that its stem is freshly leafy than in P. Parthenium. We are persuaded, nevertheless, that it is what Willdenow meant. Its leaves are conspicuously hoary, with narrower divisions than those of the last, and the flowers, on account of their long and brilliant-white radius, are more fivelent. We have had no opportunity of investigating the crown of the seed.

16. P. fustatum. Diny Feverfew. Willd. n. 16. Sm. Prod. Fl. Graec. Sib. li. 2095. (Chrysanthemum fustatum; Desfont. Atlant. v. 2. 283. t. 232.) — Leaves downy, pinnate; leaflets with a few deep linear oblong segments. Stem branched from the base, diffuse. Gathered by Desfontaines in uncultivated fields near Athens. Sibthorp found it in Greece. The root appears to be perennial, bearing many widely-spreadings or promontory stems, a flat long, which are leafe, and slightly branched. The leaves are rather fucerent. Flowers terminal, folitary, large, with a blackish calyx, pale yellow disk, becoming brown in decay, and broad white elliptical radiant florets. It blofions in winter.

18. P. inodorum. Corn Feverfew, or Scentless Mayweed. Sm. Fl. Brit. n. 2. Engl. Bot. t. 676. Willd. n. 17. Ait. n. 11. (Chrysanthemum inodorum; Linn. Sp. Pl. 1253. Fl. Dan. l. 666.) — Leaves pinnate, in many capillary segments. Stem branched, spreading. Seed-crown entire. — Found in fields and waste ground throughout most parts of Europe, espescially where the soil is gravelly, flowering in autumn. Root tapering, annual. Herb almost without any peculiar fettite, by which it is readily known, in every state of growth, from Anthemis Cotula. The stem is a foot or more in height, widely spreading, clothed with pale-green smooth leaves, whose leaflets are deeply and variously divided into linear, almost capillary, pointed segments. More fimple segments are numerous.
numerously crowded about the bottom of each leaf, rendering it, in a manner, lyrate, and surrounding the stem or branch. Branches somewhat corymbose, each terminated by a rather large flower, with long white rays, and a prominent yellow disk. The late Mr. Crowe once found in Norfolk a partly double-flowered variety.

19. P. maritimum. Sea Feverfew. Sm. Fl. Brit. ii. 3, Eng. Bot. t. 975. Wild. n. 18. Ait. n. 12. (Matri- carta maritima; Linn. Sp. Pl. 1256.) Chamaemelum maritimum perenne humiliss, folis brevibus obscure flore viridibus; Dill. in Rill. Syst. 186. t. 7. f. 1.)—Leaves doubly pinnate; segments linear, pointed, fleshy; convex above; keeled beneath. Stem diffuse. Seed-crown lobed.—Native of the sea-coast in the north of Europe. Found in several parts of Scotland, as well as on the south coast of England, and in Lancashire and Durham, flowering in July and August. The root is perennial. Stems numerous, prostrate, spreading circularly to the extent of two or three feet. The leaves are more fleshy than in the foregoing; the disk of the flower broader, in proportion to the length of the rays; and the crown of the seed divided into three or four lobes. The whole herb is slightly aromatic, and of a darker more shining green than inodorum.

20. P. parviflorum. Small-flowered Feverfew. Wild. n. 19.—“Leaves doubly pinnate; leaflets linear-thread-shaped, in two or three deep divisions. Stem erect, branched. Seed-crown two-lobed.”—Described by Willdenow from living specimens, but the native country of this species is unknown. It is said to be annual, greatly resembling P. inodorum, but having a taller and upright stem; a shorter radius; and a green two-lobed crown to the seed.

Section 2. Radius yellow.

21. P. multifida. Many-stalked yellow Feverfew. Wildl. n. 20. (Chrysanthemeum multifida; Desfont. Atlant. v. 2. 282. t. 236.)—Leaves simple, smooth, spathulate; the lower ones toothed. Stem erect, much branched from the bottom.—Native of sandy hills near Mafcar, in Barbary. Root fibrous, apparently annual. Stem branched from the base principally, bushy; the branches naked above, each bearing a solitary flower, about as big as a French Marygold, whose radiant florets are yellow, and of a very broad elliptical form, about eight or nine or number.

22. P. trifurcatum. Three-forked Yellow Feverfew. Wildl. n. 21. (Chrysanthemeum trifurcatum; Desfont. Atlant. v. 2. 281. t. 235. f. 2.)—Leaves fleshy, smooth, linear, acute; the lowermost pinnate; the uppermost undivided. Stem ascending, fingle-flowered. Native of fields near Kerwan in Barbary, flowering in winter. The stem is simple, 2 foot high; leafy below; naked above; terminated by a very large flower, with numerous yellow radiant florets. Some leaves are partly bipinnate; others three-collet: the uppermost simple; all linear, wavy, acute, and of equal breadth.

23. P. Bocconi. Dwarf Pale-yellow Feverfew. Wildl. n. 22. (Chrysanthemeum aragonef; Afo Synop. v. 845. t. 9. f. 1.) Wildl. Bellis incana, chrysantheni cretici folio; Bocc. Mut. 135. t. 98.)—Leaves hoary, falked, pinnate; leaflets linear-awl-shaped; upper ones linear, undivided, and entire. Stems fingle-flowered. Native of Spain and Sicily. Willdenow describes it thus from dried specimens. “Root many-headed, woody. Stems several, simple, a span high, fingle-flowered. Leaves hoary; the radical ones falked, oblong, fading when arrived at maturity, and altogether wanting when the flowers open; lower stem-leaves falked, pinnate at the extremity, with three or four pairs of very short linear-awl-shaped leaflets, and a membranous linear fonffeld; the upper ones linear, sefllie, and entire. Rays of the corolla pale yellow. It resembles Chrysanthem um penitatum, but differs abundantly in the calyx not being membranous, and in having a crown to the feed.”

We know nothing of Aito’s plant. Wildl now cites an additional synonymy, Barrelier’s t. 1153. f. 1, which seems to have no affinity to the figure of Boccoue, and much more resembles Cinara crispa, Cavan. 19. t. 33. f. 9, under which indeed Willdenow likewise quotes it, Sp. Pl. v. 3. 2086.

24. P. orientale. Oriental Yellow Feverfew. Wild. n. 23.—“Leaves doubly pinnate; leaflets linear. Stems ascending, fingle-flowered.”—Native of Georgia. Stems fix inches high, naked above. Lower leaves an inch long; the upper ones half as long, and only fimpate pinnate. Scales of the calyx withered at the edge. Flowers deep yellow, the size of Chrysanthemum segetum. Wildl.

25. P. millofli;atum. Milfoil-leaved Yellow Feverfew. Wildl. n. 24. Ait. n. 13. (P. n. 174; Gmel. Sibib v. 2. 207. t. 86. f. 1. 2.) Chrysanthemeum millofliatum; Linn. Synt. Veg. ed. 14. 1643. Anthems millofia; Linn. Sp. Pl. 1263. Achillea folio pinnatis, &c.; Mill. 1e. c. 9.)—Leaves doubly pinnatifid, linear, blunts. Stem corymbose. Rays half as long as the diameter of the disk.—Native of Siberia. A hardy perennial, flowering throughout the summer. The stem is twelve or eighteen inches high, leafy, branched and corymbose, bearing eight or more long-stalked yellow flowers, whose disk is about half an inch in diameter, and their radiant florets of a short roundish figure, hardly extending a quarter of an inch from the disk. Seed-crown toothed. Leaves doubly and interruptedly pinnatifid, with linear, blunts, segments, each tipped with a minute point; their surfaces both downy, or somewhat faky. The leaves, as well as flowers and seeds, are very different from Chrysanthemum italicum, to which Linneaus compares this species.

26. P. bipinnatum. Wing-leaved Yellow Feverfew. Wildl. n. 25. Ait. n. 14. (P. n. 172; Gmel. Sibib v. 2. 205. t. 83. f. 1.) Chrysanthemeum bipinnatum; Linn. Sp. Pl. 1255.)—Leaves doubly or tripily pinnatifid; their segments dilated upwards, minutely pointed. Stem nearly simple. Rays wedge-shaped, not a quarter fo long as the diameter of the disk.—Native of Siberia, flowering in June. Introduced at Kew by Mr. Busk, in 1756. This differs from the last in having more compound leaves, whose ultimate segments are almost elliptical, and all their points distinctly awned. But the flowers especially differ in being fewer, from one to three on each stem, and furnished with a disk near an inch wide, while their radiant marginal florets are short, broad, and wedge-shaped, with broad spreading teeth. The calyx, as well as all the herbage, is shaggy with soft hairs.

27. P. indicum. East Indian Yellow Feverfew. Sims in Curt. Mag. t. 1521. Ait. n. 15.—Leaves pinnatifid; their segments dilated upwards, lobed. Stem branched. Flowers on long stalks, nearly globular. Radiant florets few, very short.—Sent by Dr. Roxburgh, from the East Indies, to A. B. Lambert, eq. It proves a hardy annual in our gardens, flowering most part of the summer. The stem is much branched, but the pinnatifid, though more simple and broader, leaves, betray an affinity to the two last species, which is confirmed by the short yellow radiant florets. These however are, according to Dr. Sims, most generally wanting. The flowers are solitary, on long swelling furrowed stalks, terminating each branch; their disk nearly an inch wide, and finally convex. The herbage appears to be smooth.

28. P.
25. P. Myconi. Tongue-leaved Yellow Feverfew. (Chrysanthemum Myconi; Dalech. Hill. 673. Linn. Sp. Pl. 1254.) Wild. Sp. Pl. v. 3. 2148. \(\text{At. Hort. Rev.} v. 5. 96.\) Jacq. Obl. falc. 4. 10. t. 94.)—Leaves tongue-shaped, obtuse, toothed, clasping the much-branched stem. Radiant florets numerous, roundish.—Native of fields in the south of Europe; a hardy annual with us, but preferred for the sake of variety, rather than ornament, the flowers being inferior in size and splendour to our wild Chrysanthemum segetum, while the leaves resemble those of C. Leucanthemum. The plant however is very different from both, and a true Pyrethrum, akin to the last described, the seed having a very evident membranous crown, as Willdenow, copying Linnaeus, mentions; yet he full left this species where he found it. Our predecessor, the excellent Mr. Wood, has corrected this error. (See Chrysanthemum, at the end.) We venture likewise to correct the specific name, which authors have copied incorrectly from Dalechamp. He calls the plant Myconi, after its discoverer Myconus. The stem is very much branched. Leaves simple, an inch and a half or two inches long, smooth. Flowers on long solitary stalks, at the ends of the branches, bright yellow, an inch wide; their radiant florets numerous, crowded, short, of a roundish or oblong shape. Seed-trochon large, jagged, and fringed.

PYRETICS, formed from πυρητες, fever, of πυρ, fire, medicines good against fevers.

PYREXIA, in Medicines, from πυρητες, fever, a term used by Dr. Cullen to signify feverish action generally, whether idiopathic or sympathetic. The same writer also used the term as the denomination of his first class of diseases, including fevers and inflammations. See his Nofol. Method. class 1, Pyrexia.

PYRGi, or PYRGOS, in Ancient Geography, a town of Italy, upon the coast of Etruria; placed by Ptolemy between Cafrum Novum and Altim, and said by Livy to have been a Roman colony.—Alto, a town of the Peloponnese, in Messenia.

PYRGO, in Geography, a sea-port town on the S.E. coast of the island of Santorini. N. lat. 36° 26'. E. long. 25° 38'.

PYRGUS, among the Romans, a dice-box of the shape of a modius, open above, and having a great many shelves or partitions within it; so that when the dice were thrown into it out of the frictillum, they were thereby overturned many times before they could reach the bottom, in which there was an opening for them to fall through upon the table.

PYRGUS, in Botany, a genus of Louriciero's, Fl. Cochinch. 120, which Mr. Brown, Prodr. Nov. Holl. v. i. 533, reduces to Ardisia, see that article. The name is taken from πυργος, a tower, alluding to the conical shape assumed by the converging flames.

PYRHOPOECILOS, in the Natural History of the Ancients, a flume so called from its having a great many spots of the colour of fire.

PYRIATHERION, a word used by the ancients to express a sweating room.

PYRIATOS, a word used by some authors to express a brick when heated, in order to be applied to the body wrapped up in a cloth by way of a dry fomentation.

PYRICAUSTUM, a word used by medical writers to express a burn or scald.

PYRICUIUM, in Natural History, the name of a genus of fossil bodies, usually comprehended, with many others of very different figure and structure, under the general name pyrite.

Vol. XXIX.
PYRITES.

Word *pyrites*, formed of *pyr*, fire, denotes fire-flone; a denomination given to this substance on account of its inflammability. For the mineralogical characters of copper pyrites, and iron pyrites, see *Copper Ore*, and *Iron Ore*.

Besides these there are aherical pyrites, auriferous pyrites, and tin pyrites. Combinations of sulphur with the metals are called chemists sulphures; and the different kinds of pyrites are properly metallic sulphures. Sulphur has a great affinity for iron, and in combination with this metal, under the form of pyrites, exils in extensive beds in primary mountains, or is disseminated through the secondary rocks and strata, in veins and mafles, or varaquely crystalized; it occurs also in beds of coal and bituminous clay. Iron pyrites may be considered, after the earths, as one of the most abundant substances in the mineral kingdom, forming a constituent part of the globe, and by its decomposition giving rise to many important subterranean phenomena.

The proportions of iron and sulphur in the different full-species of iron pyrites enumerated by mineralogists are,

| 52 to 54 | Sulphur |
| 48 to 56 | Iron |

Magnetic pyrites differs from common pyrites: its constituent parts, according to Mr. Hatchett, are,

| 36.50 | Sulphur |
| 63.50 | Iron |

By the application of heat common pyrites becomes susceptible of attraction by the magnet; the excess of sulphur being expelled. Iron pyrites is not worked as an ore of iron, but is principally valued for the green vitriol or sulphate of iron, which it affords when exposed to air and moisture. Sulphur may also be obtained from pyrites when heated with charcoal.

The decomposition of pyrites is effected spontaneously by the abstraction of oxygen from water and the atmosphere, which converts the sulphur into sulphuric acid, and the iron into an oxyd. These substances unite during the process, and form the sulphate of iron, or green vitriol.

Some kinds of pyrites are rapidly decomposed, others require to have part of the sulphur expelled by heat. The pyrites, or pyritous substance intended to form vitriol, is collected in extensive heaps, spreading the surface as much as can be conveniently done. The ground on which these heaps are spread should be impervious to water, and inclined, in order that the saline matter which effloresces may be washed off, and conveyed into reservoirs to crystallize. As the decomposition proceeds the mafs becomes heated, and is occasionally moistened, particularly when the air is dry and warm. These beds continue productive for many years, and if the pyrites be pure, but little redudm is left. An excess of sulphuric acid is formed during the process, on which account a quantity of old iron is added to the solution, to saturate it, and obtain the fah in a cryftallized flate. During the decomposition of pyrites much heat is evolved, and a considerable abstraction of oxygen from the atmosphere takes place.

The fact was first observed by Henckel, who affirmed, in his "Pyritologia," that air was necessary to the processes of vitrification, and that it enters into combination with pyrites and remains fixed in it; "non ut instrumentum transtiens sed inanem." This may be considered as a happy anticipation of one of the most important doctrines of modern chemistry. Some geologists have supposed that subterranean fires, and the temperature of hot springs, are occasioned by the spontaneous decomposition of immense beds of pyrites in the interior of the earth, and an experiment made by Lemery gives some plausibility to this opinion. He found that a mixture of iron filings and sulphur, moistened with a small quantity of water, becomes hot in a few hours, the mafs swells, and the parts adhere together: it then breaks with a perceptible noise and crackling, and emits aqueous vapour, and a fetid odour like that of sulphurated hydrogen gas. If the mixture be made in a large quantity, it takes fire in twenty-four or thirty hours. As soon as the effusion of aqueous vapour has ceased, the heat becomes greater and greater; is succeeded by inflammation, the smell is then much stronger, and appears to arise from the hydrogen produced by the decomposition of water. Beaumont, who observed this phenomenon from a mixture of one hundred pounds of iron filings with an equal quantity of sulphur in powder, states that the flames rose to a foot in height, but did not continue longer than two or three minutes; the mafs, however, remained red-hot for forty hours. Lemery the elder gave to this experiment the name of the artificial volcano.

Dr. Watson, in his Chemical Essays, vol. i. p. 187, says that he has repeated this experiment more than once. When made in the open air the flame is of short duration, and the whole mafs, after the extinction of the flame, continues at intervals to throw out sparks. A ladle full of the ignited mafs being dropped down from a considerable height, defended as a flower of red-hot ashes. The success of this experiment depends on a due proportion of water. Half a pound of flower of sulphur, with half a pound of clean iron filings, mixed with fourteen ounces of water, and worked into a pafle, will acquire heat enough to make the mafs take fire.

Some dark-coloured carbonaceous and bituminous earths contain pyrites in minute grains, and decompose with great rapidity when exposed to moisture. In the month of August 1751, the cliffs near Charmouth, in Dorsetshire, containing a similar kind of pyritous earth, took fire in consequence of a heavy fall of rain after a hot dry season, and continued at intervals to emit flame for several years. Almost all kinds of pit-coal in England contain more or less pyrites: in some the quantity is very inconsiderable, in other kinds it abounds so much as to render them unfit for domestic purposes, and totally unapplicable for forges or iron works, on account of the sulphur which they emit when burned. This pyritous coal may be distinguished by its greater specific gravity, and the brafis-like metallic appearance of the pyrites with which it is intermixed. Pyritous coal and coal flake, or bituminous clay, containing pyrites, frequently take fire spontaneously in coal mines, or when exposed in heaps out of the pits, and continue burning many years. Influences of this kind now exist in the north of England; and its intense is the heat produced by the ignition of these mafles, that the coal flake is sometimes fused. We have seen specimens from these heaps which have all the characters of cellular volcanic lava. In the vicinity of Leeds there is a large heap of coal flake which has been on fire near half a century; it is covered in parts with vegetation, and prevails no appearance of ignition during the day; but if a dry stick be thrust into it the surface is changed in a few minutes. In some of the coal mines in Leiceistershire, near Ashby de la Zouch, the stratum of indurated clay over the main bed of coal contains so much pyritic matter, and is so subject to spontaneous inflammation when it falls down and is intermixed with small coal and moilure, that the miners are obliged to close up the space with brick-clay where the coal has been worked, to prevent the access of air to the combustible matter. In this flate, excluded from the air, the pyritous earth sometimes becomes ignited, as is evident by the heat communicated to the neighbouring parts of the mine; but the fire is prevented from spreading among the
coal, by the precautionary measure of closing the cavities with clay.

The great heat evolved during the decomposition of pyrites, may proceed in part from the combination of oxygen with the sulphur and iron, and may be increased by the different capacity of the new compound for heat. Whatever chemical changes take place rapidly, they produce a change in the temperature of the substances, as in the well-known instances of lime and water, nitric acid and vegetable oils, &c.

The phenomena accompanying the mud volcanoes in various parts of the world, present many appearances which give probability to the opinion, that they proceed from the decomposition of pyritic flata. See VOLCANO.

The formation of alum is also effected naturally, in many situations, by the decomposition of pyrites, the sulphuric acid combining with the alumine of pyritic clay. This is not unfrequently the case in excavations of coal mines that have been long worked out.

At Hartlet, near Glasgow, in the excavations of an old coal mine that has been worked some centuries, there is a very extensive formation of alum, from the decomposition of the roof of the pit. It is a pyritic clay ten inches thick. In the old workings of the mine which are dry the air circulates slowly, and the roof gradually decomposes and exfoliates, and falls upon the floor, in which situation the decomposition proceeds, and the substance assumes the appearance of a peculiar efflorescence. In time the whole space to the roof is filled; it is then removed. The mafs consists of earth richly impregnated with sulphate of alumine, sulphate of iron, and in some instances with sulphate of magnesia. The coal in this mine, contrary to the usual practice, is worked to the dip, so that the old workings are always dry. To this circumstance may principally be attributed the great accumulation of alum in this mine. In many of the mines in England a similar formation of alum would take place, but they contain too much water to permit the saline substances to remain. In general, alum rock or alum flake require to be exposed in heaps, and burned in the open air, to expel the sulphur, and combine it with the oxygen from the atmosphere. The sulphuric acid thus formed unites with a requisite portion of the clay during the process.

The gypsum, or the sulphate of lime which occurs in beds, among secondary flata of red sand-flone and beds of marle, probably may owe its present state to mafles of pyrites, which have exiled over common lime-flone, and been decomposed naturally. The sulphuric acid thus produced would unite with the lime, and form gypsum. The great quantity of the red oxyd of iron which is in the flone and marle that accompany this kind of gypsum, gives much probability to this opinion. The crystals of gypsum or selenite found detached in beds of clay had probably a similar origin.

Sulphuret of iron may be formed by heating together iron filings and sulphur. From the experiments of Vauquelin it is proved that there are four sulphurets of iron, according to the degree of heat and other circumstances under which the combination may be formed. The first sulphuret consists of

\[
\begin{align*}
78 & \text{ Iron} \\
22 & \text{ Sulphur} \\
& \text{ Artificial.}
\end{align*}
\]

The second sulphuret, of

\[
\begin{align*}
64 & \text{ Iron} \\
36 & \text{ Sulphur} \\
& \text{ Natural magnetic pyrites.}
\end{align*}
\]

The third sulphuret, of

\[
\begin{align*}
54.16 & \text{ Iron} \\
45.84 & \text{ Sulphur} \\
& \text{ Artificial.}
\end{align*}
\]

The fourth sulphuret, of

\[
\begin{align*}
47 & \text{ Iron} \\
33 & \text{ Sulphur} \\
& \text{ Natural common pyrites.}
\end{align*}
\]

When the quantity of sulphur does not exceed 40 per cent. pyrites is soluble in muriatic acid, and may be rendered permanently magnetic. The specific gravity of common pyrites is from 4.62 to 4.83. Of magnetic pyrites 4.51.

Arsenic pyrites, called marcasite, is distinguished from iron pyrites by its colour, which is a silver white, and by yielding a smell like garlic when rubbed or exposed to heat. See ARSENIC.

Auriferous pyrites, or iron pyrites, with a small alloy of gold: the richest specimens of this ore in Europe are found in Transylvania, containing from 0.02 to 0.03 of gold. These ores are distinguished from iron and copper pyrites by their colour, malleability, and specific gravity.

Tin pyrites. See Tin Ore.

The pyrites, in substance, are never used medicinally; nevertheless, in their products they are very important. From these common sulphur is extracted, in Sweden and Saxony; the native vitriols are produced in caverns of the earth, or on its surface; the greatest quantities of artificial vitriol are prepared; and the mineral waters, vitriolic, aluminous, sulphurous, hot or cold, are supposed to receive their impregnation.

When the matter of the pyrites is mixed with the lead ores, the method of separating the metal by assaying is this: roll two centners of the ore, as in the usual method, and keep a stronger fire than when the ore is pure. The pyrites, especially when it is merely iron, hinder ore from easily growing clumsy or turning into large lumps, or entirely melting. When the ore is sufficiently washed, let it cool, beat it to powder, and repeat the roasting to a third fire, till when it is red-hot in the fire, there is no smell of sulphur; then mix the ore with fixed centners of the black flux, and two of sandiver, and finish the work in the common way, only making the fire greater, and continuing it longer, toward the end of the operation. Cramer's Art of Assaying, p. 292.

See LEAD Ore.

PYRITES is applied by some authors to the marcasite ores of all metals; the names of which are varied according to the metals they partake of.

Thus chrysitis is that of gold; argyrinis that of silver; sideritis that of iron; chalcitis that of copper; and molybditis that of lead, &c.

PYRITICUM LIQUAMEN. See Liquamen Pyriticum.

PYRITICHIPILYLLUM, in Natural History, the name of a genus of fosils of the class of the pyrites, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose mafles not of any regularly angular figure, and of a fibrated texture, with foliaceous ends to the frix, appearing on the surface, or within the mafs.

Of this genus there are only two known species: one having the foliaceous ends of the frix on the outer surface of the mafs; and the other having a smooth external surface, and the foliaceous ends of the frix covering the sides of internal hollows.

The first of these is found in many of the English and German mines; the other has been yet only found in the mines on Mendip hills in Somersetshire, but there in considerable plenty. Hill.

PYRITRICHEM, the name of a genus of pyrites, the characters of which are these: they are compound, inflammable, metallic fosils, always found in detached mafles of
PYRITZ, in Geography. See Piritz.

PYRMONT, a town of Germany, and capital of the country so named; its citadel is fortified with a broad ditch, high ramparts, and subterranean passages and vaults; 12 miles S.W. of Hamala. N. lat. 51° 57'. E. long. 9° 17'.—
Allo, a county and principality of Germany, bounded on the N. by the principality of Calenberg, on the E. by Wolfenbuttle and Calenberg, on the S. by Wolfenbuttle, and on the W. by the county of Lippe; about nine miles long, and three broad. The revenues are estimated at 30,000 rix-dollars, principally arising from the springs and salt-works.

PYRMONT Water, in Physiology and Medicine, a very brilk, spirituous chalybeate, abounding in fixed air, and which, when taken up from the fountain at Pyrmon, in Germany, whence its name, sparkles like the brilked Champagne wine. It has a pleasant, vinous taste, and somewhat sulphurous smell. It is perfectly clear, and bears carriage better than the Spa water.

The history of these waters is accurately given by Hoffmann in his observations on them, both in their natural state, and in mixture with other bodies.

He first observes, that they contain a volatile and subtil principle, much more penetrative and strong, as well as in larger quantity, than any other mineral water; but that this is not to be expected in them any where but upon the spot, for those who transport them to other places are constrained to let a part of this fly off, to preserve the rest. If either glass or earthen vessels be filled at the spring, and immediately corked and fastened down, the consequence is, that they will boil on the first motion, or heat of the weather. They are, therefore, forced to fill them only in part at first, and let them stand awhile for this subtile spirit to exahle; and then awhile after the filling them up, to cork and fit them for carriage.

If they are drank upon the spot in a morning, on an empty stomach, they affect the nose with a pungent tingling, and disturb the head for many hours afterwards.

If they are taken at the spring, they purge but very little; but if taken in another place, after transportation, they purge considerably more, and render the stools black. It is observable also, that if they are left in an open vessel a few days, their virtue wholly exahles, and they no longer purge nor render the stools black.

If tea-leaves, balsam-flowers, or galls, are put into this water, they first change it to a blue, from that to a purple, and finally to a black. This is a ready proof that black is only a deep purple, and purple only a deep blue; a little spirit of vitriol added to this liquor destroys all the colour, and renders it limpid as before.

If any acid be mixed with Pyrmony water, there is raised an effervecence, and bubbles of air are carried up in great quantity; and this whether the stronger acids, such as spirit of vitriol, or aqua fortis, be used; or the weaker, as vinegar, lemon juice, or Rheum wine.

If an alkaline liquor be added, whether it be volatile, as the spirit of sal ammonie, or fixed, as the oil of tartar, there is no ebullition raised, but the liquor becomes turbid and milky. If spirit of vitriol be afterwards added to this, to fature the additional alkali, the liquor becomes limpid again.

Cow’s milk mixed in equal quantity with Pyrmony water does not coagulate, but, on the contrary, becomes thinner than before, and is preferred from turning four to six soon as it other wise would in hot weather. This is a proof that there is no predominating acid in these waters.

If syrup of violets be added to Pyrmony water, it turns it to a beautiful green. This is a proof of the alkaline nature of these waters; and it is further proved, by adding spirit of vitriol, or any other acid, to this green liquor, which on that becomes limpid again.

Four pints of this water evaporated over a gentle fire, yield no more than two scruples of a dry residuum. Oil of vitriol being poured on this, an acid effervescence arises, and with it an acid and pungent vapour, like that produced by mixing oil of vitriol and common salt. If spirit of vitriol be used instead of the oil, the effervescence is in a less degree, and the folt is in part changed to a bitter salmals, the remainder separated from which proves to be a calcareous earth, no longer fermenting with the spirit of vitriol.

If a quantity of Pyrmony water be exposed twenty-four hours to the open air in a basin, it will at the end be found to have lost all its virtues, tainting wholly infipid, and being turbid, instead of the fine clearness it had before, and a yellow ochreous earth is precipitated to the bottom; after this the liquor will no longer show any of those qualities, which were before its distinguishing characters; it will no longer ferment with acids, nor turn black with galls, nor green with syrup of violets.

It appears from the whole, that the Pyrmony waters possess a pure, extremely penetrative, and elastic mineral spirit, and that in a very large proportion; and to this their virtues are principally to be attributed. This mineral spirit, while it remains engaged in a calcareous earth, imitates the properties of an alkaline subsance; and when joined with a subtile martial earth, it emulates the properties of vitriol, giving the fluids a black colour, and turning a tincture of galls into ink: and while this remains in the water in these forms of an alkaline or vitriolic principle of so great subtlety, it cannot but give them very great virtues in strengthening the tone of the viscera, opening obstructions, and stimulating in a proper manner the excretory ducts, so as to make them only perform their office; but as soon as by the standing of the water open, or by any other accident, this subtile element is evaporated, all the virtues of the water must be gone with it.

The great quantity of this powerful spirit contained in the waters, makes them more fit for the robust and strong constitutions, when depraved by illnesses, or for the weak and tender ones; but even the tenderest people may take them, only observing to take but a small dose, or to dilute them with an equal quantity of common water immediately before the taking them.

Hoffmann also recommends the Pyrmony water mixed with equal quantities of milk, on his own experience, in Scorbutto and gouty cases. Hoffm. Oper. tom. v. p. 143, sqq.

We have already observed, under the articles Acipule and Carbonic Acids, that Pyrmony water, and other mineral waters of a similar nature, owe their acidulous taste and peculiar virtues to the fixed Air (carbonic acid) which they contain; and to those articles the reader is referred for a brief history of
of this important discovery. We shall here add some farther remarks on the effects and medical uses of this water.

Perfons who drink it at the well are affected with a kind of giddiness or intoxication, which is probably owing to the great quantity of carboonic acid with which the water abounds. The common operation of this water is by urine; but it is also a gentle sudorific; and if taken in large quantity, proves laxative. However, in order to this effect, it is usual to mix some falts with the first glasses. It is drank by gladsfuls in the morning, to the quantity of from one to five or six pints, according to circumstances; those who drink it walking about between each glass. This water is recommended in cafes where the constitution is relaxed; in want of appetite and digestion; weakness of the stomach, and heartburn; the green sickness; female obstructions and barrenness; the fevery, and cutaneous diaphane; and in the gout, especially, as Hoffmann observes, when mixed with milk; in colics; bloody fluxes; disorders of the bowels and lungs; in which case it is best taken lukewarm; in nervous, hysterical, and hypochondriacal disorders; in apoplexies and palisies; in the gravel and urinary obstructions; in fuffusions of the blood; and in obstructions of the finer vessels. It amends the lax tenore of the blood; exhilarates the spirits without inflaming, as vinous liquors are apt to do; and is reckoned among the best reformatives in decayed and broken conftituents. It is said to poffefs the general virtues of the Spa water, and at the fountain it is more spirituous, as well as a stronger chalybete. Elliot's Medicinal Virtues, &c. of Mineral Waters, 1781, p. 181.

Near the famous well at Pyrmont is a stone quarry under ground, from some parts in which a sulphureous leam comes out, which commonly rifes to a small height. Animals held in this leam are soon suffocated, but recover, if quickly taken out. When a man stands in this leam, and with his head over it, it proves an excellent sudorific. Dr. Seip propofes to perform cures in several difeases with it. See Phil. Tranf. No. 448, feet. 4, and Mfc. Berolin. tom. v. part 2. feet. 4. See Ghotta del Serpi.

**PYRMONT WATER.**

![Image](https://via.placeholder.com/150)

This medicinal water may be imitated very nicely by art in the following manner: take a quart of the purest and lightest water, add to it thirty drops of a strong solution of iron made in spirit of salt, a dracon of oil of tartar per deliquum, and thirty drops of spirit of vitriol, or a little more or less, as is found necessary, not to let the alkali of the oil of tartar prevail too strongly, though it must prevail a little. Shake all briskly together, and on taffing it will be found extremely to re-semble the true Pyrmont water.

The basin on which this is founded is the analysis and trial of the true Pyrmont water, by which it is found to contain a subtle aqueous fluid, a volatile iron, and a predominant alkali, all joined together into one brift pungent spirituous water. The artificial Pyrmont thus made, if the proportions are carefully minded, will extremely re-semble the natural, and will have the same effect as a medicine. Shaw's Lectures, p. 90.

But the best method of forming artificial Pyrmont water is by impregnating it with fixed air, or carbonic acid, for which we are indebted to Dr. Priedley. The first person we believe, who actually compounded an artificial ac ciduous or spirituous water, like that of Sultzer or Pyrmont, was M. Venel; though he was ignorant of the real nature of the ingredient to which it owed these qualities, and which he erroneously supposed to be common air. For this purpose he diffoloved in a pint of water two drachms of fessile alkali, to which he added an equal quantity of marine acid; in the procès he made use of a vessel with a narrowly neck, and to prevent the efcape of the air, he difpos'd the ingredients in such a manner, that they could not communicate with each other till after the bottle was corked. In this case the fixed air diffolved from the alkaline salt, in a phial nearly full and closely cork'd, being confined, fuffers a degree of comprefion that greatly promotes its combination with the water. See Memoires pre-fentés par les Sçavans Etrangers, tom. ii. containing two Memoirs of M. Venel, read before the Royal Academy of Sciences in 1759; and Lavoyer's Effays, &c. by Henry, p. 344, &c. However, Dr. Priedley was undoubtedly the first who so far improved upon the discoveries made by himself and others in relation to the principle then denominated fixed air, as to contrive an easy method of impregnating water with it. The first idea of this kind occurred to him in 1767, when, having placed shallow vessels of water within the region of fixed air on the surface of the fermenting vessels of a brewery, and left them all night in that situation, he found that the water had acquired a very feifie and peflent impregnation. He proceeded to accelerate the impregnation by pouring the water from one vessel into another, while they were both held within the sphere of the fixed air. The method of effecting this by air diffolved from chalk and other calcareous substances, did not occur to him till the year 1772, when he published his directions for this purpofe, together with a drawing of the neceffary apparatus, which he had before communicated to the Board of Admiralty. This apparatus, repre fented in Plate XV. Pneumatics, fig. 1, consists of a glafs veftel, a, with a narrow neck, and fo formed, that it will fland upright, with its mouth downwards: this veftel, when filled with water, and covered with a flip of paper or thin plateboard, prefled clofe to it, to prevent the admifion of common air, is inverted in another veftel, b, with a little water in it, fo that the flip of paper or plateboard may be withdrawn, and the end of the pipe, c, introduced into it. This tube is flexible and air-tight, and beft made of leather, sewed with a fhoemaker's waxed thread. It is kept open at both ends by a piece of a quill, while one of them is intro duced into the veftel of water, and the other into the bladder d; the opposite end of which is tied round a perforated cork, kept open by a quill, and the cork is made to fit a phial, e, two-thirds of which should be filled with chalk just covered with water. Dr. Priedley has fince found it moft convenient to use a glafs tube; and to preferve the advantage he had of agitating the veftel c, he makes use of two bladders, communicating by a perforated cork, to which they are both tied. He also observes, that the fleasile pipe is not neceffary; but instead of this a bent tube of glafs must be ready to be inferted into the hole made in the cork, when the bladder containing the fixed air is ferparated from the phial in which it was generated. The extremity of this tube being put under the veftel of water, and the bladder being comprefled, the air will be conveyed into it, as in the other case. Instead of the bladder, a fmall phial may be inter pofed between the phial containing the chalk, &c. and the veftel of water: for thus the chalk and water that may be thrown up the tube communicating with this phial will lodge at the bottom of the other, while nothing but the air will get into the pipe communicating with the water. The apparatus being thus prepared, let the phial containing the chalk and water be detached from the bladder, and the pipe also from the veftel of water; pour a little oil of vitriol upon the chalk and water; and having carefully prefled all the common air out of the bladder, put the cork into the bottle prefently after the effervescence has begun. Alfo pref the bladder once more after a little of the newly-generated air has got into it, in order the more effectually to clear it of all the remains of the common air; and then in troo
produce the end of the pipe into the mouth of the vessel of water, as in the drawing, and begin to agitate the chalk and water briskly. This will presently produce a considerable quantity of fixed air, which will fill the bottle; and this being prefixed, the air will force its way through the pipe, and ascend into the vessel of water, the water at the same time descending, and coming into the bottle.

When about one-half of the water is forced out, let the operator lay his hand upon the uppermost part of the vessel, and shake it as briskly as he can, not to throw the water out of the bottle; and in a few minutes the water will absorb the air, and taking its place, will nearly fill the vessel as at the first. Then shake the phial containing the chalk and water again, and force more air into the vessel, till, upon the whole, about an equal bulk of air has been thrown into it. Also shake the water as before, till no more of the air can be imbibed. As soon as this is perceived to be the case, the water is ready for use: and if it be not used immediately, should be put into a bottle as soon as possible, well corked, and cemented. It will keep, however, very well, if the bottle be only well corked, and kept with the mouth downwards.

It may be proper to observe on this procès, that the phial, $\alpha$, should always be placed considerably lower than the vessel $\beta$, that the water to which the chalk is put should be changed after every operation; that with a vessel of water holding three pints, and a phial containing the chalk and water of ten ounces, a little more than a tea-spoonful of oil of vitriol will produce air enough to impregnate such a quantity of water, that the whole procès does not take up more than a quarter of an hour, and the agitation not five minutes; and that in this method the water is easily made to imbibe an equal bulk of air; whereas Dr. Brownrigg found that Pyrmont water at the sparging-head did not contain so much as one-half. This apparatus has received considerable improvements, which we shall briefly recite; but in justice to the merit of the original inventor, his method deserves to be recorded; and besides, it requires less time, and is much less expensive than those that are now generally used.

The apparatus contrived by Dr. Nooth, and improved by Mr. Parker, is represented in fig. 2. It is made of glass, and stands on a wooden vessel, $\delta\delta$, resembling a tea-board; the middle vessel $\beta$ has a neck, which is inserted into the mouth of the vessel $\alpha$, to which it is ground-air-tight. This lower neck of the vessel $\beta$ has a glass stopple $S$, composed of two parts, both having holes sufficient to let a good quantity of air pass through them. Between these two parts is left a small space, containing a plano-convex lens, which acts like a valve, in letting the air pass from below upwards, and hindering its return into the vessel $\alpha$. The upper vessel $C$ terminates below in a tube $t$, which, being crooked, hinders the immediate ascent to the bubbles of fixed air into that vessel, before they reach the surface of the water in the vessel $\beta$. The vessel $C$ is also ground-air-tight to the upper neck of the middle vessel $\beta$, and has a stopple, $p$, fitted to its upper mouth, which has a hole through its middle. The upper vessel $B$ holds just half as much as the middle one $\beta$; and the end, $t$, of the crooked tube goes no lower than the middle of the vessel $B$.

For the use of this apparatus, fill the middle vessel $B$ with sparging or any other wholesome water, and join to it the vessel $C$. Pour water into the vessel $A$ (by the opening $m$, or otherwise) so as to cover the rising part of its bottom: about three-fourths of a pint will be sufficient. Fill an ounce phial with oil of vitriol, and add it to the water, shaking the vessel so as to mix them well together. As heat is generated, it will be best to add the oil by a little at a time, otherwise the vessel may be broke. Put this, through a wide glass or paper funnel, about an ounce of powdered raw chalk, or marble. White marble being first granulated, or pounded like coarse sand, is better for the purpose than pounded chalk, because it is harder; and, therefore, the action of the diluted acid upon it is slower, and lasts a considerate time. On this account the supply of fixed air is more regular than with the chalk; and besides, when no more air is produced, the water may be decanted from the vessel $A$, and the white sediment washed off, and the remaining granulated marble may be employed again, by adding to it fresh water and a new quantity of oil of vitriol. The funnel in this procès is made use of in order to prevent the powder from touching the inside of the vessel's mouth: for if that happens, it will flick so strongly to the neck of the vessel $B$, as not to admit of their being separated without breaking. Place immediately the two vessels $B$ and $C$ (fastened to each other) into the mouth of the vessel $A$, as in the figure, and all the fixed air which is disengaged from the chalk or marble by the oil of vitriol, will pass up through the valve $S$ into this vessel $B$. When this fixed air comes to the top of the vessel $B$, it will dillodge from thence as much water as is equal to its bulk; which water will be forced up through the crooked tube into the upper vessel $C$.

Care must be taken not to shake the vessel $A$ when the powdered chalk is put in; otherwise a great and sudden effervescence will ensue, which will perhaps expel part of the contents. In such case it may be necessary to open a little the stopple $p$, in order to give vent, otherwise the vessel $A$ may burst. It will be proper also to throw away the contents, and wash the vessel; for the matter will stick between the necks of the vessels, and cement them together. The operation must then be begun anew. But if the chalk be thrown in without shaking the machine, or if marble be used, the effervescence will not be violent. If the chalk be put into the vessel loosely wrapped up in paper, this accident will be still better guarded against. When the effervescence goes on well, the vessel $C$ will soon be filled with water, and the vessel $B$ half filled with air, which will easily be known to be the case, by the air going up in large bubbles through the crooked tube $t$.

When this is observed, take off the two vessels $B$ and $C$ together as they are, and shake them so that the water and air within them may be much agitated. A great part of the fixed air will be absorbed into the water; as will appear by the end of the crooked tube being considerably under the surface of the water in the vessel. The shaking them for two or three minutes will be sufficient for this purpose. These vessels must not be shook while joined to the under one $A$, otherwise too great an effervescence will be occasioned in the latter; together with the ill consequences above-mentioned. After the water and air have been sufficiently agitated, loosen the upper vessel $C$, so that the remaining water may fall down into $B$, and the unabsorbed air pass out. Put these vessels together, and replace them into the mouth of $A$, in order that $B$ may be again half filled with fixed air. Shake the vessels $B$ and $C$, and let out the unabsorbed air as before. By repeating the operation three or four times, the water will be sufficiently impregnated.

Whenever the effervescence nearly ceases in the vessel $A$, it may be renewed by giving it a gentle shake, so that the powdered chalk or marble at the bottom may be mixed with the oil of vitriol and water above it; for then a greater quantity of fixed air will be disengaged.

When the effervescence can be no longer renewed by shaking the vessel $A$, either more chalk must be put in, or more
more oil of vitriol; or more water, if neither of these produce the desired effects.

The ingenious Mr. Magellan has still farther improved the contrivance of Dr. Noot and Mr. Parker; he has two sets of the vessels B and C. While he is shaking the air and water contained in one of these sets, the other may be receiving fixed air from the vessel A. By this means twice the quantity of water may be impregnated in the same time. He has a wooden trough K (fig. 3) to fix the vessels B, C, on, when taken off from A, which is very convenient. He has a small tin trough for measuring the quantity of chalk or marble requisite for one operation, and a wide glafs funnel for putting it through into the vessel A, to prevent its sticking to the sides, as mentioned before.

He has also contrivéd a rapprolile without a hole, to be used occasionally, instead of the perforated one. It has a kind of bafon at the top, to hold an additional weight when necessary. (See fig. 4.) The rapprolile must be of a conical figure, and very loose; but so exactly and smoothly ground as to be air-tight merely by its preflure, which may be increased by additional weights put into its bafon. Its use is to comply with the fixed air on the water, and thereby increase the impregnation; for by keeping the air on the water in this compressed state, the latter may be made to sparkle like Champaigne. And if the vessels are strong, there will be no danger of their bursting in the operation.

If the vessels be suffered to stand fix or eight hours, the water will be sufficiently impregnated even without agitation. But by employing the means above described, it may be done in as many minutes.

The water thus impregnated may be drawn out at the opening K. But if it is not wanted immediately, it will be better to let it remain in the machine, where it has no communication with the external air. Otherwise the fixed air flies off by degrees, and the water becomes rapid and flat; as also happens to other acidulous waters. But it may be kept a long time in bottles well stopped, especially if they are placed with their mouths downwards.

Mr. Blades of Ludgate-Hill has still farther improved this apparatus by changing the rapprolile at K for a glass cock, which is more convenient. He has likewise altered the middle vessel B into a form more advantageous for the impregnation. See fig. 5.

For Dr. Hulme’s method of impregnating water with fixed air, we refer to his “Safe and Easy Remedy for the Stone,” &c. 1778; observing, that he merely mixes the solution of fixed alkaline salt and water, containing as much vitriolic acid as he finds necessary, ‘a priori,’ for neutralizing the alkali, and expelling from it all its fixed air.

Dr. Withering, of Birmingham, has lately contrived a new apparatus for impregnating water with fixed air, which, he says, is preferable to that in common use, because it can be made at less expense, and is more easily prepared; because the whole quantity of fixed air produced is converted to ufe, without any wafe of the vitriolic acid; because it impregnates three times the quantity of water at one time, more completely and with less trouble; and the impregnated water will always retain its virtue, if the joints and cocks of the machine are made perfectly air-tight; for which purpose they should once a year be supplied with a small quantity of unfalited lead. This apparatus is exhibited in fig. 6, and consists of a glass vessel A, about ten inches high in the cylindrical part, and fix inches and a half in diameter; another glass vessel B, about twelve inches high in the conical part, one inch and a half in the neck, and five inches in diameter at the bottom; a copper pipe C passing through the rapprolile of the vessel B, and fixed in the flexible tube D, made of strong leather, air-tight, and kept hollow by means of a spiral wire passing through its whole length; a conical brass pipe E, with a rapprolile fastened to the tube D; another conical pipe F, with a rapprolile G, into which the end of the tube E is accurately ground, so as to be air-tight, and cutting off all communication with the atmosphere when the pipe E is removed; two large hog’s bladders H, H, each of which ought to hold two quarts; a rapprolile I, to prevent the water rising into the bladders, when the vessel A is agitated; a bladder K, tied to the crooked tube with the rapprolile L, which occasionally opens or shuts the communication with the vessel B; a glass funnel M, accurately fitted with the glass stopper N; an aperture O, fitted with a glass stopper or a silver cock, from which the impregnated water is to be drawn for ufe; and, lastly, the tube P opening into the vessel A. When this apparatus is used, let the vessel A be filled with pure water, and any other ingredients that are required, in a proper proportion; into the vessel B put as much marble or whiting, in small lumps, as will cover its bottom to the height of about two inches, and pour in water to the height represented by the dotted line; let the mouth of the vessel A be well fitted with a cork, and through a hole in the cork pass the tube P, putting upon the cork melted sealing-wax of the softest kind, or modelling-wax, to make the whole air-tight. The modelling-wax may be procured at the engravers. It may be prepared by adding to half a pound of melted beeswax, two ounces of tallow, and one ounce of Venice turpentine: to this mass add a sufficient quantity of red lead, or Spanish brown, to give it a colour, and let the mixture be liued till it is cold: let the mouth of the vessel B be stoppered with a piece of mahogany, turned into a conical figure from a lathe, and of a fixe form, what larger than the mouth of the glass will admit; put this piece of wood into the melted beeswax, and heat the wax till the wood begins to grow black: when cool, turn it again till it fits the mouth of the vessel: the tubes C, L, and M, are fitted into holes bored through the wooden stopper, previous to its beingimmered in the wax, push these tubes through the holes, and press the stopper into the orifice of the vessel B, and cement the whole with sealing- or modelling-wax; in this the rapproliles I, L, having previously filled the air out of the bladder K; open the rapproliles G and E; then squeeze the air out of the bladders H, H, and afterwards press the conical pipe E into the pipe F; pour about a large spoonful of oil of vitriol through the funnel M, and fill it with its stopper N. The fixed air let loose by the effervescence in the vessel B, rising through the tube C, passes into the bladders H, H, and diftends them: In this case open the rapprolile I, and from the aperture O draw out about a quart of water, and the space before occupied by the water will be filled with fixable air, which soon begins to be absorbed by the remaining water, and is still supplied from the bladders H, H, and from the effervescing mixture in the vessel B. When the bladders are considerably collapsed, more vitriolic acid must be added through the funnel M, so that they may be always kept pretty fully diftended. When an impregnation is speedily required, turn the rapproliles at G and E, and open that at L; then separate the pipe E from the tube F, and agitate the vessel A; the fixable air will pass into the bladder K, and may be prefled into the two other bladders, when the parts of the apparatus are united. During the agitation, the rapprolile at I should be closed, and open only occasionally to supply out of the bladders H, H, the fixable air absorbed by the water. If a strong impregnation be required, this process should be carried on in a room, the heat of which does not exceed forty-eight degrees of Fahrenheit’s thermometer. Dr. Withering observes,
observes, that the impregnated water receives no taste from the bladders: and that if the vessel A with its impregnated water be separated from the vessel B, at the conical parting E F, it may be included in a pyramidal mahogany cale, out of the lower part of which the silver cock at O projects; and thus serve for an ornamental as well as a luxurious and fabulous addition to the side-board, particularly in the summer and autumnal feasts.

Mr. Henry has described a method of impregnating water in large quantities with fixed air, so as to give it the properties of mineral water, for the use of the sick on board of ships, and in hospitals. He has given the following account of his apparatus and process for this purpose. Cut off the two extremities of a calf's or pig's bladder $f$, (fig. 7.) and having previously moistened them, to one end insert the top of the tubular flopper $e$, round the neck of which is to be closely fastened with stout thread. Into the upper end introduce the part $g$ of the long bent tube $h$, and tie them round in the same manner. The pipe $b$ must be passed through a hole formed by a hot iron borer, in a large cork adapted to the orifice $i$ in the cake B B, holding about ten or twelve gallons, to which it must be cemented; and the length of the pipe from this point must be such as to reach within a few inches of the bottom of the calf: B B, which is to be completely filled with fresh water, or such as has been recovered from lime. See Purifica-

**n**

To a quantity of mild calcareous earth and water, placed in the air-vessel C, add a small portion of strong vitriolic acid, and by the time molt of the common air may be supposed to be expelled by the fixed air arising from the mild calcareous earth, add a larger quantity of acid, and putting the tubulated flopper $e$ in its place, the bladder $f$ will become inflated. Press it gently till its sides collapse; and then introducing the pipe $b$, with its cork, into the orifice $i$ of the calf B B, again press the air forward, as it dilates the bladder into the water cask, where, bubbling up through the water, it will rise to the surface, and by its pressure force the water to ascend into the funnel $k$, which is to be cemented into the head of the cake at $l$. In proportion as the water in the cake becomes impregnated with fixed air, that in the funnel will return into its place; but if, at any time, the latter should rise so high as to be in danger of overflowing, a quantity of air may be let out of the water cask, by means of the small plug $m$. And this is necessary to be done, occasionally, to discharging the residuum of the fixed air, which is not soluble in water.

If the operation be required to be performed more expeditiously, it may be quickened by agitating the water cask. To do this, the tubular flopper $e$ must be withdrawn from the air-vessel, and supported, together with the bladder, by an assistant, while the cake B B is shaken. During this time another tubular flopper must be put into the air-vessel, and it may be immersed into a quantity of lime-water to prevent waste. When the agitation has been continued for some minutes, in proportion to the falling of the water in the funnel, replace the flopper attached to the bladder $f$ in the air-vessel when taken out of the lime-water, and proceed as before, repeating the agitation occasionally.

During the process, additional quantities of vitriolic acid may be introduced into the air-vessel through the opening at $d$, which is to be, at all other times, carefully secured with its flopper.

By this process, fixed air may be imparted to wine, beer, and almost any liquor whatever. And when beer is become flat or dead, it will be revived by this means; but the delicate agreeable flavour, or acidulous taste communicable by the fixed air, and which is manifested in water, will hardly be perceived in wine, or other liquors, which have much taste of their own.

The artificial mineral waters thus made, are more palatable to the taste than the natural Pyrmont or Schützer waters; which, besides their fixed air, contain saline particles of a disagreeable taste, which are known to contribute little or nothing to their medicinal virtues, and may, in some cafes, be hurtful. They are likewise considerably stronger. According to Sir John Pringle, these waters may be made more nearly to resemble genuine Pyrmont water, by adding to each pint of them from eight to ten drops of tinctura martis cum spiritu fals. Or this may be done, by adding to the water in the middle vessel B (fig. 2.) in the proportion of about thirty grains of Ephom salt, ten grains of common salt, a scruple of magnesia alba, and a drachm of iron filings, or iron wire, clean and free from rust, to one gallon of spring water, and impregnating the whole with fixed air in the manner already described. Let them remain till the other ingredients, and as much of the iron as is necessary, are diffused, which will be in two or three days; or the magnesia may be omitted, and then the operation will be finished in less than half that time. These waters may be rendered ferruginous or chalybeate very easily, by putting in the middle vessel two or more slender phials, filled with cuttings of fine iron-binding wire, or with small iron nails; because the impregnated water will dissolve the iron so fast, as to become well saturated with it in a few hours, according to the experiments of Mr. Lane. But the method of rendering these artificial waters chalybeate, used by Dr. Hulme, is to add one grain of salt of feet to each pint (sixteen ounces) of water already impregnated with fixed air.

The discovery of an easy method of impregnating water with fixed air is of great importance; as it is now well known that such water is a very powerful antifeptic, or that it both refits and corrects putrefaction. It is, therefore, given with great success in putrid fevers, in the fea-

**f**

fevur, in dyenteries, in mortifications, and in other dis-

orders arising from a putrid caufe, or attended with putre-

faction, a draught of it being taken now and then, or even by way of common drink. But the ingenious Mr. Bewly has invented a still better method of exhibiting fixed air as a medicine. He directs a scruple of alkaline salt to be disolved in a sufficient quantity (a quarter of a pint, or less) of water, which is to be impregnated with as much fixed air as it can imbibe; this is to be drank for one dose. Mr. Bewly directs it to be prepared in larger quantities at a time, and calls it his mephitic julep. If immediately after it a spoonful of lemon juice, mixed with two or three spoonfuls of water, and sweetened with sugar, be drank, the fixed air will be extricated in the stomach; and thus a much greater quantity of it may be given than the same quantity of water alone can be made to imbibe. Fixed air acts as a corrosorant; and, therefore, may be given with success in weaknefs of the stomach, and in vomitings arising from that cause. It has also been given with success in the stone, and in nephritic complaints. When the lungs are purulent, fixed air, mixed with the air drawn into the lungs, has repeatedly been found to perform a cure. The bark also may be given with advantage in water impregnated with fixed air, as they both coincide in the same intention. Fixed air may be applied by means of a syringe, funnel, or otherwise, to inflamed breasts, putrid ulcers, mortified parts, ulcerated fore throats, and has been found in such and similar cafes to have very remarkable efficacy. It may also be given internally at the same time. In putrid dyenteries, and in putrid stools, fixed air may be given by way of clyster.
PYR

Fermenting cataplasm are of service chiefly as they supply fixed air to the part. In cases of putridity, fixed air has been successfully applied to the surface of the body, exposed to flame of it. It is also found an excellent cooling as well as strengthening beverage in hot relaxing weather, and has the advantage of being pleasant to the taste. See on the subject of this article Priestley's Exp. and Obs. on Air, vol. ii. p. 263; &c. 295, &c. Phil. Trans. vol. xxv. part i. p. 59, &c. Magellan's Description of a Glass Apparatus for making Mineral Waters, &c. p. 1, &c. Priestley's Exp. and Obs. vol. v. Appendix, p. 389, &c. Elliot's Account of the Nature and medicinal Virtues of the principal Mineral Waters, &c. 1781. Henry's Account of a Method of preferring Water at Sea, &c. 1781. p. 19, &c.

PYROBOLOGY, or the art of making fires, is derived from the Greek αέρις, fire, and βάλλειν, to throw. See Pyrotechny.

PYROBOLUS, in Natural History, a name given by many authors to the őlene more generally called pyrites; others have called it siderite, pyrobalanus, pyropus, and albomous, and the Greeks myphas.

PYROCHROA, in Entomology. See Lampyris.

PYROCTOGENON, in Natural History, the name given by Dr. Hill to a genus of fossils usually comprehended by authors, with many other bodies of a different figure and structure, under the general name pyrites.

The characters of the pyroctogenon are these: it is a compound, inflammable, metallic body, of a regular octahedral figure, or composed of eight planes.

There is only one known species of this genus, which is a very singular and elegant fossil, being composed of eight triangular planes; these being the sides of two quadrilateral pyramids, with broad bases, which being joined base to base, constitute the pyroctogenon.

It is found very frequently in Cornwall, Devonshire, and most other of our counties where there are mines. It is sometimes met with loose in the earth, sometimes lodged in the bodies of marcasites, or in the fossil coals, and varies somewhat from its iron colour to a dusky yellow. It is sometimes found with many specimens connected into a mass; these are seldom uniform in size, and cohere in various directions, often greatly injuring another's figure. Sometimes also, as in the case of the crysals, they form a large mass, of which the outer surface only is encrusted or covered with regular figures, the whole inner part being a confused substance.

Masses of this kind are not unfrequently found of a regular orbicular figure, and best all over with regularly figured pyroctogenon of various sizes. Hill.

PYROMALITE, in Mineralogy, a mineral discovered some years ago in the mine of Bjelke, in Vermeland, a province of Sweden, situated on the N. side of the lake Venner, which was observed to have the property of giving out the odour of muriatic acid when heated, and hence distinguished by the name of pyromalite. J. G. Gahn of Fahlen has given the following description of it. Its colour is commonly yellowish-brown, passing into greenish: internally, it is light greenish-yellow. It occurs crystallized in regular six-sided prisms, without any terminating pyramids. It is composed of plates lying on each other in a direction perpendicular to the axis of the prism; principal fracture, repidendent; cross fracture, uneven and without lustré; opaque; semi-hard; scratched by flint; the crysals are often several inches long; specific gravity 3.081. Before the blowpipe it becomes dark reddish-brown, and emits the odour of muriatic acid. It then melts into a black liquid, and at last a small bead is obtained, more or less attracted by the magnet. It diffuses readily, and in considerable quantity in glass of borax, and gives a colour indicating the presence of manganate and iron;—in phosphate of ammonia and soda it diffuses with great difficulty. Its constituents are silica, lime, iron, manganate, and muriatic acid. In the mine of Bjelke it occurs mixed with iron ore, calcareous spar, and black crystallized malachite. Pyromalite was lately analyzed by Mr. Hifinger, who found its constituents to be as follows:

The escape of the acid by heat seems to indicate the presence of a portion of water amounting to about two-thirds of the lods flated as sultained in the analysis. Annals of Philosophy, No. 12.

PYROËNUS, formed of αερις, fire, and στίγμα, stain, is a term sometimes used for rectified spirit of wine; thus called because made by fire, or rather becaufe rendered of a fiery nature.

PYROET, Pyroet, or rather Piroette, in the Marine. See Piroette.

Gen. Ch. Cal. Perianth inferior, small, in five deep segments, permanent. Cor. Petals five, roundish, concave, spreading. Stam. Filaments ten, awl-shaped, shorter than the corolla; anthers drooping, large, with two horns at the base, each discharging the pollen by a terminal orifice. Pj. Germin superior, roundish, angular; style cylindrical, permanent, in length and direction, sometimes scarcely any; stigma thickish, variously shaped. Peric. Capsule roundish, depressed, five-sided, of five cells, bursting at the angles. Seeds numerous, chaffy.

Eff. Ch. Calyx in five deep segments. Petals five. Cap- fule superior, with five cells, bursting at the angles, and many seeds. Anthers with two pores.

Obs. In some species the stamens and style are crecc; in others inclined to one side or the other; in some the former spread every way. The form of the stigma is different in different species. In two American ones the stigma is nearly, or quite, sessile; on which mark Mr. Pursh's genus Chimaphila is founded, its name being nearly synonymous with Winter-green, the English appellation of Pyrola.

Section i. Style elongated. Pyrola of Pursh.

Vol. XXIX.
part in mountainous situations, in the more northerly parts of Europe; also in North America, flowering in July. We have gathered it on the plain of mount Cenis, and in moist parts of the sandy downs of Holland; opposite to which, on the Norfolk coast, this plant has likewise been found by the accurate Mr. Lilly Wigg, growing among bushes, on Bradwell common, not far from Yarmouth; where we likewise have seen it. There is more difficulty in ascertaining an indubitable fixation of this species in the northern or mountainous parts of Britain, because of the media having been so much confounded with it, nor have we any specimens from those countries. The roots are perennial, long creeping, thread-shaped, scaly. Stems very short and simple, leafy, solitary at the end of each shoot of the root. Leaves four or five; on bordered smooth footstalks of various lengths (from one to two inches); roundish or elliptical, obtuse, an inch or inch and a half long, very obscurely crenate, smooth, shining, reticulated with numerous veins; paler beneath. Flower-flask terminal, solitary, about a span long, angular, slightly twisted, smooth, bearing a few scattered lanceolate membranous bracteas, and terminating in a long, rather loose, cluster, of four from to eight or ten large, handloom, white, drooping, but not quite pendulous, fragrant flowers, each having a similar bractea to the ret, at the base of the partial flalk, and fully equal to it in length. Segments of the calyx lanceolate, acute, full half the length of the petals, which, though usually rounded and blunt, have sometimes a pointed appearance. Stamens about the length of the calyx, all turned upward, and crowded together; their anthers deflexed, yellow, with orange horns. German short, five-lobed. Style twice as long as the flamen, slender and quite pendulous in its lower part, gradually swelling towards the extremity, which is recurved. Stigma dilated, annular, with five or less small central points. Capsules the size of a pea, deflexed, five-lobed, crowned with the permanent style and stigma.

2. **P. chlorantha**. Greenish-flowered Winter-green.—Swartz in Stockh. Trans. for 1810. 190. t. 5. (P. folio obtuso, flore viridi-fuco ; Rivin. Pentap. t. 138. f. 1.)—Stamens slightly ascendent. Style twice as long, club-shaped, deflexed and recurved. Cluster many-flowered. Calyx shorter than the flamen.—Native of Sweden, and probably, by the synonym of Rivinus, of Germany, flowering about the middle of July. Professor Swartz distinguishes it from the foregoing, by the smaller, often abrupt, leaves; flalk almost deflexed of bracteas below; petals of a whiteish or yellowish, green hue; and flamen less curved upwards. We gather also, from his figure and description, that the bracteas which accompany each flower are much shorter than the partial flalks, and that the calyx also is shorter, and more close-prefered, than in **P. rotundifolia**. In the posture and form of the flower we find no difference. The common flower-flask is remarkably spirial. Possibly the P. folio rotundato of Rivinus, t. 137, may represent this species in fruit; as the posture of the permanent styles agrees better with it than with the following.

3. **P. media**. Intermediate Winter-green. Swartz in Stockh. Trans. for 1804 (not 1784), 257. t. 7. f. 1. Engl. Bot. t. 1945. Wich. Guide, v. 2. 19. (P. rotundifolia ; Fl. Dan. t. 110.)—Stamens regularly inflexed. Style twice as long, deflexed perpendicularly. Cluster of many pendulous flowers. Calyx shorter than the flamen.—Native of bushy shady places in Sweden, and various parts of the north of England, flowering towards the end of June. We suspect also that this is the Oxfordshire species, commonly mistaken for **minor**, and that it has often in Scotland, from whence we have specimens, been taken for rotundifolia. The leaves most agree with the last-named, but the flowers differ essentially in being smaller, more pendulous, and of a leaf pure white. The flamen are nearly twice the length of the calyx, all regularly and equally inflexed, not at all turned upward. Style bent in a curve downward, its extremity furrowed, slightly thickened, vertical, not recurved. The flalk is spirial, as in the last, with two distinct bracteas in its lower part, the bracteas which accompany each flower being nearly as long as the partial flalks. Even Linneas may perhaps have confounded this with his true **minor**.

4. **P. minor**. Lesser Winter-green. Linn. Sp. Pl. 567. Willd. n. 2. Att. n. 2. Engl. Bot. t. 158. Fl. Dan. t. 55. Rivin. Pentap. t. 1. 136. f. 1. (P. roles ; Engl. Bot. t. 2543.)—Stamens regularly inflexed. Style the same length, straight, stigma lobed, pointless. Cluster of many drooping flowers. Stalk straight.—Native of woods and thickets on the mountains of Europe; occurring in several parts of Scotland and the county of Durham, and flowering in July. This is smaller in general than any of the foregoing; the leaves more elliptical; flalk straight, not spirial, with three principal angles and a smaller one, bearing a few broad bracteas near the base, but scarcely any other, except the small awl-shaped ones at each partial flalk. The flowers are very numerous, but small, drooping or even pendulous, white with more or less of a pink tinge. Stamens regularly incurved. Pores of the anthers dilated, not tubular. Style straight, of a much shorter proportion than any of those we have hitherto mentioned; the stigma large, five-lobed, deflexed, and delinated of points, in the centre. We can no longer doubt that t. 158 and t. 2543 of English Botany represent one and the same species, which we consider as of the genus Cenis, Savoy, and Switzerland, as well as in the Linnean herbarium. **P. media**, having been confounded by botanists in general with this, has caused all our perplexity expressed in Engl. Bot. t. 2543. The plant which Mr. Lightfoot introduced at Bullbrode, we judge from memory to have been media ; see Engl. Bot. t. 158.

5. **P. asarifolia**. Asarabacca-leaved Winter-green. Michaux Boreal-Amer. v. 1. 251. Parn. n. 2.—"Leaves kidney-shaped. Stalk with a few heathing, convoluted, distant scales. Flowers turned every way. Style decurling," Michaux.—Found by Michaux in Canada; by Parn in beech woods on the mountains of Pennsylvania, flowering in July. The flowers are yellowish-green. If it were not for the heathing scales, "we should suspect this might be the same as our chlorantha, n. 2, whose leaves are often, it seems, short and abrupt; but we have seen no specimens answerable to either.

6. **P. dentata**. Toothed Winter-green.—Leaves elliptic-obovate, obtuse, toothed. Stalk straight, obscurely angular, nearly naked. Stamens ascending. Style deflexed, strongly recurved. Stigma with a cylindrical point. Gathered by Mr. Menzies, on the west coast of North America. This species is readily distinguished from all others, hitherto discovered, by its leaves, which are obovate, or somewhat elliptical, one and a half or two inches long, half or three quarters of an inch broad; their margin bevel with very remarkable distinct, small, blunt teeth, usually near a quarter of an inch asper; their surface not reticulated, but furnished with one series of connected arching veins, on each side the midrib. Flower-flasks triangular, about as long as the leaves. Flower-flalk six inches long, nearly naked, round, very slightly angular, bearing a long loose cluster of flowers, much resembling those of the first species in hice and structure, as well as in the position of their flamen; but their style is still more remarkably recurved, so as to form a semi-circle; and the point of the stigma much more prominent, of a cylindrical shape, five-leaf at the summit.

7. **P. aphylia**. Leafless Winter-green.—Stem and stalk scaly,
fealty, without leaves. Antlers beaked. Style deflexed and recurved. Stigma with a cylindrical point.—Gathered on the west coast of North America, by Mr. Menzie, who affirms the plant is always quite different of leaves, instead of which the angular floem bears numerous laticifers, by which, the pores of the leaves are nearly as large as the leaf, but our dried specimen will not allow us to determine the pores of the floem. The petals are long and narrow, with a small acute point at the contrary end to the pores. Style deflexed, its end somewhat recurved. Stigma with a long cylindrical point, like the leaf.

S. P. _Picta_. Variegated Winter-green.—Leaves ovate, somewhat serrated. Flowers drooping all one way. Pores of the antlers contracted, tubular. Style curved. Stigma abrupt, with five small points.—This also was found by Mr. Menzie on the west coast of North America. In some places it appears with the two last, as well as with the _pyrola calocoma_, and its allies; in others it resembles the following, but is a totally distinct species. The petals are near an inch and half long, and almost an inch wide, ovate, bluish with shallow, more or less dilated, serratures, rather spreading, marked with large branching veins, and variegated with white or yellowish blotches. _Pyrola calocoma_ nearly as long as the leaves. _Pyrola saxatilis_ six inches long, obliquely ascending, quadrangular, twisted, bearing two or three short, ovate, pointed scales. _Flowers_ numerous, as big as those of the _pyrola calocoma_, as far as we can judge from the dried specimen, drooping toward one side. _Calyx_ short, broad, and spreading. _Stamens_ all, as far as can be discerned, alike disposed round the genus; their antlers short, ovate, minutely pointed, the edges prominent in the form of two short narrow tubes, contracted at the orifice. _Style_ curved, but we cannot tell in what direction. _Stigma_ scarcely at all thicker than the style, abrupt, with an acute edge, and apparently five minute sharp central points.

9. P. _secunda_. Serrated Winter-green. Linn. Sp. Pl. 567. Willd. n. 3. Ait. n. 3. Pursh n. 4. Fl. Dan. t. 431. Engl. Bot. t. 517. (P. _secunda_ tenerrima; Chuf. Hift. v. 2. 117, Ger. Em. 408. P. folio macronata; Rivin. Pentap. irr. 139. f. 1.)—Leaves ovate, acute, serrated. Flowers drooping all one way. Pores of the antlers dilated. _Style_ straight. _Stigma_ dilated, five-lobed.—Native of mossy alpine woods in various parts of Europe, from Lapland to Greenland, as well as from sandy barren woods in North America, from Canada to New Jersey, flowering in July. It occurs in fir or birch woods, in several parts of the highlands of Scotland; as also near Moffat in the lowlands; and according to Ray in Yorkshire. The _leaves_ are long and trailing. _Leaves_ scattered or crowded, an inch or more in length, with numerous fine shallow serratures, and abundance of reticulated veins. _Pyrola saxatilis_ half the length of the leaves. _Flowers_ from three to six inches long, erect, straight; round below; angular above; with two or three green ovate scales. _Calyx_ of many crowded greenish-white flowers, not half the size of the foregoing, nor so much expanded. _Stamens_ regularly placed round the genus, at first curved, then straight. _Anthers_ whith, short, pointles; their pores somewhat oblique, but not tubular, soon becoming dilated and jagged. _Style_ straight, twice the length of the flower. _Stigma_ much dilated, annular, but thin-edged, terminating in a large five-lobed umbellicum fimbriatum.

10. P. _uniflora_. Single-flowered Winter-green. Linn. Sp. Pl. 568. Willd. n. 6. Ait. n. 6. Pursh n. 5. Fl. Dan. t. 8. Engl. Bot. t. 146. (P. _quarta_ minima; Chuf. Hift. v. 2. 118. Ger. Em. 408. P. flore singulare; Rivin. Pentap. irr. 139. f. 1.)—Stalk bearing a solitary flower. Pores of the antlers contracted, tubular. _Stigma_ with five rays.—Native of alpine forests, among mossy hills, in various parts of Europe and North America. It was first discovered, in the British dominions, by Mr. James Hoggan, who gathered wild specimens, now before us, in the western islands of Harris and Bernera, in 1783. Mr. James Hoy, and Mr. Brodie of Brodie, have also gathered this most elegant and curious plant in fir woods of the county of Moray. It is, like the rel, perennial and evergreen, blooming in July. The _leaves_ vary greatly in shape and acuteness, but are generally roundish, about an inch long, more or less strongly serrated, and reticulated with many veins. _Pyrola saxatilis_ half as long. _Flowers_ solitary, simple, erect, three inches high, with one concave _bracteae_, and a large, terminal, white, or lightly reddish, _flower_, an inch in diameter, and smelling like lily of the valley. _Stamens_ spreading equally, half the length of the corolla, three of them lying on one of the petals, one only on another, and two on each of the three remaining. _Anthers_ short, ovate, pointles; their pores tubular, considerably elongated. _Style_ erect, straight, the length of the _germen_. _Stigma_ large, of five thick, spreading, acute, ray-like lobes. The wild specimen delineated in the _Botanist's Magazine_, having travelled from so great a distance, was in too imperfect a condition to allow of the figure being so good as usual.

Section 2. Stigma nearly fimbriatum. Chimalphila of Pursh.

11. P. _umbellata_. Unbudded Winter-green. Linn. Sp. Pl. 567. Willd. n. 4. Ait. n. 4. Curt. Mag. t. 778. (P. tenuifoliatas; Chuf. Hift. v. 2. 117, Ger. Em. 408. P. folio arbutiflorus; Rivin. Pentap. irr. 139. f. 2. Chimalphila corymbosa; Pursh n. 2.)—Leaves ovate, serrated. Flowers somewhat umbellate. _Stigma_ nearly fimbriatum. _Stamens_ smooth.—Native of woods in the northern parts of Europe, Asia and America, but not found wild in Britain. Mr. Menzie gathered it on the west coast of North America, and Mr. Pursh found it frequent in dry woods, from Canada to Virginia. Linnacus, Gmelin, Pollich, Roth, &c. give it in their Floras. Dr. Sims, who received this species in flower in June, from Mr. Loddis, judiciously affirms it to be the most beautiful of all the genus. The _leaves_ are woody, a span high, somewhat branched, angular, and rugged. _Leaves_ crowded together into something like whorls, flanked, narrow-ovate, bluish, strongly serrated; dark green and veiny above; paler beneath; about an inch and a half long. _Flowers_ terminal, solitary, three inches long, reddish, bearing about five, imperfectly umbellate, simple, partial stalks, each an inch long, spreading, rough with glandular pubescence, and sometimes furnished with a little lanceolate _bracteae_. _Flowers_ smaller than that of _P. uniflora_, but larger than any other of the foregoing, drooping. _Petal_ orbicular, concave, cream-coloured, crimson at the base. _Stamens_ short, red, all regularly ineflexed. _Anthers_ short, purple, with white tubular pores, dilated and lobed at the orifice. _Germen_ globosus; green. _Style_ thick and very short, but certainly present. _Stigma_ orbicular, convex, with five flight notches. The American _leaves_ are usually less umbellate, and more racemose, than the European.

12. P. _maculata_. Holly-leaved Winter-green. Linn. Sp. Pl. 567. Willd. n. 5. Ait. n. 5. Curt. Mag. t. 897. (P. mariana, arbuti foliis angustifloribus, &c.; Pluk. Mant. 157. Phyt. t. 349. f. 4. Chimalphila maculata; Pursh n. 1.)—Leaves ovato-lanceolate, with tooth-like serratures. Stalks two or three-flowered. _Stigma_ nearly fimbriatum. _Stamens_ woolly.—This is exclusively an American species. Mr. Pursh observed it in shady gravelly or sandy woods, from Canada to Carolina, and Mr. Menzie brought specimens...
mens from the north-west coast. It is now and then met with in our more curious gardens, requiring bog earth, with shade and moisture, and flowering in June and July. Its shrubby habit is like the lilac, but of more humble growth. Leaves more pointed, with sharper tooth-like serratures; their upper surface marked, along the rib and veins, with a pale stripe. Partial flowers-flakes usually two, rarely three, drooping. Flowers the size of the lilac, but white. Stamens densely fringed in their lower part. Anthers and filaments white. Papillose•

PYR

PYROLIGNOUS Acid, or Empyreumatic acid of wood, in Chemistry, a species of empyreumatic Acréous Acid (which see), prepared by distilling in a glass or earthen retort a quantity of shavings of any kind of wood, such as box, guaiacum wood, or beech; in which case an extremely strong-smelling dark-coloured empyreumatic acid liquor is obtained, nearly one-third of the weight of the wood. This acid is fomer, and also much blacker and more empyreumatic, than either the pyroneum or pyrocarbou acid, probably as requiring a stronger heat for its production. The acid of wood is obtained in a large quantity near London, from the preparation of charcoal for gunpowder, by distilling wood in cast-iron cylinders. It stains the hands deeply, and wood indelibly. This acid is procured in such a quantity as to be an object of manufacture. At the boil it is only an inferior acetic acid, and the difficulty of purifying it will prevent the profitable use of it in many of the arts to which vinegar is applied. However, as the process for procuring radical vinegar at the same time purifies this empyreumatic acid, it may probably be used for this purpose. It may be added, that much of the acid from the distilled charcoal for gunpowder, near London, is employed by calico-printers in forming the acetated iron, used as a mordant, as in this case the colour and smell of the acid are not at all detrimental. Some time ago Vauquez announced, as a new discovery, that pyroligneous acid is identically the same as the acetic; but this was known to Glauher near 200 years ago. In the folio edition of his works, p. 188, may be seen directions for its distillation, with a copper-plate of the apparatus which he employed. He there calls it the vinegar of wood. Parker's Chem. Catech. p. 195, note.

PYROMACHUS, a name given by lome to antimony, when reduced to a flaky hardness; and by others to copper, when fused with sulphur, and thus rendered less ductile. PYROMANCY, or divination, a kind of divination, performed by means of fire.

The ancients imagined they could foretell futurity by inspecting fire and flame: to this end they considered its direction, or which way it turned. Sometimes they added other matter to the fire, e. gr. a vessel full of urine, with its neck bound about with wool, watching narrowly on which side it would burst, and thence taking their augury. Sometimes they threw pitch on it, and if it took fire immediately, they esteemed it a good augury.

PYROMETER, formed of pyro, fire, and metere, in Physics, the name of a machine contrived to measure the alteration of the dimensions of metals, and other folid bodies, arising from heat. These instruments have been constructed of various forms; but as their object is to render the small expansions of solids apparent to the observer, they have consisted of a machine adapted to this purpose, and of an apparatus fit for heating the body under examination to a determined degree. The most usual, and, indeed, the most eligible mode of heating the bodies, is to place them in water, in which a thermometer is placed, and to heat the water by means of lamps. The small expansions of the heated solids have been rendered visible, by multiplying-wheels, or by levers, or by fine screws, which render a small motion communicated to one end of the mechanism productive of a great movement at the other end; and, secondly, by magnifying the small expansion through microscopes; which, being, upon the whole, to be the method that is both most certain and most manageable; for with wheels and pinions, and even with levers or screws, there is always some equivocal motion, arising from the loose connection of teeth and pinions, or from the arres and bending of other parts.

Mufchenbroek, who was the original inventor of this machine, has given a table of the expansion of the different metals, in the same degree of heat. Having prepared cylindrical rods of iron, lead, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same flame, when it began to freeze, and Fahrenheit's thermometer was at thirty-two degrees. The effects of which experiment are digested in the following table, where the degrees of expansion are marked in parts equal to the third part of an inch.

PYROMETER.

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments it appears, at first view, that iron is the least rarefied of any of these metals, whether it be heated by one or more flames; and therefore is most proper for making machines, or instruments, which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same, summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the plates, placed together, cause a greater rarefaction than when they have a sensible interval between them; iron, in the former case, being expanded 117 degrees, and only 109 in the latter; the reason of which difference is obvious. By comparing the expansion of the same metal, produced by one, two, three, or more flames, it appears, that two flames do not cause double the expansion of one; nor three flames three times that expansion, but always less; and these expansions differ much more from the ratio of the number of flames, as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but more, more, and less. Thus, tin began to run, when rarefied 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

As to the construction of M. Mushchenbroeck's pyrometer, together with Defagulier's alterations and improvements, the curious may consult Defagul. Experim. Philos. vol. i. p. 421, &c. See also Mushchenbroeck's translation of the experiments of the Academy del Cimento, printed at Leyden in 1731. And for a pyrometer of a new construction, by which the dilatations of metals in boiling fluids may be examined and compared with Fahrenheit's thermometer, see Mushen. Introduct. ad Philosophiam Nat. 4to. 1762, vol. ii. p. 616.

But it has been observed, that M. Mushchenbroeck's pyrometer was liable to some objections; and a contrivance was made, with a view of removing the; by Mr. Ellicott, who has given a description of his improved pyrometer in the Philosophical Transactions, N° 443. This may also be seen in Dr. Martyn's Abrigment, vol. viii. p. 464.

This instrument is formed with a flat piece of brass AA, (Plate XXIII. Mifellany, fig. 4.) which is screwed down to a thick piece of mahogany. Upon this plate are screwed three pieces of brass, two of which, B, B, serve to support the flat iron bar C, called the standard bar. The upper part of the third piece of brass is a circle D, about three inches in diameter, divided into three hundred and sixty equal parts, or degrees; within this circle is a moveable plate E, divided likewise into three hundred and sixty parts, and a small feel index. The bar of metal E, upon which the experiment is to be made, is laid on the standard bar. F is a lever two inches and a half long, fastened to an axis, which turns in two pieces of brass, screwed to one of the supports B. To the end of this lever is fastened a chain, or silk-line, which, after being wound round a small cylinder, to which the index in the brass circle, D, is fastened, passes over a pulley, with a weight hung to the end of it. Upon the axis, to which the lever is fixed, is a pulley, a quarter of an inch in diameter, to which a piece of watch-chain is fastened, the other end of which is hooked to a strong spring G, which bears against one end of the metal E. H is a lever, exactly of the same form and dimensions with the other; but the chain fastened to the pulley on its axis is hooked to the standard bar. The line fastened to the end of this lever, after being wound round a cylinder, to which the moveable plate is fixed, passes over a small pulley, and has a weight hung to the end of it; or rather the same line, passing under a pulley to which the weight is hung, has its other end fastened to the lever F; so that one weight serves for both levers. From this description it is plain, that whenever the bar E is lengthened, it gives liberty to the weight to draw the lever F upwards by its action to the spring G; and the index will, at the same time, by means of the silk line, be carried forward in the circle; and as the bar shortens, it will return back again: the same motion will be communicated to the standard bar. When the bar is lengthened the 20th part of an inch, the index will be carried once round the brass circle, which is divided into three hundred and sixty degrees; and, therefore, if the metal lengths the 7200th part of an inch, the index will move one degree. In order to make an experiment with this instrument, lay a bar of any kind of metal, as E, on the standard bar; then heat this bar to any degree of heat with a lamp, and mark the degree of its expansion, as indicated by the moveable plate; observe also the degree of expansion of the metal E, by the heat communicated to it from the standard bar, as marked on the brass circle by the index: let the instrument stand, till the whole is thoroughly cold; then removing the bar E, lay any others successively in its place, and proceed exactly as before; and thus the degrees of expansion of different metals, by the same degree of heat, may be estimated.

By the help of this instrument Mr. Ellicott found, upon a medium, that the expansion of bars of different metals, as nearly of the fame dimensions as possible, by the same degree of heat, were as follow:

| Gold, Silver, Brasses, Copper, Iron, Steel, Lead | 73 | 103 | 95 | 89 | 60 | 56 | 149 |

The great difference between the expansions of iron and brass, has been applied with good success to remedy the irregularities in pendulums arising from heat. Phil. Trans. vol. lxxvii. p. 485. See Pendulum.

Mr. Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four thousandth part of an inch. On this general principle Mr. Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw. A B C D, (fig. 5.) represents the main bar or base of this instrument; E F is the bar to be measured, lying in two notches, one fixed to the upright standard A B, the other to the principal lever H I; the end E of the bar E F bears against the point of G, a screw which is of use in examining the micrometer-screw; the other end of the bar F bears against a small spherically protuberant bit of hard metal, fixed at the fame height as G, in the principal lever H I; K is an arbor fixed in the base, which receives at each end the points of the screws, in the principal lever H I; L, M, upon which the lever H I turns and serves as a fulcrum to it; O is a slender spring, to keep the lever in a bearing flat against the bar; and P is a check, to prevent the lever from falling forward, when the bar is taken out; N is the feeder, somewhat in the shape of a T, suspended, and moveable up and down upon the points of the screws, I, M.
PYROMETER.

I, M, which, as well as L, H, are so adjusted as to leave the motion free, but without shake; Q R is the handle of the feeder, movable upon a loose joint at K, so that laying hold of it at Q, the feeder is moved up and down, without being affected by the irregular pressure of the hand; the extremity, S, of the feeder is also furnished with a bit of protruberant hard metal, to render its contact with the point of the micrometer-screw more perfect; T is the micrometer-screw; V the divided index-plate; and W a knob for the handle; the micrometer-screw passes through two solid screwed holes at D and Y; the piece Y Z is made a little springy, and endeavours to pull the screw backwards from the hole at D, and consequently keeps the micrometer-screw constantly bearing against its threads the same way, and thereby renders the motion thereof perfectly steady and gentle; X is the index, having divisions upon it, answering to the turns of the screw. This piece points out the divisions of the plate, as the face of the plate points out the divisors upon the index. When the instrument is used, lay hold of the knob at Q with one hand, and, moving the feeder up and down, with the other move forward the screw T, till its point comes in contact with the feeder; then will the plate and index, V and X, shew the turns and parts. The basis of this instrument, as well as the other parts of it, is brafs: one end of which is continued of the same piece at right angles, to the height of three inches and a half; and the other end acts upon the middle of a lever of the second kind, whose fulcrum is in the basis; and, therefore, the motion of the extremity of the lever is double the difference between the expansion of the bar and the basis. Hence, having the length of the lever from its fulcrum to the point of suspension of the feeder, the distance between the fulcrum and the point of contact with the bar, the inches and parts that correspond to a certain number of threads of the micrometer, and the number of divisions in the circumference of the index-plate; the fraction of an inch exprefsed by one division of the plate may be deduced. Those measures are as follow: from the fulcrum of the lever to the feeder, 5.875 inches; from the fulcrum to the point of contact, 2.895 inches; length of seventy threads of the screw, 2.455 inches; and the divisions in the circumference of the index-plate, 100. Hence the value of one division will be the \( \frac{5.875}{100} \) part of an inch; but if the screw be altered one-fourth of one of these divisions, when the contact between the screw and feeder is well adjusted, the difference of contact will be very perceivable to the slightest observer; and, consequently, \( \frac{5.875}{400} \) th part of an inch is perceivable in this instrument. When the instrument is made use of, it is immersed, together with the bar to be measured, in a cifer of water; which water, by means of lamps underneath, is made to receive any intended degree of heat not greater than that of boiling, and thereby communicates the fame degree of heat to the instrument, the bar, and to a mercurial thermometer immerged therein, for the purpofe of afferenting that degree. See fig. 6, in which A B is the cifer, C the cover, which, when the instrument (fig. 5.) is raised upon blocks, goes on between the bar E F and the basis B C; D a handle to take off the cover, when hot; E the mercurial thermometer; F the cock, to let out the water; and G H a hollow piece of tin, which supports seven spirit lamps, which are raised higher or lower by the screws L and K, in order to give the water in the cifer a proper degree of heat. With this pyrometer Mr. Smeaton performed several experiments, which are arranged in a table; and their refult agrees very well, he observes, with the proportions of expansions of several metals given by Mr. Ellicott. The following table fhews how much a foot

in length of each metal grows longer, by an increase of heat corresponding to 180° of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expreffed in such parts of which the unit is equal to the 10,000th part of an inch.

For a farther account of this instrument, with its ufe, fee Phil. Trans. vol. xlviii. art. 79. p. 598, &c.

Mr. Ferguson has constructed and described a pyrometer, which makes the expansion of metals by heat visible to the 45,000th part of an inch. The upper surface of this machine is reprefented by fig. 7. Its frame, A B C D, is made of mahogany, on which is a circle divided into three hundred and sixty equal parts; and within that circle is another, divided into eight equal parts. If the short bar B E be pushed one inch forward (or toward the centre of the circle,) the index c will be turned 125 times round the circle of 360 parts or degrees. As 125 times 360 is 45,000, it is evident, that if the bar B E be moved only the 45,000th part of an inch, the index will move one degree of the circle. But, as in this pyrometer the circle is nine inches in diameter, the motion of the index is visible to half a degree, which answers to the 90,000th part of an inch in the motion or pulling of the short bar E.

One end of a long bar of metal F is laid into a hollow place in a piece of iron G, which is fixed to the frame of the machine; and the other end of this bar is laid against the end of the short bar E, over the supporting cros-bar H I: and, as the end, f, of the long bar is placed close against the end of the short bar, it is plain that if F expands, it will push E forward, and turn the index c.

The machine stands upon four short pillars, high enough from a table, to let a spirit lamp be put on the table under the bar F; and, when that is done, the heat of the flame of the lamp expands the bar, and turns the index.

There are bars of different metals, as silver, brafs, and iron; all of the fame length as the bar F, for trying experiments on the different expansion of different metals, by equal degrees of heat applied to them for equal lengths of time; which may be measured by a pendulum that swings seconds. Thus.

Put on the brafs bar F, and set the index to the 360th degree: then put the lighted lamp under the bar, and count the number of seconds in which the index goes round the plate, from 360 to 360 again; and then blow out the lamp, and take away the bar.

This done, put on an iron bar F where the brafs one
PYROMETER.

was before, and then let the index to the 360th degree
again. Light the lamp, and put it under the iron bar, and
let it remain just as many seconds as it did under the bras
one; and then blow it out, and you will see how many
degrees the index has moved in the circle; and by that
means you will know in what proportion the expansion of
iron is to the expansion of bras; which will be found to
be as 210 is to 360, or as 7 to 12. By this method, the
relative expansion of different metals may be found.

The bars ought to be exactly of equal size, and to have
them fo, they should be drawn, like wire, through a hole.

When the lamp is blown out, you will see the index turn
backward; which shews that the metal contracts as it
cools.

The inside of this pyrometer is constructed as follows.

In fig. 8. A a is the short bar, which moves between
rollers; and, on the fide a, it has fifteen teeth in an inch,
which take into the leaves of a pinion B (twelve in number),
on whose axis is the wheel C of one hundred teeth, which
take into the ten leaves of the pinion D, on whose axis
is the wheel E of one hundred teeth, which take into the
ten leaves of the pinion F, on the top of whose axis is the index
above-mentioned.

Now, as the wheels C and E have one hundred teeth
each, and the pinions D and F have ten leaves each, it is
plain, that if the wheel C turns once round, the pinion F,
and the index on its axis, will turn one hundred times round.
But, as the first pinion B has only twelve leaves, and the
bar A a that turns it has fifteen teeth in an inch, which
is twelve and a fourth part more; one inch motion of the bar
will cause the half pinion F to turn one hundred times round,
and a fourth part of one hundred over and above, which is
twenty-five. So that if A a be pulled one inch, F will
be turned one hundred and twenty-five times round.

A flax thread b is tied to the axis of the pinion D,
and wound several times round it; and the other end of the
thread is tied to a piece of slender watch spring G, which
is fixed in the flax H. So that as the bar f expands, and
pushes the bar A a forward, the thread winds round the
axle, and draws out the spring; and as the bar contracts,
the spring pulls back the thread, and turns the work the
contrary way, which pulls back the short bar A a against
the long bar f. This spring always keeps the teeth of the
wheels in contact with the leaves of the pinions, and so
prevents any shake in the teeth.

In fig. 7, the eight divisions of the inner circle are so
many thousandth parts of an inch in the expansion or con-
traction of the bars; which is just one thousandth part of
an inch for each division moved over by the index. Fer-

Another pyrometer was invented by M. De Luc, in
consequence of a hint furggeled to him by Mr. Ranfden.
The basis of this instrument is a rectangular piece of deal
board two feet and a half long, fifteen inches broad, and
one inch and a half thick, and to this all the other parts are
fixed. This is mounted in the manner of a table, with four
deal legs, each a foot long, and an inch and a half square,
well fitted near its four angles, and kept together at the
other ends by four firm crosstieces. This small table is
fastened with a hook to a flax; the board being in a ver-
tical situation in the direction of its grain, and bearing its
legs forward in such a manner as that the crosstieces which
join them may form a frame, placed vertically facing the
observer. This frame supports a microscope, which is
firmly fixed in another frame that moves in the former by
means of grooves, but with a very considerable degree of
tightness; the friction of which may be increased by the
premure of four screws. The inner sliding frame, which is
likewise of deal, keeps the tube of the microscope in a
horizontal position, and in great part without the frame,
inasmuch that the end which carries the lens is but little
within the space between the frame and the board. This
microscope is constructed in such a manner as that the
object observed may be an inch distant from the lens; and
it has a wire which is situated in the focus of the glafs, in
which the objects appear reversed. At the top of the
apparatus there is a piece of deal, an inch and a half thick,
and two inches broad, laid in a horizontal direction from
the board to the top of the frame. To this piece the rods
differing substances, whose expansion by heat is to be
measured, are suspended: one end of it fides into a focket,
which is cut in the thickness of the board, and the other
end, which rests upon the frame, meets there with a ferew,
which makes the piece move backwards and forwards, to
bring the objects to the focus of the microscope. There
is a fork very strongly driven through a hole bored vertically
through this piece; and in another vertical hole, made
through the cork, the rods are fixed at the top; in that
they hang only, and their dilatation is not counteracted by
any pressure. In order to heat the rods, a cylindrical bottle
of thin glass, about twenty-one inches high, and four inches
in diameter, is placed in the inside of the machine, upon a
stand independent of the rest of the apparatus. In this
bottle the rods are suspended at a little less than an inch
distance from one of the fides, in order to have them near
the microscope. Into this bottle is poured water of dif-
ferent degrees of heat, which must be stirred about by
moving upwards and downwards, at one of the fides of
the bottle, a little piece of wood fastened horizontally at the
end of a stick: in this water is hung a thermometer, the
ball of which reaches to the middle of the height of the
rods. During these operations the water rises to the cork,
which thus determines the length of the heated part; the
bottle is covered to prevent the water from cooling too
rapidly at the surface; and a thin cafe of bras prevents
the vapour from fixing upon the piece of deal to which the
rods are fixed. This pyrometer is represented in fig. 9, in
which a a is the flax to which it is suspended; b the hook
from which it hang; c c the deal-board, which is the basis
of the whole apparatus; d, d, d, d, four arms, to which is
fixed the frame e e e e; the other frame which carries the
microscope is s s s s; g g, are two crosstieces, through
which passes the tube of the microscope, and which support
it near both ends; h h is the microscope; i i its micrometer;
the cork, through which passes the glass rod H; and by
which it is kept suspended; m a rod of metal, or any other
substance less dilatible than glass; n the point of union,
obtained by means of two connected rings, in which both
rods are fastened by screws: above these is another pair of
rods, in one of which the metal rod is free, and which rod
it supports; o p the piece to which the glass rod is sus-
pendied; q a square piece fixed to the frame by four ferews,
behind which is a box, in which, as well as in a groove cut
in the basis in p, the piece o p slides; r a screw, which passes
through the square piece q, whose use is to move backwards
or forwards the piece q, in order to bring the surface of the
metal rod to the focus of the microscope: s, s, s, four
ferews, with round metal plates behind their heads, which
serve to press the frame of the microscope against the
frame e e e e; the longitudinal openings, through which
the ferews pass, permit the free motion of the first frame, when
one strikes gently with a hammer to the bottom or the top
of one of the fides. If the microscope is wanted higher
or lower than the grooves permit, the ferews may be re-
moved
moved to other holes made on purpose in the side pieces or the frame eces: tili is the cylindrical bottle, in which hang the rods in order to be heated at different degrees by water of various temperatures; \( u, u \), are the supports of the bottle; \( z \), the thermometer suspended in the water; \( y, y \), a rod, to the lower end of which is fixed a small plate, to stir the water, by moving it up and down; \( a, a \), a lyphon, one branch of which is within, and the other without, the bottle, the latter being furnished with a cock, which serves to draw off the quantity of water that is necessary for changing the temperature in the bottle. For a farther account of this instrument, together with the principle of its construction and use, both in the comparative measurement of the expansions of bodies by heat, and the measure of their absolute expansion, and the experiments made with it, we must refer to an elaborate essay of M. De Luc on Pyrometry, &c. in the Phil. Trans. vol. lxviii. part i. art. 20. p. 419—546.

All the contrivances above described must be considered as inferior to that constructed by Mr. Ramden, of which general Roy has given an accurate and minute account in the Phil. Trans. vol. lxxx. p. 462. We shall here give such an account as our limits will allow of this instrument, the construction of which is so accurate, says major-general Roy, that it seems not easy to improve it; and refer for a fuller account illustrated by appropriate drawings. This pyrometer, named the microscopes, because by means of two microscopes attached to it, the expansion is measured, consists of a strong deal frame, 5 feet long, nearly 28 inches broad, and about 42 inches in height. The metallic bar, whose expansion is to be measured, and which may be even five feet long, is placed in a copper trough little longer than five feet; and this is placed over 12 spirit lamps, the flames of which heat the water of that trough fully to the boiling point, and of course heat the bar which is plunged into it. Two other wooden troughs, also full of water, are placed parallel to, and at a little distance from, the copper one. Each of these contains a cast-iron prismatric bar. To the ends of one of these bars two microscopes are fastened in an horizontal situation, perpendicularly to the bars. One of these microscopes is furnished with a micrometer, or mechanism, to measure the magnified image of an object; the other microscope has a simple mark. The parts of the microscopes, as well as the proper marks for measurement, are separately and diffusely, partly upon the ends of the cast-iron rods, and partly upon the ends of the rod under examination, that if any of them be lengthened or shortened, that alteration is clearly perceived through the microscopes, and may be measured by means of the micrometer. It follows, that if the temperature of the cast-iron prismatric bars be kept unaltered, whilst that of the bar under examination is increased, then the increase of length, which is measured by the micrometer, must be attributed to that bar only, and by these means the expansions of seven substances were ascertained. For further particulars relating to the construction and use of this instrument, we refer to the Transactions (ubi supra), and to the article Expansion in this Cyclopaedia. For an account of Wedgwood's pyrometer, see Thermometer. Also, for a description of Mr. Troughton's pyrometer, we are under the necessity of referring to the same article.

PYROMUCOUS Acid, or Empyreumatic acid of sugar, or Syrupus acid, (which see,) and denotes that pungent acid vapour of sugar, or any saccharine matter strongly heated, which is familiar to every person who has ever entered a sugar baking-house. It is prepared by chemists in the following manner: Put into a very large glass retort any quantity of pulverized sugar of any kind, so as to fill only 5th of it, as the matter very much swells in the process; adapt to it a large receiver, not closely luted, and heat it gradually on a sand-bath. A great quantity of gas arises when the sugar begins to be scorched, which is mostly carbonic acid mixed with an inflammable gas, probably the gaseous oxys of carbon. In the receiver is condensed a weak acrid liquor, coloured by an oily matter, and also apparently foiled by a portion of fuliginous matter volatilized during the distillation. The quantity of acid, obtainable in this process, varies according to the regulation of the fire, which should at least be pushed so as to make the retort red-hot, and to reduce the sugar to a perfect charcoal; but in general about 3ths of the weight of sugar may be obtained of the distilled acid. Gum mucilage, manna, honey, starch, and other mucous or mucro-faccharine substances, yield, by distillation, the same acid as sugar. Aikin, Dicht. Min.

PYRONOMIA, a term used by the chemical writers to express the art of regulating fire, so as to make it subserve to all their purposes in a determinate degree.

PYROPE, in Mineralogy, a precious stone, formerly called the Bohemian garnet. (See Garnet.) The colour is a dark red blood: when held between the eye and the light, the red colour inclines to a yellow. The pyrope is never found crystallized, but occurs in small round or angular fragments imbedded in ferpentine rock, or scattered in the sands on the sea-shore, and in alluvial ground. It scratches quartz. The specific gravity is stated by Klaproth 3.718. On account of its luster, transparence, colour, and hardness, it is much prized by jewellers. The small grains, when powdered, are applied to cut softer stones. According to Klaproth, the constituent parts of pyrope are

PYROPHAGI. See Fire-Eaters.

PYROPHANES, in Mineralogy, a variety of the semi-opal; so called because, being heated in a spou, it becomes transparent, but returns to its opaque state when cold, as Mr. Landriani has discovered. M. Sauflure, junior, renders common hydrophanes transparent, and of a topaz colour, when heated by digesting them in melted wax. It is said that some pyrophanes are found in Armenia, which are transparent while exposed to the sun, and opaque at night. See Gem.

PYROPHORUS, formed of \( \omega, \omega, \) fire, and \( \omega, \omega, \) I bear, in Chemistry, the name usually given to this substance called by some black phosphorus; a chemical preparation possessing the singular property of kindling spontaneously when exposed to the air.

This substance was accidentally discovered by M. Hornberg, who prepared it of alum and human faces. (See Phosphorus Fasciculis.) See also M. Le Fevre's preparation, described under Phosphorus of Sulphur.

It was apprehended for a considerable time after the discovery, that human faces were essential to the operation, till the youngest son of the great Lemery found, that honey, figs, flour, and, indeed, any animal or vegetable matter, might be substituted instead of the human faces; and since that time M. de Suvigny has shown that moist vitriolic salts may be substituted for the alum; having added to the alu-
pyrophorus.

Auminous pyrophorus of Homberg two other classes of substances of this kind, viz. the metallic, or those made with the three vitriols of iron, copper, and zinc; and the neutral, or those composed of vitriolated tartar and Glauber's salt.

The auminous pyrophorus may be made in the following manner. Take four or five parts of alum, and one part of wheat flour, or any animal or vegetable substance; calcine these together to a brown or blackish mass: powder the mass, and put it into a phial; fill it loosely with paper, and let it in a slow heat, so as to make it continue glowing hot for some time; after this remove the whole from the fire, let it cool gradually, and finally stop the bottle very close down.

The following process is recommended by Macquer for this preparation. Let three parts of alum and one part of coarse brown sugar be mixed together. This mixture must be dried in an iron ladle or hearth over a moderate fire, till it be almost reduced to a blackish powder or coal; during which operation it must be stirred with an iron spatula. Any large malleable masses must be broken into powder, and then it must be put into a glafs matras, the mouth of which is rather larger than wide, and its length seven or eight inches. This matras is to be placed in a crucible, or rather earthen vellum, large enough to contain the belly of the matras, with about a space equal to the thickness of a finger all round it. The space is to be filled with sand, so that the matras shall not touch the earthen vellum; the apparatus is then to be put in a furnace, and the whole to be made red-hot; the fire must be gradually applied, till any oily or fulminate matter may be expelled. After which, when the matras is made red-hot, sulphurous vapours exhale: this degree of heat is to be continued till a truly sulphurous flame, which appears at the end of the operation, has continued nearly a quarter of an hour: the fire is then to be extinguished, and the matras to cool without taking it out of the crucible; and when it ceases to be red-hot, it must be stopt with a cork. Before the matras is perfectly cold, it must be taken out of the crucible; and the powder it contains must be poured into a very dry glass phial, which must be well closed with a glass stopper. If we would preserve this pyrophorus a long time, the bottle containing it must be opened as seldom as possible. Sometimes it kindles while it is being poured into the glass phial, but it may be then extinguished by closing the phial expeditiously.

Another excellent method of preparing pyrophorus, cited by Aikin from Higgins's Minutes, is the following. Mix together three parts of Roman alum, and one of flour, and heat the mixture to dryness in an iron pot, as already described: the black calcined mass thus produced is to be put into ounce phials of green glass, coated without and within with clay. The phials thus charged are to be lightly stopped with balls of tempered clay, and then set up to their necks in sand in an iron pot; charcoal powder is then to be thrown on to the depth of half an inch, over which is to be placed an earthen cover, luted to the pot. The whole apparatus is now to be placed in a furnace, and kept at a red heat for an hour and a half; at the expiration of which period, being taken out of the furnace and cooled quickly, it is to be unpacked, and the phials containing the pyrophorus are to be placed with their mouths inverted in mercury, in which situation the pyrophorus may be kept for many years without injury.

When half a drachm of this pyrophorus is put on a piece of paper and exposed to air, it quickly kindles, becomes red like burning coals, emits a strongly sulphurous vapour, and burns the paper or other combustible body which happens to be near it; and nothing is left but the white earthy bafe of the alum. When no sensible change takes place in the pyrophorus, either from a defect in the preparation, or from some air remaining in the phial that contains it, the combustion may be effected by breathing on the powder, and thus supplying it with the moisture which seems to be the primary agent in this phenomenon. The pyrophorus that is made in the last method we have described is so highly inflammable as to take fire while it is falling from the mouth of the phial. If it be poured into a jar of pure oxygen gas, it forms a brilliant fiery shower: the oxygen is for the most part consumed, and there remain in the jar sulphurous acid and carbonic acid gases: the pyrophorus also being consumed with the exception of its auminous bafe.

The spontaneous accension of the auminous pyrophorus, on its being exposed to the air, has been a subject of considerable difficulty among chemists and philosophers; several of whom have adopted the hypothesis proposed by M. de Savigy, in the Memoires de Mathematique et de Physique, tom. iii. To explain this curious appearance, M. de Savigy observes, that the vitriolic acid in the alum, during the calcination in the phial, leaves its earthy bafe, and unites with the phlogiston in the coal. By its union with this inflammable matter, a part of it is undoubtedly rendered volatile, and exhales partly under the form of volatile vitriolic acid, and partly in that of a blue sulphurous flame; while another part of it combines likewise with the phlogiston forming a real sulphur, or an earthly hepar sulphuris, in which the sulphur is protected from the fire by the earth with which it is combined, and the particles of which remain every where intermixed with those of the powder. Thus far (says Mr. Bewly, an excellent chemist and philosopher) M. de Savigy is supported by the appearances, and by a just chemical analysis of the powder: but he proceeds farther, and supposes that, at the end of the process, a part of the vitriolic acid is left in a disengaged, or uncombined state, and highly concentrated. In this state it is well known that this acid attracts moisture, and at the same time generates a considerable degree of heat. When the pyrophorus, therefore, is exposed to the air, he again supposes that this acid, disengaged from the coal, is now concentrated and is suddenly attracted by the wet particles floating in the atmosphere, and by the heat thus generated, sets fire to the sulphur and other inflammable matter contained in the powder. This hypothesis he has endeavoured to establish by the following observations: that the pyrophorus, as he apprehends, can be made only with substances fit for producing sulphur, or with sulphur itself:—that no pyrophorus will be produced, if the mixture be calcined by too long or too violent a fire; because then the whole vitriolic acid may be combined into perfect sulphur, and consequently is engaged, and not in a proper state to attract the moisture of the air; or else if it does not combine into sulphur, being half disengaged from its bafe, it is driven off by the violence or long continuance of the fire: and, consequently, after this complete calcination, no acid remains partly disengaged, as it ought to be, that might unite with the water with sufficient activity:—that when the pyrophorus is very slowly moisened, when it is kept in a bottle not well closed, it does not kindle, because sufficient heat is not produced by this flow and gradual attraction of water; it is also spoilt and rendered incapable of kindling, when exposed to the open air; because its acid becomes then faturated, or nearly faturated with moisture, and cannot, therefore, unite with that of the air with sufficient activity:—that a pyrophorus, thus spoilt by exposure to moisture, may be restored to its peculiar properties by making it again red-hot in a matras; since by this calcination its partly-
disengaged acid is again concentrated, and resumes all its force of combining with water — and, lastly, that the inflammation of the pyrophorus is accelerated by placing it upon a paper a little wetted, or by breathing upon it; because the acid then attracts the moisture more hastily, and consequently with more heat.

M. de Suvigny extends the same reasoning to the several other pyrophoræ which he discovered, similar to that of alum; particularly to those which are made by substituting vitriolated tartar, Glauber’s salt, and other vitriolic falls with metallic, earthy, or alkaline bases, in the room of alum.

Mr. Bewly has examined this hypothesis with his usual acuteness and accuracy; and from numerous well-conducted experiments he is led to conclude, that pyrophorus of all the above-mentioned classes may be prepared, differing from them in no other particular, except that they contain no vitriolic acid, and which nevertheless kindle as readily, on being exposed to the air, as those which have been impregnated with that principle. In order to show that the presence of vitriolic acid is not necessary to constitute the pyrophorus made with vitriolated tartar, he added to a quantity of this tartar more than an equal weight of powdered charcoal, and calcined the mixture a long time, in a red heat, in an open crucible; frequently stirring the powder, in order to expel from it as much of the vitriolic acid as possible; the calcination was also sometimes repeated with fresh charcoal; and yet on heating the salt, thus deprived of a considerable part of its acid, with charcoal, in a crucible or tobacco-pipe, in the manner which we shall here subjoin, he observed no diminution in its quality of producing a pyrophorus.

Mr. Bewly, in several of his experiments, made use of the bowl of a tobacco-pipe, in which he combined the materials, which he wished to examine in small quantities, and in an expeditious manner; pressing them down slightly, so as to fill half or three-fourths of the bowl, and filling the remainder of it with fine sand. This is kept in a red heat twenty minutes, or half an hour; or it may continue there two hours longer, if the operator pleases, without any injury to the pyrophorus. The pipe being taken out of the fire, the matter is knocked out of it as soon as it becomes cool, and generally, pretty soon afterwards, takes fire spontaneously. Thus he formed his pyrophorus with a mixture confining of two parts of charcoal, previously calcined in a red heat; and of powdered charcoal and salt of tartar each one part.

In another experiment, having added successively various and increasing quantities of fixed alkali to the salt heated as above, till the vitriolic acid contained in the mixture might be considered nearly as an evanescent quantity, a pyrophorus was still produced on calcining it with charcoal as before. He also mixed equal parts of salt of tartar, and vegetable or animal coal, or sometimes three parts of the former with two of the latter, and calcined them in the usual manner; and this composition, on being exposed to the air, generally kindled in half a minute or a minute; though, as it contained no sulphur, it did not burn with so much vivacity as the vitriolic pyrophorus. This, which Mr. Bewly calls the alkaline pyrophorus, differs in no circumstance from Mr. de Suvigny’s neutral pyrophorus, except in its not containing that principle to which he ascribes their appearance. However, left it might be suspected that the salt of tartar which he employed might accidentally contain vitriolated tartar, or vitriolic acid, he repeated the experiment with tartar calcined by himself, as well as with nitre fixed or alkalified by deflagration with charcoal, and with iron fillings; and in all these cases with the same result. By diversifying in a like manner M. de Suvigny’s experiments on the metallic pyrophorus, Mr. Bewly found that none of the three vitriols, heated with charcoal alone, in his usual method, could produce a pyrophorus. And thus he found that the addition of an alkaline salt to the composition, which was a part of M. de Suvigny’s process, was essential to its success.

Treating in the usual manner equal parts of calcined green vitriol and charcoal, the powder which contained no sulphur nor hepar sulphurus, did not acquire any of the properties of a pyrophorus. The vitriolic acid seemed to have been entirely dissipated; having no hope to detain it, when dislodged from the metallic earth. The charcoal and calx of iron, left in this proceœ, were calcined again, together with some salt of tartar; and a pyrophorus was produced, which exhibited indications of its containing a scarcely perceptible portion of hepar sulphurus. Thirty grains of crocus martis affringens were calcined with fifteen grains of charcoal, and the same quantity of salt of tartar; and the mixture burnt spontaneously, though it contained no hepar sulphurus, or vitriolic acid. Having by these experiments evinced that metallic pyrophorus may be prepared without vitriolic acid, Mr. Bewly proceeded to form an aluminous pyrophorus of the same kind. For this purpose, he procured the earth of alum by a long and violent calcination; and examining a part of it, he found, by the usual tests, that it neither contained any sulphur, hepar sulphurus, nor alum undecomposed. This he considered as perfectly pure, though he afterwards found that it contained a small quantity of vitriolated tartar: and yet it repeatedly furnished a pyrophorus as active as when alum itself is employed. From these and similar experiments he infers, that the several kinds of pyrophoræ are not kindled by moisture attracted by the vitriolic acid, as M. de Suvigny has maintained; and his conclusion is further confirmed by some experiments of Dr. Priestley, from which it appears, that they are kindled in dry, nitrous, and dephlogisticated air.

M. Proust, cited by Mr. Bewly, describes a variety of new pyrophoræ, which neither contain vitriolic acid, nor seem likely to owe their accension to the attraction of humidity from the air. These principally consist of a coaly matter simply divided by metallic or other earths; such are the sediment left on the filter in preparing Goulard’s extract, various combinations of tartar, or its acid, or the acetic acid, with metals, calcareous earth, &c.

Mr. Bewly, having evinced the insufficiency of M. de Suvigny’s theory, and discovered that the pyrophorus are not kindled by moisture, attracted (merely) by the vitriolic acid, directed his attention to the nitrous acid, which Dr. Priestley has shewn to be a constituent part of atmospheric air, as the probable agent in the production of this phenomenon. The strong affinity which this acid has with phlogiston, and the heat, and even flame, which it is known to produce with certain inflammable matters, manifested that it was equal to the effect; and having excluded the vitriolic acid from having any essential concern in this operation, he suggests, either that the pyrophorus is kindled by moisture attracted by some of the other ingredients which compose it; or that it has the power of decompounding atmospheric air, by suddenly attracting its nitrous acid, and thereby generating a heat sufficient to kindle the phlogistic matter contained in it. This idea appeared plausible, when he further considered that Dr. Priestley produced the purest respirable air with this same acid combined with other principles; and that this as well as common air is diminished, and probably in part decom- pounded, in a variety of phlogistic proceœses. This ingenious writer concludes, upon the whole, from the experiments he hath made, that the pyrophorus seems to owe its singular
lar property to its being a combination of earth or alkali with phlogiston; the vitriolic acid, when present, only occasion-ally increasing or diminishing the effect, according to circum-
stances. In the process of calcination, the earth or alkali principle is not merely mixed, but actually, though loosely, combined with the phlogistic principle of the coal; so that the pyrophorus, considering it in its most simple state, is only a perfectly dry phlogificated alkali or earth. On these data, the phenomena may be explained in the two following 
methods; with respect particularly to the influence of mois-
ture and heat upon the pyrophorus. Supposing either the alkali or earthy principles to have a greater affinity to water than to the phlogiston with which either of them is united, they may, on being exposed to a moist atmosphere, attract the humidity, and therefore fit the phlogistic principle at liberty; which may, in its turn, attract and be ignited by, the fupposed aerial acid, its 4rong affinity to which is well known:—or, if this hypothesis be rejected, the inflammable matter may be kindled, merely in consequence of the heat produced by the combination of the alkali, &c. with moisture. This reasoning, however, supposes the existence of phlogiston, which modern chemists have generally exploded.

The chemical changes that take place during the formation and decomposition of pyrophorus, as they are stated by Aikin, appear to be the following: 1. By being heated below red-
nesses in the open air, the ingredients enter into fusion, and thus mix accurately with each other; then the water of clystallization is driven off from the alum, and of the fugar or flour, little else than the charcoal escapes volatilization. 2. The red heat to which it is exposed in the phial causes the sulphuric acid of the alum and charcoal of the fugar to re-act on each other, by which part of the charcoal is driven off in the form of carbonic acid, and part of the sulphuric acid escapes as sulphurous acid. The blue flame that charac-
terizes the latter part of this process is probably caused by the volatilization and combustion of a portion of sulphur, more than is requisite to saturate the potash of the alum. Thus the pyrophorus, when prepared, consists of alumine, charcoal, and sulphuret of potash in intimate mixture. 3. When this powder is exposed to the air, a rapid decom-
position of the air itself, and of the moisture which it contains, takes place; the oxygen of each being absorbed by the ful-
phuret, while a sufficient quantity of heat is diffused, to bring the charcoal and remainder of the sulphur to a rate of actual inflammation. See on the subject of this article, Macquer's Chemical Dict. art. Pyrophorus; and Priestley's Obs. on Air, vol. iii. Appendix, p. 386, &c. vol. iv. Appendix, p. 479. &c. Aikin's Dictionary.

PYROPHYLACIA, a term used by Kircher and some others, to express those magazines of fire which are placed in the cavities of mountains and other hollows of the earth, and serve to supply the several volcanoes in the different parts of the world. See Volcano.

PYROPHYSALITE, in Mineralogy, is so called from μυς, fire, and φυσιλατα, a bubble, because this mineral emits bubbles when exposed to the flame of the blowpipe. It is found at Finno, near Fladdern, in Scotland, imbedded in a granitic rock. The colour of pyrophylalite is white, incl-
ing to green, and occasionally small spots of blue floor fpar are seen on its surface. It commonly occurs in oblong pieces, some of which approach to an irregular rhomboid. It differs from felpspar, to which it has the most resemblance, in having but one determinate direction in which it can be fplit; its specific gravity is also greater, and it fules more cafily. The fragments scratch glafs, but are less hard than quartz. The powder of the fmall fragments emit a phosphorofecent light when heated. Its specific gravity is 3.45,

and the constituent parts, according to Hefinger and Ber-
zelius, are

The substance lost during the process is suspected to be fluor acid. Hally clasps this mineral with the topaz. See Topaz. B.

PYROPECEILOS, in the Natural History of the Ancients, the name by which they call the granite of Arabia, commonly known to this day under the name of the Oriental granite.

The name is derived from the Greek, πυρος, fire, or fire-co-
oured, and πειρείλος, spotted; and the ancients having used the epithet fiery to yellow, as well as red, some have imagined the granite must be a yellow stone; but it is evident that red is the colour meant by it here.

PYROSOMETER, an instrument invented by professor Leslie for measuring the intensity of fire. This is merely the differen-
tial Thermometer (which see), with one of its balls covered with vitrified leaf, while the other is naked. The fire heats the naked ball, but not the vitrified ball. Hence the liquid in the tube rises or falls, according to the intensity of the fire, and of course marks that intensity.

PYROSCOPIA, formed of πυρος, fire, and σκοπεῖν, to con-
 sider, among the Greeks, a kind of divination, being the same with pyromancy and ignipunctum.

PYROSIS, in Medicine, called in Scotland the water-
broth, is a disorder of the stomach, which is characterized by a sudden and violent attack of pain in that organ, followed by a copious discharge of a colourless, inipid, and generally cold fluid, resembling saliva, from the æsophagus, mouth, and throat.

The first description of this disease was given by Linnaeus, as a common affection of the Laplanders, under the appropriate appellation of Cardialgia Phlegatoria; whence Sauvages gave it the denomination of pyrosis Succisa. (Nofol. Meth. clafs vii. gen. 18.) Dr. Cullen adopted the generic term pyrosis, and deems it an idiopathic disease. It seems to occur, however, in conjunction with other forms of indi-
gestion, and might have been arranged as one of the symp-
toms of diphtheria.

The fits of pyrosis usually come on in the morning and forenoon, when the stomach is empty. The first symptom is a pain at the pit of the stomach, with a sense of constri-
ction, as if the stomach were drawn towards the back; the pain is increased by raising the body into an erect posture, and therefore the patient bends himself forward. This pain is often extremely severe, with a sense of burning; and after continuing for some time, it brings on an eruciaction of a thin watery fluid in considerable quantity. This fluid has sometimes an acid taste; but most commonly it is described as being absolutely insipid. It continues to be brought up for some time, and does not immediately give relief to the pain which preceded it; but at length it terminates the pain, and the fit ceases.

These paroxysms come on without any evident cause, nor is the origin of the disease always to be imputed to any par-
ticular form of diet. It seldom, if ever, attacks those peo-
ple who use fresh animal food daily; but appears to be most common among those who live almost entirely upon tea, milk, potatoes, and farinaceous substances. It is much more common
common in women than in men; sometimes it attacks pregnant women, and often those who labour under leucorrhoea. It seldom occurs in any one before the age of puberty, or in those who are considerably advanced in life: when it has once taken place, it is very prone to recur occasionally for a long time afterwards. It is more common in Scotland than in this country, and chiefly affects the lower clavies of the people.

While the same diet is continued, it is not always easy to cure the disease. The paroxysm is most effectually relieved by anodynes, especially opium; hyoscymus, comum, &c. answer a similar purpose; and with less certainty; other Stimulants and antipathodies, as sulphuric ather, ammonium, the tincture of guaiacum, &c. alleviate the fit. These remedies, however, do not materially contribute to prevent the recurrence of the paroxysms; and bitters, aromatics, and the whole of remedies against indigestion, have been often employed in vain. A combination of aromatic laxatives, with strong alkalies and narcotics, have appeared to the writer of this article to be on the whole the most effectual remedies. See Cullen, Fire Lines, vol. iv. p. 1.

**Pyrose** is also a word used to express an intense heat and redness in the face, such as that of persons who travel in extremely hot weather, and the like.

Gen. Ch. Cal. Perianth superior, short, in four deep, acute, broad segments, deciduous. *Cor.* of one petal, somewhat bell-shaped; tube threese as long as the calyx, swelling gradually upwards; limb of the same length, in four acute, equal, spreading segments; throat downy. Stam. Filaments four, short, inserted into the tube of the corolla, alternate with the segments of the limb; anthers oblong, erect, pointed, shorter than the limb. *Pf. Germin* turbinate, inferior; style short, cylindrical; stigma capitate. *Peric.* Berry small, dry, pear-shaped, with eight furrows, and eight cells, defulte of any crown. *Seeds* solitary in each cell.

Eff. Ch. Calyx four-toothed. Corolla bell-shaped, four-cleft, downy in the throat. Berry inferior, obovate, with eight furrows and eight seeds.

Obf. Jullieu, by an error which seems typographical, attributes five segments to the corolla, which Willdenow copies. There are, however, four, but as the analogy of the other parts, in this case, necessarily requires.

1. *P. foliicidia*. Willow-leaved Streps-berry. Willd. n. 1. (Pyrolstria obovata; Lamarck Illust. v. 1. 289. t. 68. f. 2; not f. 4.)—Gathered by Commerson, in the isle of Bourbon; not, as Willdenow has it, the Mauritians. A shrub, with round, smooth, greyish, leafy branches. Leaves opposite, on short stalks, rather crowded, two or three inches long, elliptic-lanceolate, sharp-pointed and toothed, entire, coriaceous, smooth, with one rib, and several lateral incurved veins, occasionally accompanied by an axillary gland-like tube-celle, that seems accidental; paler beneath. *Sipulas* between the footstalks, and of the same length, awl-shaped, erect, dilated at the base, deciduous. *Flower-stalks* axillary, solitary, somewhat umbillate, bearing one or more simple, single-flowered, partial flowers, with a pair of oblong tapering bractlets at the base of the latter. *Floors* hardly a quarter of an inch long, erect, apparently white. *Fruit*, according to Lamarck, near an inch in length, pear-shaped, umbilicated, with eight deep longitudinal furrows. When cut transversely, it swells the eight seeds, compressed, and radiating from the centre.

**Pyrotartarous Acid, or Empyreumatic acid of tartar,** a species of empyreumatic acetic acid, very different from Tartarous acid; which see. To procure this acid, distil any quantity of cream of tartar in a glass or earthen retort, as in the process for Pyromicous Acid: the retort being half full of the tartar, on raising the fire very slowly, the first produce is a limpid, acidulous, somewhat bitterish water, after which, as the heat increases, a most prodigious volume of the inflammable gas is given out, together with a stronger acid, and more empyreumatic liquid, and at last a black oil, and some volatile alkali.

The whole quantity of liquid acid procured from tartar in this method, is generally not more than about a quarter of the weight of the tartar, and is not quite so brown, nor so highly empyreumatic as the pyromicus. This acid, and also the pyruligneous and pyromicous acids, are capable of very considerable purification by easy methods, so that they lose their empy-ruma, their peculiar taste and smell, in which confit their characteristic differences, till at last, when brought into the most concentrated state by some of the modes in which vinegar is dephtagmated, they exhibit the characters of acetic acid so unequivocally, that no doubt can be entertained of their identity. Simple rectification, or redistillation in a very gentle heat, and lopping the procès when the liquor at last comes over much coloured, will purify, to a very great degree, the pyromicous and pyruligneous acids: the latter, by this process, from being of a dark coffee colour, assumes the hue of very pale clear bany. But on long exposure to light, it again becomes brown, for it retains its empyreumatic character more than any other. Charcoal, newly burnt and powdered, contributes very much to the purification of all these acids; they may be either gently distilled off it, or even merely filtered through a fraction of the boiling. But the most effectual method of purification is by uniting these acids with lime, or a fixed alkali, evaporating to dryness, and then expelling the acid by means of the sulphuric acid, in the same manner as the concentrated vinegar is prepared. The acid vapour that rises in this process has now lost its empyreuma almost entirely; it has both the strength and the powerful odour of radical vinegar; when again united to potash, forms acetated potash, which may be obtained white by repeated crystallization, or by charcoal powder, and in short is perfect acetic acid. Aikin.

**Pyrotechny,** derived from the Greek words πυρ, fire, and τεχνη, art, is a term applied to the art or science which teaches the management and application of fire in certain operations. Although this term has been used in a very extensive sense by some writers, and applied to the use and structure of fire-arms and artillery employed in the art of warfare, yet it is commonly confined, as it will be in this work, to those articles and instruments made use of for amusement, and for grand public occasions, as the celebration of victories, the demonstrations of public joy on account of peace, after long continued war, &c.

Of the origin of artificial fire-works there is nothing certain recorded. In Europe the invention of them is of recent date, and is given to the Italians. The use of fire-works in China was very general long before they were known in European countries: and from an account given of some recent exhibitions at Pekin, it should seem that they have attained to a degree of perfection not surpassed even by the artists of England, France, or Italy. "The fire-works, in some particulars," says Mr. Barrow in his Travels in China, "exceeded any thing of the kind I had ever seen. In grandeur, magnificence, and variety, they were, I own, inferior to the Chinese fire-works we had seen at Batavia, but infinitely superior in point of novelty, neatness,
neatness, and ingenuity of contrivance. One piece of machinery I greatly admired; a chest five feet square was hoisted up by a pulley to the height of sixty or sixty feet from the ground: the bottom was so constructed as then suddenly to fall out, and make way for twenty or thirty firings of lanterns enclosed in a box to descend from it, unfolding themselves from one another by degrees, so as at last to form a collection of full 500, each having a light of a beautifully coloured flame burning brightly within it. This Devilation and development of lanterns were several times repeated, and, at every time, exhibited a difference of colour and figure. On each side was a correspondence of smaller boxes, which opened in like manner as the others, and let down an immense net-work of fire, with divisions and compartiments of various forms and dimensions, round and square, hexagons, octagons, &c. which flown like the brightnest burnished copper, and flashed like prismatic lightening with every impulse of the wind. The diversitie of colours with which the Chinese have the secret of clothing fire seems one of the chief merits of their pyrotechny. The whole concluded with a volcano, or general explosion and discharge of fans and flares, sefires, crackers, rockets, and granadoes, which involved the gardens for above an hour in a cloud of intolerable smoke.

The apparatus used in making fire-works consists of solid wooden cylinders, called formers, for rolling the casks on; similar cylinders, either of wood or metal, for ramming down the composition; moulds for holding the casks while filling; a machine for contracting the cavity of the casks; another for grinding the materials; and a particular apparatus for boring some casks after they are filled.

Conflagration of the Cartridges for Rockets. A rocket is a cartridge, or case made of fluff paper, which, being filled in part with gunpowder, saltpetre, and charcoal, rises of itself into the air when fire is applied to it. There are several kinds and sizes of rockets, but the three following are the principal: viz. 1. Small ones, the calibre of which is not larger than that of a bullet of a pound weight. 2. Rockets, the calibre of which is equal to the size of a ball of from one to three pounds weight. 3. Large rockets, equal to a ball of from three pounds to a hundred weight.

To give the cartridges the fame length and thickness, they are put into a hollow cylinder of metal, or strong wood. This mould is not to be confounded with another piece of wood, called the former or roller, around which is rolled the thick paper employed to make the cartridge. The rule for the size of the mould and roller is this: if the calibre of the mould be divided into eight equal parts, the diameter of the roller must be equal to five of these parts; of course the vacuity between the roller and the interior surface of the mould is equal to 3ths of the calibre of the mould, which will be exactly filled by the cartridge.

The size of the mould is measured by its calibre; but the length of the moulds for different rockets does not always bear the same proportion to the calibre, the length being diminished as the calibre is increased. In small rockets, the length of the mould ought to be six times the diameter of the calibre; but in the larger sized rockets, it need not be more than between four and five times the calibre of the mould.

Large fluff paper of a peculiar kind is employed in making cartridges, and hence it has obtained the name of cartridge-paper. This paper is wrapped round the roller, and then cemented by means of common paste. When the cartridge is formed, the roller is drawn almost out, by turning it round, until it is distant from the edge of the cartridge the length of its diameter. A piece of cord is then made to pass twice round the cartridge at the extremity of the roller; and into the vacuity left in the cartridge another roller is introduced, so as to leave a space between the two. By means of the cord, the cartridge must be pinched till there remains only an aperture capable of admitting an instrument called a piercer: then the cord is removed, and its place is supplied by a piece of packthread.

Besides the roller, a rod is employed to load the cartridge, which must be somewhat smaller than the roller, that it may be easily introduced into the cartridge. This rod is pierced lengthwise to a sufficient depth to receive the piercer, which must enter into the mould, and unite with it exactly at the lower part. The piercer, which decreases in size, is introduced into the cartridge through the part where it has been chocked, and serves to preserve a cavity within it.

After the cartridge is placed in the mould, the prepared composition is to be poured gradually in, and rammed down with great accuracy. When the cartridge is about half filled, separate, with a bodkin, half of the folds of the paper which remains, and having turned them back on the composition, press them down, and pierce three or four holes in the folded paper, by means of a piercer, which must be made to penetrate to the composition of the rocket. These holes serve to form a communication between the body of the rocket and the cavity at the extremity of the cartridge, as it is called, or that part which has been left empty. In small rockets this cavity is filled with granulated powder, and covered over, which serves to let them off: in those that are larger, the pot, containing flars, serpentts, and running rockets, is adapted to it.

It now remains to affix the rocket to its rod, which is thus done. When it has been constructed, in the way just described, it is to be fastened to a rod of light smooth wood. Its length and weight must be proportioned to the size of the rocket; that is, it ought to be as long as to remain in equilibrium with it, when suspended on the finger, or other fulcrum, within an inch, or an inch and a half of the neck. Before it is fixed, place it with the neck downwards, and let it rest on two nails, in a direction perpendicular to the horizon: and to make it ascend to a greater height, adapt to its summit a pointed cap made of fluff paper, which will serve to facilitate its passage through the air. To these rockets may be added several other things, as a petard, which is a box of tin plate filled with fine gunpowder, placed on the summit. The petard is placed on the composition, at the end where it has been filled, and the remaining paper of the cartridge is folded down over it, to keep it firm. The petard produces its effect when the rocket is in the air, and the composition is consumed. A representation of a rocket completely fitted up is given in Plate Pyrotechny, fig. 2.

Stars, serpentts, &c. may be added to them, which is done by adjoining to the head of the rocket an empty pot or cartridge, larger than the rocket, in order that it may contain the things intended to render the exhibition the more beautiful. The following tables are necessary to those who would manufacture rockets for themselves. The first shews the size of the calibre of the mould for rockets of a pound weight and below; and the second points out the size required for the calibre of moulds of from 1lb. to 5lbs. It must be observed, that a pound rocket is that which is just capable of admitting a leaden bullet of a pound weight, and so of the reft.
Here it is evident, that the mould of a rocket of twelve ounces in weight ought to be seventeen lines in diameter; one of five ounces will require a mould of thirteen lines in diameter. Hence we derive an easy method of finding the size when the weights are given; and if the diameter of the rocket be given, it will be equally easy to find the weight of the ball corresponding to that calibre. Thus, if the diameter be fifteen lines, it will, by the table, be seen that it corresponds to a ball of eight ounces.

**TABLE II.—Size of the Calibre of Moulds, of from 1 to a 50lb. Ball.**

</table>

By this second table, if the weight of the ball be given the size of the mould may be found: suppose it be 18 pounds, opposite to it is the number 262. Then we lay by the rule of proportion (as 100 : 18 = 262 : x; therefore x = 181), which gives the required calibre to be less than 18 lines, or 5 inches and four lines, or 4½ inches. If the calibre be given in lines, the weight of the ball may be found: suppose the given calibre be 36 lines, then as 193 : 262 = 36 : x; therefore x = 181, which shows that the weight of the ball will be more than 6 lbs., or, in other words, that a rocket, the diameter or calibre of which is 36 lines, is a rocket of a 6lb. ball.

The composition of the powder for rockets must be different, according to the different sizes, it being completely ascertained that what is proper for small rockets would be too strong for the larger ones.

For rockets of one or two ounces, the composition should be one pound of gunpowder, and two ounces of finely ground soft charcoal.

For rockets of somewhat larger size, the composition may be five pounds of gunpowder, three and a half of saltpetre, and three ounces of charcoal.

If rockets be of five or six ounces weight, then to two pounds five ounces of gunpowder, add eight ounces of saltpetre, two ounces of sulphur, six ounces of charcoal, and two ounces of iron filings.

If the rockets be from ten to twelve ounces, you may add to fourteen ounces of gunpowder, four ounces of salt-petre, three and a half of sulphur, and one ounce of charcoal.

For rockets of a pound weight: to one pound of gunpowder add an ounce of sulphur, and three ounces of charcoal.

For rockets of from four to seven pounds: to thirty-one pounds of saltpetre, add four pounds and a half of sulphur, and ten of charcoal: and for those that are still larger, we may add to eight pounds of saltpetre, one pound four ounces of sulphur, and two pounds twelve ounces of charcoal. In all cases the ingredients are to be pounded separately, and finely sifted before they are used. Gunpowder, thus reduced from the corn in which it is manufactured, is called meal-powder.

**Match.**—The matches to let off rockets are thus made. Take linen, hemp, or cotton thread, and double it eight or ten times, if intended for large rockets, or only four or five times, if to be employed for flars. When the match is thus made, dip it in pure water, and being soaked, it is to be squeezed as dry as possible. Mix some gunpowder with a little water, so as to reduce it to a kind of paste, and immerse the match in it, turning and twisting it till it has imbued a sufficient quantity of gunpowder; then sprinkle it over with dry powder, and when it is dry, it is fit for use.

In answer to the inquiry what cauces rockets to ascend in the air, we may observe, that it is nearly the same as that which produces a recoil in fire-arms. Thus, when powder is inflamed in the chamber of a musket or cannon, it exerts its power against the breech of the piece, and against the bullet or wadding. But the resistence opposed by the bullet being much less than that opposed by the mass of the barrel or cannon, the bullet is forced out with great velocity. The cause of the ascent of a rocket is nearly the same. At the moment when the powder begins to inflame, its expansion produces a torrent of elastic fluid, which acts in every direction, that is, against the air which opposes its escape from the cartridge, and against the upper part of the rocket; but the resistence of the air is more considerable than the weight of the rocket; therefore the rocket ascends by the excess of the one of these forces over the other. This, however, would not be the case unless the rockets were pierced to a certain depth.

**Brilliant Fire and Chinefe Fire.**—As iron-filings, when thrown into the fire, enflame and emit a strong light, this gave rife to the idea of rendering the fire of rockets much more brilliant, than when gunpowder, or the substances of which it is composed, are alone employed. But the Chinese have long been in possession of a method of rendering this fire much more brilliant and variegated in its colours. It confisits in the use of a very simple ingredient, namely, caft iron reduced to a powder more or less fine: the Chinese give it a name that answers to iron-fond in our language. It is prepared from old iron pots pulverized, till the grains are not larger than radish seed. These, however, are passed through sieves of different degrees of fineness; those that pass through the coarsest sieve, are called sand of the first order;
order; those which pass through the next sieve in fine, sand of the second order, and so on. This sand, when it inflames, emits an exceedingly vivid light, forming almost instantaneous luminous flowers and stars of various apparent magnitudes. It should be observed that rockets, into the composition of which iron-filings and iron-sand enter, cannot be long preserved, owing to their readiness in attracting the moisture which the saltpetre gives out. The following tables exhibit the proportions of the different ingredients for rockets of this kind from 12 to 33 lbs.

When these materials have been accurately weighed, the saltpetre and charcoal must be three times sifted through a hair sieve, in order to their being well mixed: the iron-sand is then to be moistened with brandy to make the sulphur adhere, and then they are to be thoroughly incorporated.

The upper part of rockets is generally furnished with some composition, which takes fire when it has reached to its greatest height, emits a considerable blaze, or produces a loud report and whizzing noise. Of this kind are faucious, maroons, flars, showers of fire, &c. To make room for an article of this kind, the rocket is crowned with what is called a pot, which is larger than the rocket. (See fig. 5.) The following is the method of making this pot, and connecting it with the body of the rocket.

The mould for forming the pot, though of one piece, must confit of two cylindrical parts of different diameters. That on which the pot is rolled up must be three diameters of the rocket in length, and its diameter must be three fourths that of the rocket; the length of the other ought to be equal to two of these diameters, and its diameter to three that of the rocket. Having rolled the thick paper, intended for making the pot, twice round the cylinder, a portion of it must be pinched in that part of the cylinder which has the least diameter: this part must be pared in such a manner, as to leave only what is necessary for making the pot fail to the top of the rocket, and the ligature must be covered with paper.

To charge such a pot, attached to a rocket. Having pierced three or four holes in the double paper which covers the vacancy of the rocket, pour over it a small quantity of the composition with which the rocket is filled, and by shaking it, make a part enter these holes; then arrange, in the pot, the composition with which it is to be charged, taking care not to introduce it into a quantity heavier than the body of the rocket. The whole must be secured by means of a few small balls of paper, to keep everything in its place, and the pot must be covered with paper cemented to its edges: if a pointed summit be added to it, the rocket is fit for use.

When these materials have been accurately weighed, the saltpetre and charcoal must be three times sifted through a hair sieve, in order to their being well mixed: the iron-sand is then to be moistened with brandy to make the sulphur adhere, and then they are to be thoroughly incorporated.

The upper part of rockets is generally furnished with some composition, which takes fire when it has reached to its greatest height, emits a considerable blaze, or produces a loud report and whizzing noise. Of this kind are faucious, maroons, flars, showers of fire, &c. To make room for an article of this kind, the rocket is crowned with what is called a pot, which is larger than the rocket. (See fig. 5.) The following is the method of making this pot, and connecting it with the body of the rocket.

The mould for forming the pot, though of one piece, must confit of two cylindrical parts of different diameters. That on which the pot is rolled up must be three diameters of the rocket in length, and its diameter must be three fourths that of the rocket; the length of the other ought to be equal to two of these diameters, and its diameter to three that of the rocket. Having rolled the thick paper, intended for making the pot, twice round the cylinder, a portion of it must be pinched in that part of the cylinder which has the least diameter: this part must be pared in such a manner, as to leave only what is necessary for making the pot fail to the top of the rocket, and the ligature must be covered with paper.

To charge such a pot, attached to a rocket. Having pierced three or four holes in the double paper which covers the vacancy of the rocket, pour over it a small quantity of the composition with which the rocket is filled, and by shaking it, make a part enter these holes; then arrange, in the pot, the composition with which it is to be charged, taking care not to introduce it into a quantity heavier than the body of the rocket. The whole must be secured by means of a few small balls of paper, to keep everything in its place, and the pot must be covered with paper cemented to its edges: if a pointed summit be added to it, the rocket is fit for use.

### Scorpents.

These are small flying rockets, without rods, which, instead of rising in a perpendicular direction, mount obliquely, and descend in a zigzag form, without ascending to a great height. The composition of these is in nearly the same as that of rockets, and the construction is as follows. The length, A C, (fig. 4) of the cartridge is about four inches; it must be rolled on a flock somewhat larger than a goose-quill, and after being blown out at one of its ends, it is filled beyond the middle, as to B, with the composition; then it is to be pinched off so as to leave a small aperture. The remainder, B C, must be filled with a powdered powder, which will occasion a report when it bursts. Lastly, chalk the cartridge entirely towards the extremity C; and at the other extremity, A, place a train of moil powder, to which, if fire be applied, it will be communicated to the composition in the part A B, and cause the whole to rise in the air. The serpents, as it falls, will make several turns in a zigzag direction, till the fire is communicated to the powdered powder in the part B C; on which the serpent will burst with a loud report before it falls to the ground. The serpents carriages are generally made of playing cards. These are rolled round a rod of iron or hard wood, and to confine the card a piece of strong paper is cemented over it. Larger serpents may be made by cementing two playing cards together, first moistened with water.

### Maroons.

These are small cubical boxes, filled with a composition proper for making them burst. To construct these, cut a piece of paffleboard according to the method taught in geometry to form the cube (see fig. 5); join these squares at the edges, leaving one only to be cemented, and fill the cavity of the cube with powdered powder; then cement strong paper in various directions over the body, and wrap round it two rows of packthread, dipped in strong glue: then make a hole in one of the corners, and introduce into it a match. If the maroons are to be luminous, that is, which are to give out a brilliant light before they burst, they must be covered with a paste, the composition of which will be noticed below under Stars, and then rolled in meal powder to serve as a match or communication.

### Sausciffons.

These differ from maroons only in form. The cartridges of the latter are round, and must be only four times their exterior diameter in length. They are choked at one end in the same manner as a rocket, and a pellet of paper is driven into the aperture which has been left, in order to fill it up. They are then charged with corn powder, above which is placed a ball of paper, gently pressed down to prevent the powder from being bruised; the second end of the sausciffon being now choked, the edges are to be pared on both sides, and the whole is covered with several turns of packthread, dipped in strong glue, and then left to dry.

### Stars.

These are small globes which emit a most brilliant light, so that, momentarily, they may be compared to the light of the stars in the heavens. These balls are not larger than a musket-ball, and when put into rockets they must be wrapped up in tow, prepared for the purpose. The composition of these stars is as follows: To a pound of fine meal gunpowder, add four pounds of saltpetre, and two pounds of sulphur. When these ingredients are thoroughly mixed, take a piece as large as a small nutmeg, and having wrapped
wrapped it in a linen rag, or paper, form it into a ball; then tie it closely round with packthread, and pierce a hole through the middle of it, large enough to receive a piece of prepared tow, which is to serve as a match. This, when lighted, will exhibit a most beautiful appearance; because the fire as it issues from the two ends of the hole in the middle will extend to a great distance, and will make it seem very much larger than it actually is.

There are other compositions for flars; viz. with three ounces of saltpetre, mix one ounce of sulphur, and two drachms of mealed gunpowder; or with eight ounces of mealed powder, mix four ounces of sulphur, and the same quantity of saltpetre. When these materials have been well sifted, and sprinkled over with brandy, in which a small quantity of gum has been dissolved, the flar is made in the following manner. Take a rocket mould eight or nine lines in diameter, and introduce into it a nipple, the piercer of which is of uniform size throughout, and equal in length to the height of the mould. Put into this mould a cartridge, and by means of a pierced rod load it with one of the preceding compositions; when loaded, take it from the mould, without removing the nipple, the piercer of which passes through the composition, and then cut the cartridge quite round into pieces of the thickness of three or four lines. The cartridge being thus cut, draw out the piercer gently, and the pieces which resemble the men employed for playing at drafts, pierced through the middle, will be flars, which must be filed on a match thread, that may be covered with tow. To give more brilliancy to flars of this kind, a cartridge thicker than that already described, and thinner than that of a flying rocket of the same size, may be employed; but before it is cut in pieces, five or six holes must be pierced in the circumference of each piece to be cut. When the cartridge is cut, and the pieces have been filed, cement over the composition small bits of a card, each having a hole in the middle, so that these holes may correspond to the place where the composition is pierced.

Etoiles à Pet are made in the same way nearly as faucifons already described, only that it will not be necessary to cover them with packthread; it will be sufficient if they are pierced at one end, in order that flars may be fastened to them, constructed according to the first method, the composition of which is dry; for if the composition be in the form of paste, there will be no need to tie it. In this case, a little more of the paper must be left hollow at the end of the faucifon which has been pierced for the purpose of introducing the composition, and to place in the vacuity, towards the neck of the faucifon, some grained powder, which will communicate fire to the faucifon when the composition is consumed.

Shower of Fire.—To form this sort of fire-work, mould small paper cartridges on an iron-rod two lines and a half in diameter, and make them two inches and a half in length. They must not be chocked, it being sufficient to twit at the end of the cartridge, and having put the rod into it to beat it, in order to make it assume its proper form. When the cartridges are filled, which is done by immersing them in the composition, fold down the other end, and then apply a match. This will fill the surrounding air with an undulating fire. The following compositions are given as proper for flars of this kind.

Chimney Fire.—Mealed gunpowder one pound, sulphur two ounces, iron-fand of the first order five ounces.

Ancient Fire.—Mealed gunpowder one pound, charcoal two ounces.

Brilliant Fire.—Mealed gunpowder one pound, iron-fillings four ounces. The first of these compositions is thought to be the most beautiful.

Sparks differ from flars only in their size and duration, for they are made smaller than flars, and are consumed sooner. They are thus prepared. Having put into an earthen vessel an ounce of mealed gunpowder, two ounces of pulverized saltpetre, one ounce of liquid saltpetre, and four ounces of camphor reduced to powder, pour over this mixture some gum-water, or brandy in which gun has been dissolved, till the composition becomes of the consistence of thick soup. Then take some lint which has been soaked in brandy, or in vinegar, or even in a solution of saltpetre, and being dried and unravelled, throw into the mixture such a quantity of it as is sufficient to absorb it entirely, taking care to tir it well. This composition may be formed into small balls about the size of a pea, and being dried in the shade, and sprinkled with mealed powder, they will readily catch fire.

Sparks may be made by the following method: Take saw-dust of fir, poplar, &c. and boil it in water in which saltpetre has been dissolved. When the water has boiled some time, it is to be poured off, that the saw-dust may remain in the vessel. When nearly dry, it is to be spread out on a table, and sprinkled with sulphur sifted through a very fine sieve, to which may be added a little mealed powder.

Golden Rain.—Some flying rockets, which, as they fall, make small undulations in the air like frizzled hair, are called by the French writers fusées chevelues, and by us bearded rockets; they finish with a kind of shower of fire, which is called golden rain, and they are constructed in the following manner. Fill the barrels of some goose-quills with the composition of flying rockets, and place upon the mouth of each a little mealed gunpowder, both to keep in the composition, and to serve as a match. If a flying rocket be then loaded with these quills, they will produce at the end a beautiful shower of fire, which is denominated golden rain.

Contrarini, or Rockets that fly along a Rope.—A rocket may be made to run along an extended rope, by affixing to the rocket an empty cartridge, and introducing into it the rope which is to carry it along. Place the head of the rocket towards that side to which you intend it to move; if it be then let fire to, it will run along the rope without flopping till the matter it contains is entirely exhausted. If the rocket is to move in a retrograde direction, first fill one half of it with the composition, and cover it with a small round piece of wood, to serve as a partition between it, and that put into the other half; then make a hole below this partition, so as to correspond with a small canal filled with brusied powder, and terminating at the other end of the rocket. By these means the fire, when it ceases in the first half of the rocket, will be communicated through the hole into the small canal, which will convey it to the other end; and this being then kindled, the rocket will move backwards, and return to the place from whence it first issued.

Two rockets of equal size, bound together by strong packthread, and so arranged that the head of the one shall be opposite to the neck of the other, in order that when the fire has consumed the composition in the one, it may be communicated to that in the other, and oblige both of them to move in a retrograde direction, may likewise be adjusted to the rope by means of a piece of hollow reed. Rockets of this kind are generally employed for setting fire to various other pieces when large fire-works are exhibited; and to render
render them more striking, they are made in the form of different animals, such as serpents, dragons, &c.

To give a rocket a kind of rotatory motion around the rope along which it advances, it will be sufficient to tie to it another rocket, placed in a transverse direction. But the aperture of the latter, instead of being at the bottom, ought to be in the side, near one of the ends. If both rockets be fired at the same time, the latter will make the other revolve around the rope, while it advances along it.

Rockets which burn in the Water.—In these there must be a considerable variation in the construction of the mould, and also in the materials of which they are composed. The mould may be eight or nine inches in length, and an inch in diameter: the former, on which the cartridge is rolled up, may be nine lines in thicknesses. The composition should consist of three materials mixed together, viz. three ounces of mealed gunpowder, one pound of saltpetre, and eight ounces of sulphur. If the rocket is to appear on the water with a beautiful tail, the composition must consist of eight ounces of gunpowder, one pound of saltpetre, eight ounces of pounded and finely lifted sulphur, and two ounces of charcoal. When the composition has been prepared according to these proportions, and the rocket has been filled in the manner above described, apply a laccision to the end of it, and having covered the rocket with wax, pitch, &c. attach to it a small rod of white willow, about two feet in length, that the rocket may conveniently float. If it be required that these rockets should plunge down, and again rise up, a certain quantity of mealed gunpowder, without any mixture, must be introduced into them, at certain distances.

A rocket which is fired in the water, and, after burning there half the time of its duration, mounts into the air with great velocity, may be thus constructed. Take a flying rocket, furnished with a rod, and by means of a thick globe, attach it to a water-rocket, but only at the middle, A, (fig. 6,) in such a manner that the latter shall have its neck uppermost, and the other its neck downward. Adjust to their extremity, B, a small tube, to communicate the fire from the one to the other, and cover both with a coating of pitch, wax, &c. that they may not be damaged by the water. Then attach to the flying rocket, after it has been thus cemented, the water rocket, the aquatic one, a rod, as D, and from F suspend a piece of packthread, to support a musket bullet E, made fast to the rod by means of a needle or piece of iron wire. When these arrangements have been made, set fire to the part C after the rocket is in the water; and when the composition is consumed to B, the fire will be communicated through the small tube to the other rocket; the latter will then rise and leave the other, which will not be able to follow it, on account of the weight adhering to it.

Globes and Fire-Balls are made in different forms, viz. spherical, spheroidal, or cylindrical. The spherical are made in the following manner. Construct a hollow wooden globe of any size at pleasure, and very round both within and without, so that its thicknesses, A C or B D, (fig. 7,) may be about the ninth part of its diameter A B, and having an aperture, L M or O N, equal to the thicknesses A C or B D, that is, to the ninth part of the diameter A B. It is through this aperture that fire is communicated to the globe, when it has been filled with the proper composition, through the lower aperture I K. A petard of metal, loaded with good grained powder, is to be introduced also through the lower aperture, and to be placed horizontally. The aperture I K, which is nearly equal to the thicknesses, E F or G H, of the cylinder E F G H, is to be cloized by means of a wooden tompion dipped in warm pitch; and melt over it such a quantity of lead that its weight may cause the globe to sink in water, till nothing remain above it but the part G H; which will be the calf if the weight of the lead, with that of the globe and the composition, be equal to the weight of an equal volume of water. If the globe be then placed in the water, the lead, by its gravity, will keep the aperture, I K, directly downwards, and the cylinder, E F G H, in a perpendicular direction, to which fire must have been previously applied. The composition with which the globe must be filled, is as follows:—to a pound of corned powder, add thirty-two pounds of saltpetre, eight pounds of sulphur, one ounce of haresed ivory, and eight pounds of powder previously boiled in a solution of saltpetre, and dried in the open air.

Globes which leap or roll on the Ground.—Having constructed a wooden globe A, (fig. 8,) with a cylinder C, similar to the one just described, and having loaded it with the same composition, introduce into it four or even more petards, loaded with good corned powder to their orifices, as is shown at A B, which must be well fixed with paper or tow. If a globe, prepared in this manner, be fired by means of a match at C, it will leap about as it burns, on a smooth horizontal plane, according as the petards are set on fire. The petards may be affixed to the exterior surface of the globe, as is seen in the figure, which they will cause to roll and leap as they catch fire.

Aerial Globes, called Bombs.—These globes are called airals, because they are thrown into the air from a mortar. Though they are of wood, and have a suitable thickness, yet they are liable to burst unless the charge be nicely proportioned to their strength. The usual quantity is one ounce of powder for a globe of four pounds weight; two ounces for one of eight, and so on. As the chamber of the mortar may be too large to contain the exact quantity of powder sufficient for the fire-ball, which ought to be placed immediately above the powder, in order that it may be expelled and set on fire at the same time, another mortar may be constructed of wood, or of pale-board with a wooden bottom, which may be put into the large iron mortar, to be loaded with a quantity of powder proportioned to the weight of the globe. This small mortar must be of light wood, or of paper painted together, and rolled up in the form of a cylinder, but the bottom must be of wood. The charge for the powder must be pierced obliquely, so that the aperture may correspond to the aperture of the metal mortar, then the fire applied to the latter may be communicated to the powder which is at the bottom of the chamber, immediately below the globe.

The globe must be filled with several pieces of reed or cane, or common reed equal in length to the interior height of the globe, and charged with a flow composition, made of three ounces of mealed gunpowder, an ounce of sulphur moistened with a small quantity of petroleum oil, and two ounces of charcoal; and in order that these reeds or canes may catch fire the sooner, and with more facility, they must be charged at the lower ends, which rest on the bottom of the globe, with pulverized gunpowder moistened with petroleum oil or brandy, and then dried. The bottom of the globe ought to be covered with gunpowder, partly mealed and partly corned, which, when set on fire, will communicate the fire to the lower part of the reed. Instead of reeds, the globe may be charged with running rockets, or paper petards, and a quantity of fiery flares or sparks mixed with mealed powder placed above these petards, which must be chocked at unequal heights, that they may produce their effects at different times.

Jets of Fire are a sort of fixed rockets, the effect of which is to throw up into the air jets of fire similar to jets of water.
PYROTECHNY.

They serve also to represent cascades, for if a series of such rockets be placed horizontally on the same line, it may be easily seen that the fire which they emit will resemble a sheet of water. When arranged in a circular form, like the radii of a circle, they form what is called a fixed fun. To form jets of this kind, the cartridge for brilliant fires must, in thicknese, be equal to a fourth part of the diameter, and for Chinese fire only a fixth part. The cartridge is loaded on a nipple, having a point equal in length to the same diameter, and in thicknes to a fourth part of it; but as it generally happens that the mouth of the jet becomes larger than is necessary for the effect of the fire, the cartridge must be filled equal to a fourth part of the diameter with clay, which must be rammed down. This will make the jet ascend much higher. When the charge is completed with the proper composition, the cartridge must be closed with a tomption of wood, above which it must be fixed. Jets intended for representing sheets of fire ought not to be fired. They must be placed in a horizontal position, or inclined a little downwards. The following are the principal compositions for jets of fire.

1. For Jets of half an Inch or less in Diameter.—Chinese fire: Saltpetre and mealed powder 1 lb. each; sulphur 8 ounces; charcoal 2 ounces.—White fire: Saltpetre 1 lb.; mealed powder 8 ounces; sulphur 3 ounces; charcoal 2 ounces; iron-land of the first order 8 ounces.

2. For Jets of an Inch or less in Diameter.—Brilliant fire: Mealed powder 1 lb., iron-flings 5 ounces.—White fire: Saltpetre and mealed powder 1 lb. each; sulphur 8 ounces; charcoal 2 ounces.—Chinese fire: Saltpetre 16 ounces; sulphur 5 ounces; charcoal 5 ounces; iron-land of the third order 12 ounces.

3. For Jets of 15 or 18 Lines in Diameter.—Chinese fire: Saltpetre 16 ounces; sulphur 7 ounces; charcoal 5 ounces; of the several different kinds of iron-land mixed 12 ounces.

Fires of different Colours.—For white fire the gunpowder must be mixed with iron or rather steel-flings: for red fire, iron-land of the first order must be employed in the same way. Camphor mixed with the usual composition is made to the flame appear of a pale white colour. Raspings of ivory give a clear flame of a silver colour.

Pole for representing Animals, &c., in Fire.—Take sulphur reduced to a very fine powder, and having formed it into a pate with pitch, cover it with the figure of the thing to be represented, having first coated it with clay to prevent it from being burnt. After the figure is covered with the pate, it must be sprinkled, while moist, with gunpowder: and when the whole is perfectly dry, arrange about it several small matches, that the fire may be speedily communicated to it on all sides. In this way all sorts of garlands, fetcoons, and other ornaments, may be imitated by fire of different colours.

Sun, fixed and movable.—For fixed funs, let a round piece of wood be cut, into the circumference of which are to be screwed twelve or fifteen pieces in the form of radii, to which are to be attached jets of fire, of the composition described above; so that they may appear as radii tending to the same centre, the mouth of the jet being towards the circumference. Apply a match to each in such a manner that the fire communicated at the centre, may be conveyed to the same time to the mouth of each of the jets, by which means, each throwing out its fire, there will be produced the appearance of a radiating fun, that is, supposing the wheel is placed in a position perpendicular to the horizon. The rockets or jets may be so arranged as to crofs each other in an angular manner, in which case, instead of a sun, you will have a star, or a crofs. Some of these funs are made also with several rows of jets, which are called glories. For revolving funs, provide a wooden wheel, and attach to the circumference fire-jets placed in the direction of the circumference: they must not be chokeed at the bottom, and ought to be arranged in such a manner, that the mouth of the one shall be near the bottom of the other, so that when the fire of the one is ended, it may immediately proceed to another. When the fire is applied to one of these jets, the recoil of the rocket will make the wheel turn round, unless it be too large and ponderous. For this reason, when these funs are of a considerable size, that is, when they consist of perhaps twenty rockets, fire must be communicated at the same time to the first, the sixteenth, and twenty-first, from which it will proceed to the second, the seventeenth, the eighteenth, and so on. These four rockets will make the wheel turn round with great rapidity. If two similar funs be placed one behind the other, and are made to turn in a contrary direction, they will produce a fine effect of crofs-fire.

Making, loading, and firing Pots des Brins.—These are made of pate-hoard, and must be rolled pretty thick; usually made three or four inches in diameter, and four diameters long, and pinched with a neck at one end, like common cafes. A number of these are placed on a plank thus: having fixed on a plank two rows of wooden pegs, cut in the bottom of the plank a groove the whole length under each row of pegs; then, through the centre of each peg, bore a hole down to the groove at bottom, and on every peg fix and glue a pot, whose mouth must fit tight on the peg: through all the holes run a quick-match, one end of which must go into the pot, and the other into the groove, which must have a match laid in it from end to end, and covered with paper, so that, when lighted at one end, it may discharge the whole almost instantaneously: in all the pots put about one ounce of meal and corn powder; then in some put stars, and others raines, snake, serpent, crackers, &c.: when they are all loaded, pate paper over their mouths. Two or three hundred of these pots being fired together, make a very pretty show, by affording fo great a variety of fires. Fig. 9 is a range of pots des brins, with the leader A, by which they are fired.

Caduceus Rockets, in rising, form two spiral lines, or double worm, by reason of their being placed obliquely, one opposite the other; and their counterpoise is in their centre, which caufes them to rife in a vertical direction. Rockets for this purpole muft have their ends chokeed clofe, without either head or bounce, for a weight at top would be a great obtrufion to their mounting; though they have been known sometimes to be bounce, but then they did not rife fo high as those that were not; nor do any caduceus rockets affend fo high as a crofs, because of their ferpentine motion, and likewise the refillence of air, which is much greater than two rockets of the fame size would meet with, if fired fingly.

By fig. 10, we fee the method of fixing thefe rockets: the flakes for this purpole muft have all their sides equal, which sides should be equal to the breadth of a fliek proper for a fliek-rocket of the fame weight as thefe we intend to use, and to taper downwards as usual, long enough to balance them, one length of a rocket, from the crofs fliek, which muft be placed from the large fliek, fix diameters of one of the rockets, and its length five diameters; so that each rocket, when tied on, may form with the large fliek an angle of fixty degrees. In tyng on the rockets, place their heads on the oppofite sides of the crofs fliek, and their ends on the oppofite sides of the long fliek; then carafe a leader from the mouth of one into that of the other. When thefe rockets are to be fired, fulpend them between two hooks or nails,
nails, then burn the leader through the middle, and both will take fire at the same time. Rockets of one pound are a good size for this use.

_Illuminated Spiral Wheel._—First have a circular horizontal wheel, made two feet in diameter, with a hole quite through the nave; then take three thin pieces of deal, three feet long each, and three quarters of an inch broad each; one end of each of these pieces nail to the fell of the wheel, at an equal distance from one another, and the other end nail to a block with a hole in its bottom, which must be perpendicular with that in the block of the wheel, but not so large. The wheel being thus made, take a hoop planed down very thin and flat; then nail one end of it to the fell of the wheel, and wind it round the three sticks in a spiral line, from the wheel to the block at top; on the top of this block fix a cafe of Chinefe fire; on the wheel you may place any number of cafes, which must incline downwards, and burn two at a time. If the wheel should consist of ten cafes, you may let the illuminations and Chinefe fire begin with the second cafes. The spindle for this wheel must be a little longer than the cone, and made very smooth at top, on which the upper block is to turn, and the whole weight of the wheel to roll. See fig. 11.

_Fruitlon Wheels._—First take a nave, made nine inches long, and three in diameter; near the bottom of this nave fix eight spokes, with a hole in the end of each, large enough to receive a two or four-ounce cafe; each of these spokes may be fourteen inches long from the block. Near the top of this block fix eight more of the same spokes, exactly over the others, but not so long by two inches. As this wheel is to run horizontally, all the cafes in the spokes at top must play obliquely upwards, and all of them in the spokes at bottom obliquely downwards. This being done, take a small horizontal wheel, made with eight spokes, each five inches long from the block; on the top of this wheel place a cafe of brilliant fire; all the cafes on this wheel must play in an oblique direction downwards, and burn two at a time, and thole on the large wheel four at a time; that is, two of thole in the top set of spokes, and two of them in the bottom set of spokes. The four first cafes on the large wheel, and the two first on the small, must be fired at the same time, and the brilliant fire at top, at the beginning of the half cafes. The cafes of the wheels may be filled with a grey charge. When these wheels are completed, you must have a strong iron spindle, made four feet fix inches long, and fixed perpendicular on the top of a fland; on this put the large wheel, whose nave must have a hole quite through, from the bottom to the top. This hole must be large enough to turn easily round the bottom of the spindle, at which place there must be a shouder, to keep the wheel from touching the fland: at the top of the spindle put the small wheel, and join it to a large one with a leader, in order to fire them both together.

_Illuminated Globes, with horizontal Wheels._—The hoops for these globes may be made of wood, tin, or iron wire, about two feet in diameter. For a single globe take two hoops, and tie them together, one within the other, at right angles; then have a horizontal wheel made, whose diameter must be a little wider than the globe, and its nave six inches long, on the top of which the globe is fixed, so as to stand three or four inches from the wheel: on this wheel you may put any number of cafes, filled with what charge you like; but let two of them burn at a time: they may be placed horizontally, or to incline downwards, just as you choose. Now, when the wheel is clothed, fix on the hoops as many illuminations as will stand within two inches and a half of each other: these you fallon on the hoops with small iron binding wire; and when they are all on, put on your pipes of communication, which must be so managed as to light them all with the second or third cafe on the wheel. The spindle on which the globe is to run must go through the block of the wheel, up to the confide of the top of the globe, where it must be fixed a bit of brass or iron, with a hole in it to receive the point of the spindle, on which the whole weight of the wheel is to bear, as in fig. 12, which repreffents a globe on its spindle. By this method may be made a crown, which is done by having the hoops bent in the form of a crown. Sometimes globes and crowns are ordered fo as to fland still, and the wheel only to turn round; but when you would have the globe or crown to fland still, and the wheel to run by itself, the block of the wheel must not be fo long, nor the spindle any longer, than to juft raife the globe a little above the wheel, and the wheel-cafes and illumination muft begin together.

_Dodecachoron_, so called because it nearly represents a twelve-sided figure, and is made thus. First take a ball, turned out of some hard wood, fourteen inches in diameter: when done, divide its surface into fourteen equal parts, from which bore holes an inch and a half in diameter perpendicular to the centre, fo that they may all meet in the middle: then let there be turned in the confide of each hole a female screw; and to all the holes, but one, be made a round spoke, five feet long, with four inches of the screw at one end, to fit the holes; then in the screw end of all the spokes bore a hole, five inches up, which must be bored flanting, fo as to come out at one side, a little above the screw; from which cut a small groove along the spoke, within fix inches of the other end, where you make another hole through to the other side of the spoke: in this end fix a spindle, on which put a small wheel, of three or four edges, each fix or seven inches long: these fides must have grooves cut in them, large enough to receive a two or four-ounce cafe: when these wheels are clothed, put them on the spindles, and at the end of each spindle put a nut, to keep the wheel from falling off: the wheels being thus fixed, carry a pipe from the mouth of the firft cafe on each wheel, through the hole in the fide of the spoke, and from thence along the groove, and through the other hole, fo as to hang out at the screw end about an inch. The spokes being all prepared in this manner, you must have a poft, on which you intend to fire the work, with an iron screw in the top of it, to fit one of the holes in the ball: on this screw fix the ball; then in the top hole of the ball put a little meal powder, and some loose quick-match; then screw in all the spokes, and in one fide of the ball bore a hole, in which put a leader, and fixe it at the end; and your work will be ready to be fired. By this leader the powder and match in the centre are fired, which will light the match at the ends of the spokes all at once, whereby all the wheels will be lighted at once. There may be an addition to this piece, by fixing a small globe on each wheel, or one on the top wheel only. A grey charge will be proper for the wheel-cafes.

_Quadri-fo of brilliant Fire_, is repreffented by fig. 13, as it appears when burning. First, let A be an upright piece of wood, four feet long, two inches broad, and one thick: at top of this piece, on the flat side, fix a hoop, fourteen inches in diameter; and round its edge and front place illuminations, and in the centre a five-pointed farr; then at B, which is one foot and a half from the edge of the hoop, place two cafes of brilliant fire, one on each fide: these cafes should be one foot long each: below these fix two more cafes of the fame fize, and at such a distance, that their mouths may almost meet them at top; then, close to the ends of these cafes, fix two more of the fame cafes; they must fland parallel.
ralled to them at E. The cates being thus fixed, clothe them with leaders, so that they, with the illuminations and star at top, may all take fire together.

Illuminated Yew-tree.—First have a tree made of wood, such as is shewn by fig. 14. The middle piece, or stem, on which the branches are fixed, must be eight feet fix inches high: at the bottom of this piece draw a line, at right angles, two feet six inches long at each side; then from L., which is one foot six inches from the bottom, draw a line on each side to C and D; these lines will give the length of the two firr branches. Then put on the two top branches parallel to them at bottom: let the length of each of those branches be one foot from the stem; from the ends of these two branches draw a line to C and D; then fix on five more branches at an equal distance from each other, and their length will be determined by the lines A C and E D. When the branches are fixed, place illuminating port-fires on the top of each, as many as you choose; behind the top of the stem falls a garbe, or white fountain, which must be fired at the beginning of the illuminations on the tree.

Moon and Seven Stars.—Let fig. 15, be a smooth circular board, six feet diameter; out of the middle of it cut a circular piece twelve or fourteen inches diameter, and over the vacancy put white Persian silk, on which paint a moon’s face; then let I, I, I, &c. be flars each four or five inches in diameter, cut out with five points, and covered with oiled silk: on the front of the large circular board draw a seven-pointed star, as large as the circle will allow; then on the lines which form this star bore holes, wherein fix pointed stars. When this piece is to be fired, it must be fixed upon the front of a pole, on a spindle, with a wheel of brilliant fire behind the face of the moon; so that while the wheel burns, the moon and stars will appear transparent, and when the wheel has burnt out, they will disappear, and the large star in front, which is formed of flars, will begin, being lighted by a pipe of communication from the left cafe of the vertical wheel, behind the moon; this pipe must be managed in the same manner as those in regulated pieces.

Pin Wheels.—First roll some paper pipes, about fourteen inches long each; these pipes must not be made thick of paper, two or three rounds of elephant paper being sufficient. When your pipes are thoroughly dried, you must have made a tin tube, twelve inches long, to fit easily into the pipes; at one end of this tube fix a small conical cup, which done is called a funnel; then bend one end of one of the pipes, and put the funnel in at the other, as far as it will reach, and fill the cup with composition; then draw out the funnel by a little at a time, shaking it up and down, and it will fill the pipe as it comes out. Having filled some pipes, and made some small blocks, about an inch in diameter, and half an inch thick; round one of these blocks wind and pafe a pipe, and to the end of this pipe join another; which must be done by twisting the end of one pipe to a point, and putting it into the end of the other, with a little palle; in this manner join four or five pipes, winding them one upon the other, so as to form a spiral line. Having wound on your pipes, pafe two slips of paper acros them, to hold them together; besides these slips of paper the pipes must be balled together.

There is another method of making these wheels, called the French, which is, by winding on the pipe without pafe, and flicking them together with sealing wax, at every half-turn; so that, when they are fixed, the end will fall loose every time the fire pales the wax: by which means the circle of fire will be considerably increased. The formers for these pipes are made from one-half to four-sixteenths of an inch diameter, and the composition for them as follows;

meal powder eight ounces, saltpetre two ounces, and sulphur one: among these ingredients may be mixed a little stick-filings, or the dust of cast-iron: this composition should be very dry, and not made too fine, or it will flick in the funnel. These wheels may be fired on a large pin, and held in the hand with safety.

Placing Fire-works to be exhibited, with the Order of Firing. Nothing adds more to the appearance of fire-works, than the placing them properly; though the manner of placing them chiefly depends on the judgment of the maker. We shall give such rules here, as have been generally observed; for example, whether your works are to be fired on a building, or on lands. If they are a double set, place one wheel of a fort on each side of the building; and next to each of them, towards the centre, place a fixed piece, then wheels, and so on, leaving a sufficient distance between them, for the fire to play from one without burning the other. Having fixed some of your works thus in front, place the rest behind them, in the centre of their intervals: the largest piece, which is generally a regulated or transparent piece, must be placed in the centre of the building, and behind it a fun, which must always stand above all the other works: a little before the building, or lands, place your large garbes; and at the back of the works, fix your maroon batteries, pots des aigrettes, pots des brins, pots des fauf- ciffions, air-balloons, and flights of rockets: the rocket-flands may be fixed behind, or any where else, so as not to be in the way of the works.

Single collections are fired on lands, which lands are made in the same manner as theodolite flands, only the top part must be long or short occasionally: these flands may be fixed up very soon without much trouble. Having given sufficient instructions for placing of fire-works, we shall proceed with the manner of firing them.

Order of Firing.
1. Two signal rockets.
2. Six sky rockets.
3. Two honorary.
4. Four caduceus.
5. Vertical flars illuminated.
6. Two spiral wheels illuminated.
7. Transparent flars.
8. A line rocket of five changes.
11. Air-balloons illuminated.
12. Two Chinefe fountains.
13. Regulating pieces of four mutations each.
15. Three large garbes.
16. A flight of rockets.
17. Balloon wheels.
18. Cafades of brilliant fire.
19. Twelve sky-rocks.
20. Two illuminated yew-trees.
21. Two air-balloons of serpents, and two compound.
22. Four tourbillons.
23. Two Fruloni wheels.
24. Illuminated globes with horizontal wheels.
25. One pot des faufciffions.
26. Two plural wheels.
27. Maroon battery.
28. Two chandeleers illuminated.
29. Range of pots des brins.
30. Twelve sky-rocks.
31. Two yew-trees of fire.
32. Neat of serpents.
33. Two double cones illuminated.
34. Regulating piece of seven mutations, viz.
   1. Vertical wheel illuminated.
   2. Golden glory.
   3. Octagon vertical wheel.
   4. Porcupine’s quills.
   5. Crofs fires.
   7. Six vertical wheels.
35. Brilliant fun.
36. Large flight of rockets.

When water-works are to be exhibited, divide them into several paks, and fire one paf after every fifth or sixth change of land and air-works. Obferve this rule in hiring a double paf of works; always to begin with fiy-rockets, then two moveable pieces, then two fixed pieces, and fo on; ending with a large flight of rockets, or a maroon battery; if a single collection, fire a fixed piece after every wheel or two, and now and then some air and water-works. Jones’s Fire-works, 8vo. 1776.

PYROTECHNICAL SPINGLE. See SPINGLE.

PYROTECHNIK, or Pyrotechnic, formed from Epy, fire, in Medicine, caulks, or remedies, either actually or potentially hot; and which, accordingly, will burn the flesh, and raise an efchab.

PYROUET. See Piroette.

PYROXENE, in Mineralogy. See Augite and Lava.

According to Haiy, the mineral called augite by Werner is the black or greenish-black variety of pyroxene found in volcanic countries and in basalt. The primitive form of the crystals of pyroxene is an oblique rhombohedral prism.

The pyroxene-green transparent pyroxene, with the forms of the crystals distinctly marked, from the department of the Po, is the alabatite of Boulovin. Journal des Mines, N° 115.

The grey-green, or whitish-grey variety, the primitive crystals of which are indiscreet, from the same department, were called by Boulovin malafite. Both these varieties have been called by some mineralogists diaphane.

The green-grey and obscure green pericbiadal variety of pyroxene is the habite of Werner, called also malacolite by Haiy. The mineral called coccodite, discovered by Dandridge at the iron mines of Sudermanland and Nerika, in Sweden, and Arendal in Norway, is also brought under the species pyroxene by Haiy. Tableau Comparatif.

By reducing many varieties of minerals under one species, Haiy may be considered as having rendered an additional service to mineralogy, already too much loaded with pedantic or unmeaning terms; but the term pyroxene itself may be justly objected to, as being founded not on any distinct character, but on the hypothetical assumption that these crystals are foreign to the igneous products in which they are imbedded, an assumption for which there does not appear sufficient proof.

The constitutive parts of pyroxene, its specific gravity and hardness, fo nearly agree with those of basaltic hornblende, that these substances ought perhaps to be classed as varieties of the same species, without regarding the small difference of their crystalline forms. See Hornblende.

PYROXENE EN ROCHE, or Rock Pyroxene. In the Journal des Mines, Nov. 1812, a description is given of entire rocks composed of pyroxene, discovered by J. Charpentier in the Pyrenees. The substance is homogeneous, of a texture commonly granularly lamellar, which in some pieces becomes flaty. Its most common colour is green of various shades, from an olive green to an emerald green, sometimes cloudy but often clear. From a greenish-grey it passes to a reddish-brown and ochre yellow. It is amorphous. The...
PYRRHOCORAX, in Ornithology, a species of Ceres (which see), the Alpine crow of Latham, and the Choucas des Alpes of Buffon.—Allo, the Monedula, Coracias of Aldrovandi, &c., Curnishough, red-legged crow of Pennant and Latham, and Ceres Graculus, which see.

PYRRHONIANS, Pyrrhoneans, or Pyrrhonists, a sect of ancient philosophers, so called from their founder Pyrrho, a Greek philosopher, born at Elea, in Peloponnesus, who in early life studied painting, but aspiring to philosophical pursuits he became a disciple of Anaxarchus, and accompanied him as far as India. In this journey he followed Alexander the Great; and hence we may know in what time he flourished. In India he converted the Brachmans and Gymnosophists, imbibing from their doctrine whatever might seem favourable to his natural disposition towards doubting; a disposition which was cherished by his master, who had formerly been a disciple of a sceptical philosopher, Metrodorus of Chios. As he was involved in great uncertainty by every advance made in the study of philosophy, he left the school of the Dogmatists, who professed to be possessed of certain knowledge, and established a new school, in which he taught, that every object of human inquiry is involved in uncertainty, so that it is impossibly ever to arrive at the knowledge of truth.

The distinguishing character of this philosopher was, that he professed to doubt of every thing, maintaining that men only judge of truth and falsehood from appearances, which deceive. On this principle he kept himself in continual suspension of mind, never determining on any thing; to avoid the inconveniences of error and false judgments.

He found in all things (says Bayle) reasons to affirm and to deny; and therefore he suspended his assent after he had well examined the arguments for and against, and reduced all his conclusions to a non liquet, let the matter be farther enquired into. Hence it is (says he) that he fought truth as long as he lived, but he so contrived the matter, as never to grant that he had found it. Though he is not the inventor of that method of philosophizing, yet it goes by his name. The art of disputing about every thing, without doing anything else but suspending one's judgment, is called Pyrhonian, or Sceptical.

Some have said, that this philosopher acted upon his own principles, and carried his scepticism to an extreme to ridicules, that his friends were obliged to accompany him wherever he went, that he might not be run over by carriages, or fall down precipices. These reports, however, are inconsistent with the respect that is paid to him by ancient writers, and with the general history of his life, and are charged, as calumnies, upon the Dogmatists, whom he opposed. A great part of his life was spent in solitude; and he always preferred a settled compotus of countenance, undisturbed by fear, or joy, or grief. He endured bodily pain with great fortitude; and in the midst of dangers he manifested no sign of apprehension. As a disputant, he was celebrated for the subtlety of his arguments, and the perplexity of his language. So highly was Pyrrho esteemed by his countrymen, that they honoured him with the office of chief priest, and from respect to him, paid a decree by which all philosophers were indemned with an exemption from public taxes. Of the poets, and particularly of Homer, he was a great admirer; and frequently repeated passages from his poems. He flourished about the 11th Olympiad, and died about the 90th year of his age, probably in the 123rd Olympiad, B.C. 288. After his death, the Athenians honoured his memory with a statue; and a monument, as Laertius informs us, was erected to him in his own country. His scepticism may in a great measure be acribed to his early acquaintance with the system of Democritus. Having learned from this philosopher to deny the real existence of all qualities in bodies, except those that are essential to primary atoms, and to refer everything else to the perceptions of the mind produced by external objects, that is, to appearance and opinion, he concluded, that all knowledge depended upon the fallacious report of the senses, and consequently, that there can be no such thing as certainty. In this notion he was encouraged by the general spirit of the Elysian school, in which he was educated, which was unfavourable to science. But his scepticism was more confirmed by the subtleties of the Dialectic school, in which he was instructed by Bryson, the son of Stilpo. Regarding mental tranquility as the great end of all philosophy, and observing that nothing contributed so much to disturb it, as the disputes which agitated the schools of the Dogmatists, and also inferring from their endless disputes the uncertainty of the questions which they debated, he had recourse to the doctrine of universal uncertainty; and thus it happened in his case, as in that of many others, that controversy became the parent of scepticism.

Pyrrho had several discipiles, but none who merit particular notice except Timon, the Philanian, who lived to the age of 90 years, and flourished in the time of Ptolemy Philadelphia. The public speeches of Pyrrho and his discipiles in the Pyrrhonian school terminated with Timon, and in Cicero's time this school was extinct. The discipiles of Timon chose to screen their scepticism under the authority of the Academy; and after some interval, the school itself was revived by Ptolemaeus, a Cyrenian, and continued at Alexandria by Eunapius, a contemporary with Cicero; the latter wrote a treatise, "On the Principles of the Pyrrhonian Philosophy," which has been preferred by Ptolemy, from his time to our own. He was transmitted, by a series of preceptors, well known, to Sextus Empiricus, who has given a summary of the sceptical doctrine; for an account of which, see Sceptics. As for Pyrrho and his followers, they rather endeavored to demolish every other philosophical system than to erect one of their own. They affected nothing but proposed positions merely in the way of censure, without attempting to determine on which side, in any disputed question, the truth lay, or even presuming to assert, that one proposition was more probable than another.

Those now distinguished by the name of Pyrrhonians, or Sceptics, are persons who, from the great number of things that are dark and obscure, and from the averry they hear to popular credulity, maintain, that there is nothing certain in the world.

The truth is, Pyrrhonians have some foundation in nature; we do not judge of things from their real essences, but from their relations to ourselves. Most of our ideas we receive by means of our senses; but our senses are not given to judge of the essences, but of the relations of things to themselves; i.e. how they may affect us so as to do us good or harm.

Thus, e. g. our eyes do not give us the real magnitudes of objects, but their relative ones only.

The Academics differed from the Pyrrhonians, in that they owned there were some things more like or more near akin to truth than others, which the Pyrrhonians peremptorily denied. On account of the similarity of the opinions of this sect and those of the Platonic school in the Middle and New Academy, it happened, that many of the real followers of Pyrrho chose to screen themselves from the reproach of universal scepticism, by calling themselves Academics (which see); and hence the appellation of Pyrrhonists.
rhonists fell into disuse, whilst the doctrine of Pyrrho had many advocates. For the difference between them, see Sceptics.

Le Clerc observes, that the Pyrrhonians, in affirming that there is nothing certain, were the most afluming and decisive of all philosophers; since they must first have examined all things, to be able to determine precisely that all things are uncertain.

It may be added, that the very principle of the Pyrrhonians destroys itself; for if there be nothing certain, must that dogma itself be precarious; and if no one thing be more probable, or like to truth than another, why shall the principle of the Pyrrhonians be believed preferably to the opposite one? since it is come at in the same way as our other knowledge. Brucker's Hist. of Philos. by Enfield, vol. i.

PYRRHUM, in Ancient Geography, a town of Panonlia, on the route from Patovio to Sicilia, between Aquaviva and Dautona, according to the Itin. of Antonine.

PYRRHUS, in Biography, king of Epirus, one of the most distinguished warriors of the period in which he flourished, supposed to be descended from Pyrrhus, the son of Achilles, was the son of Aëcides, who was expelled the kingdom by a revolt of his subjects. When Pyrrhus was only twelve years of age, he was placed on the throne of his ancestors by Glauclus, king of Illyria, who had protected him in his infancy. He reigned in peace till he was about seventeen years of age, when, being absent from his kingdom, his subjects feized his treasures, and conferred the crown upon his great uncle, Neoptolemus. Pyrrhus being poiffessed of no force to enable him to recover his authority, repaired to Demetrius Poliorcetes, the son of Antigonus, who had married his sister, and under that eminent commander he learned the art of war, in company with many officers and soldiers of Alexander the Great. At the battle of Ipus, in the year B.C. 301, he greatly distinguished himself, and after its loss by Demetrius, he secured for him the Greek cities, with the care of which he had been entrusted. When a treaty of peace was concluded between Demetrius and Ptolemy Lagus, king of Egypt, Pyrrhus contested to be one of the hostages sent into that country for the performance of the conditions. In the Egyptian court he excited general admiration by his amiable and correct behaviour, and his dexterity in martial exercises; and he obtained from the king his daughter Antigone in marriage. The next step was to restore him to his throne, which was effected by an armament supplied by Ptolemy, with the aid of which he defeated Neoptolemus. That prince, however, being supported by his allies, Pyrrhus contested to allot him a share of his dominions; but such a partnership was not likely to be durable, and Neoptolemus, it was said, attempted to poison Pyrrhus, which gave the latter a pretence to order his death. He being setled on the throne of Epirus, began to execute those schemes of ambition, in which the remainder of his life was spent. A civil war raging between the two sons of Callander, in Macedonia, one of them, Alexander, applied to Pyrrhus for assistance. He gladly took occasion of interfering in the affairs of that kingdom, and being put in possession of all its maritime towns, proceeded to conquer the revolt for Alexander. A peace was made, by which Macedonia was divided between the two brothers, and Pyrrhus seems to have withdrawn his troops to his own country. Shortly after, Demetrius made himself master of the kingdom, and notwithstanding their former friendship, hostilities ensued between him and Pyrrhus, who harassed him by incursions into Thessaly. They mutually invaded each other's kingdoms; and in one instance, Pyrrhus gained so complete a victory over the principal general of his antagonist, and displayed so much courage, that he struck with admiration the Macedonians whom he had defeated, who deserted their own king, and chose Pyrrhus for their sovereign. This occurred in the year B.C. 287. He held this crown, however, a short time; for Lycaimachus, in the following year, entering the country with a powerful army, and remonstrating against the injustice of conferring the kingdom on a foreigner, in prejudice to him, a native and commander under Alexander the Great, the allegiance of the Macedonians seemed to Pyrrhus so little to be relied on, that he withdrew from the contest, and returned to Epirus. The Romans, engaged in a war with the Tarentines, looked for assistance to Pyrrhus. This prince eagerly listened to the proposal, and communicated his determination to his prime-minister Cynaeas, who, being more prudent than his master, endeavoured to dissuade him from it. The enterprise was, however, resolved on, and Cynaeas was sent with a body of troops to Tarentum, where he subverted the Roman influence, which was beginning to prevail, and obtained the command of the citadel for an Epirot officer. Pyrrhus followed, and having left his son Ptolemy, regent of Epirus, landed in Italy, in the year 280 B.C.; bringing with him an army of about 25,000 men, of whom 7000 were Macedonians, the veteran soldiers of Alexander the Great. He also brought a number of war-elephants, which was the first time that these animals were seen, in that character, in Italy. He was greatly endangered in his passage by a storm, which dispersed his fleet, and destroyed some of the ships that kept company with him. On his arrival at Tarentum, he began to correct the licentious manners of the inhabitants, and enure them to military discipline. At length he marched out to meet the Roman confid Valerius Laevinus, who was waiting for him on the bank of the Siris, in Lucania. The engagement was extremely obstinate, and Pyrrhus, who exerted himself in a manner worthy of his high reputation, was in great perilous danger. Victory, however, decided in his favour, and he took possession of the enemy's camp. In interfering the dead he made no distinction between his own men and the soldiers of his antagonist, but beheaded with commotion upon the bravery of his fallen foes. He followed up his victory, and had proceeded so far as to obtain a distant view of Rome. The advance of the other consuls obliged him to retire, and he finished his campaign by returning to Tarentum. Sensible that he had engaged in no easy task, he was delighted to receive an embassy from the Romans, which he imagined was to solicit peace, but it was only to negotiate an exchange of prisoners. In this embassy was included the virtuous Fabricius, whom he in vain attempted to gain to his interest by large offers. He then attempted to make a treaty, and sent his minister, Cynaeas, to Rome for that purpose, but was unsuccessful.

In the next campaign, two confuls with their armies marched against the king of Epirus; the battle was extremely bloody, and the victory so indecisive, that both parties claimed it: one of the confuls was killed, and Pyrrhus was severely wounded; and Iuch was the loss of men, that to one who congratulated him as having been the conqueror, he frankly replied, "such another victory will ruin me." Both the confuls of the next year, one of whom was Fabricius, were employed to oppose Pyrrhus, who had received fresh reinforcements from Epirus. They advanced to the Tarentine territory, where, while they were seeking an opportunity to engage, an offer was made them by the physician of Pyrrhus, to take him off by poison. Detecting
ing the treachery, they informed the king of his danger, which so affected him, that he immediately liberated all his Roman prisoners without a ransom. He now sent Cynæns to Rome in token that the attempt at negotiation, but was again unsuccessful. During the state of perplexity which a refusal had thrown him into, he was invited by the Syracusans and others to lend his aid against the Carthaginians, who had established themselves in Sicily. He accordingly seized the pretext for changing the field of action, and embarked the whole army for that island, leaving only a strong garrison in Tarentum. On his arrival he was received with general acclamations, and all the public force of Syracuse was put into his hands. He was soon so completely successful, that the Carthaginians sent deputies to Pyrrhus to treat for peace, but he refused to listen to any other condition, than that of their entirely evacuating the island. In confidence of success, he caused a feast to be proclaimed king of Sicily, and then made preparations to cross over into Africa, and carry the war into the Carthaginian territories. These projects were not agreeable to the Sicilians, who became alienated from him, and whom he treated not as friends, but as a conquered people. After this he quitted Sicily, and embarked for Italy; in his voyage he was encountered at sea by a Carthaginian fleet, which hunk a number of his vessels and dispersed the rest, so that he reached a port in Italy with no more than twelve sail. Six days did he confine in Italy and Sicily, inflicting and suffering all the evils of war, and finally exhausted in force, and with diminished reputation. His rallies spirit was not subdued; and for the purpose of employing and paying his soldiers, in conjunction with a body of Gauls, he made an irruption into Macedonia, where Antigonus Gonatus then reigned. His success was beyond his expectations, for he not only obtained the pillage of many cities, but defeated Antigonus in battle, and wrested from him almost the whole kingdom. He now marched with a powerful army into the Peloponnesus, at the request of Cleonymus, and appearing before Sparta, required the inhabitants to receive his friend as their king. Upon their determination to refit this mandate, he attacked the city, but was repulsed with the loss of many men: he now retired to Argos, where, through the treachery of Arilées, a bloody conflict ensued, during which, a woman, who saw Pyrrhus just going to kill her son, hurled a tile from the top of the house, which brought the king to the ground. In this state a Macedonian dragged him to a porch, and was going to cut off his head, when Pyrrhus opened his eyes, and gave him to see a look, that his trembling hand failed in its office, and it was not till after repeated strokes, that he could execute his purpose. Thus in the year 272 B.C. terminated the life and exploits of this great warrior, whose career of swifts of death alone could stop. His military skill was held in the highest estimation by the Romans, who were so well able to judge of it by experience. Hannibal considered Pyrrhus as second only to Alexander, as a great general. He is said to have been the first who understood the art of encampments, and of properly drawing up an army, and some treaties which he wrote on these subjects are mentioned by the ancients. He was brave to the borders of rashness, and sometimes loft the commander in the field. He had unbounded ambition, and a disposition perpetually to engage in new enterprises, for which, as we have seen, he readily abandoned such as proved more difficult than he had expected. He was fond of glory, but was perplexed with generosity, which dispossed him to acts of kindness, and to a grateful acknowledgment of obligations. All his sons were warlike, and he encouraged the dispo-
PYRUS.

Peric. Apple roundish, umbilicated, fleshy, with from two to five membranous, more or less rigid, cells. Seeds two, rarely more, in each cell, oblong, obtuse, pointed at the base, convex on one side, flat on the other.

Eff. Ch. Calyx five-cleft. Petals five. Apple inferior, of from two to five cells. Seeds two in each cell.

Our remarks under the article Mespilus apply equally to the present genus, as to the propriety of referring to it the whole Linnaean genus of Sorbus, and some species of Crataegus and Mespilus; disregarding the difference in the number of their styles, which is evidently uncertain and variable, and distinguing Mespilus by its berry, Pyrus by its apple. Even this distinction proves, in some instances, obscure enough. We shall, for convenience, follow Willdenow in the order of the species, introducing our additional ones according to their affinities.

1. P. arbutifolia. Arbutus-leafed Dwarf Apple. Linn. Suppl. 256. Willd. n. 1. Ait. n. 1. Pursh n. 1. Wangen. Amer. 89. t. 28. f. 64. (Mespilus arbutifolia; Schmidt Arb. 86. Pursh.)—Leaves obovate-oblong, pointed, serrated; smooth beneath; their mid-rib glandular above. Flowers corymbose. Calyx downy. Common in low copses and swamps, from Canada to Carolina, flowering in May and June. Pursh. Frequent in gardens. A buffy frut, without thorns, three or four feet high. Leaves two inches long, nearly serrated, more or less downy. Flowers white, terminal. Fruit red, the size of a currant, mealy, and not eatable.

4. P. ovalis. Oval Berry Apple. Willd. n. 3. Pursh n. 4. (Mespilus Amelanchier? Walt. Carol. 148. Cigaret spicata; Lamarck Dist. v. 1. 84.)—Leaves roundish-elliptical, acute, serrated, smooth. Flowers racemose. Petals obovate. Germsen and segments of the calyx downy. Native of swamps, from New Jersey to Carolina, flowering in April and May. A small frut; the fruit black, eatable. Pursh. Lamarck, who first distinguished this species, says it is twice or thrice as tall as the following, at least in the French gardens, with rounder leaves and smaller flowers, while the fruit is larger, being as big as a floe. The narrow coloured deciduous bractes moreover, which occur in both species, are in the present longer than each partial flower-flast, which is not the case with P. Amelanchier.

6. P. crenata Cretan Berry Apple. Willd. n. 5. Prodr. Pl. Graec. n. 1157. (Chamaeceras fruta; Alpin. Exot. 4.)—Leaves roundish, emarginate, with a small point, serrated; woolly beneath. Flowers racemose. Petals lanceolate. Germsen and segments of the calyx woolly. Found on the mountains of Crete. This differs from the last, of which it is jutly supposed of being a mere variety, in having rounder leaves, whose pubescence underneath is more permanent; as well as in having more woolliness about the flowers.

8. P. communis. Common Pear-tree. Linn. Sp. Pl. 686. Willd. n. 6. Ait. n. 4. Sm. Fl. Brit. n. 1. Engl. Bot. t. 1784.—Leaves ovate, serrated, finely smooth. Flower-flasts corymbose. Fruit elongated at the base. Native of various parts of Europe, but even more general as a cultivated plant, the varieties of whose fruit are many of them highly valuable for the table. The truly wild, or iron, pear is not eatable. It blooms in April or May. The tree is tall and handsome; the wood light, fine-grained, and tolerably hard, making neat furniture. The branches, at first creft, subsequently become curved downwards, and pendulous. The serratures of the leaves commonly disappear by culture, as do the strong thorns found on the wild tree. When young, the leaves are downy beneath, and fringed with white. Flowers white, with pale red anthers; their inoffensiveness corymbose, not umbellate as in the apple. Fruit obovate, more or less elongated at the base.

9. P. ponticola. Woolley-leaved Pear-tree. Linn. Mant. 2. 1244. Willd. n. 7. Ait. n. 5. (P. pollulleriana; Bauh. Hist. v. 1. 59. Munch. Hauff. v. 3. part 2. 333.)—Leaves ovoate, strongly serrated; downy beneath. Flower-flasts corymbose, subdivided. Native of Germany, according to baron Munchhausen. John Baubin first met with it in the garden of baron Pollwilt, in Aisla. It was sent to Kew, in 1786, by the late Mr. Graeffe. This differs from the common Pear-tree in having the leaves downy on both sides, but especially beneath; the flowers cream-coloured, much smaller and more numerous, even forty in each corym, their partial flasts being branched and forked. The fruit is small, sometimes but an inch long, and falls easily when ripe.

10. P. nivalis. Snow Pear-tree. Jacq. Austr. v. 2. 4. t. 177. Linn. Suppl. 255. Willd. n. 8.—Leaves obovate, obtuse, pointed, entire; hoary beneath. Flower-flasts corymbose. Fruit nearly globose. Native of mountains in Austria, about the borders of woods and vineyards, flowering
Flowering early in May. The leaves are whitish and silky beneath; nearly smooth above. Flowers large, white, strongly scented, in a simple downy corymb. Fruit about two inches in diameter, globose, rather deformed, purplish-green. When gathered in October, as年薪 as an unique medlar; but after lying a few weeks, it first acquires a sweet scent, which is but temporary, and at length towards December, the pears become soft, like medlars, and very good eating.

12. *P. divisa*. Deciduous Pear-tree. *Wildl.* n. 10. *Phytogr. falc.* 1. 8. *Moench. Weill.* 87. t. 8. *Wildl.* (Malus non flores, fructicos tamen; *Bauh. Fl.* 433.)—Leaves oval, pointed, serrated. Flowers small, dioecious. Petals linear, the length of the calyx.—The native country of this figular plant is unknown. Professor Willdenow, from whom we have dried specimens, subject to it be possibly a variety of the preceding species. The flowers are small, forming in appearance short downy umbels, at the ends of the branches, but each separate stalk is accompanied by a leaf. Petals yellowish-green, not exceeding the calyx. Styles five, smooth. We have seen the female plant only.

13. *P. spectabilis*. Chinese Apple-tree. *Ait.* n. 7. *Wildl.* n. 11. *Curt. Mag.* t. 267. *Schneb. IC.* t. 15.—Leaves oval-oblong, serrated, smooth. Umbels simple, fiddle, nearly smooth, without bracteas. Styles woolly at the base.—Native of China, from whence Dr. Forthgill is said to have imported it in 1780. The tree proves tolerably hardy in our gardens, flowering early in May. The leaves are furnished with copious shallow serratures, and have downy fruitflakes and ribs. The umbels are nearly, if not quite, smooth, and consist of eight or ten large and handsome rose-coloured flowers, for which alone this plant is cultivated, the fruit, which is yellow, an inch in length, and usually elongated a little at the base, being sparingly produced, and of no value. We can discover no bracteas, and if we are not mistaken, the want of them affords the surest mark of distinction between this species and the two following.

14. *P. prunifolia*. Siberian Crab-tree. *Wildl.* n. 12. *Ait.* n. 8. (P. Malus ?; *Ait.* ed. 1. v. 2. 1755. *Cragagus cerae folio, floribus magno*; *Mill. IC.* t. 269.)—Leaves ovate, pointed, with shallow serratures. Umbels simple, fiddle, downy. Bracteas linear, toothed, deciduous. Styles woolly at the base.—Native of Siberia, according to Miller, who says the seeds were sent from Dauria to Peterburgh, and who had it, bearing flowers and fruit, at Chelsea, before the year 1758. This tree is now common in gardens, the fruit, which resembles a white-heart cherry in size and colour, but which is liable, in both respects, to vary, being esteemed for preserving, as well as for tarts; nor is it, when mellowed by frost, unpleasant to eat raw. The leaves are rather more downy than the leaf, but their ribs are smooth. Flowers copious, with a light sweet scent, their colour much paler and their size smaller than *P. spectabilis*. Flower-flakes very downy. Bracteas smooth, membranous, very narrow, above half an inch long.

15. *P. bacatta*. Small-fruited Crab-tree. *Linn. Mant.* 75; excluding the reference to Miller. *Wildl.* n. 13. *Ait.* n. 9. *Pall. Roff.* v. p. t. 23; t. 10. *Gileke* t. 12. (Cragagus cerae folii, floribus magno; *Amm. Ruth.* 195. t. 31.)—Leaves ovato-lanceolate, pointed, sharply serrated, smooth. Umbels smooth, fiddle. Bracteas linear, slightly toothed, deciduous. Styles naked. Fruit smaller than the petals.—Found in low situations, about the banks of rivers, in Siberia, flowering the end of May. We received specimens from the garden of the late Right Hon. Charles Greville, at Paddington, in flower April 21, 1805. This differs from the last, with flower botanists have confounded it, in having broader, more acutely serrated, smoother leaves; smooth flower-flakes and styles; and a small red fruit, 'not bigger than a common haw. The calyx in both is deciduous, leaving a flared hollow on the top of the fruit.

17. *P. angustifolia*. Narrow-leaved Crab-tree. *Ait.* *Hort. Kew.* ed. 1. v. 2. 1756; ed. 2. v. 11. *Wildl.* n. 15. *Pursh n.* 8. (P. coronaria; *Wangen. Amer.* 61. t. 21. f. 47.)—Leaves lanceolate-oblong, shining, with tooth-like notches; contracted and entire at the base. Flower-flaks corymbose. Found in the low woods of Carolina, flowering in May. It resembles the foregoing species, but the fruit is very small. Pursh. This is said in Hort. Kew. to have been cultivated in 1750, by Mr. Christophor Gray. We have never examined it, nor have we any account of the stiles being downy or otherwise.

18. *P. japonica*. Japan Apple-tree. *Thumb. Japan.* 207- *Wildl.* n. 16. *Ait.* n. 12. *Curt. Mag.* t. 692. (Malus Japonica; *Andr. Repof.* t. 462. *Buks;* *Kempf. Amoen.* 844.)—Leaves elliptic-oblong, sharply serrated, very smooth. Stipulas lunate, deeply toothed. Flower-flakes somewhow aggregate. Calyx abrupt. Seeds numerous in each cell.—Gathered by Thunberg, on mount Pakou in Japan, where it flowers from February to April. It proves quite hardy in our gardens, into which for Joseph Banks introduced it in 1766, flowering at the same season, and also frequently again in autumn. When the spring is severe, the beautiful deep scarlet blossoms require the shelter of a glass frame. The stem is somewhat thorny. Leaves deep green; the stilt that come out are short and abrupt. Stipulas on the young branches, half an inch or an inch broad. Fruit globular, we have not seen it ripe. Seeds very numerous in each cell, one above another, so that we cannot but feel some scruples as to the genus of this species.

PYRUS.

Woodv. Med. Bot. t. 79. (Malus cotonae; Ger. Em. 1452. Matth. Valgr. v. i. 217.)—Leaves roundish-elliptical, entire; downy beneath. Flowers solitary, stalked. Calyx serrated, reflexed.—Native of the rocky banks of the Danube. Naturalized in the hedges of Germany. Dr. Sibthorp found it wild in the northern parts of Greece, in which country it retains the ancient name ἀρεία. This was among the first exotic fruits cultivated in England, where it blooms in May or June, and ripens fruit in autumn. The tree is rather spreading than tall. Leaves roundish, various in size; smooth and light green above; white with soft downy down beneath. Flower-flanks and calyx more or less woolly. Petals large, flesh-coloured. Fruit large, yellow, very audible and alluring, but with a peculiar and very powerful fragrance. Cookery renders it mild, and to mollify persons highly grateful. There are three or four angular seeds in each cell, ranged horizontally, not, as in the last, vertically. The quince is supposed to be the golden apple of the Heloipides, so famous in ancient fable.

20. P. fultifolius. Willow-leaved Crab-tree. Linn. Suppl. 255. Wild. n. 18. Ait. n. 14. Pallas Reff. v. 1. p. 1. t. 9.—Leaves linear-lanceolate, hoary, nearly entire; downy beneath. Flowers solitary, almost fiddle.—Native of Siberia, America, and mount Haemus. Sent to Kew, by Pallas, in 1780. It is a hardy tree, flowering early in spring, and known by its hoary, narrow, willow-like leaves. The flowers are terminal, solitary, and nearly fiddle; not axillary. Fruit pear-shaped, an inch long, brown, not at all edible till mellowed by frost, like medlars; and even then not very good.

22. P. Aria. White Beam-tree, or White Wild Pear-tree. Ehrh. Beitr. f. c. 20. Arb. 84. Sm. Fl. Brit. n. 7. Engl. Bot. t. 1858. Wild. n. 19. Ait. n. 15. (Carthagæmepæus Aria; Linn. Sp. Pl. 691. Sp. Pl. 301. t. 302. Aria Theophrasti; Ger. Em. 1357.)—Leaves elliptical, cut, and serrated; white and downy beneath, with crowded parallel veins. Corymbs compound, woolly. Styles two or more.—Native of lime-loving rocks, or chalky hills, in most parts of Europe; not rare in the mountainous countries of England, flowering in May, ripening fruit in September. A handsome small tree, much cultivated in home plantations. The young branches, like the flanks, calyx, and backs of the leaves, are very white, with mealy or cottony down. The leaves vary from an ovate or oblong-ovate figure, to a more correct oval, and are pretty regularly cut, as well as serrated, but not finetuated or lobed; their veins, or side-ribs, numerous, straight and parallel; their upper side smooth. Corymbs subdivided, many-flowered, cottony. Petals white, the size of those of the Hawthorn. Styles two, often three, rarely four. Fruit nearly globular, mealy and acid; its cells coriaceous rather than horny, equal in number to the flymes, with two seeds in each.

23. P. intermedia. Swedish White Beam-tree. Ehrh. Beitr. f. c. 20. Arb. 94. Wild. n. 20. Arb. 268. Ait. n. 16. (Sorbus alpina, folia mollis; Linn. Sp. Pl. 302. t. 301. fig. in flower only. S. hybrida; Huds. 216.)—Leaves elliptical, lobed, cut and serrated; white and downy beneath, with rather distant veins. Corymbs compound, woolly. Styles two or more.—Native of Sweden. Found by Mr. Waring, on the walls of castles Dinæ y Brún, North Wales. Hudson. Specimens from the original plant prove the same as those of Elrhart, and differ from the common P. Aria, only in having the leaves so far cut, as to be, in some degree, pinnatifid, owing to which the transverse veins are rather more distant from each other. We can scarcely admit it to be more than a variety, as Linnaeus made it in Sp. Pl. 681. It is his Lapland plant, Fl. Lapp. n. 199.

24. P. pinnatifida. Ballard Mountain Ash. Ehrh. Beitr. f. c. 6. 93. Exf. c. 145. Sm. Engl. Bot. t. 2351. (P. hybrida; Sm. Fl. Brit. n. 6, excluding the synonymy of Hudson and Withering. Sorbus hybrida; Linn. Sp. Pl. 684. Wild. Fl. Faf. t. 6. Wild. Sp. Pl. v. 2. 1008. Ait. Hort. Kew. v. 3. 204. Fl. Dan. n. 302. t. 301. fig. in fruit.) Leaves oblong, deeply pinnatifid, or half pinnate; downy beneath. Corymbs compound, woolly. Styles about three.—Native of Sweden. Gathered wild, by the late Mr. J. Mackay, in rocky places on Cairn na Callieh, and other mountains, at the north end of the isle of Arran. It is frequent in plantations, flowering in May, and propagated by seed. This was thought by Linnaeus to be a mule, between Aria, and aucuparia hereafter mentioned. It nearly accords with the former, but the leaves are more oblong and acute; very deeply pinnatifid, or even pinnate, in their lower part. The flowers and fruit almost agree with those of aucuparia. The flymes are usually three or four.

25. P. aucuparia. Mountain Ash; Quicken, or Roan Tree. Ehrh. Beitr. f. c. 6. 94. Gæfn. v. 2. 45. t. 87. (P. Sm. Fl. Brit. n. 5. (Sorbus aucuparia; Linn. Sp. Pl. 683. Wild. Sp. Pl. v. 2. 1008. Ait. Hort. Kew. v. 3. 204. Fl. Dan. n. 1034. Mill. Illus. t. 43. Engl. Bot. v. 3. 337. t. 5. S. fylaveis; Ger. Em. 1473. Matth. Valgr. v. 1. 235.) Leaves pinnate; leaflets equal, serrated, smooth. Corymbs compound, somewhat panicked. Styles about three.—Native of mountainous places, in the colder parts of Europe; abundant in Scotland, Derbyshire, &c. flowering in May, and very common in domestic plantations. An elegant and very hardy tree, of slow growth, the wood being hard and tough. Leaves all distinctly pinnate, of many pair of opposite, oblong, smooth, serrated leaflets, more or less entire towards the base, with an odd one; the young ones downy beneath. Flowers very numerous, white, the size of the three half, but rather more panicked. Fruit mealy, acid and bitter, yet edible when prepared with fuggar. According to Lightfoot, this tree is found generally about the Druidical circles in North Britain, and is still believed, by the superstitious Highlanders, to be powerfully efficacious against witchcraft.

found it in Greece, as well as on mounts Hymus and Athos, and in woods near Constantinople. Ray speaks of it as wild in the mountaneous parts of Cornwall and Staffordshire. It is now rarely cultivated, being, though a handsome tree, yet of slow growth, and inferior in the value of its fruit to the Medlar. A solitary individual of this species now and then occurs, about ancient manifolds and very old orchards. It blooms in May. The leaves are larger, and the flowers twice the dimensions of the bill, being the size of hawthorn-blossoms, rather paniced than corymbose. Fruit like a small pear, reddish, above an inch long, with five cells, answerable to the five styles; its cells with two valves, like those of a Common Pear; and though only one seed is perfect in each cell, Gartner observed two in an early state. This fruit, if tafted before it is mellow, occasions a mottl intolerable foreneces at the back of the palate, lasting many hours. When ripe it is soft, brown, and agreeably acid. The name Service is evidently a corruption of Sorbus.

28. P. hybrid. Male Service-Pear-tree. Willd. n. 22. Moench. Weifenl. 90. t. 6. Willd. —Leaves elliptical, serrated, downy beneath; simple or pinnate, the terminal one large. Flowers corymbose. Calyx hairy. —This is affected by Professor Wildenow, from whom we have specimens, to be a male production, from the first species, P. arbutifolia, impregnated by the 23th, auxuparia. It retains indeed as great a resemblance to both parents as it possibly could to what are so dissimilar to each other. The simple leaves are two inches or more in length, obtuse, strongly serrated; the lateral leaflets, of the compound ones, half, or one-third, as large, unequal at the base. Stipulas ovate, toothed, recurved. Flowers not much unlike the last, but their cymes somewhat smaller, with hairy, rather than downy, flanks. It is curious that the rib of each leaf on its upper side, retains some portion of the brown glands characteristic of P. arbutifolia.

—Leaves pinnate, entire; silky beneath. Corymbs axillary and terminal, of few flowers. —Gathered in the Sandwich islands, by Mr. Menzies, to whom we are obliged for specimens, under the name of Sorbus, to which, now abolished, Linncean genus there can be no doubt that this tree belongs, though we have not seen the fruit. The leaves are all uniformly pinnate, two or three inches long, of eight or nine pair, besides an odd one, of equal, oblong or obovate, obtuse, minutely pointed, entire leaflets, half an inch at least in length; smooth and shining above; paler and silky beneath. Stipulas lanceolate, a little hairy, deciduous.

Flower-flalks axillary and terminal, nearly the length of the leaves, downy, corymbose, though each bears but three or four flowers, which are about the size of P. auxuparia. Bracteae wheel-shaped. Calyx woolly. Styles, as far as we can see, three, hairy at the base. The leaves of this very pretty and remarkable species strikingly convey the idea, at first sight, of some kind of Anthyllis, especially A. Barb. Jovis.

Pyrus, in Gardening, contains plants of the fruit-tree kind, of which the species cultivated are the common pear-tree (P. communi); the common apple-tree (P. malus); the Chinese apple-tree (P. spectabilis); the Siberian crab-tree (P. prunifolia); the sweet-scented crab-tree (P. coronaria); and the quince-tree (P. cydonia.)

With respect to the firih, it is observed that "the wild pear, the mother of all the orchard and garden varieties, is thorny. The flutes are fetaceous, white (or reddish), deciduous; the peduncles alternate; and the calyx clothed with a ferruginous wool." There are numerous varieties; but those of most importance for cultivation are,

The little mulii, which is often termed the supreme. The fruit, when ripe, is of a yellow colour; the juice somewhat musky; and, when gathered before it be too ripe, it is a good fruit. It becomes ripe about the latter end of July, but continues good only a very short time.

The slip, or little baldar mulik, which is pretty much like the other, but smaller. The skin, when ripe, has a few streaks of red on the fun fide.

The green siffel, or Hatlings, which is a middle-priced fruit, that always remains green, and is full of juice when ripe. It becomes ripe in the beginning of August.

The red mufcanelle, which is a large early pear, of great beauty; the skin is of a beautiful yellow, flared with red, and the flesh has a rich flavour. It sometimes produces two crops in a year; the firih about the end of July, and the second in September, or thereabouts.

The little mufcat, which is a small pear, having the skin very thin, and of a yellowish colour, when ripe. This fruit has a rich musky flavour, but does not keep long. It becomes ripe about the beginning of August.

The lady's thighs, which is here commonly called jargonelle, is of a rufset-green colour from the fun, but towards it inclining to an iron colour; the flesh is breaking, and has a rich musky flavour. It becomes ripe about the middle of August.

The Windsor, which has a smooth skin, and when ripe is of a yellowish-green colour; the flesh is very soft, and, if permitted to hang but two or three days after it is ripe, grows mealy, and is good for nothing. It becomes ripe about the latter end of August.

The jargonelle, which is commoned called cuisse madame. According to Mr. Forby, it is certainly the true French jargonelle, and the pear that commonly goes by that name here is the real cuisse madame, or lady's thigh; it being very probable that the names have been changed, in coming to this country. This pear is somewhat like the Windsor; the skin is smooth, and of a pale green colour. It is a plentiful bearer; but the flesh is apt to be mealy, if it stands to be ripe, which is about the middle of August. It bears well on standards.

The orange musk, which is of a yellow colour, spotted with black; the flesh is musky, but very apt to be dry. It ripens about the latter end of August.

The great blanket, or bagpipe of Anjou, which has a smooth skin of a pale green colour; the flesh is soft, and full
full of juice of a rich flavour. It ripens about the middle of August.

The little blanquet, which is much less than the former, of a pale colour, and the flesh tender, and full of a rich musky juice. It ripens about the latter end of August.

The long-flanked blanquet has a very smooth skin, white, and a little coloured towards the fun, and is full of a rich fuggy juice. It becomes ripe at the latter end of August.

The skinless or early rufflet, which is of a reddish colour, the skin extremely thin, and the flesh melting and full of a rich fuggy juice. It ripens in the latter end of August.

The musk robin, or queen's pear, (also called the amber pear,) which is small, and of a yellow colour when ripe; it has a rich musky flavour, and is a great bearer. It ripens about the latter end of August.

The musk drone, which has a skin of a yellow colour when ripe, and a rich musky taste; but is apt to grow mealy, if left too long on the tree. It ripens about the beginning of September.

The red orange, which is of a greenish colour, but the side next the fun changes to a purple colour, when ripe; the flesh is melting, and the juice fugary, with a little perfume. It ripens in the beginning of August.

The caffolette, or green muscat, is a small greenish pear, with some specks in the skin. It is full of a rich perfumed juice, and ripens in the latter end of September.

The great onion, brown admirer, or king of summer, which is of a brownish colour next the fun, and becomes ripe in the beginning of September.

The musk orange, in which the skin is green, and the flesh melting. It ripens in the beginning of September.

The avorot, or Augustus muscat, which has a smooth skin of a whitish yellow colour; the juice is richly furred and perfumed, and it is esteemed one of the best summer pears yet known. It is a great bearer, and becomes ripe in the beginning of September.

The rofe, or thorny rofe, which is shaped like the great onion pear, but much larger, of a yellowish-green colour, but a little inclining to red next the fun. The flesh is breaking, and the juice musky. It becomes ripe in the beginning of September.

The poire du puchet, which has the flesh soft and tender, and the juice fugary. It ripens in the beginning of September.

The perfumed pear, which is of a deep red colour, spotted with brown; the flesh melting, but dry, and has a perfumed flavour. It ripens in the beginning of September.

The falfiati, which is red and yellow next the fun, but whitish on the other side; the flesh is tender, and the juice fugary and perfumed. It ripens about the middle of September.

The rofe water, which has the skin rough, and of a brown colour, the juice very sweet, tallowing like rofe-water. It ripens in the latter end of September.

The rufflet, in which the flesh is soft and tender, and the juice agreeably perfumed. It ripens in the latter end of September.

The great mouthwater, which has the flesh melting and full of juice. It ripens about the latter end of September.

The prince's pear, which has a highly-flavoured juice, and is a great bearer, ripening about the latter end of September.

The summer bergamot, which is sometimes called Hamden's bergamot. The flesh is melting, and the juice highly perfumed. It ripens about the latter end of September.

The autumn bergamot, which is smaller than the former; the flesh is melting, and the juice highly perfumed. It is a great bearer, and ripens in the beginning of October.

The summer bonechret, which is very full of juice, and is of a rich perfumed flavour. It ripens about the middle of September.

The beurré rouge, (the red butter pear,) which has the flesh very melting and full of a rich fugary juice. It ripens in the beginning of October, and, when first gathered from the tree, is one of the very best fruits of pears.

The dean's pear, which has the flesh melting and full of juice, which is very cold. It is a great bearer, and ripens in the beginning of October.

The Swifs bergamot has a melting flesh, and is full of juice. It ripens in the beginning of October.

The long green, in which the flesh is melting and full of juice. It ripens in the latter end of October. It is, by some, reckoned the same with the mouthwater.

The white and grey monfeur John, which are the same; the difference of their colour proceeding from the different soils and situations wherein they grow, or the rocks on which they are grafted. If this pear be rightly managed, there are not many pears in the same season to be compared with it. The flesh is breaking, and full of a rich fugary juice. It ripens in the latter end of October or beginning of November.

The flowered muscat, which is an excellent pear; the flesh is very tender, and of a delicate flavour. It ripens in November.

The vine pear, which is of a dark red colour; the flesh very melting, and full of a clammy juice. It comes into eating in November.

The roulechine pear, which is of a deep red colour, with spots of grey; the flesh is very tender and delicate, and the juice very sweet, with an agreeable perfume. It ripens about the latter end of October, but does not keep.

The knife's pear, which has the flesh fine and tender, and the juice very much fugared. It ripens in the latter end of October.

The marquis pear is a pear which, when it does not change yellow in ripening, is seldom good; but if it does, the flesh will be tender, delicate, and very full of juice, which is fugared. It comes into eating in November.

The Marfa pear, which has the flesh extremely tender and buttery, and full of a rich fugary juice. It is the very best pear of the season, and comes into eating about the latter end of December.

The Lanfæ, or Dauphiné pear, which has the flesh yellow, tender, and melting; the juice is fugared, and a little perfumed. It is in eating the beginning of December.

The marfian (the dry marian), which is almost like the rufflet in shape and colour; the flesh is breaking and fine; and the juice fugared, with a little perfume. It is in eating about the beginning of December.

The amadot, which is rather dry, but high-flavoured; it is in eating about the middle of December.

The little hard pear, which is extremely fine; the flesh melting; the juice much fugared, and has an agreeable musky flavour. It is in eating the latter end of December, and is esteemed one of the best fruits of that season.

The Louïfbon (the good Lewis), which has the flesh extremely tender, and full of a very sweet juice. It is in eating about the middle of December.

The Colmar pear, which is very tender, and the juice greatly fugared. It is in eating about the beginning of January, and is esteemed an excellent fruit.

The Pefchafferie, which has the flesh melting and buttery; the
the juice is fragrant, with a little perfume. It is in eating about the first of January. It bears bitts on standards.

The vigolene pear, which is esteemed by some as one of the best fruits of the season; the flesh is melting, and full of a rich juice. It is in eating about the first of January. In dry and cold seasons it is very apt to crack, which greatly diminishes its value.

The ambric, which is esteemed a very good pear; the flesh is quite melting, and full of sweet perfumed juice. It comes into eating about the beginning of January.

The epine d'hiver (the winter thorn pear), which has a very tender buttery pulp, of an agreeable taste, with a sweet juice highly perfumed. It is in eating about the latter end of December.

The St. Germain pear, which is a fine fruit and keeps long; the flesh is melting, and very full of juice, which in a dry season, or if planted on a warm dry soil, is very sweet. It is in eating from December till February. Mr. Forsyth remarks, that it is "an excellent bearer, when planted as a dwarf standard, and comes in succession after the same sort of pears on wall-trees are over."

The St. Amlin, which is pretty full of juice, and which is often a little sharp; the flesh is tender but not buttery. It is in eating the latter end of December, and continues good two months or longer.

The Spanish boochtrit, which is a large fine pear; the flesh is breaking, and the juice sweet. It is in eating in January.

The wilding of Caffay, which is also called the small winter butter pear, is a small fruit; the flesh is melting, and the juice very rich; it is an excellent bearer on standards. It is in eating in January.

The martine, or the lord martin, which is a good fruit; the flesh is breaking and full of juice, which is very sweet and a little perfumed. It is in eating in January.

Th winter ruddle, which has the flesh buttery and melting, and generally full of a sweet juice. It is in eating in the latter end of January.

The france real, or the golden end of winter, which is only esteemed for baking.

The brown beurre, which is of a reddish-brown colour on the edge next the fun, and yellowish on the other side. The flesh is melting, and full of a rich juice. It ripens in October, and is esteemed an excellent pear.

The Holland bergamot, anoiffe, or lord Cheney's, which is a very good pear; the flesh is half buttery and tender, and the juice is highly flavoured. It keeps from the end of January till April.

The German muscat, which is an excellent pear; it is buttery and tender, and the juice is highly flavoured. It is in eating from February till April or May.

The pear of Naples, or Easter St. Germain, which is half-breaking; the juice is sweet, and a little vinous. It is in eating in March.

The winter boochtrit, which is very large; the flesh is tender and breaking, and is very full of a rich sugared juice. It is in eating from the end of March till June.

The la paloret, which is tender and buttery, and the juice sweet. It is in eating in March.

The St. Martial, or the angelic pear, which has the flesh tender and buttery, and the juice very sweet. It is in eating in March.

The wilding of Chaumontelle, which is melting, the juice very rich, and a little perfumed. It is in eating in January.

The brown St. Germain, which is a very fine high-flavoured pear on dwarfs and standards, and comes in after the wall St. Germain. It continues in eating from December to the end of March.

The pear d'Anch, which was introduced by the late duke of Northumberland. It much resembles the Colmar, but is fuller towards the stalk. It is in eating from Christmas to April, and is, without exception, the best of all the winter pears.

The swan's egg, which is a middle-sized pear, in a shape like an egg; it is of a green colour, thinly covered with brown; the flesh is melting, and full of a pleasant milky juice. It comes in eating in November. It is healthy, and bears well either as a standard or in any other way.

The bergamot de paque, which has also the following names: the terling, the amoiffle, the Paddington, and the Tarquin. It is a fine handfome fruit, green when gathered, and of a yellowish or straw-colour when ripe. It comes into eating about the month of April, continues till June, and makes a very handsome appearance at table.

The golden beurré, which is a very fine pear; it is of a beautiful scarlet colour next the fun, and of a gold colour on the other side. The flesh is melting, and the juice highly-flavoured. It ripens in October. It succeeds bitt on an east aspect, and a loamy soil. It is a plentiful bearer. Mr. Forsyth observes, that it "was introduced from Burgundy by the late marquis Conway, and was first raised, in this country, at his seat of Park Place, near Henley-upon-Thames, now the seat of lord Malmesbury."

The Williams's feeding pear, which resembles a summer boochtrit, but is more juicy, is a great bearer, and ripens in September. Mr. Forsyth says that it "will be a valuable acquisition to the market-gardeners, as it immediately succeeds the Windsor pear."

The citron de Carmes, which is a middle-sized pear, of a yellowish-green cast, full at the eye; of a round shape, but tapering a little towards the stalk, which is long. It becomes ripe in July.

And the true golden beurré, which in shape and size resembles the brown beurré; but is of a reddish-brown colour next the fun. It is a very fine pear, but does not keep long. It comes into eating in October.

Mr. Forsyth gives the following selection from Anderson's and Co.'s Catalogue of Edinburgh.

Of the Summer Kinds,—The pear James, which is from ripe, and soon rotten, has a little flavour, and is the earliest pear in Scotland.

The early carnock, which is indifferent, of a yellow colour, and bright-red towards the fun; making a beautiful standard tree.

The lemon, lady's lemon, or lady Lamont, which is indifferent good, but principally valued for coming early, and being a good bearer in common.

The green pear of Pinkey, which is a small green pear, nearly round, of a sweetish taste or flavour.

The sorrow cow, a Clydefdale pear, which is a large pear with a short stalk; flat towards the eye; the colour red and yellow; the flesh tender, and marked in its flavour.

The pear farn, a Clydefdale pear, which is a big-bellied beautiful pear; the tree large, a great bearer, and fit for an orchard; but the fruit is not very good.

The grey honey, which is a pretty good pear.

The green orange pear, or orange vert, which is a very good pear.

The brute bone, chaw good, or the pope's pear, which is only an indifferent sort.

The golden knap, sippoped Scotch, which is a small summer pear, of tolerably good qualities.

The
PYRUS.

The early achat, an indifferent fruit; greatly inferior to the winter pear of that name.

The hanging leaf, which is the name in Clydesdale, is good and beautiful; almost round; its colour red and yellow; a delicious sweetet is found in its faddle.

The Scots bergamot, which is a large good pear, of a yellow and red colour; the flesh tender and juicy.

The Longueil, which is very good, but a precarious bearer; supposed French, though not in their catalogues under that name.

The mulled honydew, gratioli, cucumber, or Spinola's pear, which is a very good pear when grafted on a free flock; its pulp being somewhat between soft and tender, with a great deal of perfumed juice, its colour red on one fide, and white on the other.

And the albin pear, which is a pretty large well-shaped pear, fit for the orchard or the field.

Of the Autumnal Kinds.—The ciehan, which is a Clydesdale pear, of middling size, and oblong shape, its juice agreeable.

The French carnock, which is tolerably good.

The ellin half, or good-man pear, which is a long pear, flat towards the eye; its colour green and yellow; its flesh hard, dry, and sweet in the faddle.

The Drummond, or late Scotch carnock, which is very good, if eaten before it grows mealy; its colour a bright red and yellow.

The viar, an oblong pear, with the colour yellow, red, and striped; tender, sweet, and mulled, but dry in eating.

The royal orange bergamot, which differs from the orange bergamot in being yellower, and sometimes having a faint red on one fide.

The green pear of Yair, which is sweet, juicy, and melting; of a moderate size; taking its name from Yair, on Tweed-fide, where it was first discovered.

The rood hib, which is very indifferent.

The le befdleri, the wilding of the fores of Ileri, in Breitaine, which is a yellowish pear, of middle size, but which is indifferent.

The unicorn pear, which is of a beautiful red and yellow colour; but rather adulter in the talle or flavour.

Of the Winter Kinds.—The winter achat, which is a Scotch pear; among the best early winter pears, and equal to most of those of the French kind.

The brier bulk, which is Scotch; a good pear, and will ripen in most ffeons; it is a small pear, of a firm substance, and sweet taffle.

The Brompton park, which is a feeding fent by Jefferys of that name.

The round winter, which is a Clydesdale pear, a very excellent winter pear.

The poir portrai, or gate pear, which is proper for baking.

The la double fower, or the double-flowering pear, which is a large flat beautiful pear, with a smooth skin, and blift colour on one fide, and yellow on the other: it is the best to preferve, taking a beautiful red colour from the fire.

And to these the following list is added:—The Ambrofia pear, the Afton towne, the autumn mulle boncheretie, the bishop's thump, the bloody pear, proper for baking, the brocas bergamot, the balrand, proper for perry, the biefder, fit for baking; the beurred du roi, the black pear, or Worcleder, fit for baking, the Britanni, the burdelieu, the Doyenné or St. Michael, the cauflac, fit for baking, the Eanier St. German, the Gainfel's bergamot, the golden beurred, the grey beurred, the grey good-wife, the green beurred, the fuggar, the green bergamot, the Huntingdon pear, the hufi-cap, proper for perry, the king's Catharine, the lammas, the London fugar, the mufet almum, the mulke blanquet, the Oldfield, proper for perry, the orange bergamot, the pear piper, the pyrus poveria, the red admirable, the rough cap, proper for perry, the Scotch bergamot, the fenng-langed, the firer-libred, the Spanfih red warden, fit for baking, the squai, proper for perry, the flirped verte longue, and the white beurred.

And for small gardens, where there is room only for a few trees, the following are recommended as proper for furnishing a regular succcelfion of fruit.

Summer Kind.—The mulf pear, the green chifel, the jargoule, theummer bergamot, and the summer boncheretie.

Of the Autumnal Kinds.—The orange bergamot, the autumn bergamot, the Gainfel's bergamot, the brown beurred, the Doyenné, or St. Michael, and the Iwan's egg.

Of the Winter Kinds.—The Croflane, the Chaumontelle, the St. German, the Colmar, the d'Auch, the Pechafferie, the winter boncheretie, and the bergamot de palque.

And the second fort, in its wild fiate, is called the crab, or wilding, and is armed with thorns, as well as the wild pear. Matter mentions the varieties in the fruit of the crab, or white, the other people towards the fun; but it is commonly yellowish-green, with a tinge of red. And also a variety with variegated leaves.

There are a great many varieties of the apple, but the following are given by Mr. Forsyth as the most delivering of attention.

The Acklam's rufet, which is a small Yorkshire apple, of a rufet colour towards the fun, and yellow on the other fide; it becomes ripe in January, and keeps till March.

The aromatic pippin, which is a very good apple, of a bright rufet next the fun; and the flesh has a fine aromatic flavour. It ripens in October.

The Baxter's pearmain, which is a real Norfolk apple, of a handsome size, and pale-green colour, full of small dark spots. It is a fine kitchen fruit, and will keep till April. It is also a good eating apple.

The beauty of Kent, which is a fine large apple, resembling a codlin. It is streaked with a fine red towards the fun, and of a beautiful yellow, with some streaks of red on the other fide. It is a very good apple, coming into eating in September, and keeping till the latter end of April.

The belle grefine, which is a new feeding raised at Norwich, of much beauty, and never failing to afford crops. It was first propagated by Mr. Lindley, who gave it this name. It is a handsome apple, resembling the burdoff, of a yellow colour, with red towards the fun, and an excellent table apple, keeping till March.

The Bell's pearmain, which is a real Norfolk apple, large and handsome; red toward the fun, and yellow on the other fide. It is a fine kitchen fruit, and pretty good to eat raw, keeping till June.

The bell pool, which is a middle-sized apple, of a pale-green colour, streaked with red towards the fun. It is a good apple, in eating from January to April.

The black apple, which is a middle-sized fruit, of a dark mahogany colour next the fun, but fainter on the other fide. It is of a pleasant sweet taffle, keeping till the middle of April.

The Bland's summer pippin, which is a handsome apple, of a gold colour, and an agreeable flavour. It is a great bearer, ripe in September, and keeps till Christmas.

The Blatche's fine small table apple, which is about the size
fize of a small golden pippin; red toward the fun, and green on the other side. It has a fuggy taffe, and comes into eating in January.

The boomey, which is a pretty large handfome apple, of a flat shape, and deep-red colour; and the flesh is streaked with red. It is not fit to eat raw, but will do well for cyder, or for the kitchen. It keeps till April.

The Bovey redbreak, which is a handfome apple, of a flattish shape, beautifully streaked with a bright red next the eye, which is small, and of a yellow colour about the footstalk. It keeps till the latter end of October.

The broad-eyed pippin, which is a fine large apple, with a very large eye; the colour is a greenish-yellow, with a little red toward the fun. It is a good apple, and keeps till May.

The brandy apple, which is about the fize of a golden pippin, flat-shaped, and of a yellowish-ruffet colour. It is of a pleasant flavour; comes into eating in January, and keeps till March.

The burdoft, or queen’s apple, which is a beautiful fruit, red next the fun, and of a fine yellow on the other side. It is a very fine apple; in Mr. Forfyth’s opinion, next in perfection to the golden pippin, and about the same fize. It is of a good flavour; ripening in January, and keeping till March.

The carnation apple, which is a beautiful middle-sized fruit, finely striped with red. It is ripe in January, and keeps till May.

The Carbury pippin, which in fize and shape refembles the French crab, and is of a deep green colour. It is a good baking apple, keeping till March.

The caraway ruffet, which is a handfome ruffet-coloured apple, about the fize of a nonpareil.

The calville, red and white, which are good apples, and of a vinous taffe. Some have a red and some a white pulp, the white being reckoned of a moft delicious taffe. They are in eating in September, and the following month.

The cat’s-head, which is a large oblong apple, of a greenish-yellow colour, with a little brownish-red next the fun; sometimes the colour inclines to a ruffet. It is a good baking apple, and is in eating from October to December.

The cockagee, which is a conical-shaped middle-sized apple, red on that fide next the fun, and of a fine yellow colour on the other. If properly managed, the fruit keeps till February. It is a famous cyder apple, and also bakes well.

The codlin, which is generally the firft apple that is brought to market. Its fruit is so well known that it needs no description. It is in eating from July to December; and is good either for baking or boiling.

The Cornish nonpareil, which is rather under the middle fize, is a little flatted, and of a ruffet colour. It is a very good apple, and keeps till the middle of March.

The Cornish pearmain, which is of a middling fize, and long shape; of a dull-green colour on one fide, and ruffet on the other. It is a very good apple, and keeps till the latter end of April.

The Court-of-Wick pippin, which is decribed by Mr. Billingly, in his “Survey of Somerfetshire,” as “the favour apple, both as a table and cyder-fruit, taking its name from the spot where it was firft produced. It originated from the pip or feed of the golden pippin, and may be confidered as a beautiful variety of that fruit. In shape, colour, and flavour, it has not its superior; the tree is large, handfome, and fparing, and a very luxuriant bearer. On the whole, it cannot be too strongly recom-
PYRUS.

The colour is a striped green towards the footstalk, and red towards the eye.

The famous, which is the prettiest large apple, of a beautiful red, with a little yellow on the side from the sun. Its flesh is very white, and full of a rich juicy juice; coming into eating about the latter end of October. It was introduced from Canada by Mr. Barclay of Brownston.

The fennel, on pomme d'anis, the fennel or anise apple, which is a middle-sized fruit, of a grey colour; the pulp is tender, and has a spicy taste, like aniseed. It becomes ripe in September and October.

The flower of Kent, which is a large handsome apple, of a yellow colour, and pretty good flavour. It keeps till the middle of April.

The fox-whelk, which is a small apple, flared with red. It is ripe in January. It is a cyder apple.

The Franklin's golden pippin, which is a handsome middle-sized apple, of a conical shape and gold colour, beautifully marked with dark spots. The fruit has a fine aromatic flavour, and deserves the first place at the table; but it is a very shy bearer. It comes into eating about the middle of November.

The French crab, which is a large handsome apple, of a deep green colour, with a little red next the fun. It will keep all the year; it is a good baking apple, and, if the summer be warm, pretty good for eating, and is a great bearer.

The French codlin, which is a pretty large apple, of a conical shape, and green colour, with red towards the fun, coming into eating in January.

The Fearn's pippin, which is of the shape and size of a noup'scar. It is of a beautiful scarlet next the fun, and of a golden yellow on the side. It makes a fine show at table, and keeps till the latter end of February.

The French Spaniard, which is a large apple, in form of a hexagonal prism with the angles a little rounded, and of a yellowish-green colour; it is pretty good, and keeps till the latter end of April.

The French or white rennet, which is a large fruit, of a yellowish-green colour, with some gray spots. It has a fugary juice, and is good either for eating or baking.

The Garget apple, which is a handsome conical-shaped apple, under the middle size, of a greenish-yellow colour, with a little red towards the fun. This is a pretty good apple, and keeps till May.

The gilliflower, which is a handsome apple, red towards the fun, and of a yellowish-green on the other side, having a fine flavour, and keeping till the latter end of March.

The golden rennet, which is a beautiful apple, a little flatted of a fine red colour towards the fun, and yellow on the other side. It is a good eating apple, and keeps till February.

The golden ruffet, which is a fine middle-sized apple, of a golden ruffet colour, from which it takes its name. It is a good apple, and keeps long.

The golden pearmain, which is a fine apple, above the middle size, of a deep red towards the fun, with a little yellow on the other side; when much exposed to the sun it is sometimes red all over.

The golden Mundi, which is a fine handsome apple, beautifully flared with red; of a good flavour, excellent for baking, and will keep till January. It is a good sauce apple.

The golden Glocefter, which is a handsome middle-sized apple, of a flat shape, and gold colour, with red toward the fun. It is a good apple, and keeps till March.

The golden knob is a handsome though rather small apple,
PYRUS.

The Hubbard's, or the ruffet pearmain, which is a real Norfolk apple; and, though not handsome, is one of the best table apples. It is of a dark ruffet colour, becomes ripe in January, and keeps till April.

The John apple, which is a middle-sized handfome fruit, of a green colour, with a little red toward the fun; the footstalk being very small. It is an excellent cyder and baking apple, from Devonshire; it is of an excellent flavour, and keeps till March.

The Isle of Wight pippin, which is a handsome middle-sized apple, of a greenish-yellow colour.

The juneting, or jeneting, which is a small yellowish apple, red on the side next the fun. It is a pretty fruit for early variety, and ripens about the latter end of June or beginning of the following month.

The kernel red-treak, which is of a greenish-yellow, with broad breaks of a dark-red all over it, and a yellow ground finely speckled with red next the fun.

The kernel pearmain, which is a small handfome apple, red toward the fun, and of a yellowish-green mixed with red on the other side. It is of a good flavour, keeping till the middle of May.

The Kentish pippin, which is a good sized apple, finely streaked with red. It is of a fine flavour, comes into eating about Christmas, and keeps till February.

The Kentish nonpareil, which is a handsome flat-shaped apple, of a light-ruffet colour, inclining to red toward the fun. It is of a good flavour, and keeps till May.

The king of the pippins, which is a middle-sized apple, of a fine gold colour, a little streaked with red towards the fun. It is ripe in January, and keeps till the latter end of March, when it becomes mealy.

The king apple, which is a middle-sized apple, of a conical shape; and its colour is that of a beautiful red intermixed with a little yellow on one side. This apple is of a pefant fugary tale, and keeps till the latter end of April.

The Kirke's feedling, which is a beautiful apple of a fine red colour towards the base, and yellow towards the eye. The footstalk is slender, and the eye large.

The Kirke's scarlet pearmain, which is a handsome middle-sized apple, of a beautiful red toward the fun, and a little yellow on the other side; becoming ripe in January.

The Kirke's scarlet admirable, which is a good apple for baking, and of a beautiful scarlet colour, is eating about the month of January.

The Kentish fill-haftet, which is a species of codlin, of a large size, and generally used for baking. It is in eating from August to October.

The Kirton or crack'd pippin, which is a middle-sized apple, of a greenish-yellow colour, with little dark spots. The coat is generally rough towards the footstalk. It is a good apple for the table, coming into eating in September.

The lady's finger, which is an excellent table apple, of a conical shape; red next the fun, and of a yellowish cast on the other side, having a sweet pefant flavour, and keeping till May.

The large flyre, which is a handsome cyder apple, of a yellow colour, with a little red next the fun. It becomes ripe in November.

The Lisbon pippin, which is a handsome middle-sized apple, of a flat shape, a fine red toward the fun, and a reddish-yellow on the other side. The flesh is firm, and has a sharp pefant taste. It comes into eating in November.

The Loan's pearmain, which is a large oval-shaped apple, of a dull green colour intermixed with a brownish-red, deepest next the fun. It is a pretty good table apple, of a sharp taffie, ripening in September, and keeping till May, but is apt to grow mealy.

The London pippin, or five-crowned pippin, which is a fine large apple, of a green colour, streaked with red toward the fun. It resembles the Ribton pippin, but is larger. It has a pretty agreeable taffle; and will come into eating about the latter end of November. It is good for the kitchen and table; and is most abundant bearer. It keeps till the middle of April.

The le calville d'automne, the autumnal calville, which is a large fruit, of an oblong figure, and of a fine red colour toward the fun, having a vinous juice, and is much esteemed by the French.

The long laller, which is a middle-sized apple, of an angular shape, and fine yellow colour, with a beautiful red next the fun. It is of a tolerable flavour, and keeps till the middle of May, but is apt to become mealy.

The lemon pippin, which is a handsome oval-shaped apple, of a gold colour. It is of a fine flavour, and will keep till the beginning of March.

The long team, which is a large angular-shaped baking apple of a pretty good flavour, with light green colour. It keeps till the latter end of January.

The lord Cheneys's green, which is a middle-sized Yorkshire apple, resembling the Yorkshire greening. It is of a dark green colour, with a little of a chocolate colour next the fun. It is a baking apple, and keeps till the middle of May.

The lord Arundel's apple, which is large, of an angular shape; the colour is green, with a little dingy red towards the fun. It is from France, and good for sauce, keeping well.

The lord Camden's rennet, which is a good-sized feedling, of a yellow colour, with a little brownish-red next the fun. It is a good flavoured apple, and keeps till March.

The Lucas's pippin, which is a handsome, middle-sized, cylindrical-shaped apple, of a beautiful orange colour. It is a pretty good fruit, and keeps till the latter end of April.

The maiden's blush, which is a small apple, of a dark mahogany colour next the fun, but paler on the other side, and sometimes of a greenish call. The taffe is auffle, and of course this fruit is not fit for the table; but does very well for baking, or for cider. It keeps till the beginning of March.

The Mansfield tart, which is a large Nottingham apple, but most known in Yorkshire. It is handfome, of a green colour, having a little cast of brownish-red, with dark spots next the fun, being a baking apple, and keeping till February.

The May gennet, which is rather under the middle size, of a greenish-yellow colour, slightly streaked with red next the fun. It keeps till April.

The major Humings's apple, which is a handsome middle-sized fruit, of a light green colour, with a little brownish-red towards the fun. It is an excellent apple.

The margil, which is an excellent apple, about the size of a nonpareil. It is of a red colour, with some yellow on one side; continues in use from November to the latter end of March; and is often sold in the London markets for a nonpareil.

The Margaret apple, which is a fine and beautiful fruit, yellow, striped with red, of a delicate taffe, sweet scent, and generally eaten off the tree. It is ripe in August.

The Minchall crabb, which is a handsome middle-sized Lancashire apple, of a yellow colour, with some brown spots.
It is common in the Manchester markets, and keeps till April.

The monstrous rennet, which is a very large apple, turning red towards the fun, and of a dark green on the other side. It is generally preferred on account of its magnitude, as the leifi is apt to be mealy. It becomes ripe in October.

The mother rennet, which is rather under the middle size, of a greenish colour, with a little blitch towards the fun. The eye is large and deep, and the footstalk small.

The New-England pippin, which is a large angular-shaped apple, of a green colour, with a little brownish-red towards the fun. It has a pretty good flavour, and keeps well till March.

The Newton pippin, according to Mr. Forfyth, is an American apple, but said to be originally from Devonshire. It is a fine large apple, of a greenish-yellow colour and red, with dark spots next the fun. When much exposed, it is of a beautiful red towards the fun, and of a gold colour on the other side. It has a fine flavour when not kept till it is too ripe, as then it becomes mealy. It is in eating from November to January.

The new red mul, which is a fine large apple, of a pale red towards the footstalk, and of a greenish colour towards the eye. It is a cider apple, and fit for baking.

The new red pippin, which is a beautiful middle-sized apple, of a dark red colour, with a mixture of yellow on the side from the fun. It keeps till March.

The nonfuch, which is a good bearer, and very fit either for the table or kitchen; the cooks, however, complain that it makes but a very small proportion of sauce. It is ripe in September and October.

The king-square, which, according to Forsyth, is a Gloucester apple. It is a large angular-shaped fruit, of a fine red towards the fun, and yellow on the other side, with a small mixture of red, keeping till April.

The Norfolk colman, which is a middle-sized apple, of a mahogany colour towards the fun, and a dark green on the other side. It keeps till August.

The Norfolk beech, which is a good-faced apple, rather flatted, of a deep red colour towards the eye, but paler towards the footstalk.

The Norfolk paradise, which is a large apple, of a dark red colour towards the fun, and green on the other side. It is a nice baking apple, and of a tolerable flavour for eating. It keeps till the middle of May.

The Norfolk floaring, which is a pretty large apple, of a dark red colour towards the footstalk, and green towards the eye. It is of a pleasent sharp flavour, being in eating from the latter end of January to the latter end of April.

The northern greening, which is a fine oblong apple, full at the footstalk, of a pale green colour, with a little red towards the fun. It is nearly of an equal size from the base to the crown, and has a fine flavour, being ripe in January.

The nonparell, which is a fruit deferredly valued for the briliencs of its tafte. It is seldom ripe before Christmas, and, if well preferred, will keep till May. It is jutly esteemed one of the best apples that have been yet known.

The oak peg, or oaken pin, which is an oval-shaped middle-sized fruit, of a green colour striped with white. It is very full towards the footstalk, which is small, keeping till June.

The old English pearmain, which is an oval-shaped apple, of a middle size, and fine red colour, with a little yellow towards the eye. It is of a pleasent sweet flavour; and is in eating from January to March.

The old red mul, which is a fine large apple, somewhat resembling the new red mul, both in shape and colour, with the addition of dark red spots towards the footstalk.

The old red pippin, which is a middle-sized apple, red towards the fun, and of a greenish colour on the other side. It is a good apple, and keeps till March.

The orange pippin, which is about the size of a large golden pippin; of a beautiful gold colour, with a little pale red towards the fun. It is a handfome apple, of a good flavour, and makes a fine appearance at table, being in eating in October, and keeps till March, but gets flat in the taffe when too long kept.

The Orleans pippin, which is a small flat-shaped apple, of a dark red colour, resembling the Orleans plum.

The paradise pippin, which is a handfome middle-sized apple, of a reddish colour. It comes into eating in October, but will not keep. It grows mealy when too ripe.

The pauno, which is below the middle size, of a conical shape, and of a greenish-yellow, or-light green colour. It is ripe in January.

The Pile's suffet, which is a middle-sized longish-shaped apple, relfect about the footstalk, yellow towards the middle, and of a brownish-red about the eye. It is a very firm fruit, of a sharp acid flavour, being much esteemed for baking. It ripens in October, and will keep till April.

The pigeonette, which is rather below the middle size, of a conical shape. It is of a pink colour, pretty dark towards the fun.

The Pear's pippin, which is a nice apple, about the size of a large golden pippin, of a yellowish colour, and the form a little flat. In Devonshire, according to Mr. Forfyth, they put these pippins into the oven just after the bread is drawn, laying a weight over them to flatten them, in the same manner as they do the beem in Norfolk, and bring them to table as a sweetmeat. It is a very good dessert-apple, and keeps till March.

The pomme grife, which is a fine apple, from Canada, of a flattish form, and suffet colour, tifhed beautifully with red. It ripens late, and keeps till March. It is an excellent eating apple.

The pomme d'api, which is much valued for its colour, being of a bright red. The tree is a good bearer, and the fruit is not liable to be shaken with high winds. The fruit should be suffered to hang on the tree till October or November; if the fruit do not set in. It comes into eating in February and March, and keeps long; but is more admired for its beauty than its flavour, or fineness of taffe.

The pomme violette, the violet apple, which is a pretty large fruit, of a pale green, striped with red towards the fun. It has a fuguey juice, and a flavour of violets, from which it takes its name. It ripens in October, and continues in eating till February, or later.

The pomroy, or king's apple, which ripens nearly as soon as the juneting, and though not so beautifully covered, is larger and much better taffet. It has a sub-variety, which is a winter apple.

The pound pippin, which is a large handfome apple, of a greenish colour, and is good for baking. It becomes ripe in January.

The poor man's profit, which is a dingy coloured oval-shaped apple, below the middle size. It is raised freely from cuttings; and keeps till January.

The queening, which is from Glouceftershire, is a large apple, of irregular shape, having large ridges from the base to the crown. It is of a dark red, but deepent towards the fun. It is a good cider apple, and bakes well, keeping till the latter end of November.
The queen's kernel, which is a fine apple, above the middle size, of a deep red colour. Covered very thick with small whitish specks. It is a tolerably good apple, and keeps till the latter end of April.

The queen's pippin, which is a small handsome apple, of a yellowish-green colour, sometimes inclining to red on the side next the sun. It is a fine-flavoured apple, very fit for the table, coming into eating in January, and keeping till May, but is apt to grow mealy when kept too long. Mr. Forfyth says, "the tree never grows to the height of other apple-trees."

The quince-apple, which is a middle-sized fruit, of a yellow colour, with a little red towards the eye. It is of a plesant flat flavour, ripe in January, and keeps till April.

The Ramborn, which is a large fruit, of a fine red next the sun, and striped with a yellowish-green. It ripens about the middle of September.

The red pearmain, which is smaller than the pearmain in general. It is of a deep red, with a little yellow on one side. A plesant sweet apple, and keeps till the middle of April.

The red-streak, which is a handsome middle-sized apple, beautifully streaked with red. It is a good cider apple, becoming ripe in January.

The red-streak seedling, from Longleat, which is from the Dorsetshire red-streak, is a beautiful apple, of a yellow colour, streaked with red, particularly next the fun. Forfyth says, it is sold in the Bath and Bristol markets in the latter end of September, and beginning of October. It is a pretty good apple, but does not keep long.

The red bag, which is a beautiful large Herefordshire apple, of a longish shape, streaked all over with a dark red; and is in eating about the middle of October.

The red mullet, which resembles the old red mullet in shape; but is of a dark red colour towards the sun, and yellow on the other side. It is ripe about the middle of November.

The rennet grise, which is a middle-sized fruit, of a grey colour next the sun; it is a very good juicy apple, of a quick flavour, and ripens about the latter end of October.

The red sweet, which is a small round apple, red towards the sun, and of a greenish-yellow on the other side. It is a good bearer, according to Forfyth, "and much esteemed among the country people of Cornwall, for making a kind of tart or pie, one of their dainties at Christmas." It is a pretty good table apple, and keeps till March.

The Ribflon pippin, which is a fine apple, from Ribflon Hall, near Knareborough, in Yorkshire. It is a little streaked with red towards the sun, and yellow on the other side, being one of the best apples for eating and baking, and continues in use from the end of October till April. It bears very well as a dwarf, and no garden should be without it.

The Robinson's pippin, which is about the size of a golden pippin, of a green colour, and partakes of the flavour both of a golden pippin, and a nonpareil. It keeps till May.

The royal George, which is a fine large apple, of a beautiful yellow on one side, and green on the other. It is a good apple, and keeps till June; but then grows mealy.

The royal nonpareil, which is a handsome apple, of a flattish shape, with a small footstalk and fine eye. It is about the size of a common nonpareil, of a green colour, with red towards the fun. It is ripe in January, and keeps till the latter end of March.

The royal pearmain, which is a fine large apple, beautifully streaked with red. It is ripe in January, and keeps till March, being a pretty good apple.

The royal ruffet, or leather-coat ruffet, which is a large fruit, and one of the best kitchen apples that we have. It is also a plesant eating apple, and a great bearer, being in use from October to April.

The ruffet pippin, which is of a rough ruffet colour towards the sun, and of a green colour, sometimes inclining to yellow, on the other side. It is a good keeping apple, and fit either for baking or eating raw. It is ripe about the beginning of February, and keeps till March.

The summer pearmain, which is ripened with red next the sun; the flesh is soft, but soon turns mealy; so that it is not much esteemed. It is in eating in August and September.

The silver pippin, which is a handsome middle-sized conical-shaped apple, of a fine yellow colour, with a faint blush towards the fun. The flesh is firm and very white, and of an excellent flavour. It keeps till the middle of May, or later.

The seek no farther, which is a handsome apple, rather above the middle size, of a pale green colour, a little streaked with red. It is of a plesant though not very high flavour; and is in eating from January to May; but is apt to be mealy when kept longer than the beginning of April.

The Sykehoufe, which is a handsome middle-sized apple, from Sykehoufe in Yorkshire, of an orange colour towards the sun, sometimes inclining to red, and yellow on the other side. This is a fine eating apple; ripe in January, and keeps till April.

The flone pippin, which is of a green colour, streaked with red towards the fun. It is of a sharp tate, and is in eating from January till the middle of May.

The Stoup codlin, which is a large handsome apple, of a pale-green colour, with a little red towards the fun. It is a baking apple, of a pleasant tate, and keeps till May.

The striped nonpareil ruffet, which is a handsome apple, of a greenish-ruffet colour, with a little brownish-red towards the fun. It is about the size of a large nonpareil, is ripe in January, and keeps till March.

The spice apple, which is a handsome middle-sized angular-shaped apple, of a yellow colour, and a plesant flavour. It is ripe in January, and keeps till March.

The Skerm's kernel, which is a conical-shaped middle-sized apple, beautifully streaked with red, deepset towards the eye, and having a good deal of yellow towards the footstalk. It is ripe in January, and keeps till March.

The spice rennet, which is a handsome apple, below the middle size, red towards the fun, and yellow on the other side.

The Spanish pearmain, which is a middle-sized oblong apple of a carnation colour, and dark-red towards the fun. It is a pretty good apple, and keeps till the beginning of May.

The Spanish onion, which is a handsome round apple of a ruffet colour, with a dull red towards the fun. This apple, which is rather below the middle size, is very good for desert, keeping till March.

The Sharp's ruffet, which is below the middle size, of a brownish-red colour towards the fun, and a pale-green on the other side. It is shaped like the frutum of a cone; is of a pretty good flavour; and keeps till May.

The Spencer's pippin, which is a middle-sized apple, of a yellowish colour, with many dark spots, being a baking apple, and keeping till the middle of May.

The Tankerton, which is a conical-shaped yellow apple, with sometimes a little blush towards the fun. It is an excellent
excellent sauce apple, and bakes well, being of an agreeable
taste, but too large for the table. It will keep till
February.

The transparent apple, which was introduced from St. Peterburg; but it is more curious than useful; a tree or
two, therefore, will be sufficient for a garden. It ripens in
September or October.

The Trevoi den retinent, which is a small handsome ruffet-
coloured apple, of an excellent flavour, and will keep till
May.

The white corpendi, which is a middle-sized long-shaped
apple, of a yellowish colour. It is a good eating apple, and
ripens in January.

The ward apple, which is a beautiful flat-shaped apple,
rather below the middle size, of a fine red towards the eye,
and of a yellowish-green towards the footstalk. It is a
sharp flavoured fruit, and keeps till June.

The Wheeler’s rullet, which is of middling size, the flesh
firm, and of a quick acid flavour; it is an excellent kitchen
fruit, and keeps long. It ripens in October.

The wine rullet, which is a middle-sized conical-shaped
apple, of a dark rullet colour, and sharp flavour. It keeps
the latter end of April.

The Wheeler’s extreme, which resembles the pomme grife,
and is about the size of a nonpareil. It is a flat-shaped apple,
beautifully clouded with red on a yellowish-rulet ground;
and of an excellent flavour, and keeps till April.

The white muft, which is a middle-sized handsome flour,
of a greenish-yellow colour, with a little red towards the
fun; the flavour is rather tart, but agreeable. It is ripe
in January.

The Whitmore pippin, which is a good-sized handsome
apple, streaked with red towards the fun, and of a pale-
yellow on the other side. It has firm flesh, of a tolerably
good flavour, and is in eating from November to the latter
end of April, or later.

The Wiltshire eat’s-head, which is a large handsome apple,
red towards the sun, and green on the other side. It is
a very fine baking apple, and of a good flavour, being ripe
in January.

The winter pearmain, or Herefordshire pearmain, which
is of a fine red next the fun, and spireed with red on the
other side; the flesh is juicy, and feeds well. It is fit for
use in November, and, if properly managed, will keep till
the latter end of March.

The winter pomroy, which is a pretty large conical-
shaped apple, of a dark-green colour, a little streaked with
red towards the fun. The coat is rather tough. It is a
good baking apple, keeping till January.

The winter box apple, which is a middle-sized fruit, of a
light green colour, and keeps till February.

The woodcock, which is a good-sized apple, of a dark
red next the fun, and pale, with a little mixture of yellow,
on the other side. It is ripe in January, and keeps till
March, being a good cider apple.

The Wright’s nonpareil, which is a Salopian apple,
being a great bearer, of a good size, and a little flattened.
It is a good kitchen apple, and keeps till June. The
tree is smaller in size than most other apple-trees.

The Yorkshire greening, which is a good-sized flattened
apple, of a dull-red colour, with a little green towards the
eye. It keeps till August, or often later.

The sorts of apples adviced for a small garden are the
following: the juneting, the golden pippin, the nonpareil,
the Ribton pippin, the nonpareils, the queen’s apple, the
Sykehoufe, the golden rennet, the aromatic pippin, the grey
Leadington, the scarlet pearmain, the lemon pippin, the
pomme grife, the French crab, and different sorts of rufsetins
and codlins, for baking.

But there are other varieties and sub-varieties that may
be equally valuable with many of the above sorts.

Of the sixth sort there are the following varieties: the
pear quince, with oblong-ovate leaves, and an oblong fruit
lengthened at the base; the apple quince, with ovate leaves
and a rounder fruit; the Portugal quince, with obvate
leaves, and an oblong fruit, which is more juicy and less
harsh than the others, and therefore the most valuable.

The quince is a very beautiful tree when in flower, as
well as when the fruit is ripe in the autumn, and was cul-
tivated in this country at an early period. According to
Mr. Forthly, the best sort for planting in the fruit-garden
is the Portugal, being the fittest for baking or stewing. It
is of a fine purple colour when dressed, and is much better
for marmalade than any of the other sorts. The oblong
kind, and the apple quince, are also planted in these situa-
tions, and other sorts are employed in the shrubgeries for
producing variety. The above sorts are likewise valuable
for mixing with apples in making pies, puddings, &c., as
they add a quickness to the flavour when flat.

Method of Culture in the Pear Kind.—These trees are
raised by grafting and budding upon any kinds of pear
stocks; occasionally upon quince stocks; and sometimes
upon white-thorn stocks; but the first sort are preferable
for general use to have large trees, and the second for
moderate growers.

The numerous varieties of these trees having been first
accidentally obtained from feed, and as these feedings rarely
produce the same sorts again, the approved kinds are continued
and increased only by grafting or budding upon stocks raised
from the kernels of the kinds just mentioned. In order to
restrain the growth of these trees, white-thorn stocks have
also been used; but these are not so generally success-
ful, and are among in total diffuse in the nurseries; of course
pear stocks are proper for general use, for principal large
trees, both for walls, espaliers, and standards; and quince
stocks for smaller growths. For raising the stocks, the
seeds or kernels of the different sorts should be sown in the
latter end of autumn, as November, or December, or early
in the spring, in beds of light earth, covering them near an
inch deep; they come up in the spring; and in autumn,
winter, or spring following, the strongest should be planted
out in nursey-rows to remain for grafting and budding,
for which, after having from one to two or three years’
growth, they will be of proper size.

The operations of grafting and budding should be per-
formed in the usual method; the former in the spring, and
the latter in summer. (See Grafting and Budding.)

For this purpose the grafts and buds should be procured
from such trees as produce the finest fruit of the respective
sorts; those designed as dwarfs for walls, espaliers, or
standard-dwarfs, being grafted or budded near the bottom;
and in those for half- or full standards, the stocks may either
be previously trained up from three or four to seven or
eight feet high to form a stem, then grafted near the top,
or be grafted low in the stock, like the dwarfs, and the first
main shoot trained for a stem the above height; the grafted
trees, both dwarfs and standards, shoot the same year, but
the budded ones not till the spring after; and when their
heads are two years old from the grafting and budding, they
may, if thought proper, be planted out for good, or remain
longer in the nursey, as may be found convenient.

The dwarfs for walls, espaliers, &c. whether they remain
longer in the nursey, or be transplanted at a year old into
the garden, should have the first shoot from the graft or
bud,
PYRUS.

bud, when a year old, headed down in March to five or six eyes, to force out a proper supply of four, six, or more lateral branches near the ground, to furnish the wall or espalier with bearers quite from the bottom, these readily producing others to cover the upper part.

Standards, supposing them to be grafted on high stocks, may either be headed near the top of the stock, or permitted to run up, as the cafe may require, fo that if shortened it will force out laterals near the head of the item, and form a more spreading full head; and if suffered to run up with the first shoots entire, they form higher and generally more upright heads in the end. Such standards, however, as are grafted or budded as low in the stock as for dwarfs, must have the first shoot trained upright at full length, fix or seven feet high for a item: if for full standards, they may either be topped at six feet height, to force out laterals near that part to form a spreading head, or permitted to run and branch in its own way to form a more erect and higher head.

The headed trees, both dwarfs and standards, on being cut down in the spring, soon branch out from all the eyes immediately below; when care should be taken during the summer to trim off all shoots from the item, suffering all the top shoots to remain entire; when they will form handsome beginning young heads by the end of summer, and in autumn, winter, or spring following, may be finally planted out into the garden, &c.

When from necessity they are retained longer in the nursery, the whole should have proper pruning to reform irregular growths, and the different trees be trained accordingly, suffering the whole to branch away at full length, not shortening any after the above general heading down, when a year old, except it should seem occasionally necessary, either to reduce any casual irregularity, or to procure a more full supply of lower branches; after which no further general shortening should be practised to these sorts of trees; for, after having obtained a proper set of regular branches near the head of the item, they readily furnish more in their turn to increase the head on the upper part.

In regard to planting out the trees, they are molly of proper growth for this purpose when from one or two to four or five years old, from the graft or bud; but if larger trees are required, those of fix or eight years old may be safely transplanted; younger trees, however, always succeed well, even when only two or three years old.

In selecting pear-trees for planting, Mr. Forfyth advises the chooping of the oldest trees that can be found instead of the young ones, and such as have strong items; to have them carefully taken up, with as much of the roots as possible, and carefully planted, after cutting in the roots a little, spreading them as horizontally as can be done. Then to fill up all round the roots with light dry mould; forcing it in, about those which lie hollow, with a sharpened stick; filling the whole up to the top without treading the mould, till the hole be first filled with as much water as it will contain, leaving it a day or two until the ground has absorbed the water; then to throw on some fresh dry mould and tread it as hard as possible, filling the hole up again with mould to within an inch of the top, and giving it a second watering, leaving the mould about three inches higher than the border, to settle by itself, and to receive the rain that falls, for at least a month. When the mould has become quite dry, it may be trodden a second time; then make a large basin all round the tree, and giving it another watering, mulching the top over with some rotten leaves or dung, continuing to water the trees once a week in dry weather, and sprinkling the tops frequently with a pot, or hand engine, to keep the wood from shrivelling till they have taken fresh root; and where the trees are planted against a wall, the items should stand sloping towards it; the lower parts of them being six inches from the bottom of the wall, to give them room to grow, as when planted close to the wall at bottom, the items, in growing, will be confined on the back, grow flat, and be very unightly. If any roots are in the way, to hinder it from being planted near enough to the wall, they must be cut off; at the same time taking care that the tree does not lean to either side, but that, when viewed in front, it appear perfectly upright. Sometimes standards and half-standards are set planted a foot or two from the wall, which gives them a very disagreeable appearance; six inches is, he thinks, quite sufficient. Much care should be taken not to wound the item or root of the tree in planting.

When young trees have two items, he advises always to cut off one of them, leaving the stoutest and straightest, planting that side outwards which has most buds on it.

It is added, that when the buds begin to break well, the trees should be headed down to three or four eyes, to fill the wall with fine wood, but never afterward, except the leading shoot to fill the wall, leaving the fore-going shoots to be pruned, as hereafter directed. He has had some trees that had forty pears on them the second year; while some of the same kind bore only eleven pears the fourteenth year after planting, with the common method of pruning. When such old trees as recommended above cannot be procured, the stoutest and cleanest of the one-year's old grafting should be provided. Where any of these trees become flunted after a number of years, they should be headed down as hereafter directed, which will bring them into fresh vigour and fruitfulness. The proper season for planting them out is any time in open weather from the end of October till March, but the autumn or early winter are the most advantageous periods. They succeed well in any common garden soil, or good fertile orchard-ground, or field, that is not very wet, or of a fluff or stiilborn quality, but moderately light and friable to the depth of one foot pace at least, and more the better. The ground should be prepared by proper trenching one or two fpaes deep, as the depth of good soil will admit, wholly if for a full plantation, or only along the place for each row of trees, in the place for each tree; or only a hole for each tree at proper distances. The proper distance for planting the dwarf sorts for walls or espaliers, is for those on free stocks at not less than twenty feet, but if twenty-five, or more, the better, especially if the walls be rather low, &c. that there may be full scope to extend their branches considerably in a horizontal direction, as they will effectually fill that space, or even much more if it be allowed them; but they are often planted much nearer together. It is however of importance to give these trees sufficient room, and the higher the walls the better, as is evident by those trees growing against the ends of high buildings, as they extend themselves very considerably every way. Some plant cherry-trees or other moderate shooting fruit-trees in the intervals for a few years, till the pears advance in growth and approach one another, when they should be removed. They are to be planted in the usual way, with their heads entire. See Planting.

However, for trees that are dwarfed by grafting or budding upon quince stocks, from fifteen to eighteen feet may be a proper distance for planting, either for walls or espaliers. In respect to the distance at which pear-trees should be planted against walls, it is observed by Mr. Forfyth that when they are grafted on free stocks, such as colmars, pear d'auclie, crafanes, l'ecuflertries, miroules, and winter and summer bonchretiens, it should at least be twelve yards distant.
PYRUS.

distant from each other, supposing the walls to be from
eleven to sixteen feet high; but when they are only ten feet,
fifteen yards will be little enough for the purpose.

And where they are planted on south walls, vines, peaches,
nectarines, or apricots, may be planted between them, till
the trees extend so far as nearly to meet each other; then
they may be removed to any other situation in the garden
where they are wanted. And where the pears are planted
on west walls, the fame fort of trees may be planted between
them as on south walls; the fruit on a west aspect will come
into use to succed that on the south. On an east wall dif-
dent forts of plums and cherries may be planted between
the pear-trees till they almost meet, then transplanted as
standsards or wall trees.

It is advised that the borders for pear-trees in a large
garden should not be less than from ten to twenty feet wide,
with a foot-path about three feet from the wall, covered
over at top with coal-ashes or road-fand, to make a dry
walk for getting at the trees to cut and nail them, to gather
the fruit, &c. And that the depth of the mould for them
should never be less than three feet, laying the belt mould
at top, to encourage the roots to come as near the surface
as possible. If the bottom be clay, it will be very necceffary,
one in every five or fix years, to open the ground round
the roots of the trees, and cut off all the large ones that
are inclining to run into the clay; as, by this practice, the
trees will throw out fresh roots that will run near the sur-
face, provided the mould is good near the top of the borders.
And it is fuggested that a crop of early peas, lettuces,
spinach, or any other small crops, may be grown on the
borders, during the winter and spring; but no late crops by
any means. If the ground can be spared, he would advise
to have no summer crops, but keep the borders hoed, in
particular after rain; otherwise the ground, if a strong
loamy or clayey foil, will be apt to crack in dry weather;
but by frequent flirring between wet and dry this will in a
great measure be prevented, and the sun’s rays admitted
into the mould, which will greatly heighten the flavour of the
fruit. When you can conveniently spare the borders in
winter, they should be ridged up to sweeten the mould,
which may be very well done if you sow early peas on the
sides of the ridges; which is by far the belt way to preferve
the peas from the froid, and to prevent them from rotting,
which will sometimes happen, if the land be frong, before
they begin to vegetate or, you may low an early crop of
carrots or spinach on these borders.

With refpect to the general management in the training
and pruning of these trees, if the young wall and espalier
trees thus planted are only one year old from the graft or
budd, having their firft fhoots of a year old entire, thefe
foould in the spring be headed down to five or fix inches, to
force out lower horizontal branches; but if thev have been
previously headed, as adyved above, and have thrown out
lateral branches to form a regular set of horizontal branches,
continuing of fix or more near the bottom, they should not be
shortened, but trained to the wall or espalier at full length
horizontally, preferring an equal number on each side five
or fix inches funder, they will readily emit a further supply of
horizontal fhoots to cover the wall, &c. regularly up-
ward, and at the fame time not being fhortened, they gra-
dually form themselves for bearing, as every shortening of
the branches of thefe trees retards their bearing a year at
leaf; if, however, there is a want of branches, some of the
middlemoll may be pruned fhort, and trained to the wall
or espalier. According as the trees fhoot in fummer, a
further supply of all the regular fhoots in every part where
they occur, fhould be trained in at full length, unless it
shall seem neceffary to prune some frong fhoots to obtain a
greater supply of horizontal branches the fame year, in
order to furnish the head asfoon as possible; at this time,
howerver, diplace all the fore-right and other irregular
growths of the year, continuing the supply of regular
hoots close to the wall, as they advance in lemgth during
their fummer’s growth. And in the winter pruning, the supply
of fhoots attained in fummer fhould be well examined, le-
celting all thoee that are well placed and properly fited
for training in, to increafe the number of horizontal branches
on each fide, which fhould be left wholly entire, and at the
fame time retrenching any superfluities and ill-placed fhoots
omitted in fummer; then the whole supply of regular hori-
tontal branches in every part fhould be trained in ftraight
and close to the wall or espalier, equally on both fides of the
tree, every branch at the full length, at four, five, or fix
inches apart. See WALL, ESPALIER-TREES, and PRUNING.

But there is another method sometimes practiced in training
these trees for walls and espaliers, which is, that after their
firt heading down, and having thrown out severals laterals, to
flect three of the ftrongefit and most regularly placed, one
on each fide and one in the middle, naming the two fide ones
horizontally at full length, and the middle one upright:
the tree having produced a further supply of fhoots in the fol-
lowing year, add two or four of them as fide branches, arrang-
ing them on each fide of the item as the two former, train-
ning the middle fhoot fuft in an upright direction; observing
that where it does not furnish horizontal low enough, it may
be fhortened fo as to make it throw out fhoots at any requisite
height, continuing the middle one always upward for a flem,
and the fide ones for bearers. In either of these methods of
training the trees, continue yearly increasing the number of
horizontal fshoots, till the furface of walling or espalier is
regularly covered with fhoots at equal distances, conftantly
continuing them all at full length, as far as the scope of walling,
&c will permit; as they naturally form fruit-fpurs at every eye, almoft their whole length, and the fame branches
continue in a fruitful state a great length of time. When the
trees have once filled the wall or espalier with branches, they
need but very little further supply for many years, and
that only occasionally, according as any worn-out or decayed
branch occurs, and wants renewing with young wood. See
PRUNING.

And in the after-prunings in the fummer, which fhould
be begun in May, or early in June, rub off all the super-
fluous and unecessary fhoots of the year, and all fore-right
and other ill-placed fhoots, retrenching them quite close,
being careful to leave the terminating fhoot of every hori-
tontal or bearer entire; and referring here and there a well-
placed fhoot, towards the lower parts in particular, and
where there are any apparent vacancies, to train up between
the mother branches, till winter pruning, when, if not wanted,
they must be retrenched.

But in the winter pruning, which may be performed any
time from the fall of the leaf until March, the branches
should be generally examined, to see if they are any where
too much crowded, or trained irregularly; and where any
such occur, they should be regulated as they may require;
and where there are any vacancies, some contiguous fhoots,
referved in the fummer dressing, fhould be laid in, and all the
other fhoots not wanted muft be cut clean out close to the
branches, being careful still to preferve the terminating fhoot
of every branch entire, in all parts, as far as the allotted
space admits, likewise all the fruit-fpurs in every part, faften-
ing in all the branches regularly at full length. In pruning
old trees at this season, where decayed and worn-out branches
occur, they should be cut out, and young wood trained in
its feet; likewise, where any branch, through age or any other defect, is become barren, it should be retrenched, and some eligible lower young branch, or shoot, be laid in its place.

Where any of the choicer sorts of these trees are become worn-out and barren, they should be renewed with young bearers, by heading the branches wholly down near the bottom in winter or spring, when they break out in the old wood, and in the following summer furnish a large supply of strong young shoots, which should be trained according to the rules already laid down, when they will soon form a fort of new tree, and bear good fruit. After each winter pruning, the trees which are against walls and espaliers require a general nailing, &c. which should always be done with great regularity. See Wall-Trees, and Espalier-Trees.

The mode of training dwarf standard-trees of this sort is shown in speaking of trees of that kind. See Dwarf-Trees.

In respect to the culture of the borders where this sort of wall or espalier-trees are growing, it is commonly digging them once more every year, adding manure occasionally in common with the other parts of the garden; but if some good rotten dung be applied every other year, and the ground well dug or trenched every winter, it greatly promotes the size and perfection of the fruit. In regard to standard-trees of this kind, any of the sorts bear plentifully in any open situation, though the fruit may not always be so large and fine as those of wall and espalier-trees: summer and autumn pears, however, ripen in great perfection on standards, as also many of the common winter pears. In planting them, trees of from two to three or four or five years old, having tolerable heads, are of a proper age and size for the purpose, and are preferable to older trees for any general plantation. They should be planted with all their heads entire, except retrenching any very irregular-placed branch, in the usual manner of tree-planting. See Planting.

In their future growth they should be sufferers to branch naturally, so as to form large branchy heads, suffering them all to remain entire. The general culture of this sort of trees, in respect to pruning, is very trifling, and only required occasionally, probably only once in several years; such as the retrenching any irregular growing branches, and thinning such branches as are very much crowded, cutting out all the decayed wood, and eradicating suckers from the roots and stumps. See Pruning.

When standard-trees are situated in a garden, in which the ground is necessarily dug over and trenched annually for the reception of the under crops, and occasionally enriched with dung, they generally produce finer fruit than in orchards, or other places where the ground is not in similar culture.

Mr. Forfith observes, that the method of pruning pear-trees is very different from that praciticed for apple-trees in general, in which the constant practice has been to leave great spurs as big as a man's arm, flanging out from the walls, from one foot to eighteen inches and upwards. The constant pruning inevitably brings on the canker; and by the spurs flanging out so far from the wall, the blossom and fruit are liable to be much injured by the frost and blighting winds, and thus the sap will not have a free circulation all over the tree. The sap will always find its way first to the extremities of the shoots; and the spurs will only receive it in a small proportion, as it returns from the ends of the branches; and the fruit flanging at so great a distance from the wall is too much exposed to the weather, and, of course, is liable to be hard, spotted, and kernelly.

The following method he has practised where the trees were all over cankered, and the fruit small, and not fit to be sent to the table. He cut the tops off as near as possible to where they were grafted, always observing to cut close to a joint or bud as possible. The buds are hardly perceptible, but it can always be known where the joints, or forks, are, by the branches breaking out of the sides. He adds, that finding the pear-trees in Kerlington gardens in a very cankery and unfruitful state in the years 1784. and 1785. he took out the old mould from the borders against the wall, and put in fresh loam in its stead; at the same time he pruned and nailed the trees in the common way, and left them in that state upwards of eighteen months, to see what effect the fresh mould would have on them; but to his great surprise, he found that it had no effect. After this trial he began to consider what should be done in order to recover these old trees. In this attempt he began with cutting down four old and decayed pear-trees of different kinds, near to the place where they had been grafted; this operation was performed on the 15th of May, 1786. Finding that they put forth fine shoots, he headed down four more on the 20th of June in the same year, (for by this time the former had shoots of a foot long), which did equally well, and bore some fruit in the following year. One of the first four he headed down was a St. German, which produced nineteen fine large well-flavoured pears next year, and in the third bore more fruit than it did in its former state when it was four times the size. He left seven trees upon an east wall, treated according to the common method of pruning, which bore the following number of pears upon each tree. Epine d'hiver produced eighty-five pears, and the tree spread fifteen yards; a crafane produced one hundred pears, and the tree spread fourteen yards; another crafane produced fifteen pears, and the tree spread ten yards; a virgoullefe produced one hundred and fifty pears, and the tree spread nine yards; a colmar produced one hundred and fifty pears, and the tree spread nine yards; another colmar produced seventy-nine pears, and the tree spread ten yards; a l'echallerie produced sixty-five pears.

But seven trees headed down and pruned according to his own method, leaving the fore-right shoots in summer, bore as follows, in the fourth year after heading; a Louboisborne bore four hundred and sixty-three pears, and the tree spread nine yards; another Louboisborne bore three hundred and ninety-one pears, and spread eight yards; a colmar bore two hundred and thirteen pears, and spread fix yards; a brown beurre bore five hundred and three pears; another brown beurré bore five hundred and fifty pears; a crafane bore five hundred and twenty pears; a virgoullefe bore five hundred and eighty pears. And he adds, that the branches of the four last trees spread nearly in the same proportion as the first three. He also states that a young beurre, the second year after heading, bore two hundred and thirty pears; and a St. German four hundred. All the above trees flood in the same aspect and the same wall, and the fruit was numbered in the same year. A great many pears which dropped from the trees are not reckoned. The trees that were pruned according to the old practice covered at least one-third more wall than the other.

From this statement it appears that the trees headed down bore upwards of five times the quantity of fruit than the others did; and that it keeps increasing in proportion to the progress of the trees. This is an important statement in the culture and management of old trees of this sort; and the following fact with respect to standards is deserving of great attention: On the 20th of June he headed several standards that were almost destroyed by the canker; some of them were so loaded with fruit the following year, that he
was obliged to prop the branches, to prevent their being broken down by the weight of it. In the fourth year after these standards were headed down, one of them bore two thousand eight hundred and forty pears. There were three standards on the same border with the above, two of which were St. Germain; the old tree was of the same kind. One of these trees, twenty years old, had five hundred pears on it, which was a great crop for its size: so that there were on the old tree, which had been headed down not quite four years, two thousand three hundred and forty pears more than on the tree of twenty years' growth. When the men numbered the pears, there was near a barrel of windfalls at the bottom of the old tree, which were not included. These and other statements are given in his useful treatise on the "Culture of Fruit-Trees."

The following is the method he pursues in training trees that are cut near to the place where they are grafted. In the month of March, every year, he shortens the leading shoot to a foot or eighteen inches, according to its strength: this shoot will, if the tree be strong, grow from five to seven feet long, in one season; and, if left to nature, would run up without throwing out side-shoots. The reason for thus shortening the leading shoot is to make it throw out side-shoots, and if it be done close to a bud, it will frequently cover the cut in one season, leaving only a cecatrix. When the shoots are very strong, he cuts the leading ones twice in one season; by this method he gets two sets of side-shoots in one year, which enable him the sooner to cover the wall. The first cutting is performed any time during the spring, and the second about the middle of June. When you prune the trees, and cut the fore-right shoots, which should be done in February or March, always cut close to an eye or bud, observing where you see the greatest number of leaves at the lower bud, and cut at them; for at the footstalk of every one of these will be produced a flower-bud. The same will hold good in cutting the superfluous shoots on standard pears. He adds, that you will have in some sorts of pears, in a favourable season, from five to nine pears in a clouter. This cutting should not be later than March, or the beginning of April; on account of the leading shoot beginning to grow: the next topping, when the leading shoot grows quick enough to admit of it, should be about the middle of June; and the length of the shoots should be according to their strength, having from three eyes or buds, to fix on a side. It is added, that the cankery part beginning to affect the new bark, he cut off all the canker at the bottom, and plattered the place with some cow-dung, mixed with wood-ashes and powder of burnt bones, put into as much urine and foapuds as would make it of the confidence of thick paint; this he laid on with a painter's brush. After it had been applied about three hours, he patted it gently down, with his hand, close to the tree. By so doing, he gets rid of all the air-bubbles that may be under the compostion, and makes it adhere to the tree, preventing it from being washed off by heavy rains. And in the beginning of August he shortens the fore-right shoots to about four inches long; by this time the shoot will have made its full growth for the season, and will produce fine strong eyes for the following year. Such shoots as grow near the item of the tree, if any are wanted to fill up the wall, may be tuck-ed-in as directed for peaches. This will prevent them from looking unightly, and fave them from the fury of the autumnal and winter winds. He further advises, that whenever the trunk is hollow, it be followed under ground till you have cut out all the decayed parts and rotten roots, otherwise you will lose the tree. By proceeding according to the foregoing directions, the roots will be renewed, while the tree is forming a fine handsome head. In the mean time the borders should be trenches, taking up all the roots, and adding some fresh mould to them, if you can conveniently get it; if you cannot, remove all the mould that is about the roots of the trees, and put in some taken from the borders, at a distance from the wall; always remembering to lay the top spit next to the roots of the trees; also, to mix some vegetable mould, from the midden and cucumber beds, with rotten leaves, as a manure for the borders. He has headed down many trees that had not this preparation; and yet they thrive very well, but did not send forth such fine roots and shoots as those that were so prepared. He concludes by observing, that if the above directions be followed, more pears will be procured in three or four years than can be done in twenty-five years by planting young trees, and pruning and managing them in the common way. It is added, that if it should be found, that before the pears arrive at half their natural size, they get flunted, after cold blighting winds, and frosty nights, he would recommend a new operation to be performed when the weather begins to grow mild, which is to take a sharp penknife, and with the point of it make an incision through the rind of the pear from the footstalk to the eye, in the same way as in fearifying a bark-bounded tree, taking care to penetrate as little into the flesh of the pear as possible. At the same time beat up some fresh cow-dung with wood-ashes, and with your fore-finger rub in a little of this composition where you made the fearification; as the wound heals, the composition will be discharged from the fruit; this will prevent the pears from cracking and burkling, which renders them good for nothing. The sorts that are most liable to this disorder are, he observes, the columbia, virgoulae, and eraphan. He only, however, recommends this operation for wall pears, as it may be thought by some a troublesome operation, and it will certainly take up some time.

Signs of Ripening in the Fruit.—The maturity of the pear is generally known by its changing from a green to a yellow, or reddish colour, &c. and by the frequent falling from the tree; and, when, with a gentle twist or turn upwards, it easily quits its hold: but these signs of ripeness are more particularly observable in summer and autumn pears; as winter pears, not being maturely ripe when gathered, often require a good pull before they quit the branches.

The summer pears ripen in succession in different sorts, from about the beginning or middle of July till the middle of September; many of the earliest ripening all at once, as it were, and continuing good but a few days, either on the tree or when gathered, nor will any of the sorts keep good long; and none of these sorts should hang on the tree till soft ripe, as in that case most of them would be mealy and infixed. These sorts should be gathered as soon as they are arrived to full growth, and just begin to colour and differeniate maturity, but before they become soft and mellow. For family use, they may be gathered from the tree according as they attain perfection: but the general crops of each sort should be always taken down before they ripen fully, and be laid in any dry room; none of the kinds will keep long, some only a few days, and scarcely any of them above a fortnight, though from different varieties ripening at different times, the succussion is continued for eight or ten weeks.

The autumn sorts ripen in different varieties, from about the middle of September till the end of October; some of the forwardest become eatable on the tree, others requiring to lie some time after being gathered before they acquire perfection. The different sorts of these pears should be gathered according to the time they arrive to maturity: those designed
to keep some time, may be gathered in dry weather, just
when they have attained full growth, as shown by their
frequent dropping, and by their readily quitting the trees
on being handled, and laid in a dry close room, or in baskets,
each sort separately.

The winter kinds attain their full growth on the trees
about the end of October or beginning of November; but
the estable kinds do not acquire maturity for that purpose
on the tree, or for some considerable time after they are
gathered, some probably in a month, others two or three,
and some more, and some sorts not till the spring following.
But the baking kinds may be used any time from Oc-
tober or November during their continuance. All winter
pears should be indulged with as full growth on the tree as
the weather will permit, even until the end of October,
or first week in November, in the latter kinds, if the season
continues mild: be cautious, however, to get them gathered
before attacked by much frost. And in gathering all the
sorts for keeping, dry weather should be chosen, and when
the fruit is also quite dry, being careful not to bruise them.

See Fruit.

Method of Forcing Pears.—These sorts of trees are
sometimes forced by artificial heat, in some of the prime
early kinds, to obtain a portion of fruit as early in the sea-
son as possible. This is effected by means of hot-walls and
forcing-frames; having previously some trees of the choicest
early summer pears, such as the jargentee, or any other
carly sort, trained as wall-trees against a south wall, till ad-
vanced to some tolerable state of bearing; being then in-
closed with glass frames, in the manner of forcing-frames or
hot-walls, and having internally either flues for fire-
heat, erected forward and extending long-ways, or other-
wise a pit arranged in that direction, in the interval or space
between the trees and the glass-works, for a barn or dung
hot-bed; and by one or other of these methods a proper
degree of artificial heat is produced internally to force an
early growth in the trees, and forward them to early flower-
ing and fruiting, managing them in the common way, as
other trees in forcing-frames, so as to have some ripe fruit
early in June, or some time in that month.

Method of Culture in the Apple Kind.—The whole of the
varieties of the apple were first accidentally obtained by
raising them from the kernels of the fruit; but as these
cannot be depended upon to continue the same sort of
fruit, grafting is the mode made use of to increase and con-
tinue the different varieties of them, which is performed
upon crab, or any kind of apple stocks, raised from the
kernels, for dwarfs as well as standards; and sometimes
upon codlin and paradice apple stocks; raised from cuttings
and layers, when designed to have espaliers and other dwarf
trees, or for small standards, as low as possible, to be con-
fining within a moderate space: some sorts may also be
raised by layers and cuttings, as the common codlin.

Stocks.—The method of raising the different sorts of
stocks for the purpose is, in the crab and apple stocks,
from the kernels of the fruit; but in the codlin and pa-
radice stocks by cuttings and layers, to continue them with
certainty of the same kinds and moderate growths. The
rab and apple stocks may be raised from the kernels of any
of the sorts, procuring them in autumn or winter, either
from the fruit, or from such as have been pre pared for
juice and cider, clearing them from the sprouted part of
the pulp; then fowing them in beds of light earth, mo-
derately thick, over the bed, or in drills, covering them
about an inch deep. They come up in the spring; when,
if the sear on prove dry, they should be watered occasion-
ally, to forward and strengthen the growth of the plants;
and in the autumn, winter, or spring following, the largest
may be planted out in nursery-rows, shortening their tap-
routs a little, and placing them in lines two feet and a half
funder, to remain for grafting: after having from one to
two or three years' growth, they will be fit for grafting
upon, particularly for dwarfs, or even for full and half
standards, if intended to form the stem from the graft,
which is an eligible method for these trees; but if the rock
is to form the stem, they require three or four years'
growth, to rise to a proper height, seven feet for full,
and four or five for half standards. The modes of grafting
all the sorts is the same as for other fruit-trees, and should
be performed in March, either by whip or cleft-grafting, ac-
tording to the size of the rock. See Grafting.

Having provided proper grafts of the different sorts of
apple intended to be raised, the stocks designed for dwarfs
of all sorts must be grafted within six inches of the ground;
and the standards may also be grafted low, one shoot from
the graft being trained up for a stem, or on tall stocks, at
five or six feet in height, but for low and half standards,
at from two or three, to four or five feet, and lower for
dwarf standards. The grafts of all the sorts shoot the fame
year; and, by the autumn following, the trees having
formed little heads, consisting of two, three, or four shoots,
may then be planted out finally where they are to remain, or
be retained a year or two, or longer, in the nursery, as may
be requisite, training them for the purposes intended, as
dwarfs, espaliers, &c. &c., and uprights for standards,
heading the dwarfs down in March following, within six
inches of the graft, to force out more lateral shoots below
to form a fuller head, proceeding immediately to turn them
near the bottom, so as to fill the espalier, &c. equally
with branches, quite from within six or eight inches of
the ground, regularly upward. In the standards, those
grafted low must be trained with one shoot upright, at
full length, for a stem, five or six feet high at least, for full
standards before it is topped; though if grafted on tall
stocks of height sufficiently for a stem, the shoots from the
graft may either be headed to five or six eyes; or, if to
form a more spreading head, remain entire, and aspire
more in height, and assume a more upright growth: in
all the modes of training, care should be taken to keep
the stems clear from all lateral shoots, displacing all such as
soon as they appear, encouraging only a proper set of
branches at top to form the head. When these trees have
heads from one to two or three years old from the graft,
they are of a proper age for planting out; though trees
of four or five years old will also succeed very well, and
even those of six or eight years' growth may also be safely
planted if required. The nursery-grounds are mostly fur-
nished with all the varieties of these trees for sale, either
quite young from the graft, or trained of several years' growth.

Choice of Trees.—In choosing the different kinds of trees
for planting, care should be taken to have a collection of
the principal varieties, both in espaliers and standards, in
proportion to the extent of the ground, as the trees of the
bait sorts are as easily raised and cultivated as the in-
different ones, allotting a smaller portion of the summer
kinds, as much as ripen from August to about the middle
of September, for immediate use off the trees, as they will
not keep long; a larger supply of the autumn sorts, and
most of all of the winter keeping apples: observing, in the
summer kinds, that it is advisable to allot a principal supply
of the common codlin in small standards, as being generally
both a great bearer, and the fruit the most useful of the
summer apples for culinary purposes, from its young green
growth.
growth in June or July, till its full maturity in August and September, when it becomes also a good eating apple: and as the tree is a moderate grower, it admits of being planted in small standards closer or more abundant in a small extent of ground than most of the principal apple kinds.

In choosing apple-trees from the nursery, they should, Mr. Forfyth says, have strong, upright, and clean limbs. And he advises not to suffer the dwarf trees to run higher than twelve feet, as otherwise they become naked at bottom, the fruit is liable to be blown down, and the tops broken by high winds.

The proper season for planting all the sorts of apples is, in mild weather, from the end of October till March; but when planted in autumn, or early in winter, they establish themselves more firmly before the drought of the following summer. They succeed in any common soil and open situation, except in low very moist lands, in which they are apt to canker, and soon go off; in a pliable mellow loam they generally answer very well. The ground should be properly prepared, by good trenching, where the ranges of trees are to stand.

In the planting of espalier apple-trees they should be ranged at no less than eighteen or twenty feet distance; the latter especially for trees grafted on crab or apple stocks, which being free shootors, the branches readily fill that space. For the trees grafted on codlin and paradise stocks, fifteen or eighteen feet may be sufficient; though the latter, in particular, is sometimes planted only twelve or fifteen feet asunder, as being a very moderate shootor: it is, however, advisable to allow every fort full room, according to their growth, to have proper space to extend their branches always at full length. The trees should be planted with all their heads entire, only retrenching any very irregular growths, that do not range sufficiently with the intended form, and pruning any broken roots. Then having opened a proper hole for each tree, plant them in the usual manner, being careful to place them with their branches ranging the way of the espalier. As soon as the earth of the holes and of the roots is properly fitted, all the branches should be trained in horizontally to the right and left, an equal number on each side at full length, as above.

The general culture in espalier trees thus planted and trained, as the same branches or boughs continue fruitful many years, to continue them as long as they remain of proper growths, constantly giving them a summer and winter pruning annually, as explained above. In wall-trees also, any of the principal choice varieties of eating apples may be trained, to forward and improve the growth, beauty, and flavour of the fruit; such as jennetings, Margaret apple, golden pippin, golden rennet, pearmain, &c. or any other approved eating kinds, a tree or two of a fort, against a south, south-west, or east wall.

Standard apples, when planted in the garden, should be arranged thinly, to admit of under crops growing freely, without being shaded by their spreading branches. Full standards should be chiefly planted for the general crops, and half and dwarf standards for variety. The standards, when trained as above, should be planted out with all their heads entire, when in the kitchen garden, at thirty feet distance in the rows; and for an orchard, thirty feet distance every way. In planting, for each tree a wide hole should be opened, trimming any long straggling and broken roots, leaving all the others entire, and planting them with the usual care. As soon as planted out, every tree should be well flaked to support them firmly upright, and prevent their being disturbed in rooting by winds. See Orchard and Planting.

Smaller growing standards, such as codlins, or other low standards grafted upon codlin stocks, and dwarfs upon these or paradise stocks, may, if required, be planted only at fifteen or twenty feet distance in the rows, and not less than twenty-five feet between the lines of trees; though, if there be room to allow a greater distance both ways, it will be advantageous, especially in planting in kitchen gardens, in which it would be proper to allow double that distance between the rows of trees, of the larger growths of these kinds. The standards thus planted with their heads entire, should be pruned to advance with their branches at full length, and in general take their natural growth, when they soon form numerous natural spurs in every part for bearing.

In regard to pruning these standards, little is required, only the occasionable retrenching any irregular cross-placed bough, or the reducing to order any very long rambler; or when the head is become greatly crowded and confuted to thin out some of the most irregular growths, likewise all strong shoots growing upright in the middle of the head, and all dead wood, and suckers from the stem and root.

As to half and dwarf standards of these trees, they may be divided in different parts of the garden to cut and variety, managing them as the full standards. The nearer on dwarf paradise stocks, being very moderate shootors, may be planted in a little compass; and are sometimes planted in pots for curiosity, to place on a table, amidst a delight, with the fruit growing on them. See Dwarf-Trees.

It is observed by Mr. Forfyth, that in heading down old decayed apple-trees, for the sake of symmetry, it will be necessary to cut at the forked branch as near as can be to the upper side of the fork, cutting them in a sloping manner to carry off the wet, or the same time rounding the edges. To begin at the lower branches, cutting just above the lower fork; and proceeding upwards, cutting the rest of the branches from one to fix joints, or forks, according to their strength, till you have finished cutting in the whole head. If any of these branches should have the canker, all the infected part must be cut out. When the tree is all prepared, the composition should be immediately applied, beginning at the top of the tree, and finishing with the powder of wood-shives and burnt bones as you descend, which will save it from being rubbed off during the operation; and the composition will prevent the sun and air from injuring the naked inner bark. A tree thus prepared, will in the course of three or four years, produce more and finer fruit than a maiden tree that has been planted upwards of twenty years.

These directions, if properly attended to, will be sufficient, it is supposed, to enable any one to bring old decayed trees into a healthy bearing state.

It is believed, that in large orchards and gardens, it may be necessary, at first, to head down only every other tree, cutting some of the branches of the reft, which are in a decayed and cankered state, and which bear no fruit. This will be preparing them to throw out new wood, and furnish the tree much looser with bearing branches. He recommends the performing of the operation as early as possible; as by so doing the wood will be the stronger, as in May, or the two following months.

And it is added, that when the trees are become hollow, the same method should be followed as directed for plums; but by no means to cut them down unless the tops are quite decayed; observing to cut the loose rotten wood clean out of the hollow and other decayed parts, applying the composition; at the same time to open the ground, and cut out all
PYRUS.

all the rotten parts that may be found in the lower part of the stem, together with all the decayed roots, which, if this be not done, will infallibly injure the fresh wood and bark, and prevent a cure from being effected. He would recommend heading down all apple-trees that are much cankerred and have ill-shaped heads; as by so doing much labour will be faved, and the trees will amply pay the proprietor. He advices never to shorten the young branches, except they are very thin, when it will be necessary to do so to fill the trees with young wood; nor prune any of the young wood; nor prune any of the young shoots the second year (he means the year after they are cut), as many of the eyes, almost to the end of the shoot, will, if it be long, become fruit-buds next year; and so on every year. It is contended, that in the month of May in the first year after the trees have been so cut, it will be necessary to go over them, and rub off with your finger and thumb all the superfluous young shoots; leaving from three to fix eyes on each shoot, according to the size and strength of the branch cut. These shoots will bear from three to four years; by which time they will be pretty much exhausted by the great quantity of fruit produced from them; they should then be cut down to two eyes to produce new wood. He always leaves three different years' branches on the tree, when the first shoot is cut off. This is fully shown in a plate in his useful work; and the next shoot will be full of fruit-buds, if it has not been shortened: when it begins to grow weak, it should be cut off; and the next cutting must be made when the former branch is tired of bearing: by proceeding thus all over the tree with care and attention, the advantages of his method of pruning, above the common mode, will soon be perceived; as by it you will be able to keep the trees in a constant state of bearing, which, if left to nature, would only produce a crop of fruit once in two or three years. When the shoot that is done bearing is cut off, the composition should constantly be applied, rubbing off the shoots where they are too numerous.

It is suppos'd, that the best time to prune apple-trees is in the month of April, or in May, after the operation has been performed on the peaches, nectarines, and cherries; and that soon after this pruning, about the middle of May, it will be proper to look over the trees, and to pick off any caterpillars that may be on them. It will then be seen what shoots are infected with the canker, and which might have escaped your notice at the time of pruning; and whenever you observe the lead appearance of infection, which may be known by the wood appearing of a brownish colour, the shoot must be cut down till you come to the sound white wood. The small shoots that crofs each other should be cut off, leaving the strongest to fill up the tree, and make a fine handsome head. The suckers that spring from the root should be carefully grubbed up, and the side-shoots from the stem cut off; for, if left to grow, they greatly weaken the tree. The knobs, where old branches have been cut off, should also be pared away, leaving the surface of the tree as smooth as possible: after which, the composition should be applied: the young bark will soon begin to grow, and by degrees cover the old wounds with a fresh smooth surface, and thus prevent the canker from gaining ground on the tree. He has seen some old wounds of considerable size, healed over in one year: and he adds, in confirmation of the utility of this practice, that the trees which he pruned and treated, as above directed, in the course of the summer, 1795, are all perfectly cured, the wounds being filled up with sound wood, and covered over with fresh bark; they all continue in a healthy state, and bear fine handsome fruit. And he has advised several nurserymen to follow the practice, heading down their apple-trees after the feast of drawing for sale is over. Mells. Gray and Wear have headed a great many of such trees as were formerly thrown into the faggot-pile, and have been amply recompensed for their trouble. Trees thus headed down, provided the stems be strong, will, he thinks, in the first and second year, produce as much fruit as will refund the purchase-money; besides, a great deal of time will be saved, which would be lost by planting younger trees: as, where you can procure trees of the above description that have been headed down three or more years, they will be all covered with fruit buds; and, if carefully taken up and planted in the autumn, if the season proves favourable, they will have a tolerable crop of fruit the first year. Such trees must not be headed down like maiden trees, but only thinned off where the branches run across and rub against one another, which should never be suffered in these cases. He says, he would never recommend training apple-trees as espaliers; as by doing so the air is kept from the quarters of the garden; and by constant pruning and cutting off all the side-shoots which you cannot tie to the espaliers, you prevent them from bearing, and, moreover, bring on the canker. And when the dwarf trees have handsome heads, more and much finer fruit will be gotten from one of them than from fix espaliers; at the same time, a free air is admitted to the crops in the quarters, and the constant exposure of the flowers and labour, in laying the trees to the espaliers is faved. Espaliers may, he observes, be converted into dwarf standards by shortening the branches at different lengths, so that they may be able to support themselves without the flates; but not to shorten them all regularly; and if cut with judgment, as near to a leading shoot, or an eye, as possible, they will in the course of two years form fine heads, and in the third year bear fix times the fruit as they did in their former state, and of a finer flavour. The same method of pruning as already laid down for standard apple-trees is also applicable to espaliers.

It is remarked, that the borders where you make your croffings in gardens should be fix or eight feet broad at least, to let the trees spread on each side, at the distance of twelve feet from tree to tree, and they should be well trenches, two feet and a half deep at leaft. If there should be gravel, or four clay, it must be taken out, and good mould put in its place; leaving the ground as rough as possible for the fruit and rain to mellow it. When you level the ground it should be done after rain: you may then sow some small crops in the border; such as lettuce or spinach, or cabbage for transplanting; but let not any of the brassica tribe come to full growth. Leaving cabbage and broccoli on borders, near fruit-trees, draws the ground very much, fills the borders with insects, and also prevents the sun and air from penetrating into the ground. And when the sun can have free access to the border, it adds much to the flavour of the fruit. If you can spare the ground on the crofs-borders in winter, it will be of great service to the trees to ridge it up as low as you can, and let it lie in that state all winter, to mellow and sweeten.

Where the soil is strong, he would recommend planting of apple-trees that are grafted on paradise stocks; but if the soil be light, free stocks will do much better: and when the ground is strong clay or brick-earth, it should be mixed with old lime-rubbish or coal-ashes, street-dung, or faf; but what he uses for the borders against the walls, and which he prefers to every other manure, is a vegetable mould produced from leaves of trees. Of this a good cost should be given once in two or three years, which will be sufficient, he thinks, for the borders where the wall-trees stand, and much better than dung, which he by no means approves
upproves of for trees, unless it be perfectly rotten and mixed up with mould.

In respect to grafting old apple-trees, he says, it frequently happens, that through some mishap or other, after waiting ten or twelve years for a tree to come into a bearing state, it is found that the fruit is neither fit for the table nor kitchen; in such cases they should always be grafted the following spring, observing to graft on the twigs and healthy shoots, and as near as possible to the old graft, and where the crofs-shoots break out; as by doing you will have some fruit the second year; and in the third, if properly managed, you will have as much as on a maiden tree of fifteen years standing; the canker, if any, must be carefully pared off the branch, and the wound must be taken from a sound healthy tree. Whenever an incision is made for budding or grafting, from that moment the canker begins. He would, therefore, recommend to those employed in budding or grafting, as soon as the incision is made, and the bud or graft inserted, to rub in with the finger, or a brush, some of the composition before the baps are tied on; then to cover the baps all over with the composition as thick as it can be laid on with a brush, working it well in. If this operation be performed in a proper manner, and in a moist season, it will answer every purpose without applying any grafting clay; for he has frequently done it, and found it sufficient perfectly to his wishes. The matting which is wrapped round the bud should not be flaccided too soon; for in that case you will find the incision opened, which very often occasions the death of the bud. If, says he, nurserymen and gardeners would give this method a fair trial, and use the same composition as he uses for curing defects in trees, instead of loam and horse-dung (which binds so hard as to prevent the rain and moisture from penetrating to the graft to moisten the wood and bark), they would find that the grafts would succeed much better. The composition, for this purpose, should be rather softer than grafting clay generally is; and instead of applying so large a mass as is generally done of clay, it need not, in moist cases, be more than two or three inches in circumference, to effect the purpose.

Apples come to full growth in different sorts successively, from July until the end of October: the summer kinds continue but a short time, but the autumn and winter apples keep from two or three to fix or eight months and longer, in different varieties. The signs of perfection or full growth of the different sorts of apples, are by their assuming a lively colour, emitting a fragrant odour, frequently falling from the tree, and by quitting their hold easily on being handled.

Gathering.—In the gathering of all the sorts of apples for keeping, dry weather should always be chosen, and when the trees and fruit are also perfectly dry; observe likewise, in gathering apples for the table, and all kinds of apples designed for keeping any considerable time, that they be pulled one and one by hand. See Fruit.

The other species may be increased by grafting and bud- dung them upon the common crab-stick: they should have sheltered situations, as they are rather tender while young. These trees afford ornament and variety in the clumps and shrubbery parts of pleasure-grounds.

Method of Culture in the Quince Kind.—These trees may be raised from the kernels of the fruit found in autumn; but there is no depending on having the same sort of good fruit from seedlings, nor will they soon become bearing. But the several varieties may be continued the same by cuttings and layers; also by suckers from such trees as grow upon their own roots, and likewise be increased by grafting and budding upon their own pear-stocks, raised from the kernels in the same manner as for apples.

The raising by cuttings, layers, and suckers, is performed in autumn, winter, or spring, choosing young wood for the cuttings and layers, which should be planted and laid in the common method, when they will be rooted by the following autumn, then planted out into nursery rows two feet apart; plant the suckers also at the same distance, and then train the whole for the purposes intended; if for standards, run them up with a stem to any desired height, from three to five or six feet, then encourage them to branch out at top, to form a head; and those designed as dwarfs must be headed near the ground, and trained accordingly for espals or dwarf standards, as directed under those articles: the grafting or budding is effected on quince or pear-stocks, and trained as above. When they have formed tolerable heads, they should be planted out finally.

Mr. Forreth advises that the layers or cuttings should be planted in a shady place, in rows about a foot distant from each other, and about three inches from plant to plant in the rows; mulching them with rotten leaves, or rotten dung, which will keep the ground about them moist; and watering them frequently in hot weather. About Michaelmas those that are well rooted may be planted out, and those that are not should remain another year. They may also be propagated by budding or grafting; and these trees will bear sooner, and be more fruitful than those raised by any other method.

He observes, that the quince-tree may be pruned much in the same way as an apple-tree, taking care to cut out all the old diseased and dead wood, and the crofs branches in the middle of the tree, which are apt to injure each other by friction. In general you will find old trees much hurt by injurious pruning: in that case they should be headed down, cutting out all the cankered parts, and also all the diseased and dead wood where the tree is hollow, or where large branches have been cut or broken off, applying the composition as for apple-trees: and as quince-trees are very apt to have rough bark, and to be bark-bound, in these cases it will be necessary to shave off the rough bark with a draw-knife, and to scarify them when bark-bound, bruising them over with the composition. It is also advised to plant quince-trees at a proper distance from apples and pears, as bees and the wind may mix the farina, and occasion the apples or pears to degenerate.

Standard quinces, designated as fruit-trees, may be flationed in the garden or orchard, and some by the sides of any water, pond, wetary-ditch, &c. as they delight in moisture, suffering the whole to take their own natural growth; and as espals, they may be arranged in assemblage with other moderate growing trees, such as apples and pears on paradise and quince-stocks, cherries, &c. being trained as directed for apples and pears in espals. They may also be planted in shrubbries, either as full or low standards, and permitted to take their own way of growth. See Orchard.

PYSTERA, in Ancient Geography, an island situated on the coast of Asia Minor, over against Smyrna. Pliny.

PYTHAGORAS, in Biography. See Pythagoreans. Pottery has been very liberal to this philosopher, in flowing upon him all such inventions as others had neglected to claim, particularly in music; for there is scarcely any part of it, as a science, with which he has not been involved by his generous followers in biography. Musical ratios have been alluded to him, with the method of determining the gravity or acuteness of sounds by the greater or less degree of velocity in the vibrations of strings;
the addition of an eighth to the lyre (Pliny, lib. ii. cap. 2.); the harmony of the spheres (Plato); and the Greek musical notation (Boethius). His right, indeed, to some of these discoveries has been disputed by several authors, who have given them to others with as little reason, perhaps, as they had been before bestowed upon him.

But there is one discovery, relative to music, that has, at all times, been unanimously alluded to him, which, however, appears to us extremely doubtful, not only whether it was made by him, but whether, in the manner it is related, it was ever made by any one.

We are told by Nicomachus, Gaudentius, Jamblichus, Macrobius, and all their commentators, that Pythagoras, one day meditating on the want of some rule to guide the ear, analogous to what had been used to help the other senses, chanced to pass by a blacksmith's shop, and observing that the hammers, which were four in number, sounded very harmoniously, he had them weighed, and found them to be in the proportion of 6, 8, 9, and 12. Upon this he suspended four strings, of equal length and thickness, &c. fastened weights, in the above-mentioned proportions, to each of them respectively, and found that they gave the same sounds that the hammers had done; viz. the fourth, fifth, and octave to the grave tone; which last interval did not make part of the musical scale before; for the Greeks had gone no farther than the heptachord, or seven strings, till that time." Principles and Power of Harmony, p. 8.

This is the substance of the account, as it has been lately abridged by Mr. Stillingsfield, who points out many incredible circumstances with respect to the story in general, and denies that the weights 6, 8, 9, 12, would give the intervals pretended; but fees not to have seen the difficulty in the fact, relative to different hammers producing different sounds upon the same string. The frontispiece to M. Marpurg's History of Music, represents the Samian fage in the act of weighing the hammers.

But though both hammers and anvil have been swallowed by ancients and moderns, and have passed through them from one to another, with an ulterior-like digestion, upon examination and experiment it appears, that hammers of different size and weight will no more produce different tones upon the same string, than bows or clappers of different sizes, will from the same string or bell.

Indeed, both the hammers and anvils of antiquity must have been of a construction very different from those of our degenerate days, if they produced any tones that were strictly musical. Of the millions of well-organized mortals, who have paid by blacksmiths' shops, since the time of Pythagoras, we believe no one was ever detained by a single note, much less by an harmonious concord, from those Vul- canian instruments. A different kind of noise, indeed, will be produced by hammers of different weights and sizes; but it seems not to be in the power of the most subtle ear to discover the least imaginable difference with respect to gravity or acetaphes. But though different noises may be produced from different bodies, in proportion to their size and solidity, and every room, chair, and table, in a house, has a particular tone, yet these noises can never be ascertained like musical tones, which depend upon reiterated and regular vibrations of the aliquot parts of a string, or other elastic body; and in wind instruments, upon the undulations of the air conveyed into a tube. Noise may, indeed, be forced from a musical string, or instrument, by violence; but noise proceeding from bodies non-elastic, or immaterial, can never be fastened into sound. M. Rouleau (Dict. de Mus. art. Bruit) has ingeniously imagined that noise is of the same nature as sound, with this difference, that to produce sound, the one tone, with its consonant harmonics only, should be heard; such as the 8th, 12th, 15th, and 17th; whereas noise is produced by a jarring multitude of different tones, or even by one tone, when its vibrations are so violent as to render audible a considerable number of dissonant tones, of which the vibrations seldom or never coincide; such as the 7th, 9th, 11th, &c.

The long belief of this story proves that philosophers themselves have sometimes taken facts upon trust, without verifying them by experiment. And as the tone of the hammer was affected without proof, so was the effect of their different weights fastened to strings; this Galileo discovered. The numbers 6, 8, 9, 12, applied to different lengths of strings, would, indeed, give the intervals mentioned. But it is proved, that to produce those intervals by the tension of different weights, the weights must be the squares of those numbers; that is, 36, 64, 81, 144. It is astonishing how the Blunder had been echoed from author to author, without experiment, till the time of Galileo. And Boulemi, in trying the power of weights upon strings in the Pythagoric proportions of 6, 8, 9, 12, found, that instead of giving the 4th, 5th, and 8th of the grave tone, they produced only the minor 3d, major 3d, and tritone; so that the whole account falls to the ground. But though modern incredulity and experiment have robbed Pythagoras of the glory of discovering musical ratios by accident, he has been allowed the superior merit of arriving at them by meditation and design. At least the invention of the harmonical canon, or monochord, has been ascribed to him both by ancient and modern writers. (See Monochord.) See Airiftid. Quint. p. 116. Prin. and Power of Harm. Hist. des Mathem. par. Montuc. Euler, Tentamen rube Theor. Mus. and all the writers upon harmonics and temperament.

We shall enter no deeper into this subject here, than is absolutely necessary to explain the nature of the discovery attributed to Pythagoras, to which music is indebted for the honourable appellation of science.

Pythagoras supposed the air to be the vehicle of sound, and the agitation of that element occasioned by a similar agitation in the parts of the sounding body, to be the cause of it. The vibrations of a string, or any other resonous body, being communicated to the air, affected the auditory nerves with the sensation of sound; and this sound, according to him, was acute or grave, in proportion as the vibrations were quick or slow. It was also known, by experiment, that of two strings equal in every thing but length, the shorter made the quickest vibrations, and gave the acuter sound; in other words, that the number of vibrations made in the same time by two strings of different lengths, were inversely as those lengths; that is, the greater the length, the smaller the number of vibrations in any given time. By these discoveries it was that sound, considered in the vibrations that cause it, and the dimensions of the vibrating or resonous body, was reduced to quantity, and as such, became subject to calculation, and expressible by numbers. Thus, for instance, the two founds that form an octave are expressed by the numbers 1 and 2; which represent either the number of vibrations in a given time, or the length of the strings; and mean nothing more mysterious than that the acuter sound vibrates twice, while the graver vibrates once; or, that the string producing the lower found is twice the length of that which gives the upper. If we consider the vibrations, the higher found is as 2, the lower as 1: the reverse, if we consider only the lengths. In the same manner, and in the same fense, the 5th is expressed by the ratio of 2 to 3, and the 4th by that of 3 to 4.

Such
Such was the ancient philosophy of sounds, of which Pythagoras is recorded as the first teacher. But how much of this theory was founded on experiment and demonstration, and how much of it upon hypothesis; how much of it was known, and how much taken for granted, cannot certainly be determined. The story just now detailed is too much embarrassed with absurdities and impossibilities to guide us to any probable conjecture; as to the method by which Pythagoras actually arrived at his conclusions.

The discovery, as far as it relates to the length of strings, was easily made, because it depended upon an obvious experiment. It was, likewise, easily perceived, that a short string vibrated with more velocity than a long one; but between the certainty of this general fact, and the certainty that the vibrations were in a ratio exactly the inverse of the length, there is a considerable gulf. (See Smith's Harmonics, f.c. l. art. 7, and note f.) We have no account of the bridge upon which Pythagoras got safely over. Experiment, here, is out of the question; for the lowest vibrations that produce musical sound, are far too quick to be counted or distinguished. The inference, however, was natural, though it does not appear that the ancients were able to support it by strict and scientific proof.

Indeed it was so late as the beginning of the present century, (1714. See Phil. Trans. and Methodes incrementorum directa et inversa, by Dr. Broco Taylor,) before this ancient theory of sound was fully confirmed, and the laws of vibrations, and the whole doctrine of musical strings, elucidated upon the solid basis of mathematical demonstration.

The second musical improvement attributed to Pythagoras, was the addition of an eighth string to the lyre, which, before his time, had only seven, and was therefore a heptachord. It is supposed by several ancient writers, that the scale of this instrument, which was that of Tertander, consisted of two conjoint tetrachords, E F G A B b C D; and that Pythagoras, by adding an eighth string, at the top, and altering the tuning of the fifth, formed this scale: E F G A, B b C D e, or a similar scale, consisting of two disjunct tetrachords.

How this scale was generated by the triple progression, or series of perfect 5ths, the abbé Rouffier has lately very well detailed, in his "Memoire pour la Muzique des Anciens." We shall endeavour to explain what is meant by the triple progression in music, which is the basis of this ingenious hypothesis; referring the reader to the Mémoire itself for his proofs, as inferring them here would require too much time and space for a work of this nature.

Let any sound be represented by unity, or the number 1; and as the 3d part of a string has been found to produce the 12th, or octave of the 5th above the whole string, 2 series of 5ths may be represented by a triple geometric progression of numbers, continually multiplied by 3, as 1, 3, 9, 27, 81, 243, 729; and these terms may be equally supposed to represent 12ths, or 5ths, either ascending or descending. For whether we divide by 3, or multiply by 5, the terms will be in the proportion of a 12th, or octave to the 5th, either way. The abbé Rouffier, imagining that the ancients tuned their scale backwards, as we should call it, by descending, annexes to his numbers the sounds following the present:

Term I II III IV V VI VII
1 3 9 27 81 243 729
B E A D G C F
out of which series of 5ths, by arranging the sounds in diatonic order, may be formed the heptachord, or 7th, B C D E F G A; and to these, adding the double of the highest found, in the proportion of 2 to 1, the abbé supposes that Pythagoras acquired the octave, or prollambamos. This is throwing a mite into the charity-box of poor Pythagoras, without, however, telling us in what reign the obolus was coined; for we have met with no ancient author who allows the invention of prollambamos upon this philosopher. The abbé does not let him or his followers stop here, but supposes an 8th term, 2187, added to the progression given above, by which a B b was obtained, which furnished the minor femitone below B b. The system of Pythagoras, according to the abbé, was bounded by this 8th term, and the principle upon which it was built, being left, the Greeks penetrated no further into the regions of modulation, where they might have enriched their music, but contented themselves, in after-times, with transpositions of this series of found.

The abbé Rouffier imagines, however, that though Pythagoras went no farther than the eighth term in triple progression, yet the Egyptians, in very high antiquity, extended the series to 12 terms, which would give every possible mode and genus perfect. A curious circumstance is observed by the fame author, p. 28, § 37, with respect to the musical syllable of the Chineses, which well deserves mention here. "In collecting," says he, "what has already been advanced concerning the original formation of the Chinesian syllable, it appears to begin precisely where the Greek left off, that is, at the Vth term of the triple progression, which is purposed as far as the X1th term, by which series, arranged diatonically, the Chineses acquire their scale, e b, D b, A b, G b, E b, in descendig: or, as Rameau expresses the same intervals, in sharps, ascending, G♯, A♯, C♯, D♯, E♯, F♯, "It is observable that both these scales, which are wholly without femitones, are of the same, and correspond with the natural scale of the flat entire enharmonic, given by Ptolomeus, &c. not only the enharmonic diatons, but even the minute intervals in the warbling of birds; it is wonderful he did not apply his ratio to human speech.

After musical ratios were discovered and reduced to numbers, they were made by Pythagoras and his followers, the type of order and just proportion in all things: hence virtue, friendship, good government, celestial motion, the human soul, and God himself, were harmonious.

This discovery gave birth to various species of music, far more strange and inconceivable than chromatic and enharmonic: such as divine music, mundane music, elementary music, and many other divisions and subdivisions, upon which Zarlino, Kircher, and almost all the old writers, never fail to expatiate with wonderful complacency. It is, perhaps, equally to the credit and advantage of music and philosophy, that they have long descended from these heights, and taken their proper and separate stations upon earth. For we no longer admit of music that cannot be heard, or of philosophy that cannot be understood.

Aristides Quintilianus affirms to us, that music comprehends arithmetic, geometry, physics, and metaphysics, and teaches every thing, from subduing the scale, to the nature and constitution of the soul of man and the soul of the universe. To confirm this, he quotes, as a divine saying, a most curious account of the end and beginning of music, from one mother Panacmus, which informs us that the province of music is not only to arrange musical sounds, and to regulate the voice, but to unite and harmonize every thing in nature. This writer, p. 102, in solving the question, whence it is that the soul is so easily affected by instrumental music, acquaints us, in the Pythagorean way, how the soul, thrilling about, and
playing all kinds of tricks in the purer regions of space, approaches by degrees to our gross atmosphere; gets a taint for matter and solidity, and at length acquires a warm and comfortable body to cover her nakedness. Here she picks up nerves and arteries; there membranes; here spirit or breath; and all in a most extraordinary manner; especially the arteries and nerves: for what should they be made of, but the circles and lines of the spheres, in which the soul gets entangled in her passage, like a fly in a spider's web. Thus, continues he, the body becomes similar in its texture to instruments of the wind and stringed kind. The nerves and arteries are strings, and at the same time they are pipes filled with wind. "What wonder, then," says Arilides Quintilianus, "if the soul, being thus intimately connected with a body similar in construction to those instruments, should sympathize with their motions."

Mather Thomas Mace, author of a most delectable book, called "Mufick's Monument," would have been an excellent Pythagorean; for he maintains that the mystery of the Trinity is percievingly made plain by the connection of the three harmonical concords, 1, 3, 5; that music and divinity are nearly allied; and that the contemplation of concord and discord, of the nature of the octave and unison, will so strengthen a man's faith, "that he shall never after degenerate into that gross fab-beneficial sin of atheism." P. 268.

Pythagoras is said, by the writers of his life, to have regarded music as something celestial and divine, and to have had such an opinion of its power over the human affections, that, according to the Egyptian fyltem, he ordered his disciples to be waked every morning, and lulled to sleep every night, by sweet sounds. He likewise considered it as greatly conducive to health, and made use of it in disorders of the body, as well as in those of the mind. His biographers and secretaries even pretend to tell us what kind of music he applied upon those occasions. Grave and solemn, we may be certain; and vocal, say they, was preferred to instrumental, and the lyre to the flute, not only for its decency and gravity, but because instruction could be conveyed to him, by means of articulation in singing, at the same time as the ear was delighted by sweet sounds. This was said to have been the opinion of Minerva. In very high antiquity mankind gave human wisdom to their gods, and afterwards took it from them, to bestow it on mortals.

In perusing the life of illustrious men, who have sprung from the school of Pythagoras, it appears that the love and cultivation of music was so much a part of their discipline, that almost every one of them left a treatise behind him upon the subject.

Pythagorean's Table. See Table.

PYTHAGOREA, in Botany, received that appellation from Loureiro, in memory of the famous Pythagoras, who is said to have written a book on the qualities of plants.—Loureiro. Cochinch. 243. Clas and order, Ondandria Tetragyenia. Nat. Ord. . . . .

Gen. Ch. Cat. Perianth inferior, bell-shaped, of seven or eight linear, hairy, coloured leaves. Cor. superior, bell-shaped, of seven or eight lanceolate, concave, hairy petals, the length of the calyx. Stam. Filaments eight, awl-shaped, longer than the corolla; anthers roundish, two-lobed. Pif. Germen between the calyx and corolla, nearly ovate, hairy; styles four, awl-shaped, reflexed, shorter than the stamens; stigma acute. Peric. Capsule ovate, of four cells. Sacs numerous, roundish.

Eff. Ch. Calyx of seven or eight leaves, inferior. Corolla of seven or eight petals, superior. Capsule of four cells, with many seeds.

1. P. Cochinchinensis.—Native of Cochinchina, where it is called Xunung ca tai the la. A small tree, with numerous branches. Leaves nearly sessile, ovato-lanceolate, ferrated, smooth; their longitudinal ribs red at the extremity. Clusters axillary, long, nearly simple, with short partial Ralls. Flowers white.

Such is Loureiro's account, but we have no knowledge of the plant he describes, nor can we offer any conjecture respecting its natural affinity. We have no faith in the existence of a genus superior to the calyx and inferior to the corolla, the only influence of the kind which Linnaeus ever imagined, in Supernifora, proving not well founded.

PYTHAGOREAN, or PYTHAGORIC System, among the Ancients, was the fame with the Copernican ylem among the moderns. See System.

It was thus called, as having been maintained and cultivated by Pythagoras, and his followers; not that it was invented by him, for it was much older. PYTHAGOREANS, a sect of ancient philosophers, who adhered to the doctrine of Pythagoras.

Pythagoras, the founder of this sect, was of Samos, the son of a lapidary, and a pupil of Pherecydes, and flourished (says Bayle) about five hundred years before Chrilt, in the time of Tarquin, the last king of Rome, and not in Numa's time, as many authors have supposed. See Cicero Tufcil. Quel. lib. iv. cap. 1.

The time of his birth, however, has been much disputed. Dr. Bentley, in his "Dissertation on the Epitiles of Phalaris," relying chiefly on the authority of Eratosthenes, refers the birth of Pythagoras to the 4th year of the 43rd Olympiad, B.C. 668. Lloyd, in his "Dissertation concerning the Chronology of Pythagoras," assigns his birth to the 3rd year of the 48th Olympiad, B.C. 596. Dowel places it in the 4th year of the 52d Olympiad, B.C. 569, resting in this date chiefly on the authority of Porphyry and Jamblichus. Upon the whole, the opinion of Lloyd seems to be the most probable, which is, that he was born about the year B.C. 586, and that he died about the 3rd year of the 68th Olympiad, B.C. 506; for that it seems pretty certain, that he was not born earlier than the 4th year of the 43d Olympiad, B.C. 636, nor later than the 4th year of the 52d, B.C. 596. If we admit only the credible particulars of his childhood and early education, and no authority to the tales of Jamblichus and others, who even asserted that he was the son of God, we shall find that he was first instructed in his own country by Crescentius, and afterwards by Pherecydes, in the island of Scyros, and that after having paid his last tribute of respect to his preceptor, he returned to Samos, and pursued his studies under the direction of his first master, Jamblichus, and other later biographers, mention his journey into Ionia, and his interviews with Thales and Anaximander, but of this journey we have no authentic record, nor is any effect of it discernible in his doctrine, which is essentially different from that of the Ionic school. His first journey from the Grecian islands was probably into Egypt, which was celebrated in his time for that kind of wisdom which both suited his genius and temper. In his way thither, Jamblichus asserts that he visited Phoenicia, and conversed with the prophets and philosophers that were the successors of Mochus the Physiologist; which Mochus, Selden, and some others, will have to be Mofes.

Nor is it thought at all improbable that Pythagoras might have acquainted himself with the Phoenician philosophy, of which he must, without doubt, have received a general report from his father, and from other merchants who traded to this coast. But that he derived his knowledge of numbers from the Phoenicians is not at all probable, because their acquaintance with numbers extended no further than
to the practical science of arithmetic. It has been said, indeed, that Pythagoras travelled, not only into Egypt and Chaldæa, but even into the Indies, to inform his understanding with regard to all branches of science and prevalent customs; and that after returning to his own country, being unable to bear the tyranny of Polycrates, he retired into the eastern part of Italy, then called Magna Grecia, and established his school, denominated from this circumstance the "Italic School," or "Italic School." Whatever opinion is entertained of this journey to the East, to which Le Clerc gives no credit, we must altogether reject other stories of his visiting the temple on Mount Carmel, and remaining there for several days, without food, passing among the inhabitants for a good demon, and obtaining from them religious honours; and of his proceeding into India, and there passing through several ceremonies of the Mosaic law.

Pythagoras, whilst he was in Egypt, was introduced by the recommendation of Polycrates, tyrant of Samps, to Amasis, king of Egypt, a distinguished patron of literary men, and thus obtained access to the colleges of the priests. Having found it difficult to gain this privilege, he performed many severe and troublesome preliminary ceremonies, and even submitted to circumcision, a preferred condition of his admission. He passed twenty-two years in Egypt, availing himself of all possible means of information with regard to the recondite doctrines of the Egyptian priests, as well as their astronomy and geometry, and Egyptian learning in its most unlimited extent.

Many writers of reputation, both Pagan and Christian, who flourished after the commencement of the Christian era, relate, that after Pythagoras had left Egypt, he visited the Persian and Chaldæan Magi, and proceeded so far as to have intercourse with the Indian Gymnosophists. Jamblichus affirms, that he was taken captive by the victorious army of Cambyses, and carried to Babylon, where he acquainted himself with the learning and philosophy of the East; and that after the expiration of twelve years, when he was in the 60th year of his age, he returned to Samos. The circumstance of his having visited the Persian magi is also mentioned by Cicero, Eutubius, Laëntius, and Valerius Maximus, though they take no notice of his captivity. In this journey to the East, as some have maintained, he attended upon the instructions of the celebrated Persian sage, Zoroaster; and others, who have placed the life of Zoroaster in an earlier period than that of Pythagoras, have asserted, that he conversed with certain Jewish prophets, who were at that time in Babylon, in a state of captivity, and thus became acquainted with the Jewish laws and customs. However, several objections, particularly of a chronological kind, have been alleged against the narrative of Pythagoras's journey to the East. Chronologists unanimously agree, that Cambyses invaded Egypt in the fifth year of his reign, or the third year of the 63d Olympiad. According to Jamblichus, Pythagoras, after staying twelve years in Babylon, and visiting several other countries, went into Italy in the 62d Olympiad. The same date is affixed to this journey by Diodorus and Clemens Alexandrinus; whilst others place it about fourteen years earlier. Hence it appears, that if Pythagoras left the East before the 62d Olympiad, after remaining there twelve years, he could not have been carried thither by Cambyses in the 63d Olympiad. Moreover, the whole narrative of Pythagoras's journey into the East is contradicted by the express authority of Antiphon (quoted by Porphyry), who says that Pythagoras, after his residence in Egypt, returned into Ionia, and opened a school in his own country; and that, at the age of forty years, finding himself harassed by the tyranny of Polycrates, he withdrew into Italy; and according to this account, we have no interval for the supposed eastern expedition. The reality of this expedition is testified either by certain Alexandrian Platonists, who were devout of exalting, as much as possible, the wisdom of those ancient philosophers, whom they considered as the oracles of wisdom, or by certain Jewish and Christian writers, who were induced to credit every tale which tended to give probability to the opinion that the Pythagorean doctrine was derived from the Oriental philosophers, and ultimately from the Hebrew scriptures. In either case the authenticity of the relation is liable to just suspicion; nor is there any probable argument to prove, that Pythagoras received instruction from any prophet of the Hebrew nation, during his supposed residence at Babylon. Brucker concurs with those writers who are disposed to reject this story of Pythagoras's eastern journey as a mere fiction, and who conclude, that, having never passed from Egypt to the East, he returned thence immediately to Samos. The story of his having visited the northern Druids is so delusive of probability and of evidence, as to merit no regard.

After his return from Egypt to his native island, he wished to communicate the benefit of his twenty years' researches and studies to his fellow-citizens, and with this view he attempted to institute a school for their instruction in the elements of science; proposing to adopt the Egyptian mode of teaching, and to communicate his doctrines under a sibylline form: but the Samians were either too stupid or too indolent to profit by his instructions. Although he was obliged to relinquish his design, he did not altogether abandon it. In order to engage the attention of his countrymen by some other means, he repaired to Delos; and after presenting an offering of cakes to Apollo, he there received, or pretended to receive, moral dogmas from the priests, which he afterwards delivered to his disciples under the character of divine precepts. With the same views he also visited the island of Crete, and celebrated in mythological history: where he was conducted by the Corybantes, or priests of Cybele, into the cave of mount Ida, in which Jupiter is said to have been buried. Here he conversed with Epimenides, an eminent pretender to prophetic powers, and was by him initiated into the most sacred mysteries of Greece. About the same time he visited Sparta and Elis, and was present during the celebration of the Olympic games, where he is said to have exhibited a golden thigh to Abaris, in order to convince him that he was Apollo. Besides other places which he visited during his stay in Greece, he repaired to Phlius, where he first assumed the appellation of philosopher. (See Philosopher.) Having thus added to the stores of learning which he had previously accumulated, and acquired a kind of authority which was calculated to command respect, he returned to Samos, and made a second attempt, more successful than his first, for establishing a school of philosophy. In a semicircular kind of building, which the Samians had used as a place of retreat for public bufinefs, he delivered with an allured authority of a sacred nature, popular precepts of morality; and he also provided for himself a secret cave, into which he retired with his intimate friends and professed disciples, and here he gave his followers daily instructions, accompanied with a considerable parade of mystery, in the more abstruse parts of philosophy. His fame, and the multitude of his followers, increased. What he failed to accomplish by the mere force of learning and ability, he effected by concealing his doctrines under the veil of mysterious symbols, and lifting forth his precepts as responses from a divine oracle. About the beginning of the 59th Olympiad, Pythagoras, deified of eclipsing the

Vol. XXIX.
the tyrannical government exercised in his native island by Sylofon, the brother of Polycrates, left Samos, and, as we have already hinted, passed over into Italy, and attempted to establish his school among the colonies of Magna Graecia. It is probable that, in order to obtain credit with the populace, he about this time pretended to possess a power of performing miracles, and practiced many arts of imposture. The first place at which he arrived in Italy was Crotona, a city in the bay of Tarentum, the inhabitants of which were very corrupt in their manners. But such were his reputation and influence, that he was treated with great respect, and people of all classes assembled to hear his discourses; insomuch that the manners of the citizens were from totally changed from great luxury and licentiousness to strict sobriety and frugality. It is said that 600 (some say 2000), perfons were prevailed upon to submit to the strict discipline which he required, and to threw their effects into a common stock for the benefit of the whole fraternity. The influence of his philosophy extended from Crotona to many other cities of Magna Graecia, and obtained for Pythagoras from his followers a degree of respect little short of adoration. If he had contented himself with delivering doctrines of philosophy and precepts of practical wisdom, he might probably have continued his labours, without molestation, to the end of his life. But he manifested a strong propensity towards political innovations; and he employed his influence in urging the people to the strenuous assertion of their rights against the encroachments of their tyrannical governors. This course of conduct raised against him a very powerful opposition, which he was unable to resist and contend against, and which obliged him to retire to Metapontum. Here he found himself ill surrounded with enemies, and was under a necessity of seeking an asylum in the temple of the Muses, where not being supplied by his friends with sufficient food, he perished with hunger. The time of his death is uncertain; but according to the Chronicle of Eusebius, he died in the third year of the 68th olympiad, B.C. 526, after having lived, according to the most probable statement of his birth, to the age of 80 years. After his death his followers paid a superstitious respect to his memory. They erected statues in honour of him, converted his house at Crotona into a temple of Ceres, the street in which it stood was called the Muneum, and appealed to him as a divinity, swearing by his name.

It appears, from the history of this philosopher, that with all his talents and learning, he owed much of his celebrity and authority to imposture. His whole manner of life confirms this opinion. Clothed in a long white robe, with a flowing beard, and, as some say, with a golden crown on his head, he preferred among the people, and in the presence of his disciples, a commanding gravity and majesty of aspect. He recurred to music for promoting the tranquillity of his mind, frequently singing, for this purpose, hymns of Thales, Hesiod, and Homer. He had such an entire command over himself, that he was never seen to express, in his countenance, grief, joy, or anger. He refrained from animal food, and confined himself to a frugal vegetable diet, excluding from his simple bill of fare, for mystical reasons,pulse or beans. By this artificial demeanour, Pythagoras appeared among the vulgar as a being of an order superior to the common condition of humanity, and perfused them that he had received his doctrine from heaven. Pythagoras married Theano of Crotona, or, as some say, of Crete, by whom he had two sons, Telages and Maenarchus, who, after his death, took the charge of his school. Whether this philosopher left behind him any writings has been a subject of dispute. Many works have been ascribed under his name by Laertius, Jamblichus, and Pliny; but it is the declared opinion of Plutarch, Jophesus, Lucian, and others, that there were no genuine works of Pythagoras extant; and it appears highly probable, from the pieces which he took to compose his doctrine to his own school during his life, that he never committed his philosophical syllabus to writing, and that the pieces to which his name was affixed at an early period, were written by some of his followers, upon the principles imbibed in his school. The famous golden verses attributed to Pythagoras, and illustrated with a commentary by Hierodules, were not written by our philosopher, but are to be ascribed to Epicharmus, or Empedocles. They may, however, be considered as a brief summary of his popular doctrines.

His "Method of instruction," formed upon the Egyptian model, was, "exoteric," and "esoteric," that is, public and private. Those auditors, who attended his public lectures, did not properly belong to his school, but followed their usual mode of living. His selected disciples, called his companions and friends, were such as submitted to a peculiar plan of discipline, and were admitted, by a long course of instruction, into all the mysteries of his esoteric doctrine.

Previously to the admission of any person into this fraternity, Pythagoras examined his features and external appearance; required how he had been accustomed to behave towards his parents and friends; marked his manner of laughing, conversing, and keeping silence; and observed what passions he was most inclined to indulge; with what kind of company he chose to associate; how he passed his leisure moments; and what incidents appeared to excite in him the strongest emotions of joy or sorrow. Nor after this examination was any one admitted into his society, till he was fully persuaded of the loyalty of his disposition, the gentleness of his manners, the power of retaining in silence what he was taught, and, in fine, his capacity of becoming a true philosopher. After the first probationary admission, the fortune and self-command of the candidate were put to the trial by a long course of severe abstinence and rigorous exercise. The course of abstinence and self denial comprehended food and drink, and clothing in all which were of the most plain and simple kind; and the exercises prescribed were such as could not be performed without pain and fatigue. To teach them humility and industry, he exposed them, for three years, to a continued course of contradiction, ridicule, and contempt, among their fellows. In order to restrain the powerful passion of avarice, he required his disciples to submit to voluntary poverty; and he deprived them of all command over their own property, by calling the possessions of each individual into a common stock, to be distributed by proper officers, as occasion required. After this sequestration of their goods, they lived together on the footing of perfect equality, and fat down together daily at a common table. If any one afterwards repented of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution. That his disciples might acquire a habit of entire docility, Pythagoras enjoined upon them, from their first admission, a long term of silence, called εἶκατερία. This initiatory silence, which probably consisted in restraining from speech, not only during the hours of instruction, but through the whole term of initiation, continued from two to five years, according to the propensity discovered by the pupil towards conceit and loquacity. With regard to himself, this was a judicious expedient, as it checked impertinent curiosity, and prevented every inconvenience of contradiction. Accordingly his disciples silenced all doubts and refuted all objections.
PYTHAGOREANS.

...by appealing to his authority. *Ades ipse, ipse dixit,* decided every dispute. Moreover, during the years of initiation, the disciples were prohibited from facing their master, or hearing his lectures, except from behind a curtain, or receiving instruction from some inferior preceptor.

To the members of the eotios school (who were called ψυχωτοι κόμματις, genuine disciples) belonged the peculiar privilege of receiving a full explanation of the whole doctrine of Pythagoras, which was delivered to others in brief precepts and dogmas, under the concealment of symbols. Disciples of this class were permitted to take part of their master's lectures, in writing, as well as to propose questions, and offer remarks, upon every subject of discourse. These were particularly distinguished by the appellation of the "Pythagoreans;" they were also called "Mathematicians," from the studies upon which they entered immediately after their initiation. Having made a sufficient progress in geometrical science, they proceeded to the study of nature, the investigation of principal principles, and the knowledge of God. Those who pursued these sublime speculations were called "Theorists," and those who devoted themselves more particularly to theology, were styled ὅμορφοι, religious. Others, according to their abilities and inclinations, were engaged in the study of morals, economics, and policy; and were afterwards employed in managing the affairs of the fraternity, or sent into the cities of Greece, to instruct them in the principles of government, or allay them in the institution of laws.

The brethren of the Pythagorean college at Crotona, called ψυχωτοί κοινωνία, about 600 in number, lived together as in one family, with their wives and children; and the whole business of the society was conducted with the most perfect regularity. Every day commenced with deliberation upon the manner in which it should be spent; and concluded with a retrospect of the events that had occurred, and of the business that had been transacted. They rose before the sun, that they might pay him homage; after which they repeated their devotions at Homer and other poets, and made use of music, both vocal and instrumental, to enliven their spirits and fit them for the business of the day. They then employed several hours in the study of science. These were succeeded by an interval of leisures, which was commonly spent in a solitary walk for the purpose of contemplation. The next portion of the day was allotted to conversation. The hour immediately before dinner was filled up with various kinds of athletic exercises. Their dinner consisted chiefly of bread, honey, and water; for after they were perfectly initiated, they wholly denied themselves the use of wine. The remainder of the day was devoted to civil and domestic affairs, conversation, bathing, and religious ceremonies.

The "exoteric" disciples of Pythagoras were taught, after the Egyptian manner, by images and symbols, obscure and almost unintelligible to those who were not initiated into the mysteries of the school; and those who were admitted to this privilege were under the strictest obligation of silence with regard to the recondite doctrines of their master. The wisdom of Pythagoras, that it might not pass into the ears of the vulgar, was committed chiefly to memory; and when they found it necessary to make use of writing, they took care not to suffer their minutes to pass beyond the limits of the school.

Clemens obsevers, that the two orders above described corresponded very exactly to those among the Hebrews; for in the schools of the prophets there were two classes, viz. the sons of the prophets, who were the scholars; and the doctors or masters, who were also called perfeci: and among the Levites, the novices or tyros, who had their quinquennial exercises, by way of preparation. Lastly, even among the profelytes there were two orders; exoterici, or profelytes of the gate; and intrinseci or perfedi, profelytes of the covenant. He adds, it is highly probable, that Pythagoras himself had been a profylete of the gate, if not of the covenant.

Gale endeavours to prove, that Pythagoras borrowed his philosophy from that of the Jews; to this end producing the authorities of many of the fathers, and ancient authors; and even pointing out the tracks and footsteps of Moses in several parts of Pythagoras's doctrine.

After the dissolution of the assembly of Pythagoras's disciples by the faction of Cyelo, a man of wealth and distinction at Crotona, it was thought necessary by Lyfis and Archippus, in order to preserve the Pythagorean doctrine from oblivion, to reduce it to a systematic summary: at the same time, however, strongly enjoining their children to preserve these memoirs secret, and to transmute them in confidence to their posterity. From this time books began to multiply among the followers of Pythagoras, till at length, in the time of Plato, Philolaus exposed the Pythagorean records to sale, and Archytas of Tarentum gave Plato a copy of his commentaries upon the aphorisms and precepts of his master. Of the imperfect records of the Pythagorean philosophy left by Lyfis, Archytas, and others, nothing has escaped the wreck of time, except perhaps fundry fragments collected by the diligence of Stobæus, concerning the authenticity of which there are some grounds for suspicion; and which, if admitted as genuine, will only exhibit an imperfect view of the moral and philosophical doctrine of Pythagoras under the disguise of symbolical and enigmatical language. The strict injunction of secrecy, which was given by oath to the initiated Pythagoreans, has effectually prevented any original records of their doctrine concerning Nature and God from passing down to posterity. On this head we are to rely entirely for information, and indeed concerning the whole doctrine of Pythagoras, upon Plato and his followers. Plato himself, while he enriched his system with stories from the magazine of Pythagoras, accommodated the Pythagorean doctrines, as he also did those of his master Socrates, to his own system, and thus gave an imperfect, and, we may suppose, in many particulars, a false representation of the doctrines of the Samian philosopher. It was further corrupted by the followers of Plato, even in the old academy, and afterwards in the Alexandrian school. To which we may add, that the doctrine of Pythagoras itself, probably in its original state, and certainly in every form under which it has been transmitted to us, was observed, not only by symbolical, but by mathematical language, which is rather adapted to perplex than to illustrate metaphysical conceptions. In this fault Pythagoras was afterwards imitated by Plato, Aristotle, and others.

We extract from Brucker the following faint delineation of the Pythagorean philosophy: The end of philosophy is to free the mind from thofe incumbrances, which hinder its progress towards perfection, and to raife it to the contemplation of immutable truth, and the knowledge of divine and spiritual objects. This effect must be produced by easy steps, left the mind, hitherto converfant only with fenfible things, ſhould revolt at the change. The firft step towards wisdom is the study of mathematics, a science which contemplates objects that lie in the middle way between corporeal and incorporeal beings, and as it were on the confines of both, and which most advantageously injures the mind to...
PYTHAGOREANS.

contemplation. The whole course of mathematical science may be divided into four parts: two reflecting numbers, and two reflecting magnitude. Number may be considered either abstrusely in itself, or as applied to some object. The former science is arithmetic; of the latter kind is music. Magnitude may be considered as at rest, or as in motion; the science which treats of the former is geometry, that which treats of the latter is astronomy.

Arithmetic is the nobled science; numbers the first object of study, and a perfect acquaintance with numbers the highest good. Numbers are either scientific or intelligible.

Scientific numbers are the production of the powers involved in unity, or the progression of multitude from the monad or unity, and its return to the same. Unity and one are to be distinguished from each other; the former being an abstract conception, the latter belonging to things capable of being numbered. Number is not infinite, but is the source of that infinite divisibility into equal parts, which is the property of all bodies.

Intelligible numbers are those which subsist in the divine mind before all things, from which every thing hath received its form, and which always remain immutably the same. It is the model, or archetype, after which the world, in all its parts, is framed. Numbers are the cause of offence to beings: τῷ ἀριθμῳ αἰῶνα τοῦ ματέρα τοῦ. The monad, or unity, is that quantity, which, being deprived of all number, remains fixed; whence called monad, from τὸ μένα. It is the fountain of all number. The duad is imperfect and passive, and the cause of increase and division. The triad, composed of the monad and duad, partakes of the nature of both. The tetrad, tetraëtries, or quaternion number, is the most perfect. The decad, which is the sum of the four former, comprehends all arithmetical and musical proportions.

According to some writers, the monad denotes the active principle in nature, or God: the duad, the passive principle, or matter; the triad, the world formed by the union of the two former; and the tetraëtries, the perfection of nature. Some have understood by this mysterious number, the four elements; others, the four faculties of the human mind; others, the four cardinal virtues; and others have been so absurd as to suppose that Pythagoras made use of this number to express the name of God, in reference to the word בַּיָּטָה, by which that name is expressed in the Hebrew language. But every attempt to unfold this mystery has hitherto been unsuccessful.

The most probable explanation of the Pythagorean doctrine of numbers is, that they were used as symbolical or emblematical representations of the first principles and forms of nature, and particularly of those eternal and immutable essences, to which Plato afterwards gave the appellation of ideas. Not being able, or not choosing, to explain in simple language the abstract notions of principles and forms, Pythagoras seems to have made use of numbers, as geometers make use of diagrams, to allude the conceptions of scholars. More particularly, conceiving some analogy between numbers and the intelligent forms which subsist in the divine mind, he made the former a symbol of the latter. As numbers proceed from unity, or the monad, as a simple root, whence they branch out into various combinations, and assume new properties in their progress, so he conceived the different forms of nature to recede, at different distances, from their common source, the pure and simple essence of deity, and at every degree of distance to assume certain properties in some measure analogous to those of number; and hence he concluded, that the origin of things, their emanation from the first being, and their subsequent progression through various orders, if not capable of a perfectly clear explanation, might, however, be illustrated by symbols and reminiscences borrowed from numbers.

Next to numbers, music had the chief place in the preparatory exercises of the Pythagorean school, by means of which the mind was to be raised above the dominion of the passions, and insted to contemplation. Pythagoras considered music, not only as an art to be judged of by the ear, but as a science to be reduced to mathematical principles and proportions. We have introduced, under the article PYTHAGORAS, the manner in which he is said to have discovered the musical chords, but shall here subjoin a more minute account. As Pythagoras was one day reflecting upon the subject, happening to pass by a smith's forge, where several men were successively striking with their hammers a piece of heated iron upon an anvil, he remarked, that all the sounds produced by their strokes were harmonious except one. The sounds, which he observed to be chords, were the octave, the fifth, and the third; but that sound which he perceived to lie between the third and the fifth he found to be discordant. Going into the work-shop, he observed, that the diversity of sounds arose, not from the form of the hammers, nor from the force with which they were struck, nor from the position of the iron, but merely from the difference of weight in the hammers. Taking, therefore, the exact weight of the several hammers, he went home, and suspended four strings of the same substance, length, and thickness, and twined in the same degree, and hung a weight so as to lower each, respectively equal to the weight of the hammers: upon striking the strings, he found, that the musical chords of the strings corresponded with those of the hammers. Hence it is said, that he proceeded to form a musical scale, and to construct strung instruments. His scale was, after his death, engraved in brass, and preferred in the temple of Juno at Samos.

Pythagoras conceived that the celestial spheres in which the planets move, striking upon the ether through which they pass, must produce a sound; and that this sound must vary, according to the diversity of their magnitude, velocity, and relative distance. Taking it for granted, that every thing reflecting the heavenly bodies is adjusted with perfect regularity, he further imagined, that all the circumstances necessary to render the sounds produced by their motion harmonious, were fixed in such exact proportions, that the most perfect harmony is produced by their revolutions. This pious doctrine respecting the music of the spheres gave rise to the names which Pythagoras applied to musical tones. The last note in the musical octave he called kyate, because he supposed the sphere of Saturn, the highest planet, to give the deepest tone; and the highest note he called nate, from the sphere of the moon, which being the lowest, or nearest the earth, he imagined, produced the shrillest sound. In like manner of the rest. It was said of Pythagoras by his followers, who hesitated at no assertion; however improbable, which might seem to exalt their master's fame, that he was the only mortal so far favoured by the gods as to be permitted to hear the celestial music of the spheres. Pythagoras applied music to the cure of diseases both bodily and mental. It was, as we have seen, the custom of his school, to compose: their minds for rest in the evening, and to prepare themselves for action in the morning, by suitable airs, which they performed upon the lute, or other strung instruments. The music was, however, always accompanied with verse, so that it may be doubted, whether the effect was to be ascribed more to the musician
or to the poet. It is said of Clinius, a Pythagorean, that whenever he perceived himself inclined to anger, spleen, or other refires passions, he took up his lute, and that it never failed to restore the tranquility of his mind. Of Pythagoras himself it is related, that he checked a young man, who, in the midst of his revels, was meditating some act of Bacchanalian madness, by ordering the musician, who had inflamed his passions by Phrygian airs, to change the music on a sudden into the slow and solemn Doric mood. If the stories which are related by the ancients concerning the wonderful effects of their music are to be credited, we must acknowledge we are strangers to the method by which these effects were produced.

Besides arithmetic and music, Pythagoras cultivated geometry, which he had learned in Egypt; but he greatly improved it, by investigating many new theorems, and by digesting its principles, in an order more perfectly mathematical than had before been done. Several Grecians, about the time of Pythagoras, applied themselves to mathematical learning, particularly Thales in Ionia. But Pythagoras seems to have done more than any other philosopher of this period towards reducing geometry to a regular science. His definition of a point is, a monad or unity with position. He taught that a geometrical point corresponds to unity in arithmetic, a line to two, a superficies to three, a solid to four. Of the geometrical theorems ascribed to Pythagoras, the following are the principal: that the interior angles of every triangle are together equal to two right angles; that the only polygons which will fill up the whole space about a given point, are the equilateral triangle, the square, and the hexagon; the first to be taken six times, the second four times, and the third three times; and that, in rectangular triangles, the square of the side which subtends the right angle is equal to the two squares of the sides which contain the right angle. Upon the invention of this latter proposition (Euclid, l. i. prop. 47.), Plutarch says, that Pythagoras offered an ox, others, an hecatomb, to the gods. But this story is thought by Cicero inconsistent with the institutions of Pythagoras, which, as he supposes, did not admit of animal sacrifices. Pythagoras inferred the nature of Hercules from the length of the Olympic course, which measured six hundred of his feet. Observing how much shorter a course six hundred times the length of the foot of an ordinary-fized man was than the Olympic course, he inferred, by the law of proportion, the length of Hercules's foot: whence the usual proportion of the length of the foot to the height of a man enabled him to determine the problem. Pythagoras also applied geometrical ideas as symbolic expressions of bodies, and of natural principles; but nothing certain, or intelligible, is preferred on this head.

On astronomy, the doctrine of Pythagoras, or, however, of the ancient Pythagoreans, was as follows: The term heaven either denotes the sphere of the fixed stars, or the whole space between the fixed stars and the moon, or the whole world, including both the celestial spheres and the earth. There are ten celestial spheres, nine of which are visible to us; namely, that of the fixed stars, those of the seven planets, and that of the earth; the tenth is the antichthon, or an invisible sphere opposite to the earth, which is necessary to complete the harmony of nature, as the decade is the completion of numerical harmony. And this antichthon may be the cause of the greater number of the eclipses of the sun than of the moon. Fire holds the middle place in the universe; or, in the midst of the four elements is placed the fiery globe of unity; the earth is not without motion, nor situated in the centre of the spheres, but is one of those planets which make their revolution about the sphere of fire. The revolution of Saturn is completed in thirty years, that of Jupiter in twenty, that of Mars in two, that of the Sun, and of Mercury and Venus, in one year. The distance of the several celestial spheres from the earth correspond to the proportion of notes in the musical scale. The moon and other planetary globes are habitable. The earth is a globe, which admits of antipodes.

From several of these particulars respecting the astronomical doctrine of Pythagoras, it has been inferred, that he was poffessed of the true idea of the solar syllable, which was revived by Copernicus, and has since been fully established by Newton.

From this preparatory study the disciples of the Pythagorean school were conducted to the knowledge of natural, theological, and moral science. Concerning wisdom, in general, Pythagoras taught, that it is the science which is conversant with those objects, which are in their nature immutable, eternal, and incorruptible, and therefore alone can properly be said to exist. The man who applies himself to this kind of study is a philosopher. The end of philosophy is, that the human mind may, by such contemplation, be assimilated to the divine, and at length be qualified to join the assembly of the gods. In the pursuit of wisdom, the utmost care must be taken to raise the mind above the dominion of the passions, and the influence of sensible objects, and to disengage it from all corporeal impressions, that it may be induced to converse with itself, and to contemplate things spiritual and divine. For this purpose the allusion of God, and of good demons, must be invoked by prayer. Philosophy, as it is conversant with speculative truth, or with the rules of human conduct, is either theoretical or practical. Practical philosophy is only to be studied so far as may be necessary for the purposes of life; theoretical philosophy is the perfection of wisdom. Contemplative wisdom cannot be completely attained, without a total abdication from the ordinary affairs of life, and a perfect tranquility and freedom of mind. Hence the necessity of instituting a society, separated from the world, for the purpose of contemplation and study.

Active or moral philosophy, which prescribes rules and precepts for the conduct of life, according to Aristotle, was first taught by Pythagoras, and after his death by Socrates. Among the moral maxims and precepts ascribed to Pythagoras are the following:

Virtue is divided into two branches, private and public. Private virtue respects education, silence, abstinence from animal food, fortitude, sobriety, and prudence. The powers of the mind are reason and passion; and when the latter is preferred in subjection to the former, virtue is prevalent. Young persons should be inured to subjection, that they may always find it easy to submit to the authority of reason. Let them be conducted into the beaten course of life, and habit will soon render it the most pleasant. Silence is better than idle words. A wise man will prepare himself for every thing which is not in his own power. Do what you judge to be right, whatever the vulgar may think of you; if you despise their praise, despise also their censure. It is inconsistent with fortitude to relinquish the station appointed by the Supreme Lord, before we obtain his permission. Sobriety is the strength of the soul, for it preserves its reason unclouded by passion. No man ought to be effemiated, free, who has not the perfect command of himself. Drunkenness is a temporary phrenzy. That which is good and becoming is rather to be pursued, than that which is pleasant. The desire of superfluity is foolish, because it knows

PYTHAGOREANS.
PYTHAGOREANS.

no limits. All animal pleasures should rather be postponed, than enjoyed before their time; and should only be enjoyed according to nature, and with sobriety. Much forethought and discretion is necessary in the production and education of children. Wisdom and virtue are our best defence; every other guard is weak and unstable. It requires much wisdom to give right names to things.

Concerning public virtue, the doctrine of Pythagoras, as it is transmitted to the present time, respects conversation, friendship, religious worship, reverence to the dead, and legislation. Upon these heads he is said to have taught thus:

Conversation should be adapted to the characters and condition of the persons with whom we converse: that discourse and behaviour, which might be proper among young persons, may be exceedingly improper between the young and aged. Propriety and decorum is the first thing to be regarded in conversation. In all society, a due regard must be had to subordination. Respect is due to a worthy stranger, sometimes in preference even to countrymen or relations. It is better that those who converse with you should respect you, than that they should fear you; for respect produces admiration, but fear produces hatred. It is an evident proof of a good education, to be able to endure the want of it in others. Between friends, the utmost care should be taken to avoid contention, which can only be done by shunning as much as possible all occasions of strife, suppressing refentment, and exercising mutual forbearance. Reproof and correction are useful and becoming from the elder to the younger; especially when they are accompanied, on the part of the reprover, with evident tokens of affection.

Mutual confidence is never for a moment to be interrupted between friends, whether in杰尔 or earnest; for nothing can heal the wounds which are made by deceit. A friend must never be forfeited in adversity, nor for any infirmity in human nature, excepting only invincible obstinacy and depravity. Before we abandon a friend, we should endeavour, by actions as well as words, to reclaim him. True friendship is a kind of union which is immortal.

The design and object of all moral precepts is to lead men to the imitation of God. Since the Deity directs all things, every good thing is to be sought for from him alone; and nothing is to be done which is contrary to his pleasure. Whilς we are performing divine rites, piety should dwell in the mind. The gods are to be worshipped not under such images as represent the forms of men, but by such symbols as are suitable to their nature, by simple lustrations and offerings, and with purity of heart. Gods and heroes are to be worshipped with different degrees of homage, according to their nature. Oaths are in no case to be violated.

The bodies of the dead are not to be burned. Next to gods and demons, the highest reverence is due to parents and legislators; and the laws and customs of our country are to be religiously observed.—Thus much concerning the active or moral philosophy of Pythagoras.

Theoretical philosophy, which treats of nature and its origin, was the highest object of study of the Pythagorean school, and included all those profound mysteries, which those, who have been ambitious to report what Pythagoras said behind the curtain, have endeavoured to unfold. Upon this subject, nothing can be advanced with certainty, especially respecting theology, the doctrine of which, Pythagoras, after the manner of the Egyptian priests, was particularly careful to hide under the veil of symbols, probably through fear of disturbing the popular superstitions. The ancients have not, however, left us without some grounds of conjecture.

With respect to God, Pythagoras appears to have taught, that he is the Universal Mind, diffused through all things, the source of all animal life, the proper and intrinsic cause of all motion, in substance similar to light, in nature like truth, the first principle of the universe, incapable of pain, invisible, incorruptible; and only to be comprehended by the mind.

Cicero (Nat. Deor. 1. i. c. 12.) affirms, that Pythagoras conceived God to be a soul pervading all nature, of which every human soul is a portion: and this doctrine was perfectly consonant to the opinions received in the countries which Pythagoras visited, and where he learned theology. Julian Martyr (Orat. ad Gentes) expressly ranks Pythagoras among the thetical philosophers. "If any one," says he, "wishes to be informed more accurately concerning the doctrine of Pythagoras with respect to one God, let him hear his opinion, for he says, God is one: he is not, as some conceive, exterior to the world, but, in himself entire, pervades the universal sphere, superintends all productions, is the support of all nature, eternal, the fource of all power, the first simple principle of all things, the origin of celestial light, the father of all, the mind and animating principle of the universe, the first mover of all the spheres."

From a variety of passages that might be cited, we may reasonably infer, that Pythagoras conceived the Deity to be the informing soul of the world, animating it in a manner similar to that in which the human soul animates the body.

Subordinate to the Deity, it was taught in the Italic school, that there are three orders of intelligences, gods, demons, heroes, who are distinguished by their respective degrees of excellence and dignity, and by the nature of the homage which is due to them; gods being to be preferred in honour to demi-gods or demons, and demons to heroes or men. These three orders, in the Pythagorean system, were eminences, at different degrees of proximity, from the supreme intelligence, the particles of subtle ether affuming a grocer clothing the farther they receded from the fountain. The third order, or heroes, were supposed to be invested with a subtle material clothing. Heroes defines a hero to be a rational mind united with a luminous body. If to these three species we add a fourth, the human mind, we have the whole scale of divine eminence, as it was conceived by this sect of philosophers. All these they imagined to proceed from God, as the first source of intelligence, and to have received from him a pure, simple, immutable nature. God, being himself one, and the origin of all diversity, they represented him under the notion of Monad, and subordinate intelligences, as numbers derived and included in unity. Thus the numbers or derived intelligences of Pythagoras agree with the ideas of Plato, except, perhaps, that the latter were of a nature perfectly spiritual, but the former were clothed with a subtle ethereal body.

The region of the air was suppos'd by the Pythagoreans to be full of spirits, demons, or heroes, who caused sickness or health to man or beast, and communicate, at their pleasure, by means of dreams, and other inliriments of divination, the knowledge of future events. That Pythagoras himself held this opinion cannot be doubted, if it be true, as his biographers relate, that he professed to cure diseases by incantations. It is probable that he derived it from the Egyptians, among whom it was believed that many diseases were caused by demoniacal possessions.

The material world, according to Pythagoras, was produced by the energy of the divine intelligence. It is an animated sphere, beyond which is a perfect vacuum. It contains
contains spheres, which revolve with musical harmony. The atmosphere of the earth is a grog, immutable, and morbid mias; but the air, or ether, which surrounds it is pure, healthful, serene, perpetually moving, the region of all divine and immortal natures. The fun, moon, and stars, are inhabited by portions of the divinity, or gods. The fun is a spherical body. Its eclipses are caused by the passing of the moon between it and the earth; those of the moon by the intervention of the antichthon, before explained. The moon is inhabited by demons. Comets are stars, which are not always seen, but rise at stated periods.

Concerning man, the Pythagoreans taught, that, con- filling of an elementary nature, and a divine or rational principle, he is a microcosm, or composure of the universe; that his soul is a self-moving principle, composed of two parts, the rational, which is a portion of the soul of the world, seated in the brain, and the irrational, which includes the passions, and is seated in the heart; that man participates in both these with the brutes, which, from the temperament of their body, and their want of the power of speech, are incapable of acting rationally; that the sensitive soul, <sup>δ</sup>ε<sup>υ</sup>ς<sup>η</sup>, perishes, but the rational mind, <sup>η</sup>ε<sup>ω</sup>ς, is immortal, because the source whence it is derived is immortal; that after the rational mind is freed from the chains of the body, it assumes an ethereal vehicle, and passes into the regions of the dead, where it remains till it is sent back to this world, to be the inhabitant of some other body, brutal or human; and that after suffering ineffable purgations, when it is sufficiently purified, it is received among the gods, and returns to the eternal source from which it first proceeded.

The doctrine of the Pythagoreans, respecting the nature of brute animals, and <sup>προ</sup>εκμελ<sup>ε</sup>ται, the transmigration of souls, were the foundation of their abstinence from animal food, and of the exclusion of animal sacrifices from their religious ceremonies. The latter doctrine is thus beautifully reprefented by Ovid, who introduces Pythagoras as saying:

"Morte carent anime: femperque priore relicta
Sede, novis domibus habitant, vivantque receptae.
Omnia mutantur; nihil interit; errat et illuc,
Huc venit, hinc illuc, et quodlibet occupat artus.
Spiritus, eique feris humanae in corpore transit,
Inque feras nostrae; nec tempore deperit ulla.
Utque novis fragilis signatur ceris ignis,
Nec manet ut fuerat, nec formas servat eadem,
Sed tamen ipa eadem eff; animam hic tempore eadem,
Esse, sed in varias doceo migrare signas."  

"What then is death, but ancient matter drest
In some new figure, and a varied veil?
Thus all things are but alter'd, nothing dies;
And here and there th' unbound'd spirit flies,
By time, or force, or sicknesse dispoll'd,
And lodges where it lights, in man or beast;
Or hunts without, till ready limbs it find,
And actuates thofe according to their kind;
From tenement to tenement is tost,
The soul is full the fame, the figure only lost:
And as the soffent'd wax new seals receives,
This face allumes, and that impression leaves;
Now call'd by one, now by another name,
The form is only chang'd, the wax is fill the same;
So death, thus call'd, can but the form deface,
Th' immortal soul flies out in empty space,
To seek her fortune in some other place."

Dryden.
"Periplus of the World," and he is supposed to have written a treatise "De Oceano;" none of these pieces have reached modern times, though some of them were extant in the fourth century. From fragments collected out of Strabo, it appears that Pytheas introduced into them, as the testimony of others, a number of marvellous and incredible circumstances, which drew on him the cenure of that author and Polybius. The last named author maintained it to be utterly impossible for a private person, who was even in want, to have travelled so far as he pretended to have done by sea and land. He, however, probably visited all the countries of Europe that are situated upon the ocean, discovered the island of Thule, or Iceland, and penetrated a considerable distance into the Baltic. This fact has been proved by Gaffendi, who shows, that Pytheas was well acquainted with the northern countries, and accurately marked the distinction of climates, by the difference which he observed in the length of the days and nights in different latitudes. He also attempts to prove that Eratosthenes and Hipparchus improved their geographical works by availing themselves of the labours of Pytheas, without due acknowledgments of their obligations. There is no doubt that Pytheas was a skilful observer of the heavens, for he taught that there is no star in the precise situation of the pole, and he rendered himself famous among astronomers, by being the first calculator of the meridian altitude of the sun at the summer solstice at Marcellus. This fact he ascertained by erecting a gnomon of a given height, and finding the proportion between that height and the length of the meridian shadow. The result was found to correspond exactly with that of an observation made by Gaffendi, at the same place, in the year 1636. To obviate such objections as that advanced by Polybius against the reality of Pytheas' voyages, it has been said, that he probably was furnished with the means of accomplishing them at the public expense. For as the republic of Marcellus was then powerful at sea, largely engaged in commercial pursuits, and sent Euthymenes to make such discoveries in the southern parts of the world, as might lead to the extension of its trade, it seems very probable, that Pytheas was dispatched on the public account into the northern regions for the fame purposes.

PYTHAEUM, in Ancient Geography, a town of Macedonia, in the country of the Peltalogioi. Ptolemy places it between Azorium and Gomus.

PYTHIA, or PYTHIAN, in Antiquity, the priestesses of Apollo, by whom he delivered oracles. See DELPHOS.

She was thus called from the god himself, who was entitled Apollo Pythius, from his slaying the serpent Python; or, as others have it, από τον τοιμαστόν, because Apollo, the fun, is the cause of rottenness; or because the carcass of Python was left there to putrefy; or, according to others, from τον τοιμαστόν, I inquire, because people went to hear and consult his oracles.

This priestess was to be a pure virgin. She sat on the coverlet, or lid, of a brazen vessel, mounted on a tripod; before she ascended which, after falling three days, she used to wash her whole body, and especially her hair, in Caltaio, a fountain at the foot of Parnassus, where the poets, men inspired by the same deity, used to wash, and drink; and thence, after flaking the laurel-tree that grew by it, and sometimes eating the leaves, which were supposed to conduct to inspiration, and were succeeded by a violent enthusiasm, she delivered her oracles, or rather explained those of the god; i.e. she rehearsed a few ambiguous and obscure verses, which were taken for oracles. The oracle being pronounced, she was taken down from the tripod and conducted back to her cell, where she continued for several days, to recover herself from the violent agitation and conflict. Lucan informs us, that that speedy death was frequently the consequence of her enthusiasm. See ORACLE.

Diodorus Siculus (ib. xvi.) informs us, that these priestesses were at first virgins, but that after one of them was disfigured by Echecrates, a Thessalian, choice was made of women above fifty years of age; that so they might either be secured from the attempts of luft, or if they should at any time he forced to the violation of their chastity, having paused the time of child-bearing, they might remain undiscovered, and not bring the oracles or religion into contempt; nevertheless they wore the habit of virgins, thereby to signify their purity and virginal modesty.

"All the Pythian did not seem to have had the same talent at poetry, or to have memory enough to retain their vision. Plutarch and Strabo make mention of poets, who were kept in pay, as interpreters of Jupiter, &c.

PYTHIA, or PYTHIAN Games, were solemn games instituted in honour of Apollo, and in memory of his killing the serpent Python with his arrows.

The Pythia were celebrated in Macedonia, in a place called Pythium. They were next in fame after the Olympic games, but were more ancient than they; for it is pretended they were instituted immediately after the defeat of the serpent. The Pythia were also celebrated at Delphi; and they were thefe that were the most renowned. Their first foundress, and the precise time of their institution, are not known.

The Pythian games, according to Panthianas, were first instituted by Alcon or Dionysus, king of Etolia, and restored by Eurylochus of Thebally, in the third year of the 48th Olympiad, or the year of the world 3356, and 58 years before the birth of Christ; from which time the Greeks reckoned sometimes by Pythiades, as they had been accustomed to do by Olympiad. They were at first celebrated every eight years, but afterwards every four years, in the third year of each Olympiad; so that the pythiades, which was a term of four years, served as an epocha for the inhabitants of Delphi. At first they consisted of poetical and musical contests, but in process of time they consisted of the other exercises of the panathenium, which were performed in the Olympic games. The victors were crowned with branches of laurel; though, at the first institution, the crown was of beech-leaves. The Romans are said to have adopted these games in the year B.C. 642, and to have given them the name of Apollinares ludi.

A part of Pindar's poems was composed in praise of the victors in the Pythian games. See GAMES.

The critics are divided on the subject of the serpent Python. The poets say, that Juno made use of it to perfect Latona, and prevent her bringing into the world Apollo and Diana, whom she had conceived of Jupiter; and that it was for this reason that Apollo afterwards killed it.

Strabo says, it was no other than a famous villain, one Draco, that Apollo freed the world from. Dickin son, in his "Delphoi Phoenicizantes," maintains the Python of the Greeks to be the Typhon of the Phoenicians; and the Typhon of the Phoenicians to be the Og of Scripture; and Apollo, who slew it, he will have to be Jofha. See TYPHON.

PYTHON, in Ancient Geography, a name anciently given to the city of Delphi.

PYTHOPOLIS, a town of Asia Minor, in Bithynia, on the river So loa, according to Plutarch, founded by Theseus.
PYX

PYXIS, a small metal cæs for containing the consecrated species in the Catholic church. Anciendy it was made in the form of a dove and suspended over the altar.

PYXUS, in Ancient Geography, a small river of Italy, in Lucania; which took its rise northward towards Sontia, and running southward discharged itself into a gulf of the same name, E. of Pyxus, or Pyxuntum.

PYXUS, or Pyxuntum, Poli-Coffera, a town of Italy, belonging to Lucania, situated at the bottom of a small gulf, E. of a small river of the same name. It was founded by Mirathus, prince of Zancio and Rhegium, in the year 471 B.C. It became a Roman colony in the year 194 before the same era.

PYXUS Promontorium, a small cape of Italy, E. of a peninsula of Laconia, which had on the W. the promontory Palinarum. This promontory is found at the entrance of a small gulf of the same name.

PYZINEMIN, in Geography, a town of Bohemia, in the circle of Boleslav; 12 miles E. of Jung-Buntzel.

PYX

PYXIDANTHERA, in Botany, from πυξίς, a box, and ἄνθερα, an anther, because, according to Michaux, each cell of the anthers opens by a sort of lid; see DIAPENSA, to which genus the plant in question is referred by Mr. Pursh, in his Fl. Amer. Sept. v. i. 148, under the name of D. cunefolia, after Mr. Salisbury.

PYXIS NAUTICA, in Navigation, the seaman's compass.

The word πυξίς literally signifies a box.

Pyxis, among Anatomists, is also used for the cavity of the hip-bone. See ACETABULUM.

PYULCON, from πυλον, put, and ἀνάκειν, to drawr, an old surgical instrument anciently employed for drawing the matter out of supposes.

PYURIA, in Medicine, from πυρος, fire, and νυρία, urine, a term used by Sauvages and others to denote all purulent and mucous discharges from the bladder. See CATARRHUS Venere.

Q. A consonant, borrowed from the Latin or French, for which the Saxons generally used cp, cuw; and the sixteenth letter of the alphabet.

The name of this letter is cuw, from cuwe, Fr. tail; its form being that of an O with a tail.

The Q has this peculiar to it, that it is always followed by an U, and is therefore reckoned among the mutes.

The Q is formed from the Hebrew p, koph; which most other languages have borrowed; though some of them have rejected it again, particularly the Greeks, who now only retain it as a numeral character, called ρότον κέφαλην.

In effect, there is that resemblance between the Q and the C, in some languages, and the K in others, that many grammarians, in imitation of the Greeks, banish the Q as a superfluous letter. Pappus even afirms, that all the Latin words now wrote with a Q, were written among the ancient Romans with a C; but we want better authorities for this.

For, though that may hold in many cases, infomuch that some write indifferently querv, or cuw; cum, or quum; quodidic, or cedidic, &c. yet it does not thence follow, that they ever wrote cew, cuw, cew, for guw, guw, quid. What inscriptions authorize such a reading?

Far from this, the ancients sometimes substiuted Q for C; and wrote querv, cuw; for cuw, cuw, &c.

Varro, however, and some other grammarians, as we are told by Centorinus, &c. would never use the Q. The truth is, its use or disuse seems to have been a little settled, and agreed on, that the poets used the Q or C indifferently, as best suited their measures; it being a rule, that the Q joined the two following vowels into one syllable; and that the C imported them to be divided.

Hence it is, that Lucretius uses cewret for three syllables, in lieu of cuwret; cuw, for aqua; and that Plantus uses relicium, for relictum; as in quod dedit, datum non vellem relicium Vol. XXIX.

Q. A double letter, as well as K and X. According to them, Q is evidently a C and U joined together. It is not enough that the found is the same, but they give the traces of the C U in the figure of the Q; V being only laid obliquely, as to come within the cavity of the C; as Q —

To confirm this, they say the ancients wrote qi, qe, qid. Though Jof. Scaliger, Littleton, &c. think this is no proof of the point; for in Gruter's inscriptions we find not only the Q, but also the C, put for Q U; as Cepius, Quintus; &c. in fuis, &c. Yet nobody ever imagined the C a double letter.

Q, among the Ancients, was a numeral letter, signifying 500; as in the verse,

"Q velut A cum D quingentos vult numerare."

A daub over it, as Q, denoted it to signify five hundred thousand.

Q is also used as an abbreviation in several arts. Q, p, in physicians' bills, stands for quantum placit, or quantum vortis, as much as you please of a thing; q, f, for quantum sufficit, or as much as is necessary.

Q, in the proper names of the Romans, signifies Quintus, or Quintius. Upon the French coins this letter denotes that they were struck at Perpignan.

S

Q seems
Q seems the initial of no word in Music, except in old madrigals, where it frequently is placed at the top of the page for *quinta pars*, the fifth part, in a polyphonic composition.

Q. D. is frequently used, among *Grammaticus*, &c. for *quod dictum*, as if it were said, &c. or as who should say.

Q. E. D. among *Mathematicus*, signifies *quod erat demonstrandum*, which was to be demonstrated.

*Q. E. F. quod erat facientium*, which was to be done.

*QUAB*, in *Ethiography*, the name of a Rutilian fish, which some report to be at first a tadpole, then a frog, and at last a fish. Dr. Monney, who made many enquiries concerning these pretended changes, apprehends that they are all fabulous. He had an opportunity of seeing the fish itself, and found that they spawn like other fishes, and grew in size, without any appearances to justify the report. He adds, that they delight in very clear water, in rivers with sandy or stony bottoms, and are never found in standing lakes, or in rivers passing through marshy or molly grounds, where frogs choose moll to be.

*Phil. Trans. vol. xliv. p. 175*.

*QUABES*, in Geography, a people of Africa, in the interior country between Rio Sellos and Sierra Leone, inhabiting the southern banks of the river Sellos. They had been formerly conquered by Placido, King of Folgia; but having thrown off their subjection, they have since resided a free people, though under the protection of the emperor of Mocon, or Mons; which empire is called by English geographers, and also by M. d'Anville, Mendin Monoes. *See Equus.*

*QUACHIO*, or *QUACIO*, in Zoology. See *Equus.*

*QUACHIETO*, in Ornithology, the name of a very beautiful Brazilian bird, of the moor hen kind, called allo *vaccinina*, and *porphyrio Americanus*. It is the *Fulica purpurea*, (which fee) and is of a fine blackish purple colour, variegated with white; its beak is white while young, but becomes red as it grows older, and has a naked space at its base, resembling, in some sort, the coot; its legs are of a yellowish-green; it lives about the waters and feeds on fish, yet is a very well-tailed bird. It imitates the crowing of a common cock, and makes its musick early in the morning.

*Margrave's Hill*, Brazil.

*QUACHY*, or *QUACHIO*, a name given to the *Cotai*, or *Viverra Naja*, which see.

*QUACK*, in Medicine. See *Empyre.*

*QUACKENBRUCK*, in Geography, a town of Welfpa, in the bishopric of Osnabruk, situated on the river Habe, which runs through it in seven streams, that unite in two below the town; 20 miles N. of Osnabruk. N. lat. 51° 42'; E. long. 8° 39'.

*QUADANS*, *QUANDI*, in Ancient Geography, a people of Germany, whose territories extended from the Danube to Moravia, and the northern part of Austria. They are comprehended by some writers under the ancient name of Suevi, part of whom forced their way into Spain, and formed a kingdom there. Their country is at present known by the name of Moravia; for it extended from the mountains of Bohemia to the river Marus, now the March, and consequently comprised that province. Ptolemy mentions the following cities in the country of the Quadans; 498. Ebur-rodunum, Eburum, Medoslumium, and Celemanita, now, according to Cluerius, Brivo, Olmutz, Znaim, and Kalmun. The Quadans were a warlike people, had kings of their own, and agreed in customs, manners, and religion, with the other German nations. They, without doubt, joined their countrymen against Lollins, Germanicus, Catus, and Galba, who attempted to reduce Germany, and to subdue the several nations which inhabited that extensive country. The emperor Domitian marched against them, but was defeated by the Marcomans, and put to flight. The Quadians submitted to the emperor Titus Antoninus, and it appears by his coins, suppos'd to have been struck about the year 139, that they acknowledged, as sovereign, a king appointed by that prince. They joined the Marcomans, in the famous war made by that people on the empire under the reign of Marcus Aurelius; but being reduced to great distress, they sent ambassadors to sue for peace, and with them they restored all the Roman defaters, and about 13,000 prisoners, whom they had taken during the war. They thus obtained peace, upon condition, that they should not traffic, for the future, within the Roman dominions, nor settle within six miles of the Danube; but, differing those conditions, they again joined the Marcomans, and renewed the war. In the preformation of that extent, which was long and singular, they were totally defeated; their king Asiaticus was taken prisoner; but the emperor spared his life, confining him to the city of Alexandria, the metropolis of Egypt. The Quadians, however, seem to have continued in arms till the reign of Commodus, who granted them peace upon the following terms: that they should keep at the distance of five miles from the Danube; that they should surrender their arms, and supply the Romans with a certain number of troops when required: that they should assemble but once a month in one place, and in the presence of a Roman centurion; but that they should not make war upon the neighbouring nations without the consent of the people of Rome. In the year 214, the king of the Quadians was Gauboma, who was assassinated by order of Caracalla. In the 4th year of the reign of the emperor Valerian, the Quadians joined the Sarthians, and invading Illyricum, ravaged that province; but they were defeated by Probus, then tribune of a legion, and afterwards emperor. In the year 260, the 7th of the emperor Gallienus, they made a sudden irruption into Pannonia, but they were expelled, without their booty, by Regillianus. Upon the death of Probus, who held the barbarians in awe, A.D. 283, the Quadians, in conjunction with the Sarthians, broke into Illyricum and Thrace, and having ravaged those provinces, and advancing towards Italy, they were met by Carus, the successor of Probus, on the borders of Illyricum, and totally defeated; 16,000 being killed on the spot, and 20,000 being taken prisoners. In the 19th year of the emperor Constans, the Quadians made an irruption into Pannonia and Moesia; and having pillaged both provinces, returned home with an immense booty. They returned again in two years, and laid waste Valeria. Constans was provoked by these invasions, and leaving Milan, advanced to the confines of the Quadians, and conferred with their chiefs, who excused past hostilities, and promised, for the future, to live in peace and amity with the emperor. They soon, however, forgot their promise; and in the following year joined the Sarthians, and laid waste a great part of Pannonia and Moesia; but at the approach of Constans, they repelled the Danube, and returned home. The emperor determining to punish them for their treachery, passed the Danube on a bridge of boats, and began to destroy their country. The Quadians, unable to resist, fled for peace, and obtained it, upon delivering up hostages, and setting at liberty all the prisoners they had taken. In the year 374, their king Gabinus being treacherously murdered by America and duke of Valeria, they crossed the Danube in the utmost rage, and falling upon the reapers, in harvest time, killed the greatest number of them, laid waste the country, and took many captives. They afterwards followed Equitius, general of the troops in Illyricum, who had been
accesory to the murder of their king, into Valeria, and
committed dreadful devastations in the countries through-
which they passed. In their way they met with two legions,
the Pannonian and Moesian, who had been sent to oppose
them, and taking advantage of a contest which suffused among
them about precedence, they cut them both in pieces.
In this irruption the Quadrians had been joined by the Sar-
mations; but the latter were defeated with great slaughter
by Theodosius, then duke of Moesia, and afterwards em-
peror. Again, the Quadrians Valentinian I. marched in
person; and having made great preparations for his pro-
posed expedition into their country, he took the field;
pulled the Danube at Acinum, now Gran, or Buda, in
Lower Hungary, entered the enemy's country, and de-
stroyed it with fire and sword. At length, the Quadians
faced for peace; but whilst the emperor was speaking to the
messenger with great warmth, and threatening to extirpate
their whole nation, he fell to the ground in a fit, and soon
afterwards expired. Upon his death a treaty was con-
cluded with the Quadrians. Their refractory spirit and dif-
position for war manifested themselves again in the year 379,
when they invaded Illyricum; but they were driven out,
with some losses, by the emperor Gratian. In 407 they
entered Gaul with the other barbarians, over-ran its pro-
vinces, and committed dreadful ravages. From this time
no farther mention is made of the Quadrians; so that they
were either subdued, or utterly extirpated by the Goths,
vol. xvi.

QUADRA, in Buildings, any square border, or frame,
encompassing a baffle-releive, panel, painting, or other
work.
The word is also used, erroneously, for a frame or bor-
der, of any other form; as round, oval, or the like.
QUADRA and VANCOUR's Island, in Geography, a name
given to the island of Nootka, in compliment to gnor
Quadra, the Spanish commander at Nootka Sound, and
captain Vancouver, who expected to obtain possession of
the settlement in the year 1792. See NOOTKA, and NOOTKA
Sound.

QUADRAGESIMA, a term sometimes used for the
time of Lent, because confining of forty days.
Hence some monks are said to lead a quadragesimal life;
or to live on quadragesimal food all the year.
QUADRAGESIMA Sunday is the first Sunday in Lent; so
called because it is about the fortieth day before Easter.
On the same account, the three preceding Sundays are
called Quinquagesima, Sexagesima, and Septuagesima.

QUADRAGESIMALS, QUADRAGESIMALS, denote
Mid-laent contributions, or offerings.
It was an ancient custom for people to visit their mother-
church on Mid-lent Sunday, and to make their offerings at
the high altar; and the like was done in Whit-fun-week.
But as these latter oblations, &c. were sometimes commuted
for by a payment of penceollars, or Whit-fun-farthings; so
were the former also changed into a customary payment,
quadrageminals, demaries quadragesimals; and sometimes
Letare, Jerusalem, from a hymn so called, sung on that
day, beginning"Jerusalem, mater omnium," &c.

QUADRANGLE, in Geometry, a quadrangular, or
quadrilateral figure; or a figure which has four sides, or
four angles.

To the classs of quadrangles, or quadrangular figures,
belong the square, parallelogram, trapezium, rhombus, and
rhomboids.
A square, &c. is a regular quadrangle; a trapezium, an
irregular one.

Quadrangular figures are not proper for fortification; the
flanks, and flanked angles, being too small.
QUADRANGULARIS PISCIS, the Square-fish, in
Ichthyology, the name of a fish, which, in its most usual fize,
is about fifteen inches long, four inches high in the middle,
and three inches and a half over; the forehead is square, a
little hollow, and, by the eminence of the eye-brows, two
inches and a half over; the nose blunt, and not very steep,
with two holes in the place of nostrils, and the mouth very
small; the back is a little convex toward the tail, and on the
sides a little obtusely angled; as is also the belly, which is
plain and flat, and a little rising toward the tail; it has five
fins, two near the gills, two near the tail, and the tail-fin,
which is considerably long. Part of the head and tail are
covered with a soft skin, the rest of the body with a kind
of stunt, adorned all over with little round knots, reduced
for the most part into hexagonal figures, and subdivided

QUADRANS, in Antiquity, the fourth part of the ar, or
pound. See AS.

QUADRANS, in our Cusoms, is the fourth part of a penny
or a farthing.

QUADRANT, QUADRANS, in Geometry, an arc of a
circle, containing 90 degrees, or one-fourth of the entire
periphery.
Sometimes, also, the space, or area, included between
this arc and two radii, drawn from the centre to each ex-
tremity thereof, is called a quadrant, or, more properly, a
quadrantal space; as being a quarter of the entire circle.

Quadrant also denotes a mathematical instrument, of
great use in navigation and altronomy: for the taking of al-
titudes, and angles, &c.
The quadrant is variously contrived, and furnished with
different apparatus, according to the several uses for which
it is intended; but they have all this in common, that they
conform toa quadrat, or quarter of a circle, whose limb is
divided into 90 degrees; and that they have a plummet sub-
vented from the centre; and are furnished with pinnaule or
fights, through which to look.

QUADRANT, the Common, or Surveying, (represented
Plate VI. Surveying, fig. 13.) is made of brafs, wood, or
other material, usually twelve or fifteen inches radius. Its

The quadrant is variously contrived, and furnished with
different apparatus, according to the several uses for which
it is intended; but they have all this in common, that they
conform to a quadrat, or quarter of a circle, whose limb is
divided into 90 degrees; and that they have a plummet sub-
vented from the centre; and are furnished with pinnaule or
fights, through which to look.

On the under side, or face, of the instrument, are fitted
a ball and socket; by means of which it may be put in any
position, for use.

Besides the essentials of the quadrant, there is frequently
added on the face, near the centre, a kind of compartment,
called the quadrat, or geometrical figure; as in the figure:
this, in some measure, making a distinct instrument of itself.
See its description and use under the article Quadrat.
The quadrant is to be used in different situations, ac-
cording to the dimensions to be taken. To observe heights
and depths, its plane is disposed at right angles to the ho-
rizon; but to take horizontal distances, the plane is disposed
parallel to it.

Heights and distances, again, may be taken two ways;
Thus application of the fixed sights and plummet, and by the label.

**Quadrant, Use of the Surveying.** To take the height or depth of an object with the fixed sights, and plummet.—Place the quadrant vertically, and the eye under the fight next the arc of the quadrant; thus direct the instrument to the object, e. g., the top of a tower, till the visual rays of it strike through the fights upon the eye.

This done, the portion of the arc intercepted between the thread and the semidiameter, on which the sights are fastened, shows the complement of the object's height above the horizon, or its distance from the zenith; and the other portion of the arc intercepted between the thread and the other semidiameter, shows the height itself of the object above the horizon.

The same arc likewise gives the quantity of the angle made by the visual ray, and a horizontal line, parallel to the base of the tower.

Note, to observe depths, the eye must be placed over that fight next the centre of the quadrant.

From the height or depth of the object in degrees thus found, which suppose 35° 35'; and the distance of the foot of the object from the place of observation carefully measured, which suppose 47 feet; its height or depth in feet, yards, &c., is easily determined by the most common cafe in trigonometry.

For we have here, in a triangle, one side given, viz., the line measured, and we have all the angles; for that of the tower is always supposed a right angle; the other two, therefore, are equal to another right angle; but the angle observed is 35° 35', therefore the other is 54° 25'.

The cafe, then, will be reduced to this: as the fine of 54° 25' is to 47 feet, so is the fine of 35° 35' to a fourth term, viz., 33$\frac{1}{2}$ feet; to which add the height of the observer's eye, suppose 5 feet; and the sum, 38$\frac{1}{2}$ feet, is the height of the tower required.

**Quadrant, the farther use of the, in taking of altitudes of objects, both accessible and inaccessible, see under the article Altitude.**

**Quadrant, Use of the, in taking heights and distances by the index and fights.**—To take, e.g., a height, as that of a tower whose base is accessible; place the plane of the instrument at right angles to the plane of the horizon, and one of its edges parallel to it, by means of the plummet, which, in this case, will hang down along the other. In this situation turn the index, till, through the fight, you see the top of the tower; and the arc of the limb of the quadrant between that side thereof parallel to the horizon and the index will be the height of the tower in degrees; whence, and from the distance measured as before, its height in feet, &c., may be found by calculation, as in the former case: or, without calculation, by drawing from the data, on paper, a triangle similar to the great one, whose base is the distance; and its perpendicular, measured on the scale, is the height of the tower.

**Quadrant, Use of the, in measuring horizontal distances.**—Though the quadrant be a less proper instrument for this purpose than a theodolite, semicircle, or the like, because angles greater than quadrants cannot be taken by it, yet necessity sometimes obliges persons to have recourse to it.

The manner of its application is the same with that of the semicircle; all the difference between the two instruments consisting in this, that the one is an arc of 180°, and can therefore take an angle of any quantity; and the other is only an arc of 90°, and is therefore confined to angles of that quantity. See, therefore, Semicircle.

**Quadrant, in Astronomy, is an instrument by which the altitude of a heavenly body is measured, and is composed of one-quarter, or one-eighth of a circle, accordingly as the measurement is made by means of direct vision, or by the reflected image of the object to be viewed.** When a suspended circle was made use of with revolving fights, called an altimeter, the accuracy of an observation could never be depended on, partly because the radius was small, and partly because the instrument vibrated when suspended by the hand, and was otherwise inconvenient to use, as well as liable to have its equinoctial disturbed by the various positions of the index and fights: therefore, such a portion of the circle was adopted as was competent to measure the greatest possible altitude, and an increase of radius was thereby obtained, which promised to contribute to accuracy, without affecting the portability of the instrument. But though the construction was varied by different ingenious men, the quadrant was but little, if at all, conducive to the improvement of nautical or of astronomical science, till the application of telegraphic fights, and an improved mode of gradually the limb, together with the addition of a vernier scale, gave it powers on which the mariner and astronomer could confide. Quadrants have been constructed of different materials, such as wood, ivory, brass, &c., and of various dimensions, agreeably to the uses for which they were intended, in order to accommodate purchasers of every denomination; but as it is not our province to notice every plaything that has usurped the appellation of quadrant, we will confine our account to such instruments chiefly as have been of actual service in navigation andapeutics. We have, however, already anticipated the history, we might have here introduced, of the various improvements successively made in quadrants, at the beginning of our article Circle; and under the article Graduation we have given, at considerable length, the different methods of dividing and subdividing astronomical instruments in general; to which articles we beg to refer our readers, who wish for information on those points, and which may be read in conjunction with our present article.

Our arrangement of quadrants will be most systematic, if we divide them into two classes, viz., those which measure altitudes by direct vision, and those which determine measurements in all directions, vertically, horizontally, and obliquely, by means of reflection. The former classes have been found useful in astronomy chiefly, and the latter in navigation, where the motion of a ship interferes with theReadiness of any fixed position of an instrument.

The first quadrant, in its rude state, was probably a quarter of the altimeter enlarged, with fixed sights placed in, or parallel to, the vertical line passing through zero; and a fine thread, or wire, stretched by a plummet, indicated the altitude on the divided limb, according to the representation in fig. 4, of Plate I. of Astronomical Instruments. This construction might be used in observations of the sun, without injuring the eye of the observer, by allowing the polar ray to pass through the first fight, or, to a fall on the second, at some distance from the former, while the thread rested nearly in contact with the elevated limb; but the want of minute, and at the same time accurate subdivisions, and the sensible thickness of the thread, were impediments to accuracy that did not admit of remedy, until another mode of reading the altitudes was devised, and until a method was contrived of rendering the light of the sun tolerable to the eye of an observer. The former of these deficiencies was accomplished first by diagonal scales, with a fiducial edge of an index, and afterwards by that admirable contrivance, sometimes called a Nonius, but more properly denominated a Vernier, from the name of its inventor;
ventor; the latter was effected by semi-opaque glasses, introduced at first without, but afterwards, with better effect, with telescopic glasses; at the same time, enlarging the visual angles subtended by the fun, and yet diminishing the intensity of his light by a partial transmission through the smoked or coloured glasses.

Davis's Quadrant, or Back-Stiff.—In the year 1590, captain John Davis, a native of Sandridge, near Dartmouth, previously to his falling into the South seas under the command of Mr. Cavendish, contrived that instrument, which is represented in fig. 2. of Plate I. of Astronomical Instruments, and which has been called the English quadrant, or back-stiff. This instrument differed with the use of the plumb-line, and consequently was better adapted to nautical purposes than the old quadrant, or than the fore-quadrant, that preceded it; but wanted the telescopic glasses, which have given subsequent instruments the advantage over it. It was, however, probably the first quadrant in which the horizon was used as one of the objects in a back observation, and from which the reflecting instruments afterwards borrowed an useful principle, where altitudes are concerned; though it was in the use of the fore-quadrant (described under our article CIRCLE), that the horizon was first made one of the extreme limits of an altitude, taken by a forward observation. Captain Davis found that pear-tree answer'd very well as the material on which his instrument was constructed, and an ingenious arrangement of two divided arcs and three vanes constituted his plan, according to the following description. The vane at A was called the horizon-vane; the one seen at B the fheade-vane, because its shadow fell on the horizon-vane during the instant of completing an observation; and the third, at C, was denominated the light-vane, by reason of its being the vane to which the eye was applied in taking an observation. The arc of smaller radius, DE, contained 60°, and the other, FG, of larger radius, contained only 30°, in continuation of the former, making together the whole quadrant. The arc DE was divided into whole degrees only, on account of the smallness of its radius; but the arc FG had its degrees subdivided by concentric and diagonal lines, as seen in the figure. The manner of ascertaining the altitude of a heavenly body, by the joint use of these two arcs, is not obvious at first sight of the instrument, but may be thus explained. When the altitude of the sun is taken, the horizon-vane is fitted to the extreme end or centre A of the quadrant, and the fheade-vane B put to within about 10° or 15° of the supposed co-altitude, but to a less quantity than the co-altitude, while the fight-vane remains for adjustment on the arc FG. Things being in this state, the back of the observer is turned to the sun, and the quadrant is so elevated, that the shadow of the upper edge of the fheade-vane falls upon the upper edge of the slit in the horizon-vane A, when viewed through the small hole in the fight-vane. If now, in this situation, the horizon is seen through the fahd slit, the observation is exact; but if not, the fight-vane is moved backwards or forwards on the arc FG, accordingly as the sky or sea is seen, till the horizon appears in its place, while the shadow of the fheade-vane rests on the required situation in the slit of the horizon-vane, and then the observation is finished; and the sum of the two readings on the respective arcs, B and C, as read by the fiducial edges of the vanes, is the co-altitude or zenith distance of that limb of the fun, upper or lower, which was observed from the corresponding limb of the shadow. If a lens, of a focal length equal to the radius of the smaller arc, were used, the focal luminous point occasioned thereby would be a better object to measure the place of, than a shadow with an edge not sufficiently defined. This instrument, it should seem, was not capable of taking the altitude of a star or planet, nor of the moon, unless her disc was large enough at the time to project a shadow.

Elton's Quadrant.—An index bearing a spirit-level, with a vernier scale near the fight-vane, was added to the quadrant of Davis some time afterwards, by one Elton, the use of which was to take altitudes without an horizon; but the similarity of the two instruments renders a more particular description of this addition superfluous. An inspection of fig. 8. Plate I. will sufficiently explain the difference.

Gunter's Quadrant.—Among the numerous and useful contrivances of the ingenious professor of astronomy in Gresham college, was a portable quadrant, which now claims our attention, and which was contrived in or a little before, the year 1618. The object of the inventor was not to construct an instrument capable of measuring altitudes more accurately than that of captain Davis, which we have just described, but to make a quadrant so comprehensive in its uses, that, like the logarithmic fcale, which he divided, it might be used by inspection only, required long and tedious calculations; and in this point of view it is still to be considered. Besides the quadrantal arc for measuring altitudes, this instrument has various curves stereographically projected on it, such as the equator, the tropics, the ecliptic, and the horizon, on a supposition that the eye is situated in one of the poles, all which are represented in fig. 3. of Plate XXIII. of Astronomical Instruments. The projection, according to Dion, is thus effected; when the quadrantal arc BC has been graduated, from its centre A, with a convenient radius AT, describe the arc TD to represent one of the tropics; and let the line AT be taken as the tangent of 56° 40', or half the fun's greatest declination (supposing here to be 23° 32'), added to the radius or tangent of 45'; then to find the point E in this line for the equinoctial, there will be this proportion, as the tangent of 56° 40'; 1000 :: radius; 6555; and therefore, if 5300 parts of the line AT be taken, it will be the proper radius of the arc EF, or equinoctial.

To find the centre of the occult arc ED, which represents the ecliptic, let the meridional line AD be divided by the point G, that if AF be taken as radius, AG may be the tangent of 23° 32', the fun's greatest declination; in which case AG will be 5300 of the line AF, and the occult arc ED described from the point G will be one-fourth of the ecliptic, which may be divided into signs and degrees thus: as radius is to the tangent of any degree's distance from the nearest equinoctial point, so is the co-line of the fun's greatest declination, to the tangent of that degree's right ascension; for example, supposing the right ascension of the first point of A to be 27° 54', draw a line from A, the centre of the quadrantal arc, to this degree and minute on the said arc, and note where it intersects the occult arc of the ecliptic, and this point will be the beginning of the sign; and in like manner any other part may be inferred. The line ET, or line of declination, may be divided thus; taking AE for the radius of the equinoctial, or tangent of 45°, let the tangents of 46°, 47°, 48°, &c. up to 68° 30', be successively taken and laid down on the line ET, and the points of excess above the tangential point of 45° will be the dividing lines of the scale for 1°, 2°, 3°, &c. up to 23° 32', or greatest declination.

When the scale of declination is finished, the quadrantal arc may be taken as the measure of right ascensions, and then the place of a star or any other heavenly body may be inferred on the plane of the quadrant thus: let a line be drawn
drawn from $A$ to the degree and minute of right ascension, counted from $B$ towards $C$, and the point in this line, where an occult arc, drawn through the declination from the centre $A$, intersects it, will be the place of the heavenly body in question.

The two parallel arcs contained between the tropic $T$ and the quadrantal arc $B C$, are the scales of days and months, which are divided by the aid of a table of meridian altitudes of the sun for each day, calculated for the particular latitude, for which the quadrant is constructed. It is hardly necessary to observe, on the construction of such table, that if the latitude and declination be both north, or both south, the declination must be added to the co-latitude for the greater altitude; but if of contrary denominations, subtracted. The degrees and minutes contained in such table are transferred into the scale of months by a line extending across it from the centre $A$ to the quadrantal arc, as before.

The centre of the horizon will be in the meridional line $A C$, and if a point $B$ be taken such, for the co-latitude $38^\circ 28'$ for instance, that $A H$ may be the corresponding tangent to radius $A F$, then $\frac{1}{2} A H$ of that radius will be its distance from $A$, and the occult arc described from $H$, with the extent $H E$, beginning at $E$ in the equinoctial, and ending at the tropic $T$, will be the required horizon. This horizonal arc may be divided thus; as radius is to the fine of the latitude, so is the tangent of any number of degrees in the horizon, to the tangent of a corresponding arc in the quadrant; and from a table thus constructed any point in the horizon may be put in by interection of a line drawn from $A$ to the tabular number as read on the quadrantal arc, as in the former cases.

A third table of the sun's altitude for inferring the hour lines may be calculated thus; when the fun is in the equator, as radius is to the co-fine of the latitude, so is the co-fine of any hour from the meridian, to the fine of the sun's altitude at that hour; but when the fun has declination, say, as the co-fine of the hour from the meridian is to radius, so is the tangent of the latitude, to the tangent of a fourth arc; then if the latitude and declination have like denominations, and the hour fall between noon and fix o'clock, subtract the declination from the said fourth arc, and the remainder will be a fifth arc; but if the latitude and declination have unlike denominations, or the hour be between fix and midnight, add the declination to the fourth arc, and the fun will be a fifth arc, which must be thus used; as the fine of the fourth arc, is to the fine of the latitude, so is the co-fine of the fifth arc, to the fine of the altitude sought. The determination of such table by this fundamental method is however operose, and Margett's horary tables, which give the successive altitudes in any given latitude, would greatly shorten the labour, by giving the results by inspection, which may at the same time be inferred by transfers from the quadrantal arc, similar to those we have already described. When the horary points are put in for each successive hour, when the fun is in the equator, at each tropic, and at a few intermediate places, the horary lines may be drawn through the said points, which will give the hour for any given day, when the instrument is used as hereafter described.

A fourth table, for putting in the azimuth lines, will require the sun's altitude to be calculated for each degree of azimuth, when the fun is at the equator, at each tropic, and at other intermediate places, which may be done thus: when the fun is in the equator, as radius is to the co-fine of the azimuth from the meridian, so is the tangent of the latitude, to the tangent of the sun's altitude at the azimuth in the equator; but out of the equator the rule is, as the fine of the latitude, is to the fine of the declination, so is the co-fine of the sun's altitude at the equator, to a given azimuth, to the fine of a fourth arc. When the latitude and declination have the same name, in all azimuths from the prime vertical to the meridian, add this fourth arc to the arc of altitude at the equator; but when the azimuth is below $90^\circ$, subtract the altitude at the equator from this fourth arc; also when the latitude and declination have unlike names, subtract the said fourth arc from the arc of altitude at the equator, for the altitude of the propos'd azimuth. The points corresponding to the tabular numbers, thus ascertained, must be inferred by interection of lines drawn from $A$, as before, to the quadrantal arc $B C$, and lines uniting those points will be the lines of azimuth for each hour in every day of the year. But to complete the instruments, two sights or vanes must be fixed on the meridional line $A C$, and a small plumb-line, with an adjustable bead, must be furnished from the point $A$ of the quadrant.

In addition to the lines already described, Gunter's quadrant has sometimes a square under the angular point $A$, called a quadrat, as seen in the figure, two sides of which are divided into ten equal parts each, and these again subdivided into others, the use of which is to measure angular distances; and sometimes the large square is subdivided into a number of smaller ones, for the purpose of performing arithmetical proportions by inspection. See Bion on the Construction and principal Uses of Mathematical Instruments.

It would be tedious to enumerate all the uses of this quadrant, and to exemplify all the problems that it is capable of performing, or rather of illustrating (for great accuracy cannot be expected in the indication of so small an instrument); but we will specify a few of the most useful, which may be varied by reversing the processes, and by altering the data, to a great extent.

**Problem I.** To find the Sun's Right Ascension.

Stretch the thread from the point $A$ over the sun's place, as marked in the graduated ecliptic, and the degree cut by it in the quadrantal arc will give the corresponding right ascension.

**Problem II.** To find the Sun's Declination.

Stretch the thread as before, and slide the bead till it rests on the sun's place for the given day, and then turn it to the scale of declination, where the corresponding degree will be seen under the bead.

**Problem III.** To find the Sun's Meridian Altitude on any Day.

Extend the thread over the day of the month given, in its proper scale, till it reaches the quadrantal arc, and the sun's greatest altitude for that day will be indicated thereby.

**Problem IV.** To find the Hour of the Day.

Extend the thread over the day of the month, and, holding it there, slide the bead till it lies on the line of twelve o'clock; then elevate the quadrant so that the solar ray may pass through the upper right-hole exactly upon the second, and allow the plummet to rest, and then the bead will indicate the hour, before or after noon, as the case may be. In a similar manner the sun's altitude may be measured by the thread falling on the quadrantal arc, when the solar ray paffes as above described.

**Problem V.** To find the Sun's Amplitude.

Let the bead be rectified for the given time, and be brought
brought afterwards to the horizon, while the thread remains stretched, and it will indicate the rising or setting amplitude, as the case may be.

**Prob. VI. — To find the Ascensional Difference.**

Rectify the head as in the last problem, and bring it to the horizon, in which situation the thread, extended to the quadrantal arc, will show the ascensional difference in degrees, which converted into time will show how much the sun rises before fix in summer, and after fix in winter, and consequently will give the exact length of the given day.

**Prob. VII. — To find the Sun’s Azimuth.**

Rectify the head for the given time, and observe the sun’s altitude as explained in prob. 4. Then extend the thread to the complement of that altitude, and the head will indicate the azimuth corresponding, and vice versa.

**Prob. VIII. — To find the Hour of the Night by a Star.**

Put the head on the thread to the distance that will indicate the star’s declination, and look through the sight for the star till the plummet rests on the plane of the quadrant, and in that situation the head will show, in the hour lines, the star’s distance in time from the meridian of the place; in the next place subtract the sun’s right ascension in time from that of the star, as given in some catalogue, and to the remainder add the observed distance from twelve o’clock in sidereal time, and the sum will be the hour nearly, or the approximate distance of the sun from noon, which may be corrected by applying the sun’s variation of right ascension since the preceding noon, which in every six hours will be about a minute.

Sutton’s quadrant, and Collins’s sector on a quadrant, are very similar, both in construction and use, to the quadrant we have here described, and the dial on a card, by Ferguson, is nearly related to it, particularly as it has been lately improved by the Rev. W. Pearson.

**Of Astronomical Quadrants.** — The quadrants which we have hitherto described may be considered as by no means perfect, but as approximating only to an instrument, that is really useful in an observatory for determining the exact place of a heavenly body; hence the quadrant which we propose next to describe, has obtained the name of **astronomical** from its superior pretentions to accuracy in the measurement of altitudes taken above the horizon, and therefore merits our more particular attention.

An astronomical quadrant may be either portable or fixed; in the former case it is usually mounted on a tripod, with adjusting ferews in the feet, and has a horizontal motion as well as a vertical one, in order that it may take altitudes in any azimuth, or be made to follow the body observed in its apparent path; but in the latter case it is fixed against a steady wall, with its plane in, or very nearly in the meridian, and is therefore denominated a **mural quadrant.**

The first astronomical quadrant, of which we have any account left us, is that which Ptolemy used; it was the fourth part of a circle placed flat against a stone pier, or quadrangular log of wood, with zero of the arc in the horizontal line, and a pin of wood projecting from the central point throw a shadow on the limb when the sun shone, which shadow was used by way of index: but it is obvious that such accuracy was not to be expected from such an instrument, however well constructed or divided. We might mention here the quadrants of Tycho Brahe and Hevelius, but the former has been noticed under our article CIRCLES, and the latter was destroyed in the conflagration of the owner’s house in Danzig. In more recent times, astronomical quadrants have been made on accurate principles, and with great care, especially by Graham, Sisson, Bird, Ramsden, Cary, and Troughton, several of whose instruments we will now describe, as far as any difference in their construction renders distinct accounts necessary. We will proceed, as we have done on former occasions, chiefly in the order of time, which, generally speaking, will be found to be also in the order of successive improvements.

**Mural Quadrant by Graham.** — Before we proceed to describe the mural quadrant, contrived and made by Graham, and fixed at the west side of the stone pillar in the middle room at the Royal Observatory at Greenwich, at the expense of king George I., and for the use of that eminent astronomer Dr. Halley, it may be proper to mention that Flamsteed, and his assistant Sharp, had previously used an arc of a circle fixed against a stone pier in the meridian, which they had themselves constructed, and which was removed at Flamsteed’s death. We must, therefore, consider their instrument as having been the prototype of Graham’s mural quadrant, or arc, as it has been also called some times. In fig. 4. of Plate XXIII. of Astronomical Instruments, is given a representation of the mural quadrant of Graham’s construction, which will equally represent that of Bird, constructed after the same model, and which is the fame that both Dr. Smith, and Stone, the editor of Bion’s work, have given in their respective accounts.

The body of this quadrant is composed chiefly of bars of iron united together, as seen in the figure; some, to form the plane of the quadrant, placed flat-ways; and others, to give length and liability, fixed edge-ways. These bars are all of the same dimensions, namely 2.9 inches wide, and 0.175 thick, and are united together by right-angled short bent bars in various places, both at the intersecions made by the sides of the small squares, and at other situations, so that while great firmness is obtained, great weight is avoided. The quadrantal arc is composed of two bars, one of iron, united to the iron frame, and the other of brass, on which the divisions are made, as described under our article Graduation; this brass bar is pinned fall to the iron one, and being more slender than the iron, accommodates itself thereto, and, as time has proved, does not alter the shape of the arc, as we have lately been assured by Mr. Troughton. The breadth of the limb is 2.2 inches, the brass limb being more remote than the anterior edge of the iron arc by 1.2 inch, and the surface was planed, or rather scraped, by a tool fixed to a radial bar, that revolved on a vertical axis of motion, placed in the centre of the arc, and rolling with its superior end in a fixed beam above the plane of the quadrant, when this plane was lying in a horizontal position, it being impracticable to put so large a body in any ordinary lathe. The original divisions of Graham were inserted on two separate arcs, one graduated into 90° and its subdivisions, and the other divided into 96 parts and its subdivisions, as we have before explained in the article just referred to; but the divisions, being laid down by rough dividing, are now made use of, but a quadrantal arc of 96°, with its subdivisions, put in by Bird in 1755 between the two arcs of Graham, is that which all observations taken by Graham’s quadrant are now referred to, and the readings are transformed into degrees, minutes, and seconds, by an appropriate table. The readings were at first obtained by a double vernier-piece carried by the telescope, that revolves round the centre of the arc, one side of which vernier-piece read with the arc 96°, and the other with the arc of 96 parts, or grand divisions; the degree was subdivided into 12 parts, or 5' spaces, and 10 parts on its vernier equalled 11 out of the said 12 parts, so that
of a degree, or \( 5^{1/2} \), was the length of one of the vernier divisions, and \( 96.85 \) was the smallest quantity indicated by this vernier; but on the arc of \( 96 \) grand divisions there was, as in Bird's arc, 16 equal parts, or subdivisions, in every grand division, and the vernier for this arc had 17 divisions on it, occupying the space of 16 subdivisions in the arc, so that the length of this vernier was \( \frac{17}{16} \) of \( 96^\circ = 95.83 \) nearly, and one division of \( 5^{1/2} = 3.52 \) nearly.

Hence in the first vernier its number 11 is one less than its equivalent arc contains on the limb of \( 90^\circ \); but in the second, the number 17 is one more than its equivalent arc contains in the arc of \( 96^\circ \), on which account the reading of one vernier is in the direction from right to left, but that of the other, on the contrary, from left to right; one meets, and the other overtakes the dividing strokes of the divided limb; and for the same reason, in the common Hadley's quadrant, or rather octant, sometimes 10 subdivisions, and sometimes 21 on the limb, act against 20 in the vernier, but then the readings are not in the same direction. The telecope is clamped to the arc in any situation by the mechanism for flow motion in the usual way, which probably was first adapted in one of the large quadrants, and its counterpoise beyond the centre of the arc, gives it the advantage of remaining in any position. It has crofs hairs in the focus of the eye-glafs. When the lines of the vernier are none of them coincident with any one on the limb of either quadrant arc, the portions less than what the verniers proffes to indicate were effimated by the eye, by examining the situation of other pairs of dividing lines, to the right and left of those nearest to a coincidence; and to a want of a micrometrical nut to the screw of flow motion may be attributed the remark, that has been made, that the readings thus taken, even with so large radii as 96.85 and 95.8 inches, were not to be depended upon to \( 1^\circ \). That the motion of the telecope might be quite easy, and that the centre of the quadrant might be relieved of its weight, the following contrivance was introduced; \( ab \) represents an iron axis laid across the top of the wall, having two bras plates fixed perpendicularly to its ends, with notches cut in them for this axis to turn in, which axis points to the centre of the quadrant at right angles to its plane; to that end of it next to the quadrant, at \( a \), an iron arm, \( cd \), is fixed, having two bras plates, \( e \), \( f \), almost perpendicular to it; to these are rivetted two flender flips of deal, whose remote ends meet at \( g \), near the eye-piece of the telecope, and are held together by a bras cap. Through a small plate fixed to one side of a collar, embracing this lower end of the telecope, there passes a screw-pin at \( g \), parallel to the telecope; which pin, being screwed into the cap at the end of the said slips of deal, holds up the telecope against the centre-work, while the slips are braced by other crofs slips of the same light wood. The counterpoise \( i \) is supported by the rod \( b \) at \( b \), the retiring end of the axis \( ab \); and a pair of bras rollers \( k \), acting against the limb of the instrument, give freedom to the motion of the telecope thus counterpoised, and complete the construction. The quadrant being thus put together, some strong but small plates of bras are made fast to its posterior face, and bent so as to fall into as many hold-flaps in the wall, into which they are respectively screwed; but the weight of the whole is supported chiefly by two pins or bolts inferted into the holes \( A \) and \( B \), made in pieces of metal attached to such angular points of the iron bars, as

bell support the centre of gravity of the whole; the pin \( A \) is made fall into the wall, but allows a motion round it, and the pin \( B \) fixes the quadrant after its extreme radii are adjusted, one horizontal, and the other vertical: this position was given by means of a plum line of fine silver-wire, that at first was so suspended as to bisect both the centre of the quadrantal arc and the point \( 90^\circ \) on the limb, but which was transferred afterwards to an adjustable point of suspension out of the centre, with a corresponding dot made on the arc of excess of the limb. The plane of the quadrant was made vertical, as compared with the plum line, by the screws of the hold-flaps; and the telecope was adjusted parallel to this plane by comparison with a transit telecope viewing together both high and low cells in succession; but the line of collimation of the telecope could not be fixed properly, as it regarded the true horizontal line of the quadrant passing through its zero, without the aid of Graham's factor. This factor was, therefore, so adjusted to a level near the zenith, that it measured the fame zenith-dilference, with its plane turned to the east, as it did when turned to the west, and had its error ascertained in this way, and afterwards an altitude, taken with the quadrant, was made to correspond with such correcte altitudes of a star taken with the rectified factor in reversed positions, which property the mural quadrant does not possess.

The method of performing this adjustment for collimation will be underftood from our directions hereafter given, when treating of Ramsden's portable astronomical Quadrant.

Bird's Mural Quadrant.—After the description we have given of Graham's mural quadrant, we shall have no occasion to dwell long on the structure of Bird's, which was made of brass entirely, after a familiar model, but divided in both its arcs, of \( 90^\circ \), and of \( 96^\circ \) grand parts, with much skill than Graham proved himself master of in this part of his labours. Smith and Stone describe Graham's quadrant as fixed to the east side of the pier at Greenwich, and looking to the south, which was the situation for taking meridian altitudes of the greatest number of stars; but since the year 1753, it has been placed on the west side, looking towards the north, and Bird's then took its original place.

This quadrant, which was procured in the time of Dr. Bradley, was first placed on the west side of the pier, in 1750; and the observations of himself and of Dr. Maskelyne, taken by it since it was placed on the east side, have contributed largely to complete the best catalogues of the heavenly bodies, which otherwise must have been very defective. While, however, Mr. Pond, the present astronomer royal, was engaged in making his well-known table of declinations, with one of Troughton's circles, at Welbury, he found reason to suspect the accuracy of the total arc of this quadrant, from a comparison of his own determinations with those previously made with Bird's quadrant; and a subsequent examination of the arc by Troughton justified his suspicion. With an apparatus expressly contrived for the occasion, this celebrated mathematical instrument-maker measured the total length of the quadrantal arc, and found it too small by \( 7^\prime \), exclusive of another similar error of \( 2^\prime \), occasioned by the wear of the axis of motion; though, on a rigid trial of the intermediate divisions, he did not detect more than one second of error, or rather of inequality, among the neighbouring divisions in any part of the arc. This trial was made in the presence of the present astronomer royal, in the year 1807; and the result, while it verifies to correct past observations, by the addition of \( 7^\prime \) to every successive \( 10^\circ \) of altitude, would have tended to correct all future observations by a like addition, had not the large transit-circle, lately made and fixed in the same observatory by Troughton, superfeded
superceded the use of both the quadrants by its superior accuracy. The quadrantal arc of Graham's quadrant has not lately undergone a similar trial; but Troughton thinks it probable that the iron instrument has preferred its figure better than the brass one, and that consequently the addition of the brass arc on the face of the iron one has had no undue influence in altering either its temporary or permanent dimensions. At first, the telescope of Bird's quadrant was not braced; but after a trial, it was found to bend a little by a counterpoise of 80 pounds, and was afterwards braced by frame-work surrounding it, that prevented its yielding. A trial was made by Dr. Bradley of the total arc, in January 1753, and after it had remained three years on the west side of the pillar; and though its weight is eight hundred pounds, the error was found to be not more than two seconds. He did the same again in July, in the year 1759, when it had remained six years and a half in its new situation, on the east side of the pillar, and found the arc exactly 90°. The same examinations, having been made in the extremes of cold and heat, shew that change of temperature did not affect the total arc; and that, therefore, the 7° diminution of the arc, detected by Troughton, is occasioned by a change of figure in the space of 48 years. The difference of the readings of the two arcs has never yet amounted to 4', which is a standing proof of the accuracy and skill of Bird as a divider. Near the eye-piece of the telescope is a good micrometer, that not only gives, as motion in taking observations, but measures the number of seconds that the reading lines of the vernier is short of coincidence in any observation; and formerly the quantity indicated by the vernier had the seconds added, to obtain the whole measure; but, by Smeaton's advice, the vernier is now disfigured, and the addendum, obtained by several turns of the micrometer-screw alone, is used to complete the simple reading of the divisions and subdivisions, or 5' spaces; in other words, the screw, and not the vernier, subdivides the last 5' space in the observed arc, and gives what is due to the observation. The adjustments of this instrument, which was made of eight feet radius, on purpose to take the place of Graham's, are made in all respects as they are made in its predecessor; and the factor, which serves for adjusting Graham's line of collimation by stars near the zenith, is used for the same purpose in Bird's quadrant. If any of our readers wish to see the original plan of all the separate parts of Bird's quadrant, and to read his description of them, we beg leave to refer them to his quarto pamphlet, entitled "The Method of constructing Mural Quadrants," published by order of the commissioners of the Board of Longitude, in the year 1768. In this pamphlet, however, it is not mentioned that the vernier of the arc of 90° subdivides the space of 5' into ten parts of 30' each, by having ten divisions thereon, reading with eleven subdivisions of the limb; but we know that this was the original reading of the vernier.

Jeremiah Sifton's Mural Arc.—Perhaps it would have been more consonant to the order of time, if we had spoken of the younger Sifton, who was Bird's contemporary, and at one time his employer, next after Graham; but the histories of the two mural quadrants at Greenwich being connected, demanded that these instruments should follow each other in immediate succession. In the year 1768, Jeremiah Sifton, the son of Jonathan, made the large mural arc at the king's private observatory in Richmond gardens, which extends 45°, or more, beyond a quadrant, and consequently reaches beyond the north pole; which circumstance gives it the advantage of being put in the meridian, by an observation of the pole-star. The divisions of this arc are into degrees and its subdivisions, but the strokes are not cut very neatly; and the reading, as was the case with Bird's quadrant at first, is performed partly by a vernier, and partly by a micrometer-screw. We have selected this instrument, as a specimen of Sifton's construction, principally on account of its power that it possest, which is very important, but which probably was not contemplated, and consequently not intended by the maker himself: the extension of the divided limbs, to several degrees beyond the north pole, affords the means of using this instrument in the manner that Troughton's large mural circle is now used, at Greenwich Observatory, by the present astronomer royal: namely, to measure the polar distances of the stars directly from the true polar point, without any reference to the latitude of the observatory, which method is one of the greatest modern improvements in making astronomical observations. It is much to be desired that this mural arc should be divided again by Troughton, or some other superior divider, and that it have microscopic micrometers applied to it, which may be placed by adjustment over any optional part of the divisons, and at any assumed distance from each other; for though it would not then, as it does not now, poolish the valuable property of opposite readings, and of a motion in altitude to reverse the opposite arcs, by reason of its being less than a semicircle, yet being compactly made, and of large radius, it is capable of receiving divisions superior to those on the quadrants which we have described; and as the situation and structure of the observatory are excellent, the appointment of a regular observer to co-operate with the astronomer royal would be highly conducive to the interests of astronomy. We hope that this hint may be taken up in a quarter where the power exists of realizing our wishes in this respect. Astronomical clocks, and various other auxiliary instruments, are already in the observatory; so that the principal expense of instruments, as well as of an appropriate and elegant building, is already incurred.

Portable Astronomical Quadrant by Ramden.—It frequently happens that superior artists vary the construction of their instruments to suit the views of the purchaser, or the scale on which they are to be constructed. We will select out of the quadrants made by the late ingenious Mr. Ramden, that which he made for Dr. Shepherd for the observatory of Christ-college, Cambridge, and which professor Vince has described at considerable length in his "Treatise on Practical Astronomy." The figure exhibiting this quadrant is the 5th of Plate XXIII. of Astronomical Instruments, which requires but little explanation. The tripod on which the quadrant is mounted has爽rews of adjuftment to fix the item, on which the horizontal motion is performed, perpendicular, which is proved to be so in all directions when the plumb-line bisects both the superior and inferior dots during the whole revolution round a horizontal circle. The visible item is a brass tube, and through it sends a solid iron vertical axis, which fitting closely at the superior and inferior ends, has not the least shake, and preserves the position once given it so long as the feet screw are unmoled. The telescope is of the achromatic construction, and has the usual apparatus for flow motion, the screw of which is made a micrometer to subdivide the small residuum of the angle that the vernier alone will not indicate, when the coincidence is not perfect. The telescope lies on a bar that carries the counterpoise, and in which is the centre of its motion. It has a system of wires in the focus of the eye-glass, which are adjustable by screws, both upwards and sideways, as well as in a circular direction, so that the adjustments for collimation, and for zero in the altitude circle, may be effected thereby. The point of suspension of the plumb-line is also adjustable by a proper screw apparatus.
apparatus. At the top of the vertical tube, or stem, is a small horizontal circle with a clamping apparatus for slow horizontal motion, by means of which the whole quadrant, with its attached telescope, turns gradually round in azimuth. When observations are made in or near the zenith, the plumb-line falls in the way of the telescope, and is obliged to be removed, on which account the large quadrant made by Ramden for the duke of Marlborough, and now placed at Blenheim, has the plumb-line suspended at the posterior face of the instrument. This inconvenience is, however, remedied by the addition of a spirit-level suspended from an adjustable horizontal brass rod, under the uppermost radial bar of the quadrant, and this level not only supplies the place of the plumb-line when taken off, but at all times serves as a check on its adjustment, and, when furnished with a graduated scale, may very well be made its substitude. The construction of Ramden's portable quadrant was probably borrowed from Bird's, as well as his method of dividing the larger instrument, that exceeded the reach of his dividing engine; but the instrument before us has no other horizontal or azimuth circle, except what is used plain, for the purpose of giving slow motion. Neither is there a second horizontal or telescope, fixed permanently in that situation by which the telescope of observation may have its collimation determined, and the zero of its vernier adjusted.

The vernier of this quadrant reads with twof its divions, like that of the mural quadrant by Bird, but the radius being small, the subdivisions are made into four parts each; the inner arc is divided into 90°, and the subdivisions into 15° each, but the outer one into 96 parts, or grand divisions, and these again each into four parts, or sub-divisions; and those two arcs operate as a check on each other. The micrometer sub-divides the 15° into 3°; but it is necessary to convert the reading of the arc of 96 grand divisions into a corresponding quantity, expressed in degrees, minutes, and seconds, which may be done by direct proportion, or, which is more feasible, by a table that we have subjoined, calculated for this purpose. The readings of the arc of 96 are put down with titles divisions, sub-divisions, and vernier, where 16 (and sometimes 32) on the vernier are equal to one sub-division, and four sub-divisions to one division; for example, suppose the reading to be thus, 21° div. 2 11/2. We shall have from the table:

<table>
<thead>
<tr>
<th>Divisions</th>
<th>21</th>
<th>28.5</th>
<th>40.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sub-divisions</td>
<td>2</td>
<td>7.5</td>
<td></td>
</tr>
<tr>
<td>Vernier</td>
<td>42</td>
<td>11.2</td>
<td></td>
</tr>
</tbody>
</table>

When, however, the coincidence of the vernier is not perfect, the quantity brought up by the micrometer-screw must be added as a fractional portion of 52°1/8, which is the value of one step of the vernier, when 16 is the number of steps, but if 32 are inserted, then 26°4 would be the value of one step forwards from zero.

A Table for the Reduction of the Grand Divisions, Sub-divisions, and Vernier, of the Arc of 96, into Degrees, Minutes, and Seconds.

Adjustments:
Adjustments.—1. To adjust the axis of the pedestal vertical.—This adjustment may be performed either by the plumb-line or by the level, both which methods we will explain in succession. We have already laid that when the wire of the plumb-line will continue to bisect both the upper and lower dot, while the instrument is turned quite round in azimuth, its axis is vertical in all directions, but this could not be effected unless the plumb-line passing through the two dots were also parallel to the axis; this adjustment, therefore, is made partly by the screws at the feet of the tripod, and partly by the screw that moves the piece bearing the upper dot in a lateral direction. In the first place then turn the quadrant in azimuth till its plane, or, which is the same thing, the telescope lies parallel to a line joining any two of the three feet, and turn one of these two screws till the wire bisects the lower dot, and with the proper screw bring the upper dot to the wire; then reverse the telescope by turning 180° in azimuth, and if both dots are again bisected, the axis is vertical in the direction that the telescope has pointed; in the next place turn the telescope the space of a quadrant till it points in the same direction as the third foot of the tripod, and make the wire bisect the lower dot by the screw of this foot, and it will be found to bisect the upper dot also, if the first adjustment of the dot was properly made, but if not, repeat the operation till both dots are bisected in all the reversed situations of the telescope, and then the axis will be vertical in every direction.

In making this adjustment by the level alone, the process must be thus; first, the level must be made parallel to the rod on which it hangs, and secondly, this rod must be put perfectly horizontal, and the level will then be horizontal also, with the bubble in the middle. In order to make the level parallel to the rod, place it parallel to a line joining two of the feet screws, and bring the bubble to the middle by one of the feet screws in question; then take off and reverse the position of the level, and if the bubble is found in the middle now, the parallelism is perfect, if not, one half of the error must be rectified by the same foot-screw, and the other half by the adjusting screws at the end of the rod, by releasing one and screwing up the other. A repetition or two of this process will make the bubble stand in the middle in both of the reversed situations. In the next place, with the level thus parallel to the rod of suspension, turn the quadrant round its axis an entire semicircle as nearly as can be estimated, and if the bubble will now rest in the middle, the rod is level, and being at right angles with the axis of the quadrant's motion, proves that this axis is vertical in every direction; but if the bubble is found to run to one end of the tube, bring it one halfway back by the rod's adjusting screws, releasing one and fixing the other, as the case may be, and the other half by the proper foot-screw. A repetition of this process will soon settle the bubble in the middle during a whole revolution in azimuth, and then the adjustment of the axis is perfect, as well as of the rod and level.

2. The second adjustment is that by which the line of collimation of the telescope is made parallel to the horizontal line that passes from the centre of the quadrant to zero on the limb, or quadrantal arc, at the same time that zero on the vernier coincides with zero on the limb. This important adjustment may be made in several ways, some of which are tedious and otherwise objectionable; but we will confine ourselves to two which apply, one to the vertical, and the other to the horizontal line of the quadrant, which two methods, when duly effected, will not only check each other, but detect the error of the total arc, if there is any, at the same time; which is an acquisition of the utmost importance. First, then, to adjust by the vertical line, let the axis of the quadrant be first made truly perpendicular in all directions by the adjustment we have already described, and fix on a star within a few degrees of the zenith, when exactly on the meridian, and measure its altitude by the crose-wire in the field of view in the usual way, and note down the result; do the same on a subsequent night soon after, if possible on an evening of similar temperature, with the quadrant turned half round in azimuth, and note again the result; if these readings prove to be at equal distances from the point 90°, one on the quadrantal arc; and the other on the arc of excess beyond 90°, the horizontal wire is truly placed in the eye-piece, but if not, half of the difference of the readings must be corrected by the proper screw for raising or lowering the said wire. This may be done by directing the telescope to a distant mark till the crose-wire bisects it, then by moving the screw of flow motion of the vernier the half quantity required, and by bringing back (up or down) the crose-wire thus displaced to its original mark again. This operation repeated will place the crose-wire in such situation that zero on the vernier will be in its proper place with respect to the point 90°; or the half difference thus ascertained may remain, without altering the crose-wire, as an error of adjustment to be constantly applied with the sign + or −, as the case may be, in all subsequent observations. Again, to adjust by the horizontal line passing through zero of the quadrantal arc, it will be necessary to have a second telescope turning on pivots in adjustable Ys attached to the back of the quadrant, on the same level with the said horizontal line of the quadrant. This telescope may be called the adjusting telescope, and may be also used to watch a distant mark, before and after an altitude is taken, in order to detect any deviation in the position of the vertical axis, that may happen during the operation of measuring. Let the adjusting telescope bisect a fine distant mark with its crose-wire, and turn the tube of the telescope round one way on its pivots, as it lies in a horizontal position, and if the wire now bisects the same mark it is truly fixed, if not, look out for a new mark a little higher or lower, as the case may be, and make it cut that in the reversed positions of the crose-wire, by means of the proper screw for this purpose; now this adjusting telescope will be adjusted for collimation; in the next place, put zero on the vernier to zero on the limb, and direct the telescope of observation to the same distant mark, by which the adjusting telescope had its wire adjusted, and let this mark be bisected by both telescopes, the level and plumb-line at the same time showing that the vertical axis is perpendicular; now turn the quadrant half round in azimuth, and reverse the adjusting telescope to as to view the same distant mark again, and if it is found to bisect it as before, the horizontal line of the quadrant is right, and also the quadrantal arc without error, supposing the telescope of observation to have its adjustment for collimation as fixed by the point 90° above described; but if this adjustment of the point zero on the limb be first made, half the apparent error must be rectified by the screw at the eye-piece, by means of reversed positions and new marks; and then afterwards the adjustment by a star near the zenith will detect the error of the whole arc. If, however, no error in the total arc exists, then the adjustment for collimation may be made either from the horizontal or from the vertical measurement, as may be more convenient; one of which is more practicable by day, and the other by night. When this delicate and very essential adjustment is finally settled, the object-glass of the telescope should not be disturbed, and therefore it would be advisable to have its interior surface well cleaned previously.

It was taken for granted that the crose-wire was perfectly horizontal.
horizontal during the time the preceding adjustment was made, or, which is the same thing, that the parallel vertical wires were perpendicular to the horizon. This is proved in a simple manner thus; direct the telescope to a line small distant mark, and make the adjustment for vision, if necessary; then if one of the vertical wires will continue to biflect the said mark through the whole field of view while the telescope is elevated or depressed, the wires are right, but if not, they must be made so by the proper screws for that purpose, near the focus of the eye-glasses. This preparation ought to precede the last adjustment, and when once made, seldom requires altering, except in case of accidental injury.

It has also been affirmed in the preceding adjustment, that the maker of the instrument placed the plane of the quadrant parallel to the axis of its motion, and also the line of collimation of the telescope parallel to the said plane. The former may be known to be true thus; if, when the plumb-line is adjusted, at its centre of suspension, just to escape touching the limb, (which should always be the case,) the quadrant's motion in azimuth will not alter it in this respect, the plane is truly fixed; but if not, the screws, that fix the quadrant to its axis, must be returned to for the alteration, which is best done by the maker. When there is no plumb-line, a small spirit-level, fixed at right angles to the plane of the quadrant, will answer the same purpose; for the rising of the bubble during the quadrant's revolution in azimuth, will be a proof that the plane to which it is at right angles is vertical. With respect to the parallel position of the telescope, as this is guided by the vernier sliding on the limb, it is the business of the maker to adjust it properly, which he will best do by a comparison with a good transit instrument of the puglasses of a high and of a low star in each of the two instruments; but a small deviation of the telescope with respect to parallelism, though to be avoided if practicable, will not sensibly affect the measurement of altitudes, which is the sole business of this instrument. If, however, this deviation is considerable, the eye-end of the telescope must be let nearer to or farther from the limb, as the case may be, by the maker himself. We have been the more minute in describing these adjustments, not only because they are indispensably necessary in making good observations, but because they will apply, one or other of them, by means of the plumb-line, or of the spirit-level, to all other astronomical quadrants that have a motion in azimuth.

We have before us the drawing of a large and beautiful quadrant made by Mr. Cary, for Leopold, the late grand duke of Tuscany, with two telescopes and a graduated azimuth circle, but the description we have given of Ramden's instrument will equally apply to his, except as to the dimensions.

**Portable Astronomical Quadrant by Troughton.**—Though we have described Ramden's portable astronomical quadrant with much minuteness, and have detailed the most useful methods of making such adjustments as will apply to the other portable quadrants that have a motion in azimuth, yet we should do violence to our own feelings, as well as to the ingenuity of an existing artist of the first eminence, if we withheld from the public eye the great improvements that he has made in this instrument since the death of Ramden. Fig. 6. of the same plate that contains Ramden's instrument, is a reduced perspective view of the improved astronomical quadrant of Troughton, which was made by him and sent to Bilbao in Spain, about the time that astronomical circles began to be constructed. It has been ascertained, under our article Circle, that this instrument, as constructed by Troughton, (and we may now add, by Thomas Jones, who has learnt his mode of dividing,) is greatly superior to any quadrant that can be made, on account of properties which the circle exclusively possesses; but so far as a quadrant's accuracy can be depended on, Troughton's improved construction is to be preferred to all others. And, indeed, when we consider that simplicity, steadiness of performance, and permanence of the adjustments once made in this instrument, are properties which it peculiarly possesses, along with comparative cheapness, it is probable that there will always be purchasers, when such an instrument is on sale, provided the improver will confect to make such instrument with limited powers, when he can have rapid sale for those which he now constructs, with all the advantages that the circle affords.

The radius of this quadrant is three feet, and the body is made double, that is, of two quadrantal frames united into one, by small pillars holding their planes parallel, and enforcing the two properties, not often united in other men's instruments, of lightness and strength at the same time. The tripod, on which the quadrant is supported, is a frame of mahogany, braced in different directions, so as to resist any ordinary preasure, when the quadrant is put in motion, or the telescope used. The three feet-screws are furnished with each a Hooke's joint and long handle, so that the observer may make an adjustment with any of these screws without flooping, and consequently without withdrawing his attention from the plumb-line apparatus, or spirit-level, that indicates the quantity of adjustment that may be necessary from any individual screw. About the middle of this pedestel, or frame-work of the tripod, is a three-armed horizontal bracing piece, on which the stem of the quadrant rests; and this limb is kept vertical by a socket of brass made fast to the centre of the table, which surmounts the pedestal, in which socket the vertical axis turns both readily and freely, while it rests on the three-armed bracing piece below. The azimuth or horizontal circle is centered on this axis, but so as to admit of a motion round it of about two degrees, for the purpose of putting the zero of the quadrant right when the telescope is in the plane of the meridian. This small motion is produced by the tangent screw seen in front, and the other tangent screw regulates the flow motion of the telescope and vernier, by taking hold of the plain vernier plate, that reads at opposite points, and that may be clamped, when in use, to the azimuth circle, which is also a solid circular plate of brass, subdivided into 10°spaces, and reading by the verniers alone to 10'.
downwards, to prevent any inclination to bending by its weight, and has an axis of motion of four inches and a half long, that paffes through the thick pillar, that connects the two quadrantal portions of the double frame at the exact centre of motion, and of the divided arc. The counterpoise is applied at the redundant end of the telescope, and the vernier borne by its end, near the eye-piece, divides the 5° spaces of the vertical arc into 5', while a micrometrical microscope, attached to the metal of the telescope, subdivides this last quantity into single seconds. A nicely ground spirit-level hangs on the horizontal bar, with its proper adjustment apparatus, which alone will ascertain the position of the quadrant to a second; but, as if this were not sufficient, a plumb-line is made to descend, free from dust, or agitation by the wind, from an adjustable point of suspension through the hollow column, where there is little or no disturbance from a motion in azimuth, and ensures the position still more certainly. The water vessel in which the plumbet is immersed, to prevent vibration, is contained in the hollow short cone before described, as containing a triangular frame within it, and the situation of the wire is examined in two directions, at right angles to each other, by microscopes looking across the bore of the column, at a convenient height for the observer to see without a change of position of his body, when he has been just observing at the telescope. The mark used for each wire to bifect is a luminous disc, known by the name of Ramsden's ghost, from its being only the image of a luminous point without substance, occasioned by a contracted aperture of a tube, fixed at the remote side of the column into which light enters, and by which it is directed without parallax. Besides these appendages, there is a secondary or adjusting telescope, such as the elder Sifion made for his spirit-level, and such as we have already described, as furnishing the means of adjusting the horizontal line of a quadrant that moves in azimuth, and of ascertaining the error of the whole quadrantal arc, by comparison with the adjustment by a star near the zenith. (See Portable Astronomical Quadrant by Ramsden, before described.) Lastly, the radial bars that bear the quadrantal arc, taper downwards from the centre, thereby giving strength to the part most liable to alter its figure by weight, as it is supposed Bird's mural quadrant has done in a small degree for want of such precaution. This quadrant has an arc of excess at each end, and is capable of all the adjustments we have above described in an exquisite degree.

Of Nautical Quadrants, measuring by Reflection.

Sir Isaac Newton's reflecting Quadrant.—A manuscript account of a quadrant, measuring altitudes and distances by reflection, of the hand-writing of Sir Isaac Newton, was found among the papers of Dr. Halley after his death, which quadrant, according to Stone, was actually made in the year 1672, when Dr. Halley was preparing to go to the South seas, to make an addition to his catalogue of fixed stars; but the manuscript account was not produced, or even mentioned, when Hadley's instrument was sent to the Royal society, nor was made known till the year 1742. (See Phil. Trans. No 465.) Hence some doubt has been entertained whether Sir Isaac Newton or Hadley was the first inventor of the reflecting quadrant. The most probable inference is, that each invented his own, seeing that though the principle is the same in both constructions, yet the mode of applying it is different, as will be seen from a comparison of the figures, and from our description of each in succession. Sir Isaac Newton's quadrant was preferred for several years at the house of Mr. Heath, who was a mathematical instrument maker in the Strand, London, and it is probably in existence at this time. Dr. Hooke is also said, by Dr. Pratt, to have invented a quadrant that was, or might be, used at sea with one reflection only; and, indeed, he is asserted to have been the first man who proposed the use of a mirror in a nautical instrument. See Circle.

Sir Isaac Newton's quadrant, represented by fig. 7. of Plate I. of Astronomical Instruments, consists of an entire sectorial plate of brass, P Q R S, to the plane of which the telescope A B is fixed and lies parallel, and an index, which is moveable about an axis of motion at A. The limb D Q was accurately divided into half degrees, and, as is said, half minutes, on a scale of four feet radius, and was subdivided by a diagonal scale into 45th of a minute. The principle on which this semi-division is founded is this; viz. "If a fixed ray of light be reflected at a plane reflector, and if the reflector be made to rotate about an axis perpendicular to the plane passing through the incident and reflected rays, which may be called the plane of reflection, the angular velocity of the reflected ray will be double to the angular velocity of the reflector." See Vince's Practical Astronomy, p. 7, &c.

Hence one small mirror, G, is made fast to the plane of the sectorial plate, and perpendicular thereto, but inclined in an angle of 45° to the axis, or length of the telescope, and in such a way, as to cover one half of the aperture, while another similar mirror is borne by the index, in such a position, that when the index is at zero, both the mirrors are not only perpendicular to the plane of the quadrant, or rather octant, but are parallel to each other. Now, according to the principle that we have just mentioned, when the index is moved forward, a ray of light from any fixed luminous body, when caught by the index mirror, will be reflected on the fixed mirror, and an eye directed through the fixed telescope towards the said body, will see it divide into two bodies the infant that the index begins to move; that is, the body itself will be seenstationary through one half of the telescope's aperture, and its image will be seen in the other half in motion, and this motion has double the velocity that the index has, which bears the revolving reflector; and on this account it is, that the divisons for half degrees and half minutes, are read as whole degrees and whole minutes, as well as the 45th read as 4th by the diagonal scale. From this short explanation of the principle and structure of Sir Isaac Newton's reflecting quadrant, it is easy to perceive that the construction is derived immediately from the principle in the simplest, though in practice not the best manner; for the instrument itself illustrates the principle in the most obvious way; but, from its magnitude and mode of being used, it is very inconvenient to be supported without a stand, which on board a ship is indissoluble.

Perhaps it might be on this account that Dr. Hooke did not pay more attention to it than he appears to have done, according to the information that we at this distance of time possess. However, it is evident, that the instrument before us is capable of measuring either vertical, horizontal, or oblique angles, in the way it professes.

Coke's Quadrant by single Reflection.—Fig. 2. of Plate XXIII. of Astronomical Instruments, is the figure of an instrument, which, like Dr. Hooke's contrivance, measured altitudes by single reflection, as we conceive, the drawing having fallen into our hands without the description. An arc composed of an entire quadrant, and an index with a single mirror fixed to it at its centre of motion, constitute its leading features, while a light-vane, at the remote end of the prolonged index, instead of a telescope, has a plane hole, through which the sun is viewed after reflection from the index-glass, his rays having first passed through a coloured glass.
glafs. This construction, with the addition of sir Isaac Newton's second mirror, would constitute an union of two instruments, that would greatly refine the combination adopted by Mr. Hadley, which follows next in our list of quadrants; but which may not have been copied from such union; for Coke has got the vernier slide, which is preferable to the diagonal one adopted by Hadley, and therefore probably he followed Hadley, though the quadrant before us has not recommended itself to general use, as being an improvement.

Hadley's Quadrant.—As we cannot help considering Hadley's quadrant, or more properly octant, as a near relative at least to his friend sir Isaac Newton's, we will describe it next in order, while the principle of its construction is fresh in the reader's memory. The circumstance of Mr. Hadley's being president of the Royal Society was favourable to the early notice of his instrument; and the interest that the British nation took, and must ever take, from its inufer situation, in nautical improvements, contributed to its early adoption, at a time when such an instrument was greatly wanted.

Mr. Hadley, we learn, tried various modifications in the construction, but that which has been approved from long usage is the one we shall select for description. Fig. 1. in Plate XXIII. of Astronomical Instruments, is the representation of Hadley's octant, as it is now constructed with a vernier, which it had not at first, and which is preferable to the diagonal divisions at first applied by Hadley, as well as by sir Isaac Newton. For the sake of lightness, united with strength, the frame of the instrument, when made of any of the hard woods, is put together usually as is represented in the figure, but when made all in brass, and particularly when the limb is extended to 120 half degrees, reading as 120°, in which case it is called a sextant, the bell modern makers make it double; that is, have two separate light frames, united by short pillars, standing at right angles to their planes, which thus become parallel. This construction, we believe, was introduced by Mr. Troughton, and allows a more steady motion to all the moveable and adjustable parts, by lengthening their axes of motion, which penetrate across both parts of the double frame, and by that contrivance have longer bearings. But we are now propoing to describe a quadrant of Hadley's own construction. A B C is a frame of some hard wood, such as ebony, which may be of any convenient radius, from eighteen inches downwards to three, or less, if required for the pocket, and A D is the index bearing the vernier at D, together with the usual clamping apparatus for flow motion, in making the contact in any observation. This apparatus, together with the powers of the vernier, and mode of using it, have been explained under our article Circle. (See also Vernier,) and therefore may be referred to by the reader unacquainted with their uses. When the radius is very small, the vernier subdivides half degrees, and has thirty divisions on it, but has twenty or fifteen, accordingly as the degree of the limb is subdivided into thirds or fourths of a degree. The peculiar excellence of this instrument, either in the form of an octant or sextant, is, that all sorts of angles can be measured with it on board a ship, even while the ship is tossed by the waves; and as also, that it requires no other auxiliary means, than the natural horizon, which at sea is always, or mostly present, when a heavenly body can be seen. The plumb-line and spirit-level are equally applied with; to which may be added, that, if any accidental injury be received, a circumstance not improbable in the hands of sailors, the adjustments are so simple, that, generally speaking, the derangements may be easily rectified. In the best instruments, a small telescope is screwed into the light-vane, which not only prevents parallax, by limiting the line of sight between two parallel wires, but affords the light greatly in obtaining exact contacts. There is usually an arc of exceeds at each end of the limb, one of which is useful in adjusting the index-error by the sun or moon, and the other is serviceable when angular distances are measured beyond a quadrantal arc; indeed it would be well if the arc were always extended to measure 120°, or more, for then a sextant would be competent to measure all sorts of angles that the mariner can require, to find his latitude, time, and longitude.

When the octant has not the tangent screw of flow motion for adjustment in making the contact, the index is nicely moved by hand, and then fixed by a screw behind it for this purpose, and in either case the examination and noting down of the altitude, or horizontal angle taken, may be read at any time, for hours afterwards, which is another important advantage that this instrument posseizes in common with the sextant; for where more observers than two are not present, one observer may thus manage to take both an altitude and a distance in a lunar observation with two separate instruments in quick succession, while another observer is taking the altitude of the second object; or with the help of Margett's horary tables, the second altitude may be had by inspection, when the hour, latitude, and declination of the body are known, in which case one observer can take a lunar observation with tolerable accuracy. The limb of the instrument is built of metal, such as brass, silver, or platea, when made and divided in the bell way by a superior dividing engine, such as Troughton's; but in ordinary instruments a piece of ivory is frequently let into the wood, and sometimes the divisions are made even on the wood itself, which is liable to be affected by moisture. The index is most frequently entirely of brass, and wider as it ascends to the centre of motion, to prevent lateral bending, which would destroy the accuracy of the readings. When an observation is made by the larger fort, the right hand should be applied to the lower extremity of the index to give it steady motion, while the left holds the lower end of the remote radial bar; and the plane of the instrument must be kept in the line that joins the two objects, of which the horizon is one, when an altitude is taken, and then the instrument is held vertical. In bringing down the image of an object to the horizon by a fore observation, the body of the observer must gradually incline towards the horizon, and a little vibrating motion will assist in determining the exact plane of contact; but in taking a horizontal angle, the observer will handle the instrument as befit his convenience. The mirror at A is placed over the centre of motion of the index, in a direction pointing to zero on the vernier, and perpendicular to the flat face of the index; this index-glafs, being completely silvered, reflects the light it receives directly at right angles on the glafs E, when the zero of the vernier is at the zero of the limb; but as the limb proceeds forwards, this angle alters, and, as we have said, is double of the measure of the real angle to be measured and indicated. This glafs E is also fixed perpendicular, and has freelers of adjustment for perpendicularity above its socket of brass, and a tail-piece with a fixing-screw behind the frame, for fixing the parallax; the want of which is called the index-error; one half only of this glafs, which is called the fore-horizon glafs, is silvered, and the other half remains unsilvered, in order that both the direct rays transmitted through the unsilvered part, and the reflected rays coming from the silvered part, may meet at the eye, on which account the middle of this glafs, where the line of separation croles, is the part to be viewed.
viewed in making a contact, otherwise both the image of one object, and the sublance of the other, could not be seen at the same instant. F is the light-vane, with two holes, usually an upper and a lower, inserted into the first radial bar of the frame, so that the holes are at the same distance from the plane of the instrument as the line of separation is in the half-ilvered glass E, to prevent parallax of the reflected rays, and in the belt-instruments this vane, with its telescope, has an adjustable motion to and from the plane, in order that more or less light may fall on either of the bodies observed, which is not only useful, but necessary, in taking a lunar distance; for by this adjustment the image of one body may be made as luminous as the real body of the other, by increasing the light of one, while it decreases that of the other; that is, by making more of the silvered, or of the unsilvered part of glafs E, fall before the object-glafs of the small telescope, when this adjustment is necessary. It may be necessary to observe here, that every silvered glafs of lenitive thickness has two reflections, one on the anterior, and the other, which is the principal one, on the posterior or silvered face, and in many cafes errors may be occasioned by these double reflections; to remedy which, Dr. Maskelyne proposed, that the silvered portion of the posterior face should be ground rough and painted black, taking care that the grinding should be performed, that the line of separation between the polished and unpolished parts be parallel to the plane of the octant. In the back horizon-glafs, which is that seen with its light-vane at G, with adjustments similar to those of the fore horizon-glafs at E, the whole posterior face is silvered, except a slit, that divides it in a line parallel to the plane of the frame, through which all the body is observed in a back obfervation. But when the fun is used for the body observed, his light is not generally too intense for the eye to bear, particularly when the small telescope is used; to render the rays tolerable to the eye, a colored glass, or glafs, must be interposed, and a blank tube instead of a telescope be used, by which means the fun may be viewed without doing injury to the eye; and usually a tylem of coloured glafs are fitted into a square hole, as at H, and a joint in each allows them, or any one of them, to be brought forwards into the situation where the direct rays fall to the eye. The fame remedy is also sometimes applied at the eye-piece of the blank tube, when the fun alone is observed. The plane of the back horizon-glafs is placed not only parallel to the plane of the frame, but at right angles to the plane of the fore horizon-glafs, in order that the same readings may apply in both kinds of observation, and this object was effected by the maker by the simple rectangular position of the two horizon glaftes to each other, and by reverting the position of the body in making a back obfervation; for as the inclination of the index-glafs to the fore horizon-glafs gives double the angle directly measured, so twice the complement of this inclination to the back horizon-glafs gives the fame quantity, and on the fame part of the graduated limb, when measured in a reversed position.

Adjustments.—The adjustments of every instrument are of the utmost importance to the accuracy of observations taken thereby, but they are particularly so in the instrument before us, because a small deviation from parallelism in the fore horizon-glafs, or from perpendicularity in the back horizon-glafs, as compared with the index-glafs, with the vernier at zero of the limb,) will double the error occasioned by it in the quickest situation, as soon as motion is given to the index-glafs. 1. The first adjustment is, to set the index-glafs perpendicular to the plane of the instrument; this is done by first sliding the index to about 40° or 45° of the limb, while the octant is held with its plane nearly parallel to the horizon, then a glance into the index-glafs will shew, whether the sharp edge of the limb seen by reflection, is an exact and straight continuation of the same edge of the limb seen by direct vision, and if this is not the case, it must be made so by the screws that adjust the bed of the mirror; and in all cases where two screws are to be used, one must be released as much as the other is screwed inwards. Dr. Mackay proposes to place two small pieces of metal as adjusting tools, with each a horizontal line drawn on it, at equal heights from the plane of the limb, at some distance from each other, so that the horizontal line of one may be a continuation of the horizontal line of the other, when one is viewed by reflection, and the other by direct vision, but the sharp edge of the inner part of the limb will answer all ordinary purposes. 2. The second adjustment is, to set the fore horizon-glafs perpendicular to the plane of the instrument; this is done by first fixing the zero of the vernier at zero on the limb, and while the plane of the frame is held parallel to the horizon, by applying the eye to the lower hole of its light-vane; then if the horizon, or any distant horizontal line, appear to be a straight line, the glafs is placed perpendicular already; but if the parallax by reflection and by direct vision do not coincide, they must be made to do so by the screws at the bed of the glafs, one of which must be screwed in, as the fracture of the line demands; that is, if the line seen by reflection appear above that seen by direct vision, that screw must be urged inwards which is on the further glafs, and vice versa, until the fractured line be straight. 3. The third adjustment is, to set the index-err of the fore horizon-glafs, or to place it parallel to the index-glafs, when the zero of the vernier is placed at zero on the limb. To do this properly, a bright distant object must be choosen, such as the sun, moon, or star, and while the zeros coincide, look through the vane, or telescope, and observe if the body and its image coincide; that is, if the image is invisible; in this case, the fore horizon-glafs is parallel to the index-glafs, or is truly adjusted; but if not, release the tail-piece or lever behind this horizon-glafs, and with the thumb-piece give it a small motion, till the body and its image coincide, in which situation it must be fixed by the fixing nut before released. Sometimes the act of screwing will displace in some degree the tail-piece, and thereby again occasion a sensible index-error. When this cannot be completely avoided, the error must be ascertained and allowed for with its sign + or — in every subsequent observation, while it remains unaltered. This error may be ascertained by measuring the diameter of the fun, first forwards on the limb, and then backwards on the arc of excess, and one half of the difference of the measures will be the index-error + or — , as the case may be. 4. The fourth adjustment is, to set the back horizon-glafs perpendicular to the plane of the instrument; this adjustment is similar to the second, and may be performed by the directions there given, supposing them to be for the back horizon-glafs and its vane, instead of the fore horizon-glafs. 5. The fifth and last adjustment is, to set the back horizon-glafs perpendicular to the plane of the index-glafs produced, the zero of the vernier being placed at zero on the limb; this adjustment at sea is performed thus; let the vernier be put as much to the right of zero, as is equal to twice the dip of the horizon, in the situation where the obferver stands, then hold the quadrant in a vertical position, and apply the eye to the back-horizon vane; now, if the horizon seen by reflection happens to coincide with that seen by direct vision, the glafs is already right; but if not, the lever or tail-piece behind the frame at this place must be released by the proper fixing screw,
ferew, and turned slowly by the thumb-screw or nut, till this coincidence is perfect, and then the lever must be made fast again; the reflected horizon will be inverted when viewed in the manner here described. When the instrument is used in a back observation on the land, which is not likely to happen often, the adjustment will require some artificial aid: by Dollond's method, an index is applied to the back horizon-glares, by which it may be put parallel to the fore horizon-glares, by the third adjustment applied thereto, and then, by a graduated arc of 90°, inserted on purpose, the index of the back horizon-glares is let perpendicular to its former situation, and consequently is made perpendicular to the plane of the fore horizon-glares. By Mr. Blair's method, the under edge of the index-glares is ground and polished, so as to be at right angles to the plane of the glares, and hence the back horizon-glares is adjusted, by making the direct and reflected horizons agree, while the vernier stands at zero on the limb, exactly as is done in the third adjustment. But we are to suppose the instrument not furnished with either of the above named auxiliary means; when this is the case, a long level space must be chosen in some common or park, where three planes can be put up in the same straight line exactly, and at an interval from each other of not less than 500 yards, but if 600 or 700 the better; then, the vernier being truly placed at zero, let the plane of the octant be held horizontally with its back horizon-glares exactly on the top of the middle staff, and let one of the rods be viewed directly through the back sight-vane, then if the other rod, seen by reflection, coincide with it, the position of the back horizon-glares is true, but if not, it must be made so, by the tail-piece behind, as before directed; if in fixing the tail-piece a derangement should take place, which cannot be exactly done away by a second or third trial, then the index-error for the back observation must be ascertained.

This error may be obtained by reversed observations by two methods; thus, let the coincidence of the two extreme planes be made from the middle staff as just directed, by a motion of the vernier, instead of the tail-piece of the back horizon-glares, and read the quantity moved forwards or backwards; then turn the downward face of the frame upwards, and repeat the operation, and read again; now, if these two readings are found to be one on the limb, and the other on the arc of excess, half of their difference will be the error sought, + or −; but if they both are read on the same side of zero, half their sum, + or −, will be the error; when they are both read on the limb, or if the greater quantity be read on the limb, when the leaves is on the arc of excess, the sign will be −, and vice versâ. By the second method, instead of revering the plane of the instrument, let the observer reverse his position, making the right-hand staff to be the left-hand one, and vice versâ, and then let him repeat his first observation, with the same face of his instrument up that he had in that, and the same result will follow, that was obtained by revering the plane of the instrument. These two modes of obtaining the error in question, by reversed observations, may be made to check each other, and will then give an average of the two results, for the error to be applied to each subsequent observation, taken with the back horizon-glares in its last determined position.

Examination of the Instrument.—These several adjustments being finished, the observer might proceed to make his observations, provided he could rely on the skill and credit of the maker of his instrument; but if not, he would act prudently to examine the materials of which it is composed, before he relies on its performance, and also to put to some trial the accuracy of the divisions on the vernier and limb, as well as the care that has been taken in selecting glaeres of uniform thickness, and of good polish. The exactness of the total arc may be ascertained from comparison with measurements taken with a circle, or some well-known superior instrument; or by careful trigonometrical measurement on some level and extensive ground, where the fides of the triangle can be accurately measured, for which purpose Troughton's new chain of five-foot links is admirably calculated; but the intermediate divisions may be examined by the vernier itself, by stepping the arc with it; and if all parts of the arc are found alike divided, when examined by the coincidence of the extreme fides of the vernier, the intermediate fides of the vernier itself may lastly be examined by the fides on the limb taken in various places.

Dr. Mackay recommends a table of corrections to be made, in case of errors being detected in the dividing, but we should rather recommend new divisions from a good engine, the inferring of which can now be performed at a trifling expense. When the planes of the mirrors are examined, try if a candle reflected appears in two images; if it does, the two fides of the glares are not parallel, and consequently the glaeres is not fit for its purpose.

To try whether the surfaces of the mirrors be perfect planes, bring two distinct distant objects into good contact, and let them be seen at the upper edge of the silvered part; then move the instrument in its own plane, and move the image and body along the line of separation or edge of the silvered part, and if the coincidence is not disturbed the plane is perfect, but not otherwise. Also, when an observation is taken of the sun, and the vernier has been fixed by the fixing screw, read the altitude, as the dark glaeres, or glaeres, may have been used; then remove them from the locket that holds them, and reverse their planes, by putting their remote faces towards; and if, after this change, the same altitude is given, the planes are parallel, otherwise half the difference must be applied, in all such cases, as an error of the coloured glaeres. This examination is best made exactly at noon, when the sun's altitude is not sensibly changed during the examination; unless a good chronometer or regulator, duly regulated, and put to exact time, be at hand; for then the successive examinations may take place at equal distances from noon. Or the same thing may be done by means of a luminous object placed at a distance, and so elevated, that an artificial horizon may give its double altitude before and after the coloured glaeres are reversed in position. The best artificial horizons are either a velvèt of pure mercury, with a roof of good glaere framed over it to prevent agitation by the wind; or otherwise a piece of black glaere, well polished, and placed on screws of adjustment, with a good spirit-level in a glaere tube, so ground, that it will reverce in position, and will place the glaeres in a perfect level in the two requisite directions, at right angles to each other. It may be proper to examine further if the two holes in the sight-vane are so made that the sun or other luminous body dazzles the eye more in looking through one, than in looking through the other, the intention being that one shall take in more of the silvered part, and the other more of the unsilvered part of the glaeres, so as to accommodate the quantity of direct light to the strength of the eye.

Illustration of the Use.—When Hadley's octant, or sextant, is used for altitudes at sea, the sun, moon, or star, as the case may be, must be viewed in the way that the eye can best bear, with or without the dark glaeres, telecope, &c. as occasion may require, and as experience will dictate; and in a fore observation the body observed must have its image brought gradually down, so as to be in exact contact with
the horizon: if the sun or moon be observed, either the upper or lower limb must be subtitled for the centre, and the observation must be afterwards reduced to the centre, by applying the semi-diameter, + or −, from the proper column for the given day, as given in the Nautical Almanac, or Ephemeris; in doing this, the face of the observer must be turned towards the object whose altitude is to be measured, and while the index is gradually moved forward along the limb, the image will descend till it approaches the horizon: in this situation, care must be taken that the contact of the image be made with the visible horizon at the line of separation, between the filtered and unfiltered parts of the fore horizon-glas, that both objects may be visible together; and also that the index may not be pushed too far, so as to require a retrograde motion in finishing the contact: therefore fix the clamping piece, if there is a tangent screw, and complete the contact by a slow motion, and the altitude will remain unaltered till the vernier has been examined by a magnifying glas, which ought always to be at hand, to assist the eye in examining the coincidence of some one line of the vernier with some line of the limb; or, when there is not an exact coincidence, in eliminating the quantity that is beyond coincidence, as compared with the contiguous quantity that is short of it. To succeed well in perfecting a fore observation taken at the horizon, the observer must learn to give a vibratory flow motion of his body to the right and left, his head being the centre of motion, that the image observed may be made to move backwards and forwards in the arc of a circle, of which the horizon is a tangent, in order that the altitude may not be taken at one side of the tangential point, and consequently be too great. Care must also be taken that the faint secondary image reflected from the posterior face be not mistaken for the primary image, reflected from the proper, or anterior face of the mirror. When the altitude is marked down, as read on the limb and vernier, the corrections must be applied, for either the sun or moon, for parallax, refraction, dip of the horizon, and semi-diameter, before the true altitude of the centre is obtained: but for a star no parallax is wanted, nor yet allowance for semi-diameter; these apparently diminutive bodies being situated at such an immense distance from the earth, as to subtend no sensible angle, nor to have any perceptible parallax in altitude.

It is from meridian altitudes thus taken, that, by the application of a heavenly body’s declination, + or −, as the body may be below or above the equator, the co-latitude, and consequently the latitude, is readily determined; and also, the latitude being known, from an altitude taken towards the east or west, that the time is determined at one observation, but more accurately by a series of equal altitudes taken at opposite fides of the meridian; the reduction, however, for the sun’s change of declination during the interval, must, in this case, be taken from tables of correction for equal altitudes, such as are contained in the pamphlet of the late Mr. Wales.

In making the back observation, the coloured glas, or glaesses, must be selected, as before, to suit the eye, and the plane of the instrument held vertically, as in the fore observation, but the face of the observer must view the point of the horizon opposite the sun, or that pointed to by his own shadow; first, let the eye be directed through the vane of the back horizon-glases to the transparent slit that divides the mirror, and let it view the horizon, then move the index till the image of the sun is just seen on the filtered part of the glases; a vibratory motion now given to the ocular from the eye, as the centre of motion, will make the sun’s image move in a curve of which the convex part appears uppermost; in this situation, let the slow motion by the tangent screw, if any, bring this image till one of its limbs coincides with the horizon seen through the transparent slit, and the observed altitude will be determined as before. Whenever the horizon is clear both before and behind the observer, he may reverse his instrument and also his body hastily, when the sun is on the meridian, and make the fore and back observations check each other, which will also, from time to time, prove the respective positions of the two mirrors, and lead to a detection of the error of the back horizon-glasses, when that of the former is known, which it may always be from a double measure, one back and one forwards, of the sun’s diameter. If the difference of the altitudes of the same body taken both ways be equal to the known index-error of the fore horizon-glasses, it will be known that the back horizon-glasses has no error; but if the said quantities are not the same, their difference, + or −, will be the index-error of the back horizon-glasses: hence the back horizon-glasses may be adjusted from a knowledge of the error of adjustment of the fore horizon-glasses, which method, we believe, was never before suggested.

Quadrant. Hadley’s. Theory of. It is a first principle in optics, that the angle of incidence, whatever be the inclination of the incident ray, is equal to the angle of reflection, i.e. if the angle of incidence $\angle DBC$ be $30^\circ$, the angle of reflection $\angle DBC$ will also be $30^\circ$. It is also plain, that if while the radiant $A$ (Plate II. Navigation, figs. 1 and 2.) remains in the same place, the mirror $EF$, by revolving round $B$, moves into the position $E_f$, then the alteration in the angle between the incident and reflected ray will be double to the angle describing the change of position in the mirror. Suppose the mirror changes $10^\circ$ from the incident ray, then the perpendicular $BD$ goes $10^\circ$ farther from the radiant $A$ into the position $B_d$; and the incident angle $\angle DGA$ is $45^\circ$, and the reflected angle $\angle DCE$ is $45^\circ$; so the angle $\angle ABC$ is altered from $60^\circ$ to $80^\circ$; a difference of $20^\circ$ for $10^\circ$ change of position in the mirror. Suppose again the mirror to change, in position, $10^\circ$ towards the radiant $A$, then the perpendicular is changed into $B_d$, $10^\circ$ nearer to the radiant; and the angle $\angle DGA$ of $30^\circ$ becomes $\angle DGA$ of $20^\circ = dBC$; so that the angle $\angle ABC$ is $40^\circ$, whereas $\angle ABC$ was $60^\circ$; that is, by altering the position of the mirror $10^\circ$, the angle $\angle ABC$ was altered $20^\circ$. It may be otherwise demonstrated in that, with a Hadley’s quadrant, the angle of elevation under which an object is seen, is equal to twice the arc which the index has passed over. The instrument or angle $\angle ABC$ (fig. 3.) is $45^\circ$: $ab$ is a reflecting glases fixed parallel to $CB$; $CD$ is the index with a reflecting glases at $G$, so fixed as to be parallel to $ab$, when $CD$ coincides with $CB$; $S$ the sun; $SG$ a polar ray reflected from $G$ to $F$, and from $F$ to $E$, the place of the eye; and $HFE$ the horizontal line at the time of the observation. Then will the angle of elevation $\angle ISG$ be equal to twice the angle $\angle BCD$; for the angle of reflection $\angle DGF$ = the angle of incidence $\angle GSC = CGL$. And the angle of reflection $\angle BFE$ = the angle of incidence $\angle AFG = \angle FLE$ (ab being parallel to $LE$) = $FEL$. But $\angle IGC = HPC = PCE + PEC$ (the external angle being equal to the two internal and opposite) = $PCE + FLE = PCE + GCL + CGL$. Or, $\angle IGC = IGS + SGC = PCE$ (or $GCL$) $GCL + CGL = 2BCD + CGL$. Consequently $\angle IGS = 2BCD$. See Robertson’s Navigation, book ix. p. 295; &c. p. 390, &c.

Mr. Mitchell has recommended Hadley’s quadrant for surveying, and especially the surveying of harbours, and also for piloting ships into harbours. Phil. Trans. vol. iv. art. 10. p. 70.
Mr. Wales, in captain Cook's Voyage, applied it to measuring the quantity eclipsed in an eclipse of the sun; in which operation it answers the purpose of a micrometer, to a great degree of certainty. See an account of the improvements suggested in the construction of these instruments, and also of the various uses to which they may be applied, in Magellan's Description des Écarts & Sextants Anglais, &c. 4to.

Other quadrants have been contrived since, by some ingenious artists, all of which have their merit; but the particulars of their construction are too many for this place; and perhaps, on the whole, nothing preferable to Mr. Hadley's invention has yet been found.

Quadrant, Herodotical, is a pretty commodious instrument; thus called from its use in telling the hour of the day.

Its construction is so simple and easy, and its application so ready, that we shall describe both, for the use of some who may want other conveniences.

Quadrant, Construction and Use of the Horodotical. From the centre of the quadrant, C, (Plate XIX. Astronomy, fig. 8.) whose limb A B is divided into 90°, describe seven concentric circles at intervals, at pleasure; and then add the signs of the zodiac in the order they are represented in the scheme.

2. Applying a ruler to the centre C, and the limb A B, mark upon the several parallels the degrees corresponding to the altitude of the sun when therein, for the given hours; connect the points belonging to the same hour with a curve line, to which add the number of the hour. To the radius C A fit a couple of sights, and to the centre of the quadrant C, tie a thread with a plummet; and, upon a thread, a bead to slide.

If, now, the bead be brought to the parallel in which the sun is, and the quadrant be directed to the sun till a visual ray pass through the sights, the bead will wend the hour.

For the plummet, in this situation, cuts all the parallels in the degrees corresponding to the sun's altitude. Since, then, the bead is in the parallel which the sun then describes, and through the degree of altitude to which the sun is elevated every hour there pass hour-lines, the bead must fly the present hour. Some persons, who are not very nice, represent the hour-lines by arcs of circles, or even by straight lines; and that without any sensible error.

Quadrant, Sinical, is an instrument of use in navigation. It is represented Plate II. Navigation, fig. 3, and consists of several concentric quadrants arcs, divided into eight equal parts by radii, with parallel right lines crossing each other at right angles.

Now any of the arcs, e. gr. B C, may be accounted a quadrant, of any of the great circles of the sphere, chiefly of the horizon and meridian: if, then, B C be taken for a quadrant, e. gr. of the horizon, either of the sides, e. gr. A B, may represent the meridian; and the other, A C, will represent a parallel, or line of east and west; and all the other lines parallel to A B will also be meridians; and all these parallel to A C will be east and west parallels, or east and west lines.

Again, the eight spaces into which the arcs are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing 11° 15'.

The arc B C is likewise divided into 90', and each degree is subdivided into 12', diagonalwise.

To the centre is fixed a thread, as A L; which being laid over any degree of the quadrant, serves to divide the horizon.

If the finical quadrant be taken for a fourth part of the meridian, one side thereof, A B, may be taken for the common radius of the meridian and the equator; and then the other, A C, will be half the axis of the world. The degrees of the circumference, B C, will represent degrees of latitude, and the parallels to the side A B, allurned from every point of latitude to the axis A C, will be radii of the parallels of latitude, as likewise the fine-complements of those latitudes.

Suppose, then, it be required to find the degrees of longitude contained in 83 of the lesser leagues, in the parallel of 48°. Lay the thread over 45° of latitude, on the circumference, and count thence the 83 leagues, on A B, beginning at A; these will terminate at H, allowing every small interval four leagues, and the interval between the broad lines twenty leagues. Then tracing out the parallel H G, from the point H to the thread; the part A G of the thread shews that 125 greater, or equinocial leagues, make 6° 15', allowing twenty leagues to a degree, and three minutes for one league; and therefore that 83 lesser leagues A H, which make the difference of longitude of the course, and are equal to the radius of the parallel G I, make 6° 15' of the said parallel.

If the ship fail on an oblique course, such course, besides the north and south greater leagues, gives lesser leagues calterly and westerly; to be reduced to degrees of longitude of the equator. But these leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, we must find a mean proportional between them.

To find this, we have on the instrument a scale of cross latitudes. Suppose, then, it were required to find a mean parallel between the parallels of 40° and 60°. With your compasses take the middle between the 40th and 60th degree on the scale; this middle point will terminate against the 51st degree, which is the mean parallel required.

Quadrant, Use of the Sinical. There are formed triangles upon this instrument similar to those made by a ship's way, with the meridians and parallels; the sides of which triangles are measured by the equal intervals between the concentric quadrants, and the lines N. and S. E. and W.

The lines and arcs are distinguished, every fifth, by a broader line; so that if each interval be taken for one league, there will be five between one broad line and another; and if every interval be taken for four leagues, then there will be twenty leagues, which make a hea degree, from one broad line to the other.

Now, suppose a ship to have failed 150 leagues northeast, one fourth north; which is the third point, and makes an angle of 33° 45' with the north part of the meridian. Here are given two things: viz. the course, and the distance failed; by which a triangle may be found on the instrument, similar to that made by the ship's course, and her longitude and latitude; and hence may the unknown parts of the triangle be found.

Thus, supposing the centre A to represent the place of departure; count, by means of the concentric arcs, along the point the ship failed on, as A D, 150 leagues from A to D; then is the point D the place the ship is arrived at, which note. This done, let D E be parallel to the side A C; and then there will be formed a right-angled triangle A E D, similar to that of the ship's course, difference of longitude, and latitude; the side A E gives 125 leagues for the difference of latitude northward; which makes 6° 15', reckoning twenty leagues to a degree, &c. and the side D E gives 83 lesser leagues answering to the parallels; which
which being reduced, as shewn above, gives the difference of longitude. And thus is the whole triangle found.

QUADRANT, in Gunnery, called also the gunner's square, is an instrument serving to elevate or point cannons, mortars, &c. according to the places they are to be levelled or directed to.

It consists of two branches, made of brafs or wood; one about a foot long, eight lines broad, and one line in thickness; the other four inches long, and of the same thickness and breadth as the former. Between these branches is a quadrant divided into ninety degrees, beginning from the shorter branch, and furnished with a thread and plummet. See its figure represented in Plate I. Gunnery, fig. 5.

The use of this instrument is cagy; nothing more being required but to place the longest branch in the mouth of the cannon or mortar, and elevate or lower it till the thread cuts the degree necessary to hit a proposed object. See Pointing of a Gun.

Sometimes, also, on one of the surfaces of the long branch, is noted the division of diameters, and weights of iron bullets; as also the bores of pieces. See Caliber.

QUADRANT of Altitude, is an appendage of the artificial globe, consisting of a lamina or flip of brafs, the length of a quadrant of one of the great circles of the globe; and divided into ninety degrees.

At the end, where the divisions terminate, there is a nut rivetted on, and furnished with a fervey, by means of which the instrument is fitted on to the meridian; and is moveable round upon the rivet, to all points of the horizon. See its figure in Plate XIX. Astronomy, fig. 9.

Its use is to serve as a scale in measuring altitudes, amplitudes, azimuths, &c. See the manner of its application under the Use of the Globe.

QUADRANTAL, in Antiquity, a vessel in use among the Romans for the measuring of liquids.

It was at first called amphora; and afterward quadrantal, from its form, which was square every way, like a dice.

Its capacity was eighty ibus, or pounds of water, which made forty-eight sextaries, two urae, or eight congii.

QUADRANTAL Space, in Geometry. See Quadrant.

QUADRANTAL Triangle, is a spherical triangle, one of whose sides at least is a quadrant of a circle, and one of its angles a right angle.

QUADRANTATA Terræ, in our Ancient Law Books, is used for a quarter of an acre, now called a rood; which fee.

QUADRAS Isles, in Geography, islands situated on the N.W. coast of North America, between Pintard's found and the shores of Fua; among which lies Nootka's found, which fee. They were so called by Capt. Ingraham, after the name of a Spanish commander of two schooners, who passed through this channel in the year 1752.

QUADRAT, Quadratum, called also geometrical square, and line of shadow, is an additional member on the face of the common Gunter's and Sutton's quadrants; of some use in taking altitudes, &c.

The quadrant more distinctly exhibited in Plate VI. Surveying, fig. 13, has each of its sides divided into a hundred equal parts, commencing from the extremes; so that the number 100 falls on the angle, representing tangents to the arc of the limb.

The divisions are distinguished by little lines from 5 to 5; and by numbers from 10 to 10; and the divisions being occasionally produced across, form a kind of lattice, consisting of 10,000 little squares.

The proportion here is, as radius is to the tangent of the angle of altitude at the place of observation (i. e. to the parts of the quadrant cut by the thread), so is the distance between the station and the foot of the object, to its height above the eye. See Altitude.

Use of the Quadrat, Geometrical Square, or Line of Shadows.

1. The quadrant being vertically placed, and the rights directed to the top of the tower, or other object, whose height is required; if the thread cuts the side of the quadrant marked right shadows, the distance from the base of the tower to the point of station is less than the tower's height. If the thread falls on the diagonal of the square, the distance is just equal to the height. If it fall on that side marked vertical shadows, the distance exceeds the height.

Hence, measuring the distance, the height is found by the rule of three; as much as there are three terms given. Indeed, their disposition is not always the same; for when the thread cuts the side of right shadows, the first term in the rule of three ought to be that part of the side cut by the thread; the second, the side of the quadrant; and the third, the distance measured. If the thread cut the other side, the first term is the whole side of the quadrant; the second, the parts of the side cut by the thread; and the third, the distance.

For an inference of each. Suppose, i. e. in looking at the top of a steeple, the thread cut the side of right shadows in the point 40, and that the distance measures 20 poles, the case will then stand thus: as 40 is to 100, so 20 is to a fourth term, which we find to be 50; the height of the steeple in poles. Again, supposing the thread to fall on the other side, in the point 60, and the distance to measure 50 poles; the terms are to be disposed thus: as 100 is to 60, so 50 is to a fourth term, viz. 21, the height required. See Altitude.

Use of the Quadrat without Calculation.—The preceding cases may be formed without calculation, where the divisions of the square are produced both ways, so as to form the area into little squares.

Thus, suppose, 1. The thread to fall on 40 in the side of right shadows, and the distance be measured 20 poles; seek among the little squares for that perpendicular to the side which is 20 parts from the thread; this perpendicular will cut the side of the square next the centre, in the point 50, which is the height required in poles.

Note. In all cases the height of the centre of the instrument is to be added. See Altitude, and Shadow.

QUADRAT, in Astrology, called also Quadrile, an aspect of the heavenly bodies, in which they are distant from each other a quadrant, or ninety degrees. See Aspect.

QUADRAT, in Printing, is a sort of space; that is, a piece of metal, call like the letters, to be used occasionally in composing, in order to form the intervals between words, at the end of lines, &c. See Printing.

There are quadrats of divers sizes, as m quadrats, n quadrats, &c. which are respectively of the dimensions of such letters.

QUADRATA, in Ancient Geography, a town of Higher Pannonia, placed on the banks of the Save by Antonine's Itinerary.

QUADRATA, in Geography, a town of Naples, in the province of Bari; five miles N.W. of Ruvo.

QUADRATA is the Italian term in canto fermo for Gregorian or square black notes.
**Quadrata Legis**, among the Romans. See **Square Legion**.

**Quadratic Equation**, in **Algebra**, is an equation of which the highest power of the unknown quantity rises only to the second degree. If this power enters alone, it is called a *simple quadratic*; and when the second power and simple quantity both occur, it is termed an *affected quadratic* equation, thus:

\[ x^2 + a = b \]

is an *affected* quadratic, and

\[ x^2 = b, \text{ or } ax^2 = b, \] a *simple* quadratic equation.

Some authors class all such equations as contain two different powers of the unknown quantity, the one being the double of the other, under the general term quadratics, thus as \(x^2 + ax = b\), \(x^2 + ax + \frac{a^2}{4} = b\), &c. each of which is called a quadratic equation, because their solution depends upon precisely the same principles as the former.

Every quadratic may be reduced to the form \(x^2 + ax = b\); in which it is, however, to be understood, that \(a\) and \(b\) may be either positive or negative; and the general solution of it is expressed by the formula

\[ x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \]

If we give to \(a\) and \(b\) all the variety of signs they admit of, quadratic equations may be divided into four distinct classes, viz.

1. \(x^2 + ax = -b\)
2. \(x^2 - ax = -b\)
3. \(x^2 + ax = +b\)
4. \(x^2 - ax = +b\)

and their several roots will be exhibited by the following formulae, viz.

1. \(x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)}\)
2. \(x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} - b\right)}\)
3. \(x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}\)
4. \(x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)}\)

See **Equations**.

From these forms it is obvious that every quadratic equation has two roots arising out of the ambiguous sign \(\pm\); prefixed to the second member of the root. It is also obvious, that if in the 1st and 2d form, \(b\) be greater than \(\frac{a^2}{4}\), the two roots in both forms are imaginary, or impossible; but if \(b\) be less than \(\frac{a^2}{4}\), then they are in each form both real, being in the 1st both negative, and in the 2d both positive; because the quantity exhibited under the radical forms, in both equations, less than that without the radical; and consequently both the sign and difference will have the same sign as \(\frac{a}{2}\).

In the 3d and 4th forms, the roots are necessarily both real, but one positive and the other negative; the 3d form having its greatest root negative, and 4th its greatest root positive; as is obvious by inspection.

It is, however, not necessary to consider quadratic equations under these four forms, as the solution of them all may be reduced to one general rule, as exhibited in the preceding part of this article, and which may be given in words as follows. Having reduced the proposed equation to any one of the above forms, the roots of it will be equal to half the coefficient of the second term, with its sign changed; plus and minus the square root of the square of that half coefficient prefixed to \(b\), with its proper sign, whether plus or minus. The principles on which the preceding formulæ are obtained, are these, viz. \((x \pm \frac{a}{2})^2 = x^2 + ax + \frac{a^2}{4}\); therefore, if an equation be reduced under the form \(x^2 + ax = \pm b\), by adding \(\frac{a^2}{4}\) to both sides, we shall preserve the equality, and render the first side a complete square, that is, we have

\[ x^2 + ax + \frac{a^2}{4} = \frac{a^2}{2} + b \]

and, by extraction,

\[ x = \frac{-a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \]

consequently

\[ x = \frac{a}{2} \pm \sqrt{\left(\frac{a^2}{4} + b\right)} \]

which form includes all the preceding formulæ. We shall not here give the solution of any examples, as the reader will find sufficient exercises under the article **Equation**; but it may not be amiss to shew other methods of obtaining the roots of quadratic equations, viz. by sines and tangents, continued fractions, &c.

**The Solution of Quadratic Equations by means of a Table of Sines, Tangents, &c.**—Here, referring to our preceding four forms, the solution of them may be exhibited as follows:

Form 1. \(x^2 + ax = -b\).

Put \(\frac{2}{a} \sqrt{b} = \sin \theta\); then

\[ x = \left\{ \frac{-\sqrt{b} \cdot \tan \frac{\omega}{2}}{\tan \frac{\omega}{2}} \right\} \]

Form 2. \(x^2 - ax = -b\).

Put \(\frac{2}{a} \sqrt{b} = \sin \theta\); then

\[ x = \left\{ \frac{\sqrt{b} \cdot \tan \frac{\omega}{2}}{\tan \frac{\omega}{2}} \right\} \]

Form 3. \(x^2 + ax = b\).

Put \(\frac{2}{a} \sqrt{b} = \tan \theta\); then

\[ x = \left\{ \frac{\sqrt{b} \cdot \tan \frac{\omega}{2}}{\tan \frac{\omega}{2}} \right\} \]

Form 4. \(x^2 - ax = b\).

Put \(\frac{2}{a} \sqrt{b} = \tan \theta\); then

\[ x = \left\{ \frac{-\sqrt{b} \cdot \tan \frac{\omega}{2}}{\tan \frac{\omega}{2}} \right\} \]

The above formulæ result immediately from the construction of quadratic equations. Thus, in the two first forms, let \(A\) and \(B\) (Plate XIII. fig. 6. Analytica) represent \(a\) and \(C\) \(D\) \(= \sqrt{b}\), then \(A\) \(D\) and \(B\) \(D\) will be the required roots from the known construction of equations. See Con-struction.

Now here it is obvious that the \(\sin \theta\) represents the \(\sin\) of CED,
C E D, and therefore angle D C B, which is \( \frac{1}{2} \) angle C E D, \( \frac{1}{2} \) angle \( \angle D \), and therefore angle D C B, which is \( \frac{1}{2} \) angle C E D, \( \frac{1}{2} \) angle \( \angle D \), because the angle C A D = angle B C D; which agree with the leading formulæ above given. As to the two latter formulæ for the two first cases, they are obvious without any explanation.

In the 3d and 4th cases, let A B represent \( a \), and A C = \( \sqrt{b} \), then A D and A B will represent the two roots; join B C, and draw D E parallel to B C, so shall C E = B D, and the angle C E D = \( \frac{1}{2} \) the angle B O C. Now here the \( \tan \) \( z \) will represent the \( \tan \) of B O C, and \( \frac{1}{2} \) \( z \) = C D E; but C E = B D is obviously equal to D C \( \times \) \( \tan \) C D E = \( \sqrt{b} \) \( \times \) \( \tan \) \( \frac{1}{2} \) \( z \); and in the same manner A D = \( \sqrt{b} \) \( \times \) \( \cot \) \( \frac{1}{2} \) \( z \). The two latter formulæ require no illustration.

The same results might have been obtained, though not perhaps quite so obviously, from the preceding analytical solution.

There are but few cases in which it is advisable to employ the methods above described to the solution of quadratics, and therefore one example will be considered a sufficient illumination.

Exam.—Given \( x^2 + \frac{7}{4} x = \frac{1695}{12716} \) to find the two roots of the equation by lines and tangents.

Here \( \tan \) \( z \) = \( \frac{88}{7} \), \( \sqrt{1695} \), \( \frac{1}{2} \) \( \sqrt{12716} \), \( \log \) 88 = \( \frac{1695}{12716} \), \( \log \) 12716 = 3.2291697, \( \log \) 1.1248192.

\( \log \) \( \sqrt{12716} \) = -1.5624606.

\( \log \) 88 = 9.1549520.

\( \log \) \( \tan \) \( z \) = 10.6617943.

whence \( \sqrt{77^7} \) \( 42^3 \) \( 32^2 \), and \( \frac{1}{2} \) \( z \) = \( 38^5 \) \( 51^1 \) \( 16^6 \), \( \log \) \( \tan \) \( \frac{1}{2} \) \( z \) = 9.0661115.

\( \log \) \( \sqrt{1695} \) = -1.5624606.

\( \log \) \( \sqrt{12716} \) = -1.4685211.

\( \log \) \( \sqrt{12716} \) = 10.0000000.

\( \log \) \( \sqrt{12716} \) = 10.0000000.

\( \log \) \( \sqrt{12716} \) = 10.0000000.

or \( x = \sqrt{1695} \) \( \sqrt{12716} \) \( \text{the positive root} \); and if \( \cot \) \( \frac{1}{2} \) \( z \) be taken instead of \( \tan \) \( \frac{1}{2} \) \( z \), the other value of \( x \) will be found = \( 77^7 \) \( 42^3 \) \( 32^2 \) \( \sqrt{77^7} \) \( 42^3 \) \( 32^2 \) \( \frac{1}{2} \) \( z \) = \( 38^5 \) \( 51^1 \) \( 16^6 \). See Bonnyceaffle's Algebra, vol. i. p. 141.

For the solution of quadratic equations by the method of continued fractions, we must refer the reader to the "Élémens de la Théorie des Nombres," by Le Gendre.

The root of a quadratic equation may be exhibited under the form of a continued fund, as follows:

Let \( x^2 - a x = b, \) or \( x^3 = a x + b; \) then

\( x = \sqrt{b} + a \sqrt{b} + a x \)

or, by substituting for \( x \) under the radical, its whole value \( \sqrt{b} + a \), we have

\( x = \sqrt{b} + a \sqrt{b} + a x \)

Substituting again for \( x \) as above, we obtain

\( x = \sqrt{b} + a \sqrt{b} + a \sqrt{b} + a \sqrt{b} + &c. \)

By continuing thus our successive substitutions for \( x \), we have

\( x = \sqrt{b} + a \sqrt{b} + a \sqrt{b} + a \sqrt{b} + &c. \)

which is an analytical expression for the positive value of \( x \) in the proposed equation.

It is obvious, however, that such an expression as this is of little or no use for solving quadratic equations; but by means of the latter, a very ready means of finding the ultimate value of such a continued fund. Suppose, for example, the value of the following continued fund were required, viz.

\( \sqrt{12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + &c.} \}

\text{Asume} \)

\( x = \sqrt{12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + &c.} \)

By squaring both sides

\( x^2 = 12 + \sqrt{12 + \sqrt{12 + \sqrt{12 + &c.} \)

Or, since the latter part

\( \sqrt{12 + \sqrt{12 + \sqrt{12 + &c.} = x \)

this becomes

\( x^2 = 12 + x, \) or \( x^3 - x = 12 \)

whence \( x = \sqrt{\frac{12}{2}} + \sqrt{\frac{12}{2}} = 3 ; \)

which is the value of the infinite fund proposed.

Again, let there be proposed the following infinite fund, viz.

\( \sqrt{5 + 4 \sqrt{5 + 4 \sqrt{5 + &c.} \)

Asume the infinite fund = \( x \), then by squaring

\( x^2 = 5 + 4 \sqrt{5 + 4 \sqrt{5 + 5 + &c.} \), or

\( x^2 = 5 + 4 x, \) or \( x^3 - 4 x = 5 \)

whence \( x = 2 \pm \sqrt{4 + 5} = 5 \), the value sought. For other examples of this kind, see Surds.

QUADRATING of a Pierce, among Gunners, is the seeing that a piece of ordnance be duly placed, and poised in its carriages; and that its wheels be of an equal height, &c.

QUADRATO, in Music. See QUADRO.

QUADRATO-CUBUS, QUADRATO-CUBATRUM, and QUADRATO-CUBO-CUBUS, are names used by Diophantus, Vieta Oughtred, and others, for the fifth, seventh, and eighth powers of numbers. See Power.

QUADRATO-QUADRATUM, or BIQUADRATUM, the fourth power of numbers; or the product of the cube multiplied by the root.

QUADRATRIX, in Geometry, a mechanical line, by means of which we would find right lines equal to the circumference
cumference of circles, or other curves, and of the several parts of it.

Or, more accurately, the quadratrix of a curve is a transcendental curve described on the same axis, the ordinates of which being given, the quadrature of the corresponding parts in the other curve is likewise given. See Curve.

Thus, e. gr. the curve A N B (Plate XIII. Analysis, fig. 7.) may be called the quadratrix of the parabola A M C, since it is demonstrated, that A P M A = P N, or A P M A = A P X P N, or A P M A = P N X s, a constant quantity, & c.

The most eminent of these quadratrices are, that of Dio- niores, and that of Mr. Tschirnhausen, for the circle; that of Mr. Perks for the hyperbola.

Quadratrix of Dinostrates, is a curve A M m m (fig. 8.) by which the quadrature of the circle is effected, though not geometrically, but mechanically; it is thus called from its inventor Dinostrates.

Its genesis is thus: divide the quadrantal arc A N B into any number of equal parts, in N, n, & c. by a continual bisection; divide the radius A C into the same number of parts in the points P, p, & c. Draw radii C N, C n, & c. Lastly, on the points P, p, & c. erect perpendiculars P M, b m, & c. The curve formed by connecting these lines is the quadratrix of Dinostrates.

This curve may be described by continual motion; if we suppose the radius C N by its extreme N to describe uniformly the arc A B, and at the same time a ruler P M, always parallel to itself, to move uniformly along A C, in such a manner that when the ruler P M arrives at C, the radius C N may coincide with C B; and thus the continual intersection of C N with the ruler P M will describe the quadratrix A M D.

Here, from the construction, A N B : A N :: A C : A P; and therefore, if A N B = a, A C = b, A N = x, A P = y; a y = b x. See Quadrature.

Quadratrix Tschirnhausiana, is a transcendental curve A M m m B (fig. 9.) by which the quadrature of the circle is likewise effected; invented by Mr. Tschirnhausen, in imitation of that of Dinostrates.

Its genesis is thus conceived: divide the quadrant A N B, and its radius A C, into equal parts, as in the former; and from the points P, p, & c. draw the right lines P M, p m, & c. parallel to C B; and from the points N, n, & c. the right lines N M, n m, & c. parallel to A C. The points A, M, m, being connected, the quadratrix is formed; in which A N B : A N :: A C : A P. And therefore, if A B = a, and A C = b, A N = x, and A P = y; a y = b x. See Quadrature.

This curve may also be described by continued motion, if two rulers, N M and P M, perpendicular to each other, be made to move uniformly and parallel to themselves, the one along the quadrant of the circle A C, and the other along the radius.

Quadratum-Cubi, Quadrato-Quadrato-Qua-
tratum, and Quadratum Sarcolis, & c. are names used by the Arabs for the sixth, eighth, and tenth powers of numbers. See Power.

Quadratum Ov, in Comparative Anatomy, is carré of the French; a small bone in the head of birds, to which the lower mandible is articulated. See Birds, in Comparative Anatomy, in the division relating to the bones.

Quadrature, in Geometry, signifies literally the finding of a square equal to any given figure, which was the method the ancients made use of when they had in view the determination of the surface of any space; but the term quadrature has now a more indefinite signification; implying, in general, the determination of the area of a figure, without any reference to the geometrical exhibition of it, in a square or other rectilinear form.

All rectilinear figures being immediately reduced to, or dependent upon, the area of triangles, their quadratures have been known from the highest antiquity; but the quadratures of curvilinear spaces are, with very few exceptions, of modern date, two only having been known till near the beginning of the eighteenth century.

The first curvilinear space whose quadrature was accurately determined, was the lune of Hippocrates, of which an account will be found under the article LUNA. Archimedes next found the area of the common parabola; which he obtained in a very ingenious manner, by inscribing an isosceles triangle in the parabola, then two isosceles triangles on the equal sides of the former, four others on the side, and so on, which he found to have a certain relation, decreasing in the proportion 1, 3, 7, & c., the infinite sum of which series would therefore express the area of the parabola, or the area of all the triangles of which he thus conceived it to be composed; and which sum was found to be 1 or of the circumference of the rectangle. After this time, a period of near two thousand years elapsed, without producing the quadrature of a single curvilinear figure, although the subject seems to have engaged the attention of the most eminent mathematicians during that long interval, particularly the quadrature of the circle. This figure, being the smallest simple in appearance and construction of any contained under the curve line, was well calculated to excite the curiosity of mathematicians. Archimedes doubled it is attempted the solution of this problem; but failing in producing the exact quadrature, he contented himself with giving an approximation, testimony by the inscription and circumference of a polygon of many sides, that the diameter being 1, and the circumference was greater than 31/2; but less than 31/2, and as it was known, even before the time of Archimedes, that the area of a circle is equal to that of a right-angled triangle, whose altitude is equal to the radius, and base equal to the circumference of the circle, it follows, that the area would be greater than 31/2, but less than 31/2.

It would be idle to attempt in this place to enumerate the various absurd quadratures which have been, from time to time, published by minor geometers, with all that conceit and confidence which felden fail to accompany inferiority. Some attributed their success to divine inspiration others to their own superior talents; some offered large sums of money to those who should discover any error in their investigation, while others expected great rewards from their government, as a recompense for their discovery, foolishly attaching great importance to a problem, which, if it could be accurately solved, would serve no other purpose but to gratify the curiosity of mathematicians. Many of these attempts, however, have been rendered somewhat amusing by an excess of absurdity. This is particularly the case with regard to the work of Jaime Falcon, a Spaniard of the order of Notre Dame, of Montesa, published at Anuers in 1587. This treatise opens with a dialogue in verse between himself and the circle, which thanks him very affectionately for having squared him; but the good and modest knight attributes all the honour of the discovery to the holy patron of his order. See Montucla's "Histoire des Recherches sur la Quadrature du Circle," or his "Histoire des Mathematiques," vol. iv. p. 65, &c.

Referring those readers who have the curiosity to examine the reveries above-mentioned to the two preceding works, we propose to give here an abstract from the same, of what has
QUADRATURE.

has been done on this subject, by way of approximation. We have already observed that Archimedes was the first who gave an approximation of the ratio of the diameter to the circumference of a circle, placing it between the limits 3 1/4 and 3 1/3; and it is said that Apollonius and Philo found more accurate approximations, which, however, have not been transmitted to us.

Towards the year 1555, Metius, combatting the false quadrature of Simon Duchêne, gave the ratio of 113 to 355, which is very exact, being only 1/4340 in excess. Vieta found a still nearer approximation, carrying it to ten decimals, whereas the former is true only to six places. He also gave a kind of series, the infinite sum of which was equal to the entire circle.

Adrianus Romanus carried the approximation to seventeen figures, and Ludolph van Ceulen to thirty-six; which he published in his work "De Circulo et Adscriptis," and of which Snellius published a Latin translation in 1619. He afterwards verified Van Ceulen's approximation by some theorems of his own invention, which greatly facilitated the computation, and which he published in 1621, under the title of "Willebrordi Snelli Cyclometricus de Circuli Dimensione, &c."

Defaerts found a geometrical construction from which it was easy to draw an expression in the form of a series; and Huygens afterwards discovered some curious theorems connected with this subject, but did not advance the approximation, though he made some useful rules for approximating towards the length of the circular arc.

One of the most curious discoveries connected with this subject, which had yet been published, was that given by Wallis in his "Arithmetica Infinitorum," in 1655; where he showed that the ratio of a circle to the square of its diameter, is truly expressed by the infinite fraction

\[
\frac{3}{2} - \frac{3}{2} - \frac{5}{4} - \frac{7}{6} - \frac{9}{8} - \ldots
\]

If we limit ourselves, as we must do, to a finite number of terms, we shall have a ratio alternately too great and too small, according as we take an even or an odd number of terms:

\[
\begin{align*}
\text{Thus, } & \frac{3}{2} \text{ is too great; } \frac{5}{2} \text{ too small; } \frac{7}{4} \text{ too great; and } \\
\frac{3}{2} \frac{5}{2} \frac{7}{4} & \text{ too small, and so on; but each of these is a nearer approximation than the preceding ones. But in order to approach still nearer in both cases, the author proposed to multiply the whole product by the square root of a binomial, viz., unity, plus unity divided by the last figure, with which the figures terminated either in the numerator or denominator; in which case, the product will be a much nearer approximation; it will be too great if we use the last figure of the numerator, and too small if the last of the denominator.
\end{align*}
\]

Thus we shall have for the ratio sought, alternately in excesses and defect.

In excess.

\[
\begin{align*}
3.3.3.3.3 & \sqrt{1} \\
2.4.4.6 & \sqrt{1} \\
3.3.3.3.3.7 & \sqrt{1} \\
2.4.4.6.8 & \sqrt{1} \\
& & & & & & psychosis
\end{align*}
\]

In defect.

\[
\begin{align*}
3.3.3.3.3 & \sqrt{1} \\
2.4.4.6 & \sqrt{1} \\
3.3.3.3.3.7 & \sqrt{1} \\
2.4.4.6.8 & \sqrt{1} \\
& & & & & & psychosis
\end{align*}
\]

Prior to the above series of Dr. Wallis, however, some thing of an equivalent expression, though given under a different form, was discovered by Lord Broucker, which is as follows. The circle itself being 1, the square of its diameter is expressed by the infinite continued fraction.

\[
\begin{align*}
1 + \frac{1}{2 + 3^1} \\
2 + 5^2 \\
2 + 7^2 \\
2 + \ldots \ldots \\
\end{align*}
\]

of which the law of the denominators is obvious. See CIRCLE.

Thus was the progress which mathematicians had made towards the solution of this interesting problem prior to the invention of fluxions, which, by reducing the quadrature of all curves to one general principle, again revived the hopes of success with regard to the circle, notwithstanding some pretended demonstrations of its impossibility; and its quadrature was accordingly again attempted with the greatest eagerness. The quadrature of a space, and the rectification of a curve, were now reduced to that of finding the fluent of a given fluxion but still the problem was found to be incapable of a general solution in infinite terms. The fluxion of a given fluent was found to be always affirmative, but the converse proposition, viz., of finding the fluent of a given fluxion, could only be effected in particular cases; and amongst the exceptions, to the great regret and disappointment of geometers, was included the case of the circle with regard to every form of fluxion under which it could be obtained. Some exceedingly near approximations have, however, since been made towards the true ratio of the diameter to the circumference of the circle, but these belonging rather to the article Rectification than to Quadrature, we shall enter again upon the subject under the former term, and shall occupy the remainder of the present article on the quadrature of curves in general.

On the Quadrature of Curves by Fluxions. In order to exhibit more distinctly and at large the use of fluxions, according to the modern method of notation, in finding the areas of curves, we shall premise the two following cases.

Case 1. Let A R C (Plate XIII. Analysis, fig. 10.) be a curve of any kind, whose ordinates R, C, B, are perpendicular to an axis A B. Imagine a right line b R g, perpendicular to A B, to move parallel to itself from A towards B; and let its velocity, or the fluxion of the abscisse A b, in any proposed situation of that line, be denoted by b d; then will the rectangle b u express the fluxion of the generated area A b R, which, if A b = x, and b R = y, will be = y x; whence, by substituting for y x (according to the equation of the curve,) and taking the fluent, the area itself will become known.

Case 2. Let A R M (fig. 11.) be any curve whose ordinates C R, C R, are all referred to a point or centre; and conceive a right line C R H to revolve about the given centre C, and a point R to move along the said line, so as to describe the curve live A R M. If this point were to move from Q, without changing its direction or velocity, it would proceed along the tangent Q S (instead of the curve), and describe areas Q S C, Q S C, about the centre C, proportional to the times in which they were described; because, having the same altitude C P, they are as the bases Q S and Q S. Consequently, if RS be taken to denote the value of 1 over the fluxion of the curve line A R, the corresponding fluxion
QUADRATURE.

fluxion of the area $ARC$ will be truly represented by the uniformly generated triangle $QCS$; which, expressing $CP$ by $s$, will be
$$\frac{QS \times CP}{2} = \frac{sz}{2} \quad \text{whence the area itself may be determined. But since, in many cases, the value of $z$ cannot be computed (from the property of the curve) without trouble, the two following expressions, for the fluxion of the area, will be found more commodious, viz. } \frac{zy \hat{x}}{2t} \text{ and } \frac{y^2 \hat{x}}{2a};$$

where $z = RP$, and $x = \text{the arc }BN\text{ of a circle, described about the centre }C, \text{ at any distance }a = CB$. These expressions are derived from those above in the following manner; viz. $\frac{iz}{2} = \frac{y^2 \hat{x}}{t}$; consequently $\frac{iz}{2} = \frac{2t}{y}$.

Moreover, because the celerity of $R$ in the direction of the tangent is denoted by $\frac{iz}{y}$, that in a direction perpendicular to $CQ$ (whereby the point $R$ revolves about the centre $C$) will, therefore, be $\frac{CP \times z}{CR} = \frac{iz}{y}$, which being to $x$ the celerity of the point $N$ about the same centre as the distance or radius $CR(y)$ to the radius $CN(a)$, we shall, by multiplying extremes and means, have
$$\frac{axz}{y} = y \hat{x}, \text{ and, consequently, } \frac{iz}{2} = \frac{y^2 \hat{x}}{2a}. \text{ In the examples subjoined, the letters } x, y, z, \text{ and } u \text{ will be used to denote the abscissae, ordinates, curve-line, and area respectively.}

Quadrature of a Right-angled Triangle. Let the base $\triangle{AH}$ ($\triangle{12}$) = $a$, the perpendicular $\triangle{HM} = b$, and let $\triangle{AB(x)}$ be any portion of the base, considered as a flowing quantity, and $\triangle{BR(y)}$ be the corresponding ordinate. Then, the triangles $\triangle{AHM}$ and $\triangle{ABR}$ being similar, we shall have
$$\frac{a}{b} : \frac{x}{: y} = \frac{x}{a}; \text{ Whence } y \hat{x} \text{ (the fluxion of the area } \triangle{ABR}) = \frac{b^2 \hat{x}}{2a}; \text{ and its flux, (see Inverse Method of Fluxions) or the area itself } \frac{b^2 \hat{x}}{2a}, \text{ when } x = a,$$

and $\triangle{BR}$ coincides with $\triangle{HM}$, will become $\frac{ab}{2} = \frac{AH \times HM}{2}$ = the area of the whole triangle $\triangle{AHM}$. See Mensuration of Triangles.

Quadrature of a Circular Sector. Let $\triangle{AOR}$ ($\triangle{13}$) be the sector; $\triangle{AO}$ or $\triangle{OR}$, its radius, = $a$, the arc $\triangle{AR}$, considered as variable by the motion of $R$, = $z$, and $\triangle{OR}$ = $\frac{z}{2}$; the fluxion of the area will be
$$\frac{a \cdot z}{2} = \frac{a \cdot z}{2} \quad \text{the triangle } \triangle{OR}: \text{ whence the area itself is } \frac{az}{2} = \frac{AO \times \frac{1}{2}AR}: \text{ that is, the area of any circle is expressed by a rectangle under half the circumference and half the diameter. See Circle.}

Quadrature of a Semicircle. Let the semicircle be $\triangle{AHE}$ ($\triangle{14}$); its diameter $\triangle{AH} = a$, $\triangle{AB} = x$, and $\triangle{BR} = y$, &c. and we have $y^2 (\triangle{BR^2}) = ax - x^2$ ($\triangle{AB} \times \triangle{BH}$), and, consequently, $u (y \hat{x}) = \hat{x} \sqrt{ax - x^2}$; which expression being

resolved into an infinite series, we shall have
$$u = a^2 y \hat{x} \times \left(1 - \frac{x}{2a^2} - \frac{x^2}{8a^4} - \frac{x^3}{32a^6} - \frac{5x^4}{128a^8} + \cdots \right) = a^2 y \hat{x} \times \left(\frac{x^2}{2a} - \frac{x^3}{2a^2} - \frac{x^2}{2a^2} - \frac{5x^4}{128a^8} + \cdots \right), \text{ &c.}$$

Thence, the fluent of every term being taken, there will arise $u = a^2 y \hat{x} \times \left(\frac{x^2}{3a^2} - \frac{5x^4}{72a^4} + \cdots \right)$, &c. = the area $\triangle{ABR}$. When $z = \frac{1}{4} a$, the ordinate $\triangle{BR}$ will coincide with the radius $OE$; in which case the area becomes $\frac{1}{4} a^3 \frac{1}{2} a a \times (\frac{1}{4} - \frac{1}{4} - \frac{1}{4} - \frac{1}{4} - \frac{1}{4} - \frac{1}{4} - \frac{1}{4})$, &c. = $\frac{1}{2} a^3 (0.666^2 - 0.1 - 0.003)$

$- 0.0017 - 0.0004, \text{ &c.} = 0.1954 a^3;$ which, multiplied by 2, gives 0.3928 $a^3$ for the area of the semicircle, nearly. In order to obtain a more converging series, let the arc $\triangle{AR} = \frac{1}{2} \triangle{AE} = 30^\circ$, and the fine $\triangle{BR}$ (being half the chord of double the arc or half the side of a hexagon, i.e. half the radius), will be $\frac{1}{2} \triangle{AO}$; and $\triangle{BR(y)} = \triangle{AO} - \triangle{OB} = \triangle{AO} - \sqrt{(\triangle{OR} - \triangle{BR})};$ which, radius being 1, will be 0.1339746 nearly; substituting this quantity, with the value of $a$ in the above series,

$\sqrt{a \hat{x}} \times \left(\frac{1}{3} - \frac{x^2}{5a^2} - \frac{x^3}{28a^4} + \cdots \right)$ and we shall have

0.0693505 (0.666666666 - 0.0137975 - 0.0001623 - 0.0000242 - &c. = 0.0693505 - 0.0531046 = 0.045293) = the area $\triangle{ABR}$; which, added to the area $\triangle{OB}$ (= $\frac{1}{2} \triangle{BR} = \sqrt{\frac{1}{2} \times \frac{1}{2}} = 0.2165063$) gives the content of which, or 0.7853982 ($\triangle{AR}$ being $\frac{1}{4} \triangle{AE}$), will be the content of the whole quadrant $\triangle{AOE}$; which number, found by taking only four terms of the series, is true to the last decimal place.

We might have found a series of more rapid convergency, but shall reserve that part of our investigation for the article Rectification.

Quadrature of the Lunes. See Lunes.

Quadrature of the Ellipse. The ellipse, also, is a curve whose precise quadrature in definite terms is not yet effected. Indeed the area of an ellipse, being an exact mean proportional between the areas of the circles described upon its two axes, is obviously dependent upon the latter; and it is, therefore, useless to repeat the operation.

Quadrature of the Parabola. Let the curve $\triangle{ARM}$ ($\triangle{15}$), be the common parabola, in which $y^2 (\triangle{BR^2}) = ax (\triangle{AB} \times a)$, the parameter. See Conic Sections. Whence we have $y = a^2 x^2$ and $u (y \hat{x}) = a^2 x^2 \hat{x}$; and therefore, $u = \frac{2y^2 \hat{x}^2}{a}$; whence $u = \frac{2y^2 \hat{x}^2}{a}$, $\frac{2y^3 \hat{x}}{a^3} \hat{x} = \frac{2y^3}{a^3} \hat{x}$, and $x = \frac{2y}{a} \triangle{AB} \times \triangle{BR}$. See Parabola.

In the cubic parabola, whose equation is $p^3 x = y^3$; we have
have \( y = p^{\frac{1}{2}} x^{\frac{1}{2}} \); multiply this by \( \dot{x} \), and we have \( y \dot{x} = p^{\frac{1}{2}} x^{\frac{3}{2}} \), for the fluxion of the area. Therefore fluent \( y \dot{x} = \frac{3}{2} p^{\frac{1}{2}} x^2 = \frac{3}{2} of xy \), that is, area \( = \frac{3}{4} \) of circumscribing rectangle.

And in the same manner, it will be found that in the general parabola, whose equation is \( a^{n-1} x = y^n \); the area = \( \frac{n}{n+1} \) of circumscribing rectangle.

**Quadrature of the Hyperbola.** The analytical quadrature of this curve was first given by N. Mercator of Holland, the first inventor of infinite series. But Mercator finding his series by division, Sir Isaac Newton and M. Leibnitz improved upon his method; the one seeking them by the extractions of roots, the other by a series presupposed. See Hyperbola.

**Quadrature of the Asymptotic Spaces in an Hyperbola.**

Let \( DEF \) (fig. 16.) be an hyperbola, of which the asymptotes are \( CM \) and \( CN \); to find the area \( GEFH \), comprehended between the ordinates \( GE \) and \( FH \).

Let \( CG = a \), \( GE = b \), \( GH = x \), \( FH = y \); then by the property of the hyperbola, \( CG \times GE = CH \times HI \), or \( ab = (a - x) y \), or \( y = \frac{ab}{a + x} \); and, therefore, \( y \dot{x} = \frac{ab \dot{x}}{a + x} \); the fluent of which is \( ab \times \text{hyp. log.} \ (a + x) \), which fluent, however, requires a correction, for when \( x = 0 \), the area = \( 0 \); but the above expression when \( x = 0 \) is \( ab \times \text{hyp. log. of} \ a \), therefore the correction is \( - ab \times \text{hyp. log. of} \ a \), that is, the correct fluent which expresses the area \( ab \times \text{hyp. log.} \ (a + x) - ab \times \text{hyp. log.} \ a \), or area \( \text{EFGH} = ab \times \text{hyp. log.} \ \frac{a + x}{a} \).

If \( CG \) and \( GE \) each = \( 1 \); \( y \dot{x} = \frac{x}{1 + x} \), the fluent of which is \( \text{hyp. log.} (1 + x) \), which requires no correction.

**Quadrature of the Cycloid.**

Let \( CAL \) (fig. 17.) be a cycloid, \( AD \) the axis, \( ABD \) the generating circle, \( AF \) a tangent at the vertex, \( CF \) parallel to \( AD \).

Take any point \( P \) in the arc, and draw \( PM \) perpendicular to \( AM \). Then the fluxion of the external area \( AMP = PM \times \text{fluxion of} \ AM \).

Let \( AE = x \), \( AD = 2a \); then \( BE = \sqrt{(2a - x^2)} \) and the fluxion of \( BE = \frac{a \dot{x}}{\sqrt{(2a - x^2)}} \); and the fluxion of \( PB + BE \), or of \( AM \) = \( \frac{(2a - x) \dot{x}}{\sqrt{(2a - x^2)}} \); therefore the fluxion of the area \( AMP \), or \( PM, x \) by the fluxion \( AM = \frac{(2a x - x^2) \dot{x}}{\sqrt{(2a - x^2)}} = \dot{x} \sqrt{(2a - x^2)} \).

But the fluent of this fluxion is the same as that found above for a circle, whose radius is \( a \), and versed sine \( x \); that is, the area \( ABE \); and, therefore, when \( x = 2a \), the whole external area \( CFA \) is equal to the area of the semicircle \( ABD \). But \( CD \) being equal to the semicircumference \( AD \), the whole rectangle \( CDAB \) = four times the semicircle \( ABD \); and consequently the internal area \( ACD = \) three times the semicircle \( ABD \); or the whole area of the cycloid equal three times the area of its generating circle.

**Quadrature of the Logarithmic, or Logarithmetic Curve.**

Let the subtangent \( PT \) (fig. 18.) = \( x \), \( PM = x \), \( Pp = dx \); then will

\[
\frac{y \dot{x}}{y} = a \\
\frac{y \dot{x}}{x} = a \dot{y}
\]

and fluent of \( y \dot{x} = ay \).

Wherefore the indeterminate space \( HPMI \), is equal to the rectangle of \( PM \) into \( PT \).

Hence, 1. Let \( QS = x \); then will the indeterminate space \( IQSH = ax \); and, consequently, \( SMQ = ay - ax = (a - x) y \); that is, the space intercepted between the two logarithmic semiordinates is equal to the rectangle of the subtangent into the difference of the semiordinates.

2. Therefore, the space \( BAPM \) is to the space \( PMSQ \) as the difference of the semiordinates \( AB \) and \( PM \) is to the difference of the semiordinates \( PM \) and \( SQ \). See Logarithmic Curve.

**Quadrature of the Logarithmic Spiral.**

Let \( CBAC \) (fig. 19.), be the area propoted: let the right line \( AT \) touch the curve at \( A \), upon which, from the centre \( C \), let fall the perpendicular \( CT \); then, since by the nature of the curve, the angle \( TAC \) is every where the same, the ratio of \( AT \) to \( CT \) will be constant: and, therefore, the fluent of \( \frac{x}{t} \times y \frac{\dot{y}}{t} = \frac{t}{2} \times \frac{y^2}{4} \) is the required area.

**Quadrature of the Spiral of Archimedes.**

Let \( CR \) (fig. 20.) be the curve, whose area \( CRG \) is required. Let \( A \) be a tangent at the centre \( C \), about which centre, with any radius \( AC = a \), suppute a circle \( AG \) to be described; then the arc or abscissa \( AG \) corresponding to any proposed ordinate \( CR \), being to that ordinate in a constant ratio (e. gr., as \( m \) to \( n \)) we have \( x = (AG) = \frac{m y}{n} \); therefore \( u = \frac{y \dot{x}}{a} = \frac{my \dot{x}}{2an} \); consequently \( u = \frac{my \dot{x}}{2an} \) is the area \( CRG \). See Spiral of Archimedes.

**Quadrature of Desartret’s Curve,** which is defined by the expression, \( b^2 x^2 + b^2 y = 2a \).

Since \( b^2 y = b x^2 - x^2 \)
\[
y \dot{x} = (b x^2 - x^2) \div b^2
\]
\[
\text{flu. } \dot{y} = x^2 \div 3b - x^2 \div 4b^2.
\]

**Quadrature of all Curves comprehended under the general Equation,** \( y = \frac{1}{x} (x + a) \).

Since \( y = (x + a)^{\frac{1}{a}} \)
\[
y \dot{x} = \dot{x} (x + a)^{\frac{1}{a} - 1}
\]

Make \( (x + a) = \nu \), or \( x = \nu^n - \nu \)

Then \( x + a = \nu^n, \) or \( x = \nu^n - \nu \)

Whence \( \dot{x} = m \nu^{n-1} \nu \)
\[
\dot{y} = m \nu^{n-1} \nu^2, \) the fluent of which is \( \frac{m \nu^{n+1}}{m + 1} \).

Let \( x = 0 \); the remainder will be \( \frac{m}{m + 1} a \sqrt[n]{a} \).

\[
\text{X}
\]

Whence
Whence, the area of the curve \( m \int \frac{a}{m + 1} \sqrt{x + a} \)

See on the subject of this article Maclaurin’s Fluxions, and Simpson’s Fluxions, vol. i. sect. 7, p. 121, &c.

**QUADRATURE.** In Astronomy, that aspect, or situation of the moon, when she is 90 degrees distant from the sun.

Or, the quadrature is when she is in a middle point of her orbit, between the points of conjunction and opposition; which happens twice in each revolution, viz. in the first and third quarter.

When the moon is in her quadrature, she exhibits that phase which we call the half-moon, i.e. she shines with half half her face; and is said to be bisected, or dichotomized.

In the moon’s progress from the syzygies to her quadrature, her gravity towards the earth is continually increasing by the action of the sun; and her motion is retarded for the same reason. Her motion then, in her orbit, is slowest as her gravity to the earth is greatest when in the quadratures.

In her reces from the quadratures to the syzygies, the gravity continually decreases, and the velocity increases. The ratio is thus: as radius is to the sum, or difference of one and a half the cosine of double the distance of the moon from the syzygy, and half the radius; so is the addition of gravity in the quadratures to the diminution or increase of it in any other situation. See Syzygy.

Hence the moon’s orbit is more convex in the quadratures, than in the syzygies; and hence the circular figure of the moon’s orbit is changed into an oval, whose greater axis goes through the quadratures; and hence, also, the moon is least distant from the earth at the syzygies, and more at the quadratures.

It is no wonder, therefore, that the moon should approach nearer the earth when her gravity is diminished; that access not being the immediate effect of this diminution, but of the inflexion of the orbit towards the quadratures.

In the quadratures, and within thirty-five degrees of them, the apsides of the moon go backwards, or move in antecedentia; but they move forwards in the syzygies. See Apsides.

The moon’s orbit undergoes various alterations in each revolution. Its eccentricity is the greatest when the line of the apsides is in the syzygies; and the least, when in the quadratures.

Considering one entire revolution, the nodes move flower and flower as the moon approaches the quadratures, and they recede when she is in them; but considering several revolutions, the nodes go back faster in the quadratures.

The inclination of the plane of the moon’s orbit increases as the nodes go from the syzygies, and is greatest when the nodes are in the quadratures. See Moon and Nodes.

**Quadrature Lines, or Lines of Quadrature, are two lines frequently placed on Gunter’s Lector.**

They are marked with the letter Q, and the figures 5, 6, 7, 8, 9, 10; of which Q signifies the side of a square, and the other figures the sides of polygons of 5, 6, 7, &c. sides.

There stands for the semi-diameter of a circle; and go for a line equal to ninety degrees in circumference.

**QUADRATUS, in Biography, an early Chriftian writer, who flourished under the reigns of Trajan and Adrian.** He is ited by Jerome and Eufebius “a disciple of the apolites,” and he was reported to have been endowed with the gift of prophecy. According to Eufebius, Quadratus presented to the emperor Adrian, in the year 126, an apology for the Christian religion, with a view of mitigating the sufferings inflicted upon the professors of that period.

This is supposed to have been the first written apology presented on the same subject to any of the Roman emperors, and it produced a considerable effect on the mind of Adrian.

Of this work only a fragment remains, which is preferred by Eufebius, and which is extremely valuable on account of the testimony which it affords to the reality of the miracles of Chrifi and his apostles, by asserting that some of those miracles were wrought on persons who were living at the time when Quadratus wrote. Nothing is known respecting the time and manner of his death. Lardner.

**QUADRATUS, in Anatomy, a name given to several muscles of the body, on account of their form.**

**QUADRATUS Femoris, le carré, ischio-trochanterien;** is situated at the upper and back part of the thigh, and extends from the tuberosity of the ischium to the great trochanter. It is flattened, quadrilateral, and tolerably thick. The posterior surface is covered by the gluteus maximus, the sciatic nerve, and the semi-membranous; the anterior surface covers the obturator externus, the extremity of the tendon of the psoas magnus, and the back of the trochanter minor. The superior edge is parallel to the inferior geminus; and the inferior to the upper fibres of the adductor magnus. The inner edge, or origin of the muscle, is fixed to the outer side of the tuberosity of the ischium, in front of the semi-membranous; the outer is attached to the bony ridge, which runs from the great to the small trochanter. It is tendinous at its two attachments, and fleshy in other parts. It will rotate the thigh outwards upon the pelvis; or, if the former be fixed, it will move the pelvis upon the thigh. When the thigh has been carried upwards and outwards, it will restore the limb to its natural position.

**QUADRATUS Genae, a muscle of the lower lip; see the article Deglutition, where it is described under the name of depressor labii inferioris.**

**QUADRATUS Lumborum. See Lumborum.**

**QUADRATUS Occipititis, a name of the posterior or occipital portion of the Epicranium; which see.**

**QUADRELLA, in Geography, a town of Naples, in Lavora; 20 miles E.N.E. of Naples.**

**QUADRELS, in Building, a kind of artificial stones, perfectly square; whence their name. They are made of a chalky, or whitish and pliable earth, &c. dried in the shade for at least two years.**

They were formerly in great request among the Italian architects.

**QUADRICEPS, in Anatomy, a name under which it has been proposed to describe the extensors of the knee-joint, viz. the vastus internus and externus, the crurales, and rectus; and the adductors of the thigh, with the pectinals.**

**QUADRIGA, formed from quadrup, four, and jegum, yoke, in Antiquity, a car, or chariot, drawn by four horses, harnessed abreast.**

Various are the accounts we have of the inventor of the quadriga. Cicero makes it the invention of Minerva. Hyginus attributes it to Eriugolius IV. king of the Athenians; which sentiment Virgil also follows in his Georges, lib. iii. ver. 112. Ezechiel gives Prometheus the honour of it. Tertullian, De Speccct. lib. ix. fays, it was invented among the Argians, by Trophias, in honour of Juno; and at Rome, by Romulus, in honour of Mars, or Quirinus. Ado of Vienne, Chronic. act. iii. will have it to have been invented by one Procisus, about the time of the establishment of the kingdom of Athens. Laziardels, Hist.
QUADRILATERAL, in Geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure.

If the several angles are right, the figure is a rectangular quadrilateral. If oblique, an oblique-angular quadrilateral.

If the sides of a quadrilateral be equal, and the angles right, the figure is a square.

If the sides be equal, but the angles unequal, the figure is a rhombus.

If the angles be equal, and the sides unequal, the figure is a rectangle.

If only the opposite angles and sides be equal, the quadrilateral is a rhomboides.

If the opposite angles and sides be unequal, the quadrilateral is a trapezium.

If any side of a quadrilateral, inscribed in a circle, be produced out of the circle, the external angle will be equal to the opposite, internal angle.

Hence, the two opposite angles of any quadrilateral figure inscribed in a circle, always make two right angles; and, therefore, no oblique-angled parallelogram can have a circle described about it, because its opposite angles being equal, must together be greater or less than two right angles. See Circle.

QUADRILL, QUADRELLA, a little troop or company of cavaliers, pompously drest and mounted; for the performance of carousals, jults, tournaments, runnings at the ring, and other gallant divertissements.

The word is borrowed from the Italian, being a diminutive of squdra, a company of soldiers ranged in a square: for quadrare is, properly, to divide any thing square; whence their quadrigila, the French quadrille and quadrille, and our quadrill. The French formerly wrote quadrille, and cquadirile.

A regular caroufale is to have at least four, and at most twelve, quadrills.

Of these quadrills, each is to consist of at least three cavaliers, and at most of twelve.

The quadrills are distinguished by the form of their habits, or the diversity of their colours.

QUADRILLE, a well-known game at cards; and which has been, in several cafes, the object of mathematical computations. See M. de Moivre's Doctrine of Chances, 3d edit. p. 97, &c.

QUADRI, Francesco Saverio, in Biography, a Jesuit, author of a voluminous history and description of every kind of Italian poetry, "Della storia e della Ragione d'ogni Poesia," eight vols. 4to. published at Bologna between the years 1739 and 1752.

The author seems a mere compiler, without selection, taste, or accuracy. It is a heavy work, hardly interesting enough to stimulate a regular perusal; and from the disorder of arrangement, very difficult to consult. Creelman is as superior to Quadrio in every requisite of an historian of literature, as Tirabolchi is to Creelman.

QUADRIPARTITION, the dividing by four; or a taking of the fourth part of any number, or quantity.

Hence quadrpartite, &c. something divided into four.

QUADRIREME, QUADRIMEMIS, a galley, or vessel, with four oars on a side, the invention of which was attributed by the ancients to the Carthaginians.

QUADRISETAE, the four-strained flies, a term used by the writers in natural history to express those flies of the fucida or hair-tailed kind, which have four hairs or bristles growing from the tail, as the others have three, two, or one.

QUADRIVIUM, the centre of four ways, where four roads meet and crofs each other. By latitude, pofts with inscriptions are to be set up at such crofs-ways, as a direction to travellers, &c. 8 & 9 W. III. c. 10.

QUADRIVIUM, besides the centre of four ways, was a scholastic division, used in the middle ages in our universities, to express the highest classes of philosophical learning and science; comprehending arithmetic, geometry, astronomy, and music: as the trivium did grammar, logic, and rhetoric.

During this period, music, such as it was, must have been highly prized to be ranked with the most sublime sciences, and thought an essential part of a learned education.

QUADRO, Ital. literally means square, and in music, at present, it implies a natural, &c. or Gothic B, in opposition to tondo, round, or the round B, used for a flat. The durum hexachord is sometimes called the quadro hexachord, from the circumstance of B being $b$.

It was the opinion of Padre Martini and the prince abbot of St. Blasius, that accents and points, enlarged, disfigured, and lengthened, became musical characters for time as well as tune. At first, when lines and spaces were used, from their being chiefly employed in a square form for writing the chants established by St. Gregory, they acquired the name of Gregorian notes, quadrata, and in barbarous Latin, quadriquarta. As the church is slow in receiving new doctrines, and generally a century later in admitting those improvements or corrections in music (the reader may call them which he pleases) that are adopted by the fairs as the fortunate efforts of cultivated genius, the notation of chants was at first cenfured and prohibited by several councils; and figurative harmony being regarded as a crying sin by pope John XXII., was formally excommunicated by a bull from the conclave 1321. See Notes, and Time-table.

QUADRUGATA TERRA, in Old Law Records, denotes a team-land; or so much as can be tilled by four horses.

QUADRULA, in Natural History, a word sometimes used in the fame fenes as telfela, and spoken of the cubic pyrites. Sometimes it is used also as the name of those little fapes of shining matter that are mixed among fand. These are generally fragments of tale; and are of various colours, white, yellow, and blackish.

Solinus has used the word quadrula to express the fragments of yellow tale that are found in that fand called ammochrysalt, or golden fand. He miftakes these shining particles for mafles of real gold, and makes the fand itself a kind of precious fubftance ranked among the gems, and brought from Peria; but in this he does not agree with the reft of the ancients.

QUADRUPELED. The effential character of quadrul-
Quadrupeds.

Peds is, that they have a hairy body and four feet, and that the females are viviparous, and give suck to their young.

Quadrupeds are distinguished, by the number of their feet, from other animals, which have only two feet, as birds; from those which have no feet, as fishes and reptiles; and from those which have more than two feet, as insects.

Aristotle distinguishes quadrupeds into three classes; denoting those whose feet are terminated by a hoof in one piece, *fulipedes*; those which have a cloven hoof he distinguishes by the name of forked or cloven-footed; and those whose feet are digerated he called *sufficvtes*. With this general division he contented himself, without defending to a methodical distribution of each class into their several orders, genera, &c. Gestr, Aldrovand, Jonston, and many other naturalists, have adopted the distribution of Aristotle; but we are indebted for the regular systematic arrangement of quadrupeds to Mr. Ray, who published his "Synopsis Methodica Animalium Quadrupedum et Serpentini generis," &c. in 1693. According to this writer, quadrupeds are divided into those which are hoofed, *ungulata*; and those which are cloven, or digerated, *ungulucula*.

**Quadrupeds. Hoofed, are either,**

1. *With-cloven*, *fulipedes*, *protox*, *protoc*, *sulpidungula*; as the horse and ass, the onager or wild ass, the mule; and the zebra of Africa, or the wild oryx of Indian or African race, which look like a mule in form and stature.

Of the whole-footed kind, Aristotle has observed, that no one hath two horns (he might have had any horns); no one hath the talus, or astragalus; nor have the males any appearance of teeth.

2. *Cloven-footed*; and that either, 1. Into two divisions only; as the *cyclopes*, or bisulate kind; which are again subdivided into such as are,

First, *Ruminantia*, *protox*; that is, such as chew the cud; and these either have hollow and perpetual horns, as the bull, sheep, and goat kind; or deciduous horns, as the hart and deer kind, which usually shed their horns annually.

Of the bull kind are reckoned the common ox or bullock, of which the male is taurus, the female vacca; the German urus, urochs, or aurochs; the bison; the bonasus; the bubalus, or buffalo; and the bos Arickan of Bellonius, Obs. lib. ii. c. 50, which he takes to be the bubalus of the ancients.

Of the sheep kind, besides the common fort, are reckoned the Arabian ovis laticauda, whose tail is sometimes of thirty pounds weight; the ovis *hercules* Cretica Bellonii; the ovis Africana, with short hair instead of wool; and the ovis Guineensis, or Angolensis, of Marckgrave, Hist. Brazil. lib. vi. c. 10.

Of the goat kind are, besides the common capra domestic, the ibex, or German steinbock, found on the tops of the Alps; the rupicapra, French chamois, or German gems; the gazella Africana, or antelope; the gazella Indica; the gazella Africana with shorter, anulated, and bent horns; the capra *fytleridae* Africana Grimmi; the capra Mammbrina, or Syriaca of Gufer; the boccephalus, or moschelaphus Cail, in Gestr; the tragelaphus Cail, in Gestr; and the tragelaphus of Bellonius.

Of the hart, or deer kind, are reckoned, the cervus, *cyclopes*, or red deer; the cervus platyceorus, or palmatus, the fallow deer; alce, or the elk; rangifer, the rein deer; the axis *Plinius*; according to Bellonius; the caprea *Plinius*, the cuquau-este, and cuguauc-appara, of Marckgrave; the caprea Groelandica.

Secondly, of animals whose feet are divided into two parts only, and which do not chew the cud, there is only the hog and swine kind. Under this head, besides the common swine, are reckoned the wild boar, or swine; the Guineensis Maregravi; the porcus Indicus, or baburola; the tajacu or aper Mexicanus mochiferus of Dr. Tyfon, called, by Marckgrave, tajacu caianoara; by others, quaudla coyamat; and quapizote; and by Acosta, and some others, zalino.

2. There are some quadrupeds, whose hoof is cloven into four divisions, and these seem to be not ruminant; as the rhinoceros, the hippopotamus, the tapirjeure of Brazil, the capybara of Brazil, and the animal mochiferum.

**Quadrupeds, Cloven or Digerate.** Of this kind, there is, first, a fort whose claws are not divided or separated, but adhere to one another, and are covered with one common skin, but with obsolete nails, sticking out round the margin of the foot; as the elephant, which is animalious, and not clearly referrible to this kind, or to that of cloven-footed quadrupeds.

A second species of this digerate kind of quadrupeds, which has only two claws, is the camel; and though these have no horns, they both ruminate, and have also the four flomachs of horned ruminant animals.

Of the camel there are two forts; one having but one hunch on the back, the other two.

To this kind also belong the Peruvian glama, which none have reckoned among the sheep kind; as also the paco, the ovis Indica, or Peruviana vulgo, which is much less than the glama.

A third species of this ungulate kind includes such animals as the Greeks called *Braemonyx*, and *Adipheres*; which have the foot divided into many claws, with broad nails on them; as the ape and monkey kind.

Of these, some have no tails, and are called simiae, or apes; others have tails, and are called monkeys, cercopitheci; and such as have either long or short tails, if they are of a larger faze, are called papiones, or baboons. There are great numbers and varieties of this species of quadrupeds, of which naturalists have described of these, viz. the orang-outang, or homo fylceus of Dr. Tyfon, described by him in a particular discourse; the guara of Brazil, Maregravi; the capus of Brafil, greater and lesser; the ey of the same region, described by Lebrius; the caitaia of the same country; the cercopithecius barbatus Guineensis, two or three forts of it; the cercopithecius androgenus major; the cercopithecius non barbatus Clusi; the cercopithecius Cluf. called fageoun. Lastly, if apes and monkeys have their fnots very prominent, like dogs, they are called canis apicambial.

A fourth species of this ungulate kind is, when, though the claws are many, yet they are not coved at the end with broad flat nails, like monkeys or apes; but are rather like the talons of hawks, &c. crooked and sharp-pointed.

These, in respect of their teeth, may be divided into such as have many dentes primitores, or incisores (that is, cutting teeth) in each jaw, of which there are two forts; a greater, which either have a short, round head, as the cat kind, and a lesser fort, having a long slender body, with very short legs, as the weasel or weaver kind. There are also some of this species of quadrupeds which have only two large remarkable teeth in each jaw; these are the bare kind; and these live only upon herbs, grass, &c.

Of the cat kind of quadrupeds are reckoned to be the lion; the tyger; the pardali, whose male is pardus, and female panthera; the leopard; the lupus cervarius, or lynx; the catus pardus, or cat-s-mountain; the common cat; and the bear.

Of the dog kind are reckoned the wolf; the lupus aureus, or jackall; besides the common dog, of which kind
they enumerate the mastive, or mastiff; the canis venaticus Graius, Gracius, or Scoticus, the greyhound; Graius Hibernicus, or the Irish greyhound; canis venaticus fagus, indagator, fedator ferarum, &c. the hound; canis venaticus Hispacificus, or avarius, the spaniel for land or water; vertagus, or tumbler; canis Oeno-, or domesticus, the house dog; canis molitissus, or the lap-dog; canis Getulus, or Ilandicus, the hound; and of all these sorts there are many varieties of mongrels, and hybridx breeds.

Other species of the dog kind are, the fox; the animal zibethicum, or sweet-cat, as it is corruptly called, but by its teeth and snout is plainly of the dog tribe; the American conti, or raccoon, or ratton; the yzquipedat; the carigneya, maritacca, carigoy, ropoza, or opollum; the talibus; the taxus, or meles, the badger, grey, or pale; the lutra, or otter. To these some add the phoca, sea-calv or seal; the equus marinus, moris, or sea-horse, mistaken by some for the hippopotamus; the Dutch call him wadrus, the Dames and Icelanders roflmarus; lastly, the manati, or vacca marina, the sea-cow.

Of the vermin, or weasel kind of quadrupeds, is, first, the mustela vulgaris, the common weasel, in Yorkshire called founart, or fitchet; second, the vivera Indica, called quill and quirelle; another sort called mungo, and mungathia, of a reddish-grey; the mustela, ermine, or fowat, and mustela fylfryns, the ferret; putorus, the pole-cat; martes, or foyna, the martin, or martlet; mustella zibellina, the sable; lastly, the genetta; and the Ichneumon Belloni.

Of the hare kind of quadrupeds are, first, lepus, or the common hare; cuniculus, the rabbit, or coney; tapeti, or Brash coney, and the aperea Brash, or the hyftrix, or porcupine, and the hyftrix Americanus, or cuanda of Brash; caitor, fiber, or the beaver; fiatus vulg. or squirel; the Virginian, Zeylandic, Barbary, and America. flying squirel; mus domesticus, major and minor, the common rat and mouse; to these also may be referred mus major aquaticus, the water-rat; the mus-kat, mus avellanarum, major and minor; the dormouse or fleaper, mus Noricus, Cruccetus, Alpinus, feu marmotta; the cavia cobaya, or cuniculus Americanus, the Guinea-pig; the aguti, and paca of Brash; the mus Norwegiensis, or lemias; the glis Gernieri, or the rell; the mus Indicus, &c.

**QUADRUPEDS, ANOMALOUS.** To these several kinds, the following anomalous ones must also be added:

1. Such four-footed viviparous animals as have a longish snout, with their feet divided into many claws, and toes, and having teeth; as the echinus terresrillus, or common urchin, or hedge-hog; erinaceus Indicus abus; tatru or armadillo prima of Maregrave; tatru or armadillo of flaire, or the second species of the armadillo, according to Maregrave; tatru aparia, his third species of armadillo; tatru mulcillius, Soc. Reg. Mus. the weasel-headd armadillo; talpa, the mole-warp, or molder; and the mus araneus, threaw, hardly threaw, threemouse.

2. Quadrupedous and viviparous animals with a longish snout, having their feet divided into many claws or toes, but without teeth; as the tamanda guacu of Brash, Maregravi, urius fornicarius Cardani, the great ant-eater; the tamanda of Brash, or Maregrave, the keller ant-bear.

3. Anomalous flying quadrupeds, with a shorter snout, and their feet divided as above; being of the bat kind, or flitter-mice, of which there are several clases, and of different forms.

4. There is one very anomalous animal, which has but three claws on each foot; and that is the ai or ignamus of Maregrave, the floth or sluggard.

5. Viviparous and fangious quadrupeds, breathing with lungs, but having only one ventricle in the heart; as the rana aquatica, the frog, or froth; rana arborea, feu ranunculus viridis, the small tree or green frog; bufo, feu rubeus, the toad; teftudo, the tortoise; in Greek τέντον, of these there are land and water ones, and many different species in foreign parts.

6. Oviparous quadrupeds, with a long tail, tretched out horizontally. Such are the lizard kind; as lacertus omnium maximus, the crocodile; cordylus, five caudiverbera, nlo-axem azureus, greater than the green lizard; tapayaxin Nove Hispianus, or lacertus orbitalis of Hernandez; lacertus vulgaris, the common eft, swift, or newt; lacertus viridis, the green lizard; lacertus factanum Aldrovandi, at Rome and Naples called the tarantula; lacertus Indicus, called senembol and iguana; lacertus Braziensis, called toje-guacu, and tamapara by Maregrave; the tarangira amciva, or Argentine Arcuraba, Americana, Curapopba, Teliwhana, &c of Maregrave; the lacertus Indicus; the incinus, or crocodilus terresrillus; the feps, or lacerta chalcidica, a kind of footed ferpent; felleo, the swift, or spotted lizard; salamandra, called the salamandra aquatica, the water-št, lacerta volans Indica; and the chameleo, or cameleon.

This fystem of Mr. Ray obtained very generally among naturalists, till, in the year 1735, Linnæus firft published his fystem. This was followed by several others, varying in the arrangement of the animal kingdom, even to the laft edition of 1767. Under the clas, which he denominates Mammalia, (which see,) he comprehends not only all the animals which we call quadrupeds (the lizard genus, or rather the reptiles pedati excepted), but also the cetaceous order, or whales, cachalots, and porpoises; justifying this arrangement of whales with quadrupeds, from the agreement of these animals in the structure of the heart, in the respiration by means of lungs, in their having moveable eye-lids and ears, in being viviparous, furnished with teeth, and other particulars, by which they differ so materially from fishes, as more than to counterbalance their living with them in the same element.

The mammalia are divided into seven orders, the distinctions of which are principally established on the difference in the numbers, situation, and form of the three kinds of teeth, viz. the primums or incisors, called fore-teeth, or cutting-teeth; the canini or canins, called dog-teeth, caning or lacerating teeth; and the molares, double teeth or grinders.

But Linnæus does not entirely neglect the feet. See the charaters of the several orders under Primates, Brute, Felle, Gis, Peora, Bella, and Cete or Whale. This part of the Linnæan fystem, including a few species described in the Appendix of the third tome, and in the Mantilla of 1771, contains about two hundred and thirty species.

Mr. Pennant, in his "Synopsis of Quadrupeds," and professor Martin, in his "Elements of Natural History," by including some animals that were unknown to Linnæus, and giving the rank of species to several that were considered by him as varieties, have extended the number of mammalia to two hundred and eighty-nine species. Mr. Klein, in 1751, published a new fystem of quadrupeds, intitled "Quadrup. Difposito breviqve Hist. Natur." in which he distributes them into two orders, the firft comprehending those whose feet are terminated by one or more hoofs, and the second those which are digitated; and each of these orders is subdivided into five families or classes. In his firft order he follows the general arrangement of Mr. Ray, which he has considerably improved; but in the second, by a fervile regard to a method founded on the number of toces, he has combined very opposite animals; the camel and the floth, the mole and the bat,
bat, the glutton and apes. Mr. Brisson, in 1756, published another system, in which he has arranged animals by the number or defect of their teeth; beginning with those that are toothless, such as the ant-eater, and ending with those that have the greatest number, such as the opalum. By this arrangement, some quadrupeds are very distant from each other in their manners, and are nearly connected. We shall lay nothing of Mr. Buffon’s “History of Quadrupeds,” though it contains much valuable information, because he seems to have disregarded systematic arrangement. Mr. Pennant has introduced some useful alterations in his “History of Quadrupeds;” this ingenious naturalist has followed Mr. Ray in his greater division of animals into hoofed and digested; but, after the manner of Mr. Klein, he has formed separate genera of the rhinoceros, hippopotamus, tapir, and mufk. The apes are continued in the rank in which Mr. Ray placed them, and are followed by the mammeuses. The carnivorous animals are arranged according to the sytem of Linnaeus, omitting the true, mole, shrew, and hedge-hog. The herbivorous or frugivorous quadrupeds occupy the classes assigned to them by Mr. Ray, to which he has added likewise the shrew, the mole, and the hedge-hog. The fourth section of digested quadrupeds consists of those which are absolutely destitute of cutting teeth, such as the floth and armadillo. The fifth section is formed of those which are dentulous of teeth of every kind, such as the manis and ant-eater. The third and fourth orders or divisions which Mr. Pennant has added, are the pininated and the winged quadrupeds: the first comprehends the walrus, the seals, and (in conformity to preceding writers) the manatee. But these, he observes, seem as the links between the quadrupeds and the cetaceous animals. The bats are winged quadrupeds, and form the next gradation from this to the class of birds. See Pennant’s Hist. of Quadrupeds, ed. 8vo. 1781. Preface. See Classification.

Quadrupeds, Alated. Among the many fabulous things with which natural history has been loaded, stories of flying quadrupeds seem to claim a very high rank; the gryphon, the quadruped dragon, and a great many other imaginary animals, having been introduced so seriously among the descriptions of real animals, that too many have been taught to believe them. Schuochzer, in his “Physica Sacra Jobi,” has done much toward disconfounding such relations; and Hyacinthus Gemma, who has written expressly “De Fabulosi Animalibus,” has added much on the fame occasion; yet all is not done. The world has late histories of lentmas and bafilfs, which never existed but in the imagination of the relation, or in the subtle contrivance of the fabricator; as is evidently the case in the bafilfs which we find in the museums of the curious, and which are all made out of the ray-fish. And the generality of readers are fo fond of any thing that is marvellous, that these things are sure to be remembered, while perhaps all the truths in the book are forgotten.

Upon the whole, the standard of the flying or alated quadrupeds seems to be properly enough reducible to this: that the words flying and alated are not synonymous terms, and that there are three kinds of flying among the quadruped clafs. The first absolute and swift, flying as perfect as in birds: this peculiarly belongs to the bat; which is the only alated or winged quadruped, properly speaking. 2. An imperfect flying by means of certain membranes serving as wings, but imperfectly, and not turning quick, or enduring long flights: such is the flying of the lizard, which is not properly an alated animal. And lastly, the imperfect flying of the squirrel kind, which even in that species called, by way of eminence, the flying squirrel, is not properly flying, but only long leaping; the creature being able to turn but very little out of a right line, and only to propel itself during a short time in a leap from a high place to a lower. Phil. Trans. N° 247. p. 34.

Quadrupeds, in Agriculture, all such animals as walk on four legs, and are of the domestic kind, as horses, cattle, sheep, fwine, and many other forts, which are beneficial either for the purposes of working, fattening, or in any other way. Some animals of this nature are disposed for one of these purposes in preference to others; while others are capable of being made to serve more than one of them. Thus, horses of the lighter and more active kind are adapted to the saddle, and some sorts of road work, and those of the more heavy fort to all descriptions of team work in the field or other places. And neat cattle of the ox kind, in the lefs heavy breeds, as the Devonshire, Herefordshire, and some others, are well suited to team labour as well as fattening; while those of the more heavy forts, as the Lancashire breed, or long horses, &c. are better calculated for feeding only. Among sheep, some breeds are valuable for their mutton as well as their wool; some for the farmer, or latter, of these articles only; and others again for their ready disposition in taking on flees. In fwine, some breeds are much better formed than others; require much less food, in proportion to their sizes, in keeping and fattening, and are more disposed to feed, &c.

The fame is likewise the cafe with some other animals of this description, which should constantly be taken into the account in selecting and chosing them for the use of the farmer.

Quadrupeds of all sorts, should also, in all cafes, be well adapted in their numbers, natures, and kinds, to the quantities of the lands as farms, their extents, and the quantities of labour to be performed upon them, as much in the successe of farming depends on this being properly done. They should likewise be constantly well kept and in proper condition, according to the different intentions for which they are designed, as badly fed or half-starved animals never answer any good purpose for the farmer, they always requiring a much larger proportion of food for restoring or bringing them again into proper order and for fattening them, than would otherwise have been necessary; and they never ultimately turn out so well, or produce so much advantage, as might have been the case under other circumstances. And, in labouring animals, where this is the case, they are never capable of performing nearly so much work, in conquence of which a vast continual los is sustained, though scarcely perceived. See Live-Stock, and Team.

Quadruplatores, among the Romans, were informers, who had the fourth part of the confiscated goods for their pains.

Quadruple, a sum or number multiplied by four, or taken four times.

Quadruple is particularly used for a gold coin, worth four times as much as that of which it is the quadruple. The quadruple of the Spanish piflole is a piece of four pifloles, called also the double doubloon.

The quadruple of the louis d’or is a piece of gold coined in the reign of Louis XIII. in 1641. The legend on one side is christus vincit, regnat, imperat: and on the middle of this side it has a croes with four crowns, and cantoned in four fleurs-de-dis: on the other side it has the legend, ludovicus diximus tertius de graia francorum rex, with the head of Louis XIII. Its value under this king was twenty livres.

Quadruple Crocbs, in French Music, is a note with four hooks or four ties, one degree quicker than our demi-semiquaver,
femiquaver, and for which we have no name. The term
crotch, in French a quaver, is not derived from crotchet, but
from the tail being crooked. And why our crotchet, with a
straight tail, has its name, is a whimsical absurdity, for which
we are unable to account.

QUÆ ost edam, in Pleading, is used to supply the want
of a traverze. (2 Lill. Abr. 405.) In a clauum fragi
tsuch a day, the defendant pleads the plaintiff's licencce to
him to enter on the same day, and that virtutinde he entered;
he need not say, quæ ost edam transegrifio.

QUÆ Prima, a writ that anciently lay where inquisition
had been made by an eclesiastic, of such lands or tenements
as any man died feiled of, and all was supposed not to be
found by the office or inquisition.

This writ was to inquire what more lands or tenements
the parties died feiled of. But it is now made useless, by
taking away the courts of wards and offices poft mortem.

QUÆ Servita. See Per quæ servita.

QUÆRENS non inventit plogium, a return made by
the inquisitor upon a writ directed to him with this clause,
viz. Si A. fecerit B. fecurum de clamore suo profequendo, &c.
F. N. B. 38.

QUÆRINES, in Geography, a town of Norway; 55
miles N. of Romidal.

QUÆSITA, in our Ancient Writs, denotes an indul-
gence, or remission of penance, expefled to faie by the
pope.

QUESTIONARII, in our Ancient Law Books, were
men who went about with indulements from door to door,
defiring charity either for themselves or others.

Matt. Well obferves, 1240, that the king, "Terram fidam
per papale quætionarios, depauperari, &c. permittu." "

QUESTOR. See QUESTOR.

QUÆSTUS, in Law, is that elate, or those effects,
which a man hath by acquisition or purchase ; in contradif-
tion to hereditatis, which is what he hath by de/cent. See
ACQUEST, and GOODS.

Clav. lib. vii. "aut habet hereditatem tantum, vel
quaenam tantum, aut hereditatem & quaenam."

QUAC, in Agriculture, a name given to any fort of wet,
swampy, mor oily, or boggy situation in land, which has
a tremulous or thailing feel under the foot, and which pro-
duces nothing but a coarse grassy herbage that is unfit for
the food of animals. Low as well as high grounds are sub-
ject to spots of this kind wherever water is confined and
retained near the surface. They are to be removed by proper
means of draining, and the application of solid earthy matters
of different kinds upon the surfaces of them, with the use
of rollers in order to consolidate the whole. See BOC and
SWAMP.

QUAGGA, in Zoology. See EQUUS.

QUAGLIATI, Paolo, in Biography, the music-maker
of the celebrated traveller, Pietro della Valle, at Rome, in
the beginning of the 17th century. His disciple, della
Valle, lays, "that he was an excel lent maestro di cappella,
who introduced a new species of music into the Roman
churches, but not only in compositions for a single voice (mon-
dic), but for two, three, or four, and very often more voices,
in chorus, ending with a numerous crowd of many choirs or
chorusps, singing together; specimens of which may be
seen in many of his masses that have been since printed.
And the manner of mia cart, or movable-slave, composed
by the fame Quagliati, in my own room, chiefly in the man-
ner he found most agreeable to me, and performed in malks
through the streets of Rome during the carnival of 1666,
was the first attempt at an opera, or lecular drama in music,
which had been heard in that city." See OPERA, RESI-
DATIVE, and PIETRO DELLA VALLE.

QUAGMIRE, in Agriculture, the name of a fort of soft
miry sinking or quaking bog, swamp, or morass, which is fre-
quently and commonly met with in low hollow situations,
where there is none, or very little deficient, for the discharge
of the stagnant water or wet lands. They are formed in
many different ways according to the nature of the circum-
stances which first gave rise to them, and of the places
in which they are found. The author of the "Treatise on
Landed Property," has remarked, that besides the common
moor y quagmires or bogs, there is a species which is con-
stantly charged with moisture, yet does not accumulate a
thick covering of moory earth, owing probably, it is sup-
pofed, to the want of fertility in the water by which it
fed. These sorts of quagmires are, in his opinion, for the
most part, found in mountainous and lilly situations. Other
kinds are occasionally seen on large peat mofles, and hollow
meadows, in spots where the water is confined and kept
up nearly to their upper parts, and where there is much
decay of vegetable productions on their surfaces, and the
reception of earthy materials from other places. These
quagmires occupy large spots on ground in many different
situations, and are, of course, a great loss to individuals
and the public, as little or nothing of any use is ever pro-
duced by them. (See MORASS.) They are, for the most
part, capable of being readily drained by proper means,
a sort of improvement which ought never to be neglected
where it can be performed with any chance of success.

QUAHU, in Geography, a district of Africa, on the
Gold Coast, in the kingdom of Acambou, or Aquamboe;
which see.

QUAHVITLA, in Botany, a name used by some au-
thors for the tree from which the resin commonly called gum
copal is procured.

QUAICA, in Geography, a town of Africa, in Sen-
nar; 48 miles E.S.E. of Giefil.

QUAIL, Coturnix, or Tetrao coturnix of Linneus, in
Ornithology, the least of all the birds of the gallinaceous
kind. They have, however, the genius of the cock kind, and
may be bred to fight like our game cocks.

This was an old custom among the Athenians, and is still
kept up in some parts of Italy, and in Asia.

Quails are birds of passage, some entirely quitting our
island, others shifting their quarters from one county to an-
other, and sheltering themselves among the woods near the
sea-side; with us they frequent the corn-fields, and some-
times the meadows. They begin to sing in April, and make
their nests in the month of May, building on the ground,
and seldom lay more than six or seven whitish eggs,
marked with ragged ruf-f coloured spots.

Quails are to be taken by means of the call during their
whole wintering time, which lasts from April to August. The
proper times for using the call are at fun-rising, at nine
o'clock in the morning, at three in the afternoon, and at
sun-set; for these are the natural times of the quail's call-
ing. The notes of the cock and hen-quail are very different,
and the sportman who expects to succeed in the taking
of them, must be expert in both; for when the cock calls, the
answer is to be made in the hen's note; and when the hen
calls, the answer is to be made in the cock's. By this
means they will come up to the perfon, so that he may, with
great ease, throw the net over them, and take them. If a
cock-quail be fingle, on hearing the hen's note he will im-
mediately come; but if he have a hen already with him, he
will not forsake her. Sometimes, though only one quail
answers to the call, there will three or four come up;
and
and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The quail is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings they will oft-en fly instead of running to the call: and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top, and the sportsman then changing fides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; this is to be filled half full of horfe-hair, and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other fuch bone; this is to be about two inches long, and the end formed like a flag-folet, with a little soft wax. This is to be the end fast-tened into the purse; the other is to be closed up with the fame wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this found, it is to be held full in the hand of the hand, with one of the fingers placed over the top of the wax: then the purfe is to be prefled, and the finger is to fhake over the middle of it, to modulate the found it gives into a fort of fhake. This is the molt utile call; for it imitates the note of the hen-quafl, and feldom fails to bring a cock to the net, if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire, turned round and curled, and covered with leather; and one end of it muft be closed up with a piece of flat wood, about the middle of which there muft be a small thread or ftrap of leather, and at the other end is to be placed the fame fort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiraf, and gives the fame found that the cock does when he gives the hen a signal that he is near her.

QUAKERS, in Ecclefiafical History, the common denominafion of a fociety of Chriftians, who appeared firft in England about the middle of the seventeenth century, and who continue to be diftinguifhed from others by peculiar tenets and practices. They call themselves Friends. They are remarkable for aferting the contimuation, to the prefent time, of immediate revelation, or the communication of divine inftruction to the mind, by the testimony of the Spirit of God. This revelation they affirm to be neceffary for the production of true faih, and that it neither doe nor can con-tradict the outward testimony of the scriptures, or right and found reason. Their doctrine on this fubjeft has been often misunderstood, even by theological writers; and they have in conqueflence been subjected to much obloquy. It is, however, the principal feature in that peculiar view of Chriftianity, which has occasioned their feparation from other churches.

Origin and History.—Before the period above mentioned, many ferior persons, fatisfafted with none of the modes of religion which the reformation brought forth, had withdrawn from the communion of every visible church, to cultivate in retirement, impressions which they attributed to the operation of the Spirit of Chrift on their own minds: it is chiefly from fuch, when brought to recognize each other by the miniftiy of an individual, that the Quakers confider their fociety to have been originally gathered. George Fox, the individual in quifition, was born in 1624. He has left a journal of his own life, written with a simphicity of styfe, which proves that he has fairly laid open his own character. In this work, the peculiar principles of Quakerism may be factually explored in their early beginnings, which it may be worth while briefly to review. Fox's parents, who were pious members of the church of England, had inten-ded him for the priesthood, his character affording very early promise of fruits for religious service; but others per-fuading to the contrary, he was put under a mafter to a country bufinefs. Being engaged herein at a fair, when about the age of nineteen, a confufion of his, with another profefor of religion, attempted to engage him in drinking to intoxication. "The Lord had shewn me," says George, "that I might not eat or drink to make myself wanting, but for health, using the creatures in their service, as fervants in their places, to the glory of Him who created them."

Accordingly, on perceiving the defign of his companions, he rose up, paid for the refreshment they had had, and departed, with emotions of virtuous indignation. Returning home, he passed a fleepless night, walking up and down, and crying to the Lord; who, he affirms, faid unto him, "Thou feeff how young people go together into vanity, and old people into the earth; thou muft forfaie all, young and old, keep out of all, and he as a forger unto all." The reader will understand this, and generally all revelations profefled to have been received by Quakers, as confiding not in an outward voice, but in an internal communica- tion to the mind. Taking the command literally, he detached himself from his connexions; and having some property of his own whereon to fubfift, removed from place to place, obferving the religion and profefors of the age, without engaging in clofe fellowship with any. He devoted much of his time to faihing, foltary prayer, and reading the bible.

He became at length quite detached in his affections from the world, dillirfed at the spiritual condition of his fellow men, and in much anxiety, bordering on delfair, about his own; yet was not without intervals of heavenly joy and comfort. Such a rate of mind naturally led him to fearch for spiritual counsel from others, and he had conferences with many of the clergy, beginning with his own parish priest. In anfwer to a quefion from the latter, we find him profefling faih in Chrift, who, by his death as man, (for he died not as he was God,) became an off-fring for the sins of the whole world. The general refult of these conferences was, however, unfaftifactory to him; for, he obferves, "they could not reach my condition." Purifying, therefore, his meditations on the fubjeft as before, he came to be fatis-fied respecting severa propositions which it involved, fuch as the following:—that although it was faid that all Chriftians are believers, both Praftbians and Papifts, yet that none were truly fuch, but thofe who were born of God, and who had paffed from death into life. Again, that to be bred at Oxford or Cambridge, was not enough to fit and qualify men to be ministers of Chrift. At this he had placed, because it was the common belief that fuch qualifications were fufficient. "At another time," he fays, "it was opened to me, that God, who made the world, did not dwell in temples made with hands. This at firft seemed ftrange, because both priests and people used to call their temples or churches dreadful places, holy ground, and the temples of God; but the Lord fhewed me clearly that he did not dwell in thofe temples, which men had con- fented and fet up, but in people's hearts." George Fox now ceafed to attend the eftablfihed preachers; at which his relations being offended, he fhewed them from the fcritures, "that there was an anointing within man to teach him, and that the Lord would teach his people himfelf."
Observing, as he thought, more of the fruits of this internal teaching among the "diluting people," he went for a while among them; but, he continues, "as I had forsaken the priests, so I left the separate preachers also, and those called the most experienced people; for I saw there was none among them all that could speak to my condition. And when all my hopes in them, and in all men, were gone, so that I had nothing outwardly to help me, nor could tell what to do, then, O then, I heard a voice, which said, 'There is One, even Christ Jesus, that can speak to thy condition.' When I heard it my heart did leap for joy. Then the Lord let me see why there was none that could speak to my condition, namely, that I might give him all the glory. For all (he continues, alluding to Rom. xi. 32.) are concluded under sin, and shut up in unbelief, as I had been, that Jesus Christ might have the pre-eminence, who enlightens and gives grace, faith, and power."

The preceding is a specimen of Fox's own account of the manner in which the doctrine he afterwards preached arose in his mind. The reader will perceive that he refers all his real edification to the means which have been already indicated, immediate revelation. He says, "though I read the scriptures, that spoke of Christ, and of God, yet I knew Him not but by revelation, as he who hath the key did open, and as the Father of grace drew me to His Son by His Spirit."
Yet that he was capable of the importance of the holy scriptures, as the source from whence, under this influence, Christian instruction must be drawn, is evident, both from his declaring that they were very precious to him, and from his having incessantly used, and constantly appealed to them, both before and after beginning to promulgate his system.

Having at length attained to a view of Christianitv in which he found peace of mind, he believed himself required and divinely commissioned to become a teacher of it to others: and from the year 1647, the reader may conceive him always engaged in this office. He travelled as before, preaching first to small companies of enquiring persons, then to public congregations, such as upon his appearance among them were willing to hear him, and at length to large assemblies of people, convened on purpose. This he did with the courage and perseverance of a reformer; in the face of opposition from the national and stipendiary preachers, of frequent personal abuse from their hearers, and occasional severe treatment by the magistrates. In most places where he came, he met with persons who received his doctrines, a proportion of whom, after associating with him for a time, became impressed with the like apprehensions of duty to propagate their principles; which they attempted by similar methods. Thus, although interrupted at different periods by imprisonment, he found himself, before many years had elapsed, in connection with a numerous band of fellow-labourers, and a widely diffused and respectable society of religious friends. No inconsiderable number of these quitted, for the sake of their principles, livings in the church, commissions in the army, or feats as magistrates.

When we consider that this happened in an age equally remarkable for religious zeal and political turbulence, it will appear that some deviations from Christian propriety, some fruits of the mixture of imagination with good intentions, could scarcely fail to be exhibited among them. If the new society, from a regard to its principle of internal impulses to particular duties, was slow to condemn theft, it was careful, on the other hand, not to engraft them, by imitation on its practice. Individuals, therefore, were alone responsible for such acts, and the general conduct of the members, from the period of their first associating together, was found in no mean degree conformable to the morality of the gospel.

The most serious instance of misconduct occurred in the case of James Nayler and his followers. This fell out in 1650, and was magnified beyond its real importance by being suffered to occupy for ten days the attention of parliament. Nayler had been an Independent, and a quaker-preacher of horse under Major-General Lambert. He was one of George Fox's earliest converts, and for some years an able preacher and disputant in the same cause. Coming to London, he found a set of people who extolled him in his office above measure. His friends, and George Fox among the rest, fearing his danger, gave him suitable cautions; but flying thence, he became exposed to the flatteries of a train of followers, chiefly women, whom he suffered, at length, from a delusive notion of its being done to Christ in him, to address him with the name and titles of the Saviour, and with acts amounting to worship. In particular, his entrance into Bristol was conducted, by these infatuated people, in imitation of the procession of Christ into Jerusalem. The parties implicated in this transgression were committed to prison; but Nayler alone was selected by parliament, after examination and long debates on his case, for punishment as a blasphemer. Cromwell kept aloof from the proceedings, which, by their excelle'l severity, moved great commotion in the public. The culprit was twice scourged through the streets, twice pilloried, branded in the forehead, and bored through the tongue with a hot iron: all which he endured with surpising patience and fortitude. His punishment ended with two years' close imprisonment in Bridewell, during which he attained to repentance, and a founder mind. Having given proof of this by several public confessions, the Quakers, who had disowned both him and his followers, received him back into their communion, in which he lived circumspectly the short remainder of his life.

Quakerism prevailed at first chiefly in the northern counties; but many preachers having risen up here, who travelled in different directions, it was not long in spreading to the metropolis, and the remotest southern and western parts. Wherever its professors appeared, the ordeal of suffering awaited them; for which their negative tenets commonly furnished the occasion. They refused to the priests every kind of payment, to the government military service, to the magistrate oaths, and to all persons the customary, and at that time much looked for worship, of kneeling or bowing with the head uncovered. They adhered too, in every instance, to their northern English of thou and thee, judging the plural mode of addressing one person to have originated, together with all empty titles, in a spirit of flattering unbecoming Christians. These peculiarities were a check to superficial conversions; since an upright conformity to the profession was in most cafes purchased by the los of friends, contempt, and hardships. Even the privilege of meeting to worship, apart from the national congregations, was acquired only by persevering in the practice, through almost every kind and degree of coercive obstruction, down to the period of complete toleration, the revolution of 1688. Hence their history confints in great part of a detail of buffetings, imprisonments, and spoiling of goods. So early as 1659 they flated to parliament, that in the preceding six years about two thousand individuals had suffered in person and estate, for being Quakers: and this representation was accompanied by one of the most extraordinary public acts on record. One hundred and sixty-four Friends offered themselves by name to the house, to be imprisoned in the places of an equal number, who from sickness or the hardships...
ships of their confinement, were conceived to be in danger of perishing. The house, however, rejected this proposal, and expressed some displeasure at "the reflections on magistracy and ministry" found to be contained in the memorial. It will be proper to give some particular instances of their sufferings.

James Parnel, a youth of good parts and education, going to see George Fox in a dungeon at Carlisle, became a convert to his principles; and, preaching in Ellex, was the means of raising many congregations of Quakers in that county. He was imprisoned in Colchester castle, and at the age of nineteen minutes under the cruel treatment there inflicted on him. In 1656, two Quaker women arrived at Bolton, New England. They were apprehended there; they could land, committed to close prison, and searched in a brutal manner, by stripping them naked, lest they might also be watches; an object to the colonists of equal and equally rational dread. These two, with eight others who arrived afterwards, were forcibly sent away: but the precaution was in vain, their principles entered the colony. An aged citizen, and church member of Bolton, was first found favourably inclined to them; he was fined, imprisoned, and banished in the depth of winter. In Rhode island he was hospitably received by an Indian chief, who offered, if he would live with him, "to make him a warm house"; observing, "What a God have the English who deal to with one another about their God!" So far is intolerance from recommending the religion of those who practice it. Penal laws against Quakerism soon followed the appearance of this people in New England. The scourge was first applied, without regard to age or sex: mutilation, by cutting off the ears, followed: but these being found insufficient, cruelty proceeded through another intermediate step, banishment on pain of death, to its dreadful extreme; and four Quakers were hanged at Bolton. Their names were William Robinson, Mannduke Stevenfon, William Leddra, and Mary Dyar. Their cafes, as related by Sewel, in his "History of the Quakers," form an interesting piece of martyrlogy.

Charles II., on notice of these proceedings, granted a mandamus, which prevented further executions in the colonies; but he was not equally ready to restrain persecution at home. The Quakers had several meeting houses in London. When assembled at these, they were often dispersed by orderlies, under the direction of the magistrates; these effected the purpose by severe beatings with their arms. One John Trowell being evidently mortally wounded in this way, a coroner's inquest was held, but the verdict of the jury was suppreffed; and the king, on being informed of the facts, evaded interference, telling the complainants to prosecute the law against the orderlies! Similar proceedings took place at Colchester; where the congregation, being kept out of their house, met for many weeks in winter standing in the street. Here they were assaulted by orderlies on horse-back, who wounded many of them, and a man of seventy-kilt his life in consequence. On one of these occasions a trooper's sword, by violent using, came out of the hilt. The man he had been beating handed it up to him with these words, "I defire the Lord may not lay this day's work to thy charge." In this instance, as in others, the patience of the sufferers at length triumphed, and they were quietly allowed their right of meeting.

In 1665 a hundred and twenty Quakers were in Newgate, sentenced to transportation, under an act recently made "to prevent and suppress seditions conventions." The matters of ships generally refusing to carry them, an embargo was laid, and it was made a condition of failing to the West Indies, that some Quakers should be taken thither by every vessel. A mercenary wardp being at length found for the service, the Quakers, unwilling to be active in their own banishment, refused to walk on board, as also the men to hoist them in. By the help of soldiers from the Tower, fifty-five of them were at length shipped. But the matter was now in prison for debt; and the ship, after seven months' detention, quitting the coast, was immediately taken by a Dutchman, and twenty-eight of the prisoners (the remainder having died of the plague) were liberated in Holland and sent home. Other parties of Quakers were sent on shore again from different vessels, so that the number actually sent to the West Indies was small.

The preceding instances may serve to shew the kind of persecution which this society endured for many years; it may be observed in conclusion, that the court (or rather the clergy) of Charles, in their eagerness to suppress the growing sect, actually defended to the measure of stifling a formal order of council for demailing their meeting-houses in Southwark, which was addressed to no less a person than Christopher Wren, esq. surveyor-general of his majesty's works; but it was executed by the military, by whom the congregation, who had the courage to meet on the ruins, were dragooned as often as they assembled, for nearly three months together, without however overcoming their firmness.

Though the Quakers never sent out missionaries, in the manner of some other societies, we have seen that individuals went, under apprehensions of religious duty, to distant parts. Several of these visited Italy, where they did not conceal their dislike of superstition; and one John Love, being detained at Rome on this account, died (as it seems a violent death) in the prison of the inquisition. Catherine Evans, and Sarah Cheevers, after three years' confinement, and many sufferings in the inquisition at Malta, were released and returned to England. But the most extraordinary enterprise, in this way, was performed by Mary Fisher, a maiden, and one of the two who had been so ill treated at Bolton. She, apprehending she had a message from God to fulfill Mahomet IV. actually made her way from England to his camp before Adrianople, where she delivered, through his interpreters, what was on her mind, was treated with respect, and offered an effort to Constantinople, which she declined, and returned, as she had gone, alone and in perfect safety. A young man, named George Robinson, went, through still greater difficulties, to Jerusalem, where, speaking against the superfluity of the pilgrimages, the friars procured him to be forced into a moque, whence the Turks, on his refusing to turn Mahometan, led him out to be put to death, as for wilfully violating the place; but a sudden change taking place in their sentiments concerning him, he also was permitted to return.

In 1660 the Quakers held their first general meeting, for the care of their poor and other concerns of the society, at Skipton in Yorkshire; within a few years after which, meetings for discipline were established throughout England and Ireland, chiefly by the inarticulate personal labours and epistolary recommendations of George Fox. At this period the society received a considerable accession of respectability by the conversion of William Penn and Robert Barclay. The celebrated Apology of the latter gave the world an opportunity of fairly appreciating doctrines till then but partially known, and on this account the more desired; and the settlement of the Jerseys, and subsequently, of Pennsylavna, under the auspices of Penn, opened to the Quakers a new and promising field of increase, which they did not fail speedily to occupy. Another period of considerable
QUAKERS.

considerable learning, George Keith, after associating with them for near thirty years, became the author of a lefthin, the circumstances of which it will be proper to notice. Keith was a native of Scotland, and educated at Aberdeen; he was imprisoned, as a Quaker, in 1664, and in 1675 assisted Barclay in a public disputation against the students at Aberdeen: he wrote much in defence of the principles of the Quakers, which he thoroughly understood, and was employed in the education of their youth; but is thought by them to have indulged too much in curious and useless speculations, which his brethren did not encourage. Being again repeatedly imprisoned, about 1684, he removed to America in difficulty. Here, after some previous general concern of his friends, he acceded several, in particular, of grofs error in doctrine; the pretext for which was, their holding (as he himself had done) that the knowledge and belief of the history of Christ is not necessary for the salvation of those who have no possible means of acquiring it. His complaints against individuals leading to more general contention, the Friends in England interfered, and the parties were heard before the yearly meeting in London, which decided the cause against Keith, and he remained under the "disownment" pronounced against him in America. He now let up a separate Quakers' meeting in London, attacked the principles he had formerly defended, (on which occasions the Quakers replied by quotations from his own works,) and finally entered into the church of England. He was soon after ordained priest, and made a missionary to America, to bring over his former brethren. But his efforts, though for a while troublesome to the Quakers, were attended with very little success: he returned to England, sunk into obscurity on a small living in Suffeis, and his party gradually disappeared.

The prejudice in which the Quakers most constantly stood on account of their principles, very early introduced them to an immediate intercourse with the throne; and they thus acquired the privilege, which they still exercise, of presenting public addresses to the king, by a deputation from their body, in a manner which does not violate their conscientious scruples. The accession of a new sovereign, the conclusion of a peace, or an impending war, have commonly drawn from them addresses, in which sentiments not unworthy of their Christian profession, are conveyed in simple but respectful language. And very recently (1814), they availed themselves of the presence in this country of the emperor of Russia, and the king of Prussia, to address each of these monarchs in favour of a perfect toleration in their respective dominions: in which they met with a favourable reception. Another great and interesting object, the abolition of the slave trade, has frequently brought them forward to government in this way. In the cause of humanity, as it regards the oppressed Africans, they have proved themselves firenosed and indefatigable; the reproach, even of holding a fellow man in slavery, was wiped away from the members of this society many years before the abolition of the trade was decreed, either in England or America. This was effected by their discipline; and it was made a part of this, in consequence of that view of Christianity, which regards every individual of the human race as a fit object of its benefits, and as entitled to the charitable regard which it inculcates. Much was done on the Negroes' behalf, in America, by Anthony Benezet, whose character is well known to the world; and by John Woolman, a minister of the society, whose writings discourse over a mind of uncommon purity, simplicity, and tenderness.

The Quakers as a body have been long relieved from actual persecution: yet they are still involved by their principles in occasional trouble as individuals. The refusal to bear arms, or to pay military fines, subjects them to legal disfrunt on their goods, and if none of these be found, to imprisonment. Tithes and other ecclesiastical claims, enforced upon them, likewise render disfrunt a very common, and sometimes an oppressive occurrence: and it the prosecutor be more rigorous, they may be imprisoned for an indefinite time. In America they are exempt from ecclesiastical but not from military feitures; by which, during the war for independence, many of them were impoverished. It is obvious that, refusing to swear, they cannot fill any office of profit or trust under government. Except for these purposes however, for serving on juries, and in cases of criminal prosecution, their solemn affirmation before the magistrate has the legal force of an oath.

The Quakers are dispersed over the united kingdom, and most of the states of North America; from the southern states of the latter they have mostly emigrated of late to the Ohio. In America they are chiefly engaged in agriculture; and for a series of years have been making judicious and successful efforts to introduce this, with the other arts, and the manners of civilized life, among the Indian natives. There are a few Quakers in Germany, and their principles are entertained by some perfons in France.

In this country they are found chiefly in the middle class of citizens, and in trade or manufacture. Their general delification of agriculture seems to have resulted from the impediments offered by the tithing system: a yoke which, under their scruple, becomes doubly heavy on the farmer. There is a greater approach to equality in the civil condition of the Quakers, than obtains in almost any other body: the children of such as become very rich are apt to quit the society, either by marrying persons not in its communion, or for the sake of liberties which it prohibits: and the children of the poor commonly get a plain but solid education, superior to their condition, by means of which they rise in civil society to a higher level. They have several excellent establishments for this purpose: the principal of which, situated at Ackworth in Yorkshire, contains, of both sexes, three hundred children, and was founded in 1778, at the instance of Dr. Fothergill. With provision for mathematical and classical learning, the Quakers, though they have some good private schools, are but flenderly furnished; and they have in consequence few accomplished men in these branches. They are by no means deficient in general information, and of late years many of them have cultivated natural philosophy with success. The society in its earlier stages, including many men of regular scholastic education, who had joined it on principle, had of course the advantage, in point of theological knowledge, over the modern Friends, who chiefly inherit their profession, and whose education has but of late begun to include systematic instruction in the doctrines of Christianity at large.

In morals they are allowed to excel: their youth is watched over in this respect with more than ordinary care; and when grown up, their discipline prohibits, to all conditions, those amusements which offer to the mind the ready means of dissipating serious impressions. Habitual offenders against their peculiar regulations forfeit their membership, as well as those who violate the more obvious rules of justice and morality: their moral character, and constancy as a body, are thus kept up. But it is alleged, that they are not equally well guarded against a money-getting spirit; which is apt to grow upon those who intently prosecute trade and commerce to the exclusion of all other pursuits. From the occasional tenor of the society's advice to its members, it should seem that this is in a certain degree true; and that it behoves
obeys them to seek for an adequate remedy. They are not, however, chargeable with the love of money for its own sake; no class of men being more beneficent, or more prompt to contribute their time and substance to various public institutions, which the spirit of the Christian religion has at length raised up, for relieving the distresses, promoting the comfort, and improving the moral and religious condition of mankind.

As to the minuter features of their character, the Quakers are prudent and methodical in their business; generally good economists of time and money. Their conversation has many peculiarities; some of which flow from their principles, others merely from their associating chiefly among themselves. They were early taught to be habitually crafty; "the Quaker fly," says Pope; but there seems no other ground for this, than the extreme caution with which they incur engagements, or make professions and promises. Viewed at a distance, they appear cold, formal, and referred in their manners; and have hence been unjustly concluded void of domestic cheerfulness, and incapable of the enjoyments arising from social converse, and the intercourse of cultivated minds. They are plain in their dress; the peculiarities observable in which result, not from any regulations on the subject, but from an indigposition to vary with the fashion; they have, however, slowly followed changes which have proved general and permanent, and thus become less confusively singular. Mourning habits they reject on principle; and with a people whose ordinary dress is so grave, the moral reason for them seems not to exilt. They are averse to splendour in furniture and equipage; though they rich among them, in these articles, and most of their females in dresses, have contrived, without ceasing to be known as Quakers, to refine considerably upon absolute simplicity.

Doctrinel—A recent publication on behalf of the society, entitled, "A Summary of the History, Doctrine, and Discipline of Friends," ascribed to one of the society, held in high estimation, viz. Mr. J. G. Bavan, who died whilst this article was in the press, states their doctrine as follows:

"We agree with other professors of the Christian name, in the belief of one eternal God, the creator and preserver of the universe; and in Jesus Christ his Son, the Messiah, and mediator of the new covenant.

"When we speak of the gracious display of the love of God to mankind, in the miraculous conception, birth, life, miracles, death, resurrection, and ascension of our Saviour, we prefer the use of such terms as we find in scripture; and contented with that knowledge, which divine wisdom hath seen meet to reveal, we attempt not to explain those mysteries which remain under the veil; nevertheless we acknowledge and assert the divinity of Christ, who is the wisdom and power of God unto salvation.

"To Christ alone we give the title of the Word of God, and not to the scriptures; although we highly esteem these sacred writings, in subordination to the Spirit from which they were given forth; and we hold with the apostle Paul, that they are able to make wise unto salvation, through faith which is in Christ Jesus.

"We revere those most excellent precepts, which are recorded in scripture to have been delivered by our great Lord, and we firmly believe that they are practicable and binding on every Christian; and that in the life to come every man will be rewarded according to his works. And further it is our belief, that, in order to enable mankind to put in practice these sacred precepts, many of which are contradictory to the regenerate will of man, every man coming into the world, is endowed with a measure of the light, grace, or good Spirit of Christ; by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his fallen nature, which mere reason is altogether insufficient to overcome. For all that belongs to man is fallible, and within the reach of temptation; but this divine grace, which comes by Him, who hath overcome the world, is, to those who humbly and sincerely seek it, an all-sufficient and present help in time of need. By this, the snares of the enemy are detected, his allurements avoided, and deliverance is experienced through faith in its effectual operation: whereby the soul is translated out of the kingdom of darkness, and from under the power of Satan, into the marvellous light and kingdom of the Son of God.

"Being thus persuaded that man, without the spirit of Christ inwardly revealed, can do nothing to the glory of God, or to effect his own salvation; we think this influence especially necessary to the performance of the highest act of which the human mind is capable; even the worship of the Father of lights and of spirits, in spirit and in truth: therefore we consider as obstructions to pure worship, all forms which divert the attention of the mind from the secret influence of this union from the Holy One. Yet, although true worship is not confined to time and place, we think it incumbent on Christians to meet often together, in testimony of their dependence on the heavenly Father, and for a renewal of their spiritual strength: thus, 'Each not only partakes of the particular refreshment and strength which comes from the good in himself, but is a sharer of the whole body, as being a living member of the body, having a joint fellowship and communion with all.' Barclay.

"Nevertheless, in the performance of worship, we dare not depend, for our acceptance, on a formal repetition of the words and experiences of others; but we believe it to be our duty to lay aside the activity of the imagination, and to wait in silence to have a true fight of our condition bellowed upon us; believing even a single sigh, arising from such a sense of our infirmities, and of the need we have of divine help, to be more acceptable to God, than any performances, however specious, which originate in the will of man. If any should object the difficulty of laying aside the activity of the imagination, let such consider the following statement—That it is our duty to maintain a watch over our thoughts, by endeavouring to preserve our attention from being carried away by such as manifestly originate in our own natural will, or habits, and to wait patiently for the arising of the life of Christ; which by bringing every thought into subjection, produces a true inward silence, and therein affords a true sense of our condition.

"From what has been laid respecting worship, it follows that the ministry we approve must have its origin from the same source; for that which is needful for a man's own direction, and for his acceptance with God, must be eminently so to enable him to be helpful to others. Accordingly we believe, that the renewed affiance of the light and power of Christ is indispensably necessary for all true ministry; and that this holy influence is not at our command, or to be procured by study, but is the free gift of God to chosen and devoted servants.—Hence arises our testimony against preaching for hire, in contradiction to Christ's positive command, 'Freely ye have received, freely give;' and hence our conscientious refusal to support such ministry, by tithes or other means.

"As we dare not encourage any ministry, but that which we believe to spring from the influence of the Holy Spirit, so neither do we attempt to restrain this ministry to persons of any condition in life, or to the male sex alone; but,
as male and female are one in Christ, we hold it proper that such of the female sex as we believe to be endowed with a right qualification for the ministry, should exercise their gifts for the general edification of the church; and this liberty we esteem a peculiar mark of the gospel dispensation, as foretold by the prophet Joel, and noticed by the apostle Peter.

"Three are two ceremonies in use among most professors of the Christian name, water-baptism, and what is termed the Lord's supper. The first of these is generally esteemed the essential means of initiation into the church of Christ; and the latter, of maintaining communion with him. But as we have been convinced that nothing short of his redeeming power, inwardly revealed, can set the soul free from the thraldom of sin; by this power alone we believe salvation to be effected. We hold that as there is one Lord and one faith, so his baptism is one, in nature and operation; that nothing short of it can make us living members of his mystical body; and that the baptism with water, administered by his fore-runner John, belonged, as the latter confessed, to an inferior and decreasing dispensation.

"With respect to the other rite, we believe that communion between Christ and his church is not maintained by that, or by any other external performance, but only by a real participation of his divine nature through faith; that this is the supper alluded to in the Revelation. Behold I stand at the door and knock: if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me, and that where the substance is attained, it is unnecessary to attend to the shadow: which doth not confer grace, and concerning which, opinions so different, and animosities so violent, have arisen.

"Now, as we thus believe that the grace of God, which comes by Jesus Christ, is alone sufficient for salvation, we cannot admit that it is conferred on a few only, whilst others are left without it; nor, thus affecting its universality, can we limit its operation to a partial cleansing of the soul from sin, even in this life. We entertain worthier notions both of the power and goodness of our heavenly Father, and believe that he doth vouchsafe to all the obedient to experience a total surrender of the natural will, to the guidance of his pure unerring Spirit; through whose renewed affluence they are enabled to bring forth fruits unto holiness, and to stand perfect in their present rank.

"There are not many of our tenets more generally known than our testimony against oaths, and against war. With respect to the former of these, we abide literally by Christ's positive injunction, delivered in his sermon on the mount, 'Swear not at all.' From the same sacred collection of the most excellent precepts of moral and religious duty, from the example of our Lord himself, and from the corresponding convictions of his Spirit in our hearts, we are confirmed in the belief that wars and fightings are, in their origin and effects, utterly repugnant to the gospel; which full breathes peace and good-will to men. We also are clearly of the judgment, that if the benevolence of the gospel were generally prevalent in the minds of men, it would effectually prevent them from oppressing, much more from enflaving, their brethren (of whatever colour or complexion), for whom, as for themselves, Christ died; and would even influence their conduct in their treatment of the brute creation, which would no longer groan, the victims of their avarice, or of their false ideas of pleasure.

"Some of our tenets have in former times, as hath been shewn, subjected our Friends to much suffering from government, though to the salutary purposes of government, our principles are a security. They inculcate submission to the laws, in all cases wherein conscience is not violated. But we hold, that as Christ's kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion, but to maintain the external peace and good order of the community. We therefore think persecution, even in the smallest degree, unwarrantable. We are careful in requiring our members not to be concerned in illicit trade, nor in any manner to defraud the revenue.

"It is well known that the society, from its first appearance, has diffused those names of the months and days, which have been given in honour of the heroes or false gods of the heathen, originated in their flattery or superition; and also the custom of speaking to a single person in the plural number, as having likewise arisen from motives of adulation. Compliments, superfluity of apparel, of furniture, and of provision for the table, outward shows of rejoicing and mourning, and the observance of days and times, we esteem to be incompatible with the simplicity of a Christian life; and public diversions, gaming, and other vain amusements of the world, we cannot but condemn. They are a waste of that time which is given us for nobler purposes; and divert the attention of the mind from the sober duties of life, and from the reproofs of instruction, by which we are guided to an everlasting inheritance.

"To conclude, although we have exhibited the several tenets which distinguish our religious society, as objects of our belief; yet we are sensible that a true and living faith is not produced in the mind of man by his own effort; but is the free gift of God in Christ Jesus, nourished and increased by the progressive operation of his Spirit in our hearts, and our proportionate obedience. Therefore, although for the preservation of the testimonies given us to bear, and for the peace and good order of the society, we deem it necessary that those who are admitted into membership with us, should be previously convinced of those doctrines which we esteem essential; yet we require no formal subscription to any articles, either as a condition of membership, or a qualification for the service of the church. We prefer judging of men by their fruits, and depending on the aid of Him, who, by his prophet, hath promised to be 'a spirit of judgment to him that fittest in judgment.' Without this, there is a danger of receiving numbers into outward communion, without any addition to that spiritual sheep-fold, whereof our blest Lord declared himself to be both the door and the shepherd; that is, such as know his voice, and follow him in the paths of obedience.'

To this statement may be added the following extracts, the first of which is from a declaration prefixed on behalf of the society in 1693.

"We sincerely profess faith in God by his only-begotten Son Jesus Christ, as being our light and life, our only way to the Father, and also our only Mediator and Advocate with the Father;—that God created all things, he made the worlds, by his Son Jesus Christ, he begat that powerful and living Word of God by whom all things were made; and that the Father, the Word, and the Holy Spirit, are One, in divine Being inseparable; One true, living, and eternal God blessed for ever;—yet that this Word or Son of God, in the fulness of time, took flesh, became perfect Man, according to the flesh descended and came of the seed of Abraham and David, but was miraculously conceived by the Holy Ghost, and born of the Virgin Mary, and also, farther, declared powerfully to be the Son of God, according to the Spirit of sanctification, by the resurrection from the dead;—that, as Man, Christ died for our sins, rose again, and was received up into glory in the heavens; he having, in his dying for all, been that one, great, universal offering and sacrifice for peace, atonement, and reconciliation between God and man; and he is the propitiation
tion not for our sins only, but for the sins of the whole world; we were reconciled by his death, but saved by his life:—that divine honour and worship is due to the Son of God; and that he is in true faith to be prayed unto, and the name of the Lord Jesus Christ called upon, (as the primitive Christians did,) because of the glorious union or oneness of the Father and the Son." Sewell's History, p. 643.

"The doctrine of the resurrection of the dead is so connected with the Christian religion, that it will be also proper to say something on this subject. In explaining our belief of this doctrine, we refer to the 15th chapter of the 11th Epistle to the Corinthians. In this chapter (verses 40-42, 44-50) is clearly laid down the resurrection of a body, though not of the same body that dies. Here we rest our belief in this 'mystery,' without desiring to pry into it beyond what is revealed to us; remembering that 'secret things belong unto the Lord our God, but those things which are revealed belong unto us and to our children.'

Principles of Religion, as professed by the Quakers, by Henry Take.

Discipline: from the "Summary," with some abridgment.—"The purposes which our discipline hath chiefly in view, are, the relief of the poor, the maintenance of good order, the support of the testimonies which we believe it is our duty to bear to the world, and the help and recovery of such as are overtaken in faults: in a few words, the promotion of piety and charity.

In the practice of discipline, we think it indispensable that the order recommended by Christ Himself be invariably observed. If thy brother shall trespass against thee, go and tell him his fault between thee and him alone: if he shall hear thee, thou hast gained thy brother; but if he will not hear thee, then take with thee one or two more, that in the mouth of two or three witnesses, every word may be established; and if he shall neglect to hear them, tell it unto the church.

To effect the salutary purposes of discipline, meetings were appointed, at an early period of the society, which, from the times of their being held, were called quarterly meetings. It was afterwards found expedient to divide the districts of the society, and to meet more frequently: from whence arose monthly meetings, for business, and those held quarterly. At length, in 1669, a Yearly Meeting was established, to superintend, advise, and provide rules for, the whole: previously to which, general meetings had been occasionally held.

A monthly meeting is usually composed of several particular congregations, situated within a convenient distance from each other. Its business is to provide for the subsistence of the poor, and for the education of their offspring; to judge of the sincerity and fitness of persons appearing to be convinced of the religious principles of the society, and to require them to be admitted into membership; to excite due attention to the discharge of religious and moral duties; and to deal with disorderly members. Monthly meetings also grant to such of their members as are known to the society, certificates of their membership and conduct, without which they cannot gain membership in such meetings. Each monthly meeting is required to appoint certain persons, under the name of overseers, who are to take care that the rules of our discipline be put in practice; and when any case of complaint, or disorderly conduct, comes to their knowledge, to see that private admonition, agreeably to the gospel rule before mentioned, be given, previously to its being laid before the monthly meeting.

When a case is introduced, it is usual for a small committee to be appointed, to visit the offender, to endeavour to convince him of his error, and to induce him to forsake and condemn it. If they succeed, the person is by minute declared to have made satisfaction for the offence; if not, he is denounced as a member of the society.

In disputes between individuals, it has long been the decided judgment of the society, that its members should not seek each other at law. It therefore enjoins all to end their differences by speedy and impartial arbitration, agreeably to rules laid down. If any refuse to adopt this mode, or, having adopted it, to submit to the award, it is the direction of the yearly meeting that such be denounced.

To monthly meetings also belongs the allowing of marriages: for our society hath always decreed to acknowledge the exclusive authority of the priests in the solemnization of marriage. Those who intend to marry, appear together, and propound their intention to the monthly meeting; and, if not attended by their parents or guardians, produce a written certificate of their capacity, signed in the presence of witnesses. The meeting then appoints a committee to inquire whether they be clear of other engagements respecting marriage; and if, at a subsequent meeting, no objections be reported, they have the meeting's consent to solemnize their intended marriage. This is done in a public meeting for worship, towards the close whereof of the parties stand up, and solemnly take each other for husband and wife. A certificate of the proceedings is then publicly read, and signed by the parties, and afterwards by the relations, and others as witnesses. Of such marriages the yearly meeting keeps a record; as also of the births and burials of its members. A certificate of the date, of the name of the infant, and of its parents, signed by those present at the birth, is the subject of one of these last mentioned records; and an order for the interment, counter signed by the grave-maker, of the other. The naming of children is without ceremony. Births and deaths are also conducted in a simple manner. The body, followed by the relations and friends, is sometimes, previously to interment, carried to a meeting; and at the grave a pause is generally made; on both which occasions it frequently falls out, that one or more friends present have something to express for the edification of those who attend; but no religious rite is considered as an essential part of burial.

Several monthly meetings compose a quarterly meeting. At the quarterly meeting are produced written answers from the monthly meetings, to certain queries respecting the conduct of their members, and the meeting's care over them. The accounts thus received, are digested into one, which is sent, also in the form of answers to queries, by representatives, to the yearly meeting. Appeals from the judgment of monthly meetings are brought to the quarterly meetings; whose business also is to abide in any difficult case, or where remembrances appear in the care of the monthly meetings over the individuals who compose them.

The yearly meeting has the general superintendence of the society in the country in which it is established; and therefore, as the accounts which it receives delivereth the state of inferior meetings, as particular exigencies require, or as the meeting is impressed with a sense of duty, it gives forth its advice, makes such regulations as appear to be requisite, or excites to the observance of those already made; and sometimes appoints committees to visit those quarterly meetings which appear to be in need of immediate advice. Appeals from the judgment of quarterly meetings are here finally determined, and a brotherly correspondence, by epistles, is maintained with other yearly meetings.

In this place it is proper to add, that, as we believe women may be rightly called to the work of the ministry, we also think that to them belongs a share in the support of our Christian discipline; and that some parts of it wherein their own sex is concerned, devolve on them with peculiar propriety. Accordingly they have monthly, quarterly, and yearly meetings of their own sex, held at the same time with those of the men; but separately, and without the power of making rules.

In order to those who are in the situation of ministers may have the tender sympathy and counsel of those of either sex, who, by their experience in the work of religion, are qualified for that service, the monthly meetings are advised to select such, under the denomination of elders. These, and ministers approved by their monthly meetings, have meetings peculiar to themselves, called meetings of ministers and elders; in which they have an opportunity of exciting each other to a discharge of their several duties, and of extending advice to those who may appear to be weak, without any needless exposure. Such, it may be here observed, as believe themselves required to speak in meetings for worship, are not immediately acknowledged as ministers by their monthly meetings; but time is taken for judgment, that the meeting may be satisfied of their call and qualification. It will also sometimes happen, that such as are not approved will obtrude themselves as ministers, to the grief of their brethren; but much forbearance is used towards them, before the disapprobation of the meeting is publicly defined. These meetings of ministers and elders are generally held in the compas of each monthly, quarterly, and yearly meeting. They are conducted by rules prescribed by the yearly meeting, and have no authority to make any alteration or addition to them. The members of them unite with their brethren in the meetings for discipline, and are equally accountable to the latter for their conduct.

It is to a meeting of this kind in London, called the second day's morning meeting, that the reviual of manuscripts concerning our principles, previously to publication, is intrusted by the yearly meeting held in London; and also the granting, in the intervals of the yearly meeting, of certificates of approbation to such ministers as are concerned to travel in the work of the ministry in foreign parts; in addition to those granted by their monthly and quarterly meetings.

The yearly meeting of London, in the year 1675, appointed a meeting to be held in that city, for the purposes of advising and assisting in cases of suffering for conscience' sake, which hath continued with great use to the society to this day. It is composed of friends under the name of correspondents, chosen by the several quarterly meetings, and who reside in or near the city. The same meetings also appoint members of their own in the country as correspondents, who are to join their brethren in London on emergency. The names of all these correspondents, previously to their being recorded, are submitted to the approbation of the yearly meeting. Such men as are approved ministers are also members of this meeting, which is called the Meeting for Sufferings; a name arising from its original purpose, and which is not yet become entirely obsolete.

The yearly meeting has intrusted the meeting for sufferers with the care of printing and distributing books, and with the management of its flock; and, considered as a standing committee of the yearly meeting, it hath a general care of whatever may arise, during the intervals of that meeting, affecting the society, and requiring immediate attention: particularly of those circumstances which may occasion an application to government. The flock of the yearly meeting, just mentioned, is an occasional voluntary contribution, expended in printing books,—salary of a clerk for keeping records,—the passage of ministers who visit their brethren beyond sea,—and some small incidental charges: but not, as has been falsely suppos'd, the reimbursement of those who suffer discomfiture for titles and other demands with which they scruple to comply." G. Fox's Journal. Sewell's History of the Quakers. Gough's History of the Quakers. Belle's Sufferings of the Quakers. Barclay's Apology. Clarkston's Portraiture of Quakerism.

The editor is indebted for the historical part of the preceding article to a respectable member of the society of Friends. Mr. Clarkston's work, which was composed in consequence of his intimate personal acquaintance with many of its leading members, produced by his labours for the abolition of the slave trade, may be consulted for a more ample account of the manners, practices, and opinions of this society.

QUAKER-TOWN, in Geography, a post-town of America, in Bucks county, Pennsylvania; 184 miles from Washington.

QUAKING-Bog, in Agriculture, a name usually given to a fort of soft pulpy, flexible, earthy depositions, which are formed in hollow moist situations, in consequence of the stagnation of water in them in some manner or other. Bogs of this kind differ much in their nature, qualities, and properties, according to the difference of circumstancies and situations, but they have all a tremulous motion under the foot, when capable of being trodden upon. See Bog and Quagmire.

Draining is here equally necessary, as in all other cafes of a similar kind, and may profitably be carried into execution without any great difficulty.

QUAKING-Grass, in Botany, so called from the trembling of the little pendulous spikelets, occasioned by their capillary zigzag stalks. See Briza.

QUAKING-Grass, in Agriculture, the common name of a fort of grass, which is laid to thrive and flourish well on most kinds of poor cold land, and which cattle eat in a greedy manner; but which is not much adopted for cultivation in grassy grounds, though it makes tolerably good hay. See Briza.

QUAKU, or QUAKUA, in Geography, a district of Africa, on the Gold Coast.

QUALATCHE, a town of the state of Georgia; 40 miles W.N.W. of Tugdoo.

QUALE Jus, in Law, was an ancient writ judicial, which lay where a religious person had judgment to recover land; before execution was made of the judgment.

This writ was issued forth to the ejecutator between judgment and execution, to enquire whether the religious person had right to recover, or whether the judgment were obtained by collusion between the demandant and tenant; to the intent that the true lord might not be defrauded.

QUALEA, in Botany, a Caribbean name, used by Anblet, and inadvertently adopted by Schreber; possibly because, as it appears, he suspected the genus not to be sufficiently distinct from Vechy of the same author, his own Cucullaria; see that article. Willdenow, however, has followed him; and thus one name more is added to duagkill, which some future botanical Hercules must sweep away.—Aubl. Guian. v. 15. Schreb. 7. Willd. Sp. Pl. v. 1. 18. Mart. Mill. Dict. v. 4. Jull. 424. Lamarck Illust. v. 4. —Clas and order, Monandria Mowagnisia. Nat. Ord, perhaps Guttiferae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four very deep ovate, coriaceous, concave, unequal segments: the two lowermost largest, spreading widely. Cor. Petals two, unequal, inserted into the calyx; the uppermost erect, roundish, emarginate, terminating at the base behind, in a short, obtuse, horn-like nectary, projecting between the upper seg-
ments of the calyx; lowermost largest, floping downward. Stam. Filament filiform, short, ascending, inferted between the lower petal and the germen; anther oblong, narrowed, recurved. Pist. Germen superior, globose; style thread-like, ascending, the length of the stamina; stigma obtuse. Fruit. Berry of one cell. Seeds numerous, imbedded in pulp.

Obft. The corolla is, as it were, two-lipped. This genus is akin to Gaudinia. Schreb.

1. Q. rofa. Aubl. Guian. t. i. Wild. n. 1._Lower petal undivided. Leaves elongated at the point.—Native of the woods of Guiana, flowering in September. This inhabitant calls this species Lako-laka. A tree, whose trunk is fifty feet or more in height, terminating in large spreading branches. Wood red, compact. Leaves opposite, in pairs, crotchting each other, on shortish stalks, elliptical, three or four inches long, entire, smooth, with an elongated blunt point; their transverse veins very numerous, straight and parallel.

Stipulas deciduous. Panicles terminal. Flowers numerous, two inches long, powerfully and agreeably scented, white on the outside, rose-coloured, and finally yellowish, within.

2. Q. cerasa. Aubl. Guian. t. 2. Wild. n. 2._Petals two-lobed. Leaves with a short point.—Native of the Guiana forests. This species flowers in October, and is known by the name of Quale. It differs from the former in having smaller flowers, of a grey or bluish colour, but fragrant like those of Q. rofa. Their petals are emarginate, or almost obcordate. Points of the leaves left elongated.

QUALIFICATION for killing game, for jurors, justices, members of parliament, and electors of members. See GAME, Jury, JUSTICE, and Parliament.

Qualifications for a complete musician, required by Zarino. This venerable theorist had very exalted ideas of a perfect musician, and tells us (Instut. vol. ii. part iv. p. 340; et seq.) that it is necessary he should have a knowledge in arithmetic, for the calculation of musical proportions; of geometry, to measure them; of the monochord and harpichord, to try experiments and effects; that he should be able to tune instruments, in order to acclum the ear to distinguishing and judge of intervals; that he should sing with truth and taste, and perfectly understand counterfeit; that he should be a grammarian, in order to write correctly, and set words with propriety; that he should read history, to know the progress of his art; be a master of logic, to reason upon, and investigate the more abstruse parts of it; and of rhetoric, to express his thoughts with precision; and, further, that he would do well to add to those sciences some acquaintance with natural philosophy, and the philosophy of sound; that his ears being perfectly exercised and purified, may not be easily deceived. And adds, that he who aspires at the title of perfect musician, has occasion for all these qualifications, as a deficiency in any one of them will frequently render the rest useless. An additional qualification is now become necessary to be added to those enumerated by Zarino, which is a perfect knowledge of the genius and powers of all the instruments for which a musician writes; otherwise he will not only embarrass a performer by useless and meaningless difficulties, but lose opportunities of producing effects by the bow of a violin, the coup de langue of flutes, and a selection of the purest and best tones on other wind instruments.

Qualifications of Land-managers, &c. The requisite qualifications which are proper and essential to them in order to the due and full performance of all the different sorts of business in which they may be engaged or employed. In this view, a considerable knowledge of the principles and practices of different sorts of farming and farm-management, some acquaintance and experience in surveying land, in mechanics, in rural architecture, and in the business of planting, are indispensably necessary, as well as a notion of the various mineral and other substances contained in the bowels of the earth, and a ready facility in arranging the management of different sorts of accounts.

They should at the same time possess mild, conciliatory dispositions, exact upright principles, and strict moral characters. See LAND-REVENUE, LAND-STEWARDS, and OFFICE OF ESTATE.

The duties and uses of these sorts of managers, besides those of regulating and directing the husbandry, management, and other matters, are, the preventing all sorts of encroachments from taking place; the seeing that a proper and right method of stock is pursued on the commonable lands; the guarding against the turf or foil being injured by being broken up or pared off; the looking after the public and private roads, lanes, and driveways, to see that the fences on the sides of them are properly cut and pruned as occasion may require, the travelling parts of them kept free from obstructions, and in a suitable state of repair, and that the farm-ways are well calculated to the uses and intentions for which they were designed; the duly attending to the open drains, water courses, and common fences, to take care that they are kept clear and free at all times, without doing injury to any one; the considering the state of the natural streams and running waters as fit for the purposes of watering live-stock at home or in other places, those of irrigating land, the turning of mills, &c.; the examining the borders of rivers, brooks, &c. to see that they are not carried away, or their courses altered in any injurious manner; the taking care of plantations, and all sorts of woodlands, as well as timber-trees and young plants, by seeing that they are preserved in a proper manner, and no damages committed by cutting them down, or in any other ways; the attending to the situation of the fences, gateways, &c. to see that the live hedges, with their banks, be duly cut, weeded, pruned, and kept up, as well as the gates, fences, pale, and other dead fences properly preserved and in repair; the keeping the home buildings, farm cottages, and garden grounds, belonging to them, in proper condition, with their tenants in a full state of industry; and lastly, the regulating the order of the different occupations, by preventing improper meetings of all kinds, the reprefing of bad housewives, and all sorts of irregularities that have a tendency to lessen industry and frugality.

Besides these, there are many other duties which properly belong to them, but which need not be mentioned in this place. See BAILIFF.

Qualifications of Tenants, the necessary properties and circumstances which render them fit for holding lands as farms. The importance of having persons perfectly qualified as tenants, is very great, in the superintendence and management of all landed property, being, in a great measure, the basis, or principal bearing, on which its uniform and lasting prosperity depends.

The proper qualifications of a good tenant, according to the author of the "Treatise on Landed Property," are the having capital, skill, industry, and character. And he contends, that without a sufficient capital, the rent are unavailing; but that, at the same time, an indolent, frugal, good farmer will strive with difficulties, and get on with less money than a man of contrary qualifications. But if he has not sufficient strength to work his lands, nor a sufficiency of live-stock to raise manure, or money wherewith to purchase it, he must, under ordinary circumstances, live in a state of poverty and hard labour; and, on the first attack of misfortunes, or the first failing season of crops, he will probably sink.
fink under the weight of his accumulated burden, and be ruined.

Further, that in regard to the proper ratio or proportion between the rent and capital, it depends on the existing state and circumstances of the farms, and the style of management in which they are intended to be conducted; as well as on the number and strength of the occupiers’ families, and their industry and frugality. However, in order to afford some general notions on the matter, it may be said that, for farms of size, as those of from one to five hundred pounds a year, the occupiers should have at their commands from five hundred to a thousand pounds of capital, for every hundred pounds of rent which they may pay. Yet still, on the greater number of farms, the first proportion is too small to manage them with full advantage and profit. And, if they be farmed with spirit, and the higher order of improvements be attempted, particularly the introduction of the best breeds of live-flock adopted by modern farmers, the last will not be found too large for the purpose.

It may be remarked, that it is constantly the best way for tenants to farm somewhat within their capitals, as a few pounds kept in their pockets enables them to embrace and take the advantage of every favourable opportunity that may offer, and to sell or buy with the greatest benefit. While such as are straightforward for money, are forced to take the chance of markets, and liable to make bargains of a losing and disadvantageous nature, as well as experience many other inconveniences of different kinds.

Notwithstanding, where there is a want of sufficient experience and skill in the art, and different branches of practical husbandry, tenants cannot farm or manage their lands with the most profit, either to themselves, or the proprietors of them. Where, however, their capitals and exertions are great, they may, by observation and practice, acquire skill; and by this means be enabled to perform the business in a tolerable manner, and in some measure do justice to their farms, whatever they may do for their families in the way of getting money for their benefit. But where, with a want of skill, scanty capitals are joined, it is not all the exertion, industry, and frugality in the power of man, that can save or preserve the families or the farms from injury and inconvenience.

However, without industry, capital and skill may be lost to be thrown away. In the management of rural business, in which so much depends on the nature of f easons and weather, idleness is a vice of the darkest cast. Every instance of negligence is not only injurious in itself, but operates as a dangerous and bad example: serving as an apology or excuse for the half industrious, with whom every farm or estate is incumbered in a greater or less degree.

In consequence of the intimate connection which necessarily subsists between the proprietors and the occupiers of land, and seeing how advantageous and profitable it is to prefer good order and regularity upon farm lands, as giving thereby full liberty and freedom to the exertions of their tenantry, it becomes a matter of some importance, in the selection of farm-tenants, to make proper and necessary inquiries into their characters for morality, and particularly as they relate to habits of frugality or extravagance, as well as to a peaceable frame of character, as in providing for the widows and orphans of deceased tenants, &c. A farm-manager should not suffer himself to be influenced by any sort of family connection, favour, or reward. Superintendents of this kind, merely as such, cannot have any true interests separate and distinct from those of the farms or lands they may overlook. It, therefore, becomes a dilftent act in any agent of this sort, to put an inferior tenant into the possession of a farm, through his own interest, even at a fair rent for the farm.

Lastly, it may be noticed, that in a district which stands forward in a prominent manner in the ranks of rural improvements, merit should be looked for and encouraged near home. But to advance or bring up a farm or estate which remains in the rear of modern practices, two or more tenants of the higher classes should be sought for, at a distance, in such districts as are of a kindred nature, but in which the more modern and profitable management of farming prevails, in order to lead and direct the native tenantry of the situation.

There are some of the principal and leading qualifications which ought in all cases to direct and regulate the choice of farm-tenants; there are, however, many others which should have an influence in certain circumstances, and particular methods of farm-management, otherwise the full interests and advantages of the proprietors of the lands may be overlooked and neglected.

QUALIFICATOR, in the Canon Law, a divine appointed to qualify, or declare the quality of, a proposition brought before an ecclesiastical tribunal; chiefly before the inquisition.

The qualifications of the office are not judges; they only give their sentiments on the propositions presented to them. They are the inquirers that judge.

QUALITY, Qualitas, that affection of a thing, whence it is denominated such; or that which occasions a thing to affect our senses in this or that manner, and gives it this or that denomination. Accordingly quality is said to be an attribute, from which no substance is exempt. See MODE.

Thus, that power in fire, whatever it be, by which it excites in us the sensation of heat, since it is that which when the fire is denominated hot, is called the quality of fire.

The word quality, qualitas, is said to have been first introduced into the Latin by Cicero; till his time the Romans studiously avoided using a term which denoted an abstract; and in lieu of it only considered concrete, signified by quale. The like is observed of the ancient Greeks, who did not use ταυτότητα, but ὑπάρχοντα.

Quality, it is to be observed, is an ambiguous term; and has been applied to some things which ought rather to have been looked upon as states of matter, or assemblages of several qualities; as life, health, beauty, &c.

There are, also, other attributes, as size, shape, motion, and rest, usually reckoned among qualities, which might more conveniently be ranked among the primary modes of the parts of matter; since, from these simple attributes, all the qualities are derived.

The ancient school-philosophers distinguishing quality in the general, which they call metaphysical and predicamental quality, into essential and accidental. The moderns more usually divide it into spiritual and corporeal.

QUALITIES, Spiritual, or Qualities of the Soul, are affections of the mind, considered in this or that habit, or disposition. Of these they make two kinds; the one belonging to the understanding, the other to the will; of the former kind are knowledge, opinion, certainty, doubting, &c. Of the latter are all the moral virtues and vices.
Qualities, Corporal or Physical, are what we chiefly consider under this denomination, and to which the definition above laid down is accommodated.

Philosophers are divided as to the nature of these qualities, or what they are in the body. The general language of the Peripatetic school is, that they are things distinct from the bodies themselves; and are superadded to them, or flow from their substantial forms: on which principle, they hold qualities to be real, and denominate them accidents; supposing them to be inherent in substances, though not in the relation of parts, but to be fulfilled by them as in a subject, and incapable of subsisting without them. In effect, the Thomists deny the qualities to be accidents following or arising from the form; in the same manner as quality is an accident following or arising from the substance.

The moderns absolutely explode the notion of qualities distinct from the body; and infilt, that the powers by which bodies excite in us the ideas of such qualities, are no other than the mechanical affections of the bodies themselves, viz., the figure, magnitude, motion, &c. of the parts of which they consist.

The principal considerations insisted on by the retainers to real qualities are, that these powers may be actually separated from the substances they inherin to; as we see in light, heat, &c. That from these very qualities, considered as so many determinations, there arises a very great diversity in bodies; and that bodies, according to the diversity of their qualities, affect our senses very differently.

The adherents to the experimental way, on the contrary, account for all the qualities of bodies from mechanical causes. Thus all the phenomena of a clock, the motion of its wheels, its hands, &c. by which it strikes the hour, points the minute; day, month's age, &c. do all evidently arise from the single spring; which we never imagine to have any particular powers by which it should be enabled to make such discoveries; nor any other principle but that of elasticity. Why, then, may we not conceive, as to fequal qualities, that though, by virtue of a certain congeality or incongruity in point of figure, texture, or other mechanical properties, the portions of matter they modify are enabled to produce various effects, on account of which the bodies are said to be endowed with qualities; yet these are not, in the bodies endowed with them, any real or distinct entities, or differing from the matter itself of such a determinate bigness, shape, and other mechanical modifications? Thus, though the modern goldsmiths and refiners reckon it among the most distinguished qualities of gold that it is diffusible in aqua regia, whilst aqua fortis will not work upon it; yet these attributes are not in the gold any thing distinct from its peculiar texture; nor is the gold we have now of any other nature than it was in Pliny's time, when aqua fortis and aqua regia were unknown.

We all know that the fun hath a power to harden clay, soften wax, melt butter, thaw ice, turn water into vapour, make air expand itself in weather-glasses, contribute to blanch linen, render the white film of the face swarthy, and mowed grass yellow, ripen fruit, hatch the eggs of fikworms, caterpillars, &c. and perform many other things, some of which seem contrary to others; yet these are not distinct powers, or faculties in the fun, but only the product of its heat, diversified by the different textures of the body it chances to work on, and the condition of the other substances concerned in the operation. And, therefore, whether or not the fun, in some cases, has any influence at all distinct from its light and heat, we see that all the phenomena mentioned are producible by the heat of common fire, duly applied and regulated. Some of the ancients, and particularly the Peripatetics, have distinguished qualities into sensible and insensible.

Qualities, Sensible or Manifest, are those arising from certain modifications of matter, and which become immediately the objects of our senses. Such are all those above mentioned.

Though, in strictness, those only are said to be sensible qualities which affect some one sense alone; as colour does the eye, found the ear, &c. These are sometimes, also, called tangible qualities, because they only produce their effect, i.e. excite their idea in us, when contiguous, or in contact with the organs.

Qualities, Occult, are certain latent powers arising from the specific forms of things, of which no rational solution can be given on any principles of physics.

Sensible qualities are usually subdivided into primary and secondary. See Ideas.

Qualities, Primary, or General, are such as are found in all bodies; or which agree to all matter, considered as matter, and therefore to the elements themselves. Such are extension, figure, motion, red, solidity, impenetrability, and number.

Qualities, Secondary, or Particular, are such as result from a composition or mixture of elements, and do not agree to body as body, but as a mixt. Such are light, heat, cold, colour, found, taste, smell, hardness, softness, fluidity, firmness, roughness, smoothness, opacity, transparency, &c.

According to Aristotle, and the Peripatetics, the primary, or elementary qualities, are those of the four elements themselves; viz. heat, cold, moisture, and dryness.

The secondary qualities, according to the same, are all the red, which are combinations or allusions of the former elementary ones; as colour, odour, taste, &c.

To give an idea of Aristotle's method of accounting for these secondary qualities from these primary ones, we shall inchose in his account of colour. All colours, then, says he, are generated of a mixture of the four elementary qualities: white, or gr. is produced when the humidity surrounds the heat, as in old men, whose hair grows grey; black is produced when the humidity dries off, as in walls, cinders, &c. red, &c.

Among the school-philosophers we meet with other divisions of qualities; as active, and passive; real, and intentional.

Qualities, Active, are those by virtue of which effects and operations are actually produced on other bodies, duly disposed with respect to them. Such are the heat of fire, the moisture of water, &c.

Qualities, Passive, are those by which bodies are disposed to receive the action of others. Such are inflammability in oil, &c.

Qualities, Real, are those by which remain in the subject, and only act on things adjacent to it. As fire in a piece of iron not ignited, &c.

Qualities, Intentional, are those which issue from the subject, and operate at a distance. Such is the light emitted from the sun, &c.

But the moderns are agreed, that either all qualities are real, or all alike intentional. So that the distinction is inappertinent. See on the subject of quality, its various species, and its different properties, Harris's Philosophical Arrangements, chap. viii.

However ignorant we may be of the nature of qualities, or of the manner of their operation, yet we know the laws of their intention and remission. Dr. Keill demonstrates, that every quality which is propagated in orien, such as light,
light, heat, cold, odour, &c. has its efficacy increased, or abated, in a duplicate ratio of the distances from the centre of radiation, or exertion of the quality, reciprocally.

Thus, let A (Plate XII. Geometry, fig. 1.) be a centre from whence any quality exert itself round about, according to the right lines, A, A', A", &c. The efficacy of the quality, is: at heat, cold, odour, &c. will be (at equal distances from A) as the spollitude or density of the rays, A b, A' b', A" b", &c. But the rays within the inner circle, or rather spherical surfaces, &c; when they come to be extended to the other spherical surface, ef g, K, will be much less clofe than they were before, and that in the reciprocal proportion of the spaces they take up; that is, if the outer surface be the double of the inner, the rays there will be but half as thick; but the spherical surfaces are as the squares of their radius; therefore the efficacy of the quality in the inner surface will be to that of the outer, as A e square to A b square. Q. E. D.

Sir Ifaac Newton lays it down as one of the rules of philosopizing, that those qualities of bodies which are incapable of being intended and remitted, and which are found to obtain in all bodies in which the experiment could ever be tried, are to be esteemed universal qualities of all bodies. See Philosophy.

Qualities, Cosmical. See COSMICAL Qualities. Quality is also used for a kind of title, or degree of eminence given to certain perrons, in regard of their territories, dignities, or other pretensions.

Thus the king of Great Britain used to take the quality of king of France; the king of Poland that of king of Sweden; the king of Sardinia that of king of Cyprus and Jerusalem; the cazes of Ruffia, and kings of Spain, have whole pages of qualities. The emperor of China affumes the quality of fon of the fun.

Quality of Curvature, in Geometry, is used to signify its form, as it is more or less inequable, or as it is varied more or less in its progresse through different parts of the curve. Newton's Meth. of Flux. and Inf. Ser. p. 75. Maclaur. Flux. art. 369. See Curvature.

Qualities of Trees and Plants, in Agriculture and Gardening, are the properties which are peculiar to them, in relation to their magnitude, modes of growth, textures or confitances, forms, colours, tailes, feafts, means of propagation, culture, ufe, and values.

In regard to the firit, as soon as the simple confitute fibres of plants are evolved and increafe, as far as the nature of them and the arrangement of the primary nutrient substances will permit, they cave to receive any more for their fuperior increafe; the primary matters merely replacing the lofs which is occasioned by the performance of the natural functions of the plants; consequently they have each a particular preffered increafe or measure of growth. Some are very large, others extremely small. The Indian fig, in confequence of ramifications being fent off, which concrete with the primitive trunk, by inftinfe degrees acquire a very confiderable bulk or thicknefs, being frequently twenty, or even thirty cubic feet in its diametric fection. And there are accounts given of particular plants, which are scarcely visible to the naked eye; and of some trees, which are fo large as to cover with their branches two hundred perrons, or more.

In this country, fome trees and shrubs of the ornamental fort are either very high, or very low; of the former kind are the hornbe-cheinfut, larch, cornelian cherry, snowdrop-tree, and many others; and of the latter, the mountain-ash, hemlock, fir, Scotch rofe, butchers' broom, and many more. There are fome trees which are very broad, in pro-

portion to their height, as the oak, Spanish cheiffut, &c.; others which are very narrow, as the larch, spruce fir, &c. And there are fome others, in which there is a medium between these extremes, preserved and kept up, as in the aif-leaved maple, the evergreen oak, the Virginian rapsberry, the Guelder rose, and a number of others.

The modes or habits of growth in trees and shrubs are also extremely different; fome feeding out their branches in a horizontal manner, as in the oak; in others they have an upward direction, as in the Huntington willow; while in a few they fall downwards, as in the lime, acacia, and others. Again, there are fome which have an oblique inclination, as may be seen in the Scotch fir; or they recline, and then rise up again, as in the larch kind; and there are fome others, in which they hang directly downwards, as in the weeping willow, or the alder. There are alike fome well-shaped plants, which creep along the surface of the ground, as the periwinkle; others which clasp themselves to trees, as the passion-flower; and a few which fix and attach themselves to buildings, walls, &c. as the ivy. Further, there are fome trees that, in whatever way they may be placed, cut, or pruned, constantly amufe and take on one principal stem, from which all the different branches proceed or go off, as rays from a centre, as in the fir tribe; while in others, the trunks divide themselves into arms, or large branches, which fend out branches or smaller branches in a irregular manner, as in the oak and others. Some kinds of shrubs have merely one fingle ftem, as the althea; while other forts irnvariably spread and extend along the surface of the ground, throwing or sending up a greater number, as the hypericum, and fome others.

The texture or confitance of plants of different kinds is likewise very different, as hard, loft, membranous, carceous, smooth, downy, thorny, &c. which are mostly obvious to the feld. Plants of the young kind are commonly mucilaginous, becoming hard as they advance in growth; though many luxuriate in the flate of continual foffinefs, as the trelli; yet fome are fo hard as to fink in water, as the iron wood of the ifland of Ceylon, &c. Thus among trees and shrubs, fome have a foft smooth appearance, as the lime, the fcorpion fenna, &c.; while others have a hard, rough, ffirm appearance, as the evergreen oak, the holly, &c. There are fome fho which have a smooth, fily appearance, as the tamarisk, &c.; while others have a downy, woolly appearance, as the hoary poplar, &c. And fome appear wholly befet and covered with thorns or prickles, as the urze, hedgehog holly, &c.; while others, again, appear wholly compofed of thready fhofts, as the Portugal broom, &c.

Besides thefe, there are many other forts, which fhew different appearances from any of thefe.

The forms in the different forts and varieties are fiIl equally, if not more, various; fome being apparently folid and compafs, from being thick fett with branches and foliage, as in the hoibbe-cheinfut, the English elm, the lilac, the fyringa, &c.; while others are of a more light, airy, elegant form, being thin of boughs, branches, and leaves, as the ah, the hoary poplar, the bird cherry, the Canadian mefplufus; &c.; and there is a middle degree between these extremes, in the broad-leaved euonymus, the aif-leaved maple, and many others. They may alfo be further dillinguished into fome whose branches begin from nearly the surface of the ground, as in the fir tribe of trees, and most shrubs; and into fome which shoot up into a ftem before their branches are begun to be fent off, as in the mountain-ash, the althea frutex, &c. It may likewise be noticed in refept to fome whose branches begin from the ground, that fome of them riie in an elegant cone, as the larch, the
holly, &c.; others in a cone, whose base is very broad, as in the cedar; or whose base is very small, as in the upright cypresses. There are some which swell out in the middle of their growth, and diminish or contract at both ends, as in the Weymouth pine, &c.; while others are broadest at the top, as in the raspberry, the alpine honeysuckle, &c.; and some few irregular and bushy throughout, as in the evergreen oak, the snowball tree, &c. Among those which shoot up into a stem before their branches are sent off, there are some which are in the shape of slender cones, as in the deciduous cypresses; others in those of broad cones, as in the fable poplar. Still others assume a globular form, as in the mountain-ash; while many are irregular throughout, as in the Scotch elm, the acacia, and several others.

As to colour, it appears to depend upon the colouring principle, the proportion of vital air and light which is contained, and is proper to different parts of the same tree or plant; hence, when the exhalation is prevented, and light intercepted, the green colour is changed into white. In trees and shrubs it is either accidental or permanent; the latter including all the different shades of green in the summer months; the former, the different tints of red and yellow, which are peculiar to the autumnal and vernal feasons.

There are some of the permanent kinds of colour, which are of a dark green, as those in the horne-chefnut, the yew, &c.; while others are of a light green, as those in the ash, the hornbeam laurel, &c.; and others, again, which are of a blueish-green, as those in the Scotch fir, the bladder fenne, &c. Some trees have a green tinged with brown, as the Virginia cedar; others a green tinged with white, as the able and the Lapland willow. Also, in some trees the greens are tinged with yellow, as in the ash-leaved maple, the Chinese arbor vitae, &c.; in others with red, as in the scarlet maple, &c.; and in a few with purple, as in the purple beech. There are some greens which are spotted with white, yellow, and red, as that in the variegated holly, privet, fycamore, box, and various others. The colours which arise from accident are almost infinite in number, each kind of which is liable to great variation; nay, however, it will be found that in autumn the wild cherry assumes a bright red, the birch a deep red, the beech a brownish-red, the scarlet oak a deep scarlet, the hornbeam a ruflet colour, the sugar maple a rich yellow, the common oak a reddish-yellow, the lime and all a straw colour, the fballam poplar a black, the fycamore a dark brown, and others different forts of other colours.

In regard to taste and smell, the former depends upon the different principles which compose and constitute the juices or humours of the different kinds, and varies as well in the different forts, as in the different parts of the same fort of trees or plants. The latter depends on the volatile principle, or principles, which illume or exhale from them, and differs in its nature, according to the kinds of plants, or the parts of them, in which it chiefly resides or is present. There are some trees and shrubs which have scarcely any smell, as the evergreen oak, platanus, &c.; others have a most grateful rich fragrance, as the birch, sweetbriar, honeysuckle, &c.; some again have a lucrative, powerful smell, as the mezercon, the lyringa, &c.; others a disagreeable nauseous smell, as the elder, &c.; in some the smell is very sweet, as in the flowering lime; in others it is deleterious, as in those of the walnut, the armabia, &c. There is also the greatest fragrance in some while they are in blossom, as in the hawthorn, and in some it is solely confined to it, as in the lince; while in others it is equally diffused over or throughout the whole plant, as in the sweetbriar, and many others.

There may be considered as some of the most general characteristic qualities of trees and shrubs; but various other peculiarities incident to them present themselves, on a more minute investigation, which equally intert in and deserve the attention of the ornamental planter and gardener, as well as the cultivator of all sorts of wood and timber; and which principally relate to differences in the barks, the buds, the leaves, the flowers, and the fruits. The appearance of the bark is very different in many different sorts of trees and shrubs, as red, white, black, brown, and green, as in the dogwood, birch, oak, Guilder rose, and holly. It differs also in its properties, as in some it is firm, in others fpongy, in some thin, in others thick, brittle, glutinous, or thready, as in the oak, the cor-trely, the beech, the Scotch fir, the hornbeam, the holly, the lime, and the elm. It varies likewise in its duration, the outer bark or coat in some trees being thrown off annually, as in the arbutus, the birch, &c.; while in others, for the most part, it is constantly retained or kept on. It differs equally in respect to its properties of talle, being in some alluring in its nature, in others sweet, bitter, relieves, &c., as in the oak and bramble, lime, soft, &c.; in regard to buds, some trees have none at all, as the pine and evergreen forts; in some they are very large, in others very small, as in the horne-chefnut, and the willow. In some they are coated over with a covering of glutinous or relievous mater, as in the horne-chefnut, &c.; in others they are covered with a dry film or tegument, as in the beech, &c. There are likewise some buds which are of a red colour; others which are yellow, black, brown, or red and greenish; as those in the lime, the willow, the ash, the beech, and the common fycamore, in the order in which they occur.

The variety in the leaves is still much greater; some being very broad, as those of the common laurel; others very narrow, as those of the barch. And there is a medium between these extremes, in those of the willow and the almand. In some they are entire, as in the bay; in others serrated, as in the cherry; and pinatifid, as in the acacia, &c. In some again they are covered with down, as in the sea buckthorn; in others with wool, as in the hoary poplar; with prickleis, as in the holly; with a glutinous matter, as in the gum fycus, &c. They are of all the different shades of green in the fummer season; and of all the different tints of red and yellow, in the autumnal and vernal feasons.

There are some which retain their leaves and colours during or throughout the whole year, as the pine tribe, &c.; others which lose their green colour in the autumn; but retain their leaves all the winter, as the beech, hornbeam, &c. in particular circumstances. A great number of trees, among which are the elm and the as, drop their leaves in the autumn, and are naked all the winter. In general, the leaves have the fame properties; as the barks, but in a fainter and less perfect degree; which are of much importance in some points of view. Thos of the alder, the box, &c. are refused by most sorts of cattle; those of the elm, the horn, &c. greedily devoured by them; while those of the fir tribe are offensive to many sorts of insects, which are liable to infest hot-housies, and other similar places.

And the flowers are much less various than the leaves. Those of some trees being large and showy, as of the rose, the honeysuckle, &c.; while those of others are small and obscure, as of the alaternus, &c. In some they cover the whole plant, and quickly fade away, as those of the hawthorn; while in others they are but thinly distributed, yet continue a considerable length of time, as those of the passion-flower, &c. There are some, which come into blossom at an early period, as those of the mezercon, almand, &c.;
&c.; others that are very late, as those of the sweet chestnut, the alder, &c. And there are some trees and shrubs which cease flowering before their leaves expand, as the almond; and others in which the blossom makes its appearance only when the leaves fall off, as that of the hazel.

In the fruits or seeds of trees and plants the variety is likewise considerable. There are none, in which they are brilliantly coloured and flowy in their appearance, as in the clustered berries of the mountain-ash; while in others, the seed is very much hidden and obscure, as in the willow. On some trees they remain two or more years, as the cones on the fir tribe; on others but a few weeks, as the capsules of the elm. The fruits and seeds of some are used for culinary purposes, and contribute to increase and enrich the defects of the table, as the apple, pear, walnut, &c.; while others are appropriated to and have the properties of fattening the inferior forts of animals, as the acorn, the beech mast, &c.; and others again are poisonous, as the berries of the deadly nightshade, and those of the mezereon, &c.

Further, along with their characteristic distinctions, some trees and plants combine and comprise what may be considered particular properties.

In the roots, they are as much varied underneath the ground, as the trunks, stems, and branches are above the surface of it. There are some which spread themselves in a horizontal manner, as those of the pine, and fir tribes; others which lead down perpendicular roots to a great depth, as those of the oak, the chestnut, &c.; and there are those which form a medium between these extremes, as in those of the lime, the beech, &c.

In the modes or means of propagation in trees and plants there is equal or more variety. There are some which are raised from seeds, as the malt part of forest-trees, such as the oak, elm, alh, larch, &c.; others from layers, as the lime, platanus, rofe, and many forts of shrubs; still others from suckers, as the abele, gale, spirees, &c. And some are propagated by ingrafting, as the weeping alh, apple, &c.; others by inoculation, as the double-blossomed almond, the weeping cherry, &c. And some kinds, again, by the roots, as the thorn, mezereon, and others.

In respect to culture they require different kinds of soils, situations, and management; some delight in a deep, strong soil, as the oak; some in a dry gravelly one, as the beech; some in a deep moil one, as the poplar; others in a soil of the peat-earthly kind, as the erica, and various other forts; still others are natural to a rather moil soil, as the alder, &c. And there are some trees which will grow in a soil of almost any kind, as the Scotch fir tribe; while others will scarcely grow in any, but that of their natural one, as the rhododendron, the andromeda, &c. There are some again which hardly stand in need of the aid or assistance of any fort of soil, as the ivy, &c.; while others are of the parasite kind, as the millet, &c.

There is likewise much variety in the situations and expences which trees and plants naturally affect. Some kinds will endure almost every fort of exposure, with the exception of that of strong powerful sea breezes, as the larch, the Scotch fir, the mountain-ash, &c.; while some again endure and withstand the sea breezes in a much better and far superior manner to others, as the fycamore, alh, service, elder, &c.; others will not prosper except in low, or sheltered situations, as the black spruce, mott forts of American plants, &c.; while others will rise and grow under the drip and shade of others, as the Scotch elm, the Norway maple, hemlock, spruce, dogwood, box, &c.; but others again die in such situations, as the larch, the pine, the willow, and many other forts.

In their more young growths trees and plants not only demand soils, situations, and aspects suited to their particular natures and habits, but also such methods of culture as are adapted to them. Some kinds requiring the earth and mould about their roots to be repeatedly dug up and flirred, as the lime, the hlace, &c.; others advance with equal rapidity, where the ground on the surface is preserved free and clean from other injurious vegetable productions, as the oak, the chestnut, &c.; while others again succeed in the best manner, where the surface of the land is covered with mossy matter, as the rhododendron, the erica, &c.

In regard to cutting and pruning, there are some trees which will not bear the knife, as the cherry, &c.; the wood in others is many times hurt by it, as in the pine and the fir tribes. Some are again capable of bearing it to any extent, as the hawthorn, the crab-apple, &c. However, these peculiarities are mostly applicable to trees of considerable height; as mott forts which very young endure cutting in, and pruning very well, many kinds requiring their operations to train and bring them to single items. For instance, the silver fir, while in the nursery state, requires the side shoots of it to be cut and shortened; and young oak plants, some time after they have been finally planted out, are often cut over just above the surface of the ground, and fupposed to grow up stronger by it.

A great many forts of trees and plants stand in need of being removed or transplanted the first or second year of their growth from the feed, while in the nursery ground; and to be set out from that situation into plantations of different kinds, while under the height of four feet, or in their more early growth. There are some forts which are little or not at all hurt by such removals, as the elm; while others are liable to die after it, as the spruce fir, the Weymouth pine, &c.; some kinds are also apt to die on being transplanted, after they are eight, ten, or more feet in height, as the pine, the fir tribes, &c.; while other forts may be safely transplanted at nearly double such ages and sizes, as the lime, the elm, the fycamore, and various other deciduous kinds; however, a year or more before their removal is to take place, they should have their roots cut in, and their tops thinned by the pruning knife, or other means, as such precautions are highly important and necessary, and should never be omitted, in removing trees of the latter of the above heights.

In respect to the uses of trees and shrubby plants, though the latter fort are commonly set out for the purpose of ornament, variety, &c., and the former for that of timber, as well as thefe and other uses; there are fill some other ways in which they occasionally contribute, and become of utility and importance to the planter. There are different products of some of them, which are useful in different arts and professions. For instance, the bark of some is useful in chemistry, for the making of bird-line, as that of the holly; that of others, as of the lime, the elm, &c., for the manufacturers of mats. The leaves of some, as those of the mulberry, for the growers and rafters of flax. The blossoms of others, as those of the rose, for the apothecary, and those of the syringa for the confectioner. Those parts of the seeds of the beech which are proper, are converted into bread. And the fruits of others, as those of the pear, apple, plum, &c. are of very general utility and value. Some kinds of wood are of particular use and value for particular purposes, as the oak to ship-builders; and others might be trained for this application, as the larch, by bending down the item when about twenty feet in height, securing it in that position, and then re-bending it again some considerable
able time afterwards, leaving the hole or trunk in a differently crooked state. The woody parts of the fir and pine are employed by house-carpenters, of the crab-tree by millwrights, of the ash by ploughwrights, of the beech, the walnut, the cherry, the plum, the box, the holly, the yew, and others, by the cabinet-makers. The line is particularly useful to the carver, the fycamore to the turner, the box and holly to the mathematical instrument-maker, and the alder and the birch to the lathe and the heel-maker. Charcoal of any of the kinds is valuable for the iron-founders; that of the dogwood, fallow, alder, hazel, &c. for the gunpowder manufacturers. The larch, the silver fir, &c. afford the coarse turpentine and its spirit; the spruce and pine tribes, red, tar, pitch, lampblack, &c. Most woods, but especially the beech, ash, elm, &c. afford potash. The sap-juice of some trees, as the birch, &c. yields a vinous liquor; and that of others, as of the sugar-maple, &c. affords sugar.

The value of wood as timber, and for other purposes, differs much according to local situation, and other circumstances; when near a dry-dock or ship-yard, oak, elm, &c. suited to ship-building, are of much higher value than when at a great distance in the country. The undergrowths of several forts of trees, as dogwood, fallow, willow, alder, &c. are of the most value when near large manufactories of gunpowder, being of little utility, except as fuel, when at a distance. Some forts of wood, however, from the generality of their application and employment, are of great value in all situations, as those of the oak, the elm, the ash, the beech, and perhaps the larch has still more value than any of them. Others, on account of their scarcity, are also valuable in all places, as the box, the holly, the yew, &c. All the lighter products of some forts of trees, as those of bird-lime, potash, turpentine, tar, pitch, &c. may likewise be considered of equal value in all situations. But a tree which would be of the greatest value in a particular situation or place, may not be in it that fort of soil that is suitable to its nature or habits of growth; in which circumstances that which will come to the most perfection in it, will commonly be found of the most value. Such woods as may not be valuable in consequence of local circumstances, may be rendered a great deal more high in their value, by having them manufactured in the places where they are met with, thus lessening the expenses of conveyance, &c. In consequence of the great improvements in roads, canals, &c. and the general promotion of them, woods and plantations for timber, mint, in almost all places, be valuable, and there can be few in which the other sorts of products will not be of great importance. In the measuring of standard trees for the purpose of ascertaining their value, though many think themselves fully qualified by being simply able to measure them; it is only by the perfect knowledge of the use and application of the different shapes, bends, and woods of them, that a correct estimate can be given; as a small portion of wood may be of little consequence in one sort of business, while it is of much in another, which is a secret of great interest and importance to the purchasers of timber of the flanding kind.

In addition to these qualities, almost every tree and plant is possessed of various others, which excite emotions that have a relation to them, and which give their characters or expressions. For instance, the cypresses of great, invariable shape, or form, and always, in colour, of a dark green, having a full, solemn appearance; hence it has acquired the character of melancholy. A similar, but somewhat fainter, train of emotions, is produced in the mind by the falling branches, drooping spray, and yellow greennish colour of the weeping willow; hence it suits with scenes of solitude, and induces meditation. In the light, airy form of the ash, and the bright white of the variegated holly, there are some traits of certain degrees of the cheerful kind; in the foliage of the virgin’s bower, calm and graceful notes; in the myrtle, delicacy and neatness; and in the sweep of the item, the curve of the branches, &c. of the larch, a peculiar elegance. In the oak and the chestnut are forms which have long given the notions of grandeur and sublimity. Both these and other trees are particularly expressive of peculiar known characters, arising, in some degree, from their own nature, and in part from affiliations in the mind. Those of the cypresses and yew kinds have been planted in burying grounds, and other similar places; the weeping willow, as the shade of urns; the laurel used as the crown of warriors; and the chestnut introduced in landscapes.

Some accidental characters and expressions of plants are produced by novelty and singularity either in their nature, forms, or appearances; hence exotics are at first distinguished from those of the indigenous kind, and called beautiful, elegant, fanciful, strange, rare, &c. according to circumstances. The creeping ash, the stone pine, &c. derive and retain their characters from their comparative scarcity and unusual shape; while others have that of elegance and novelty in a much less degree, as the cedar of Lebanon and the cypresses; the hemlock spruce, and the scarlet oak, &c. Some trees and plants are common, and thought nothing of in one district or country, while, in others, they are uncommon, and thought highly of; thus, the weeping willow, the narrow-leaved elm, the acacia, &c. which, abound, and are little valued, in the southern parts of the island; are scarce, highly esteemed, and termed elegant in those of the north; while the arbutus, the uva ursi, the erica alba, and even the mountain-ash, which are plentiful, unnoticed, and common in the north, are held in estimation, and thought highly elegant in the south.

These are some of the most particular qualities of trees and plants, which are concerned in the classification and arrangement of them, as the materials by which the objects of planting and ornamental gardening are to be accomplished, but there are others which are peculiar to them in other points of view, that it is quite unnecessary to notice in this place, as they are fully explained in speaking of them individually under their proper heads.

More ample information on the above subject may, however, be obtained by consulting Mr. Loudon’s work “On Forming, Improving, and Managing Country Residences,” in which will be seen their particular utility, and their most appropriate modes of application in the business of planting and ornamenting different kinds of pleasure grounds, under all the various circumstances which may occur, if far as their nature, situation, soil, and other similar particulars are concerned, as well as the picturesque effect which will be produced.

Qualities of Seeds, Sets, and Produce, the properties which are essential to them for the production of full and beneficial crops of the several different kinds, and the most perfect and advantageous states of growth and maturation of such crops, for their being consumed, either as food or otherwise. In all sorts of seeds of the grain kind, those which are the most fully bodied, bright, thinness in the skin, and the most found, without being too long kept, are the most suitable for making use of as seed. Such as are small, lean, ill fed, and shrunk in their skins, or which have been in any way heated in the maw or flack, are mostly quite improper for this purpose. Some have, however, supposed the contrary to be the case, but these are frequently ascribed no proofs whatever, of the fact, while the former opinion is supported
supported by the daily experience of the beet farmers in the country. There is another circumstance which is of some importance in this business, which is that of the grain for this use being constantly newly threshed out from the straw, as such, for the molasses, sprouts and grows more expensively, and is less liable to rot and perish in unfavourable seasons and situations.

All sorts of dehaired grain, and such as is not perfectly free from the mixture of the seeds of weeds with it, should always be, as much as possible, avoided in this intention.

In regard to the smaller sorts of seeds for raising all kinds of plant-crops in the field, as well as those of the grains long, both natural and artificial, the principal necessary qualities, in each, are those of their being of a bright, lively, shining colour, perfectly found, and fresh, or lately collected from the plants. Such as are old, or kept more than a few months, are mostly improper for this application. The beet sorts commonly slide freely over each other, without sticking or being heavy in the hand, and have a brilliant bloomy appearance.

In gardening, most sorts of seeds also are the beet, and require to have these properties and qualities as much as possible; but there are a few which are apt to grow too luxuriantly for fruiting well, as some of the cucumber, melon, kidney-bean, and other kinds, which are better for being kept for some length of time, as this property is thereby in some measure corrected and restrained. Most sorts of nuts and flones, when used as feed, should, however, be employed in as fresh a state as possible.

Sets are different in their nature, being of the root or plant kinds. In the former, the sets or cuttings should have the eyes or buds in a perfect state, and be of a minding size, as both those which are very large and very small are objectionable. This is the case with the potatoe and some other sorts. In the latter, the plants should not have too large growths, but be in a fine young state of vegetation, so that they can be got out with facility, and readily take root again, having their heads or upper parts, for the production of the produce, wholly in an uninjured condition. They should also be quite newly drawn up, cut or flapped from the stalks of the old plants, without any sort of clubbing near the roots in those which are drawn. Such as have been the most quickly from the seed are, in general, the best. They should none of them ever be kept any great length of time after being drawn, before they are re-planted. This is equally applicable to the field and garden kinds. See Seed, Set, and Sowing.

The produce in all the white or grain crops, which are employed either for the purpose of meal or malting, should cautiously be well ripened; but where the flour is to be made use of as cattle food, the crops are better to be cut before they have reached the state of full maturity, as this purpose is thereby more completely answered. There is much loss in the produce of most sorts of field plant-crops, by taking them before they have formed their heads or heads in a perfect manner. But many of such like products, in the garden, are the beet and mallow advantageously taken in such imperfect states, being tough and coarse when full grown, and without the necessary tenderness. Others require to be cut or drawn early in order to have the proper degrees of sweetness and flavour. The fruit kind of produce is taken both before and when nearly ripe, according to the uses for which it is intended. Some sorts of vegetable produce are used quite in their green state, as food; while others are kept in a somewhat more advanced state: and others, again, in both these states. And there are those which require to be well ripened, and kept for some length of time before they are used in this way.

All sorts of produce of the grubs-kind, are cut and used to the most benefit, when they are taken a little before they become perfectly ripe, as they go the farther, whether they are to be consumed in the green state, or in that of hay. This is equally the case with the more luxuriant artificial sorts, as with those of least growth, of the natural kind. This is explained more fully in speaking of the different plants and crops individually, and in the article Hay; which fee.

QUALO, in Geography, a town on the N.E. coast of Sumatra. Lat. 2° 45'. E. long. 99° 40'.

QUALUGA, a town of Africa, in the country of Whidalt; 18 miles N.W. of Sabi.

QUAM, a town of Norway, in the diocese of Drammen; 68 miles N. of Drammen.

Quam dies bene geritur, a clause frequent in letters patent, or grants of offices, to secure them for so long as the person they are granted to shall not be guilty of abusing the same.

Thus, e. g. we find it in those given to the barons of the exchequer; where it intimates, that they shall hold the same as long as they shall behave themselves well; which is to be restrained to matters of their offices; and signifies no more than the law would have implied, had the office been granted expressly for life. See Judge.

A grant therefore, with this clause, is equivalent to a grant for life.

QUAMASH, in Botany, a name given, by the North American Indians, to a plant called Phalangium Quamash, by Mr. Pursh, in his Flora, v. 1. 226; who nevertheless mentions an irregularity in the petals, that might possibly oblige it as a new genus. See Phalangium.

This plant was observed by governor Lewis, about the upper part of the Missouri, near the Rocky-mountains, flowering in June. The bulb is roundish, tunicaled. Stem none. Leaves radial, few, long, and linear, half an inch broad, smooth; keeled underneath. Flowers white, solitary, naked, erect, round, smooth, unbranched, a foot or more in height, terminating in a spike, or rather cymes, of large, pale-blue flowers, each accompanied by a linear, membranous, withering bract, longer than the partial spike. Petals lanceolate, nearly equal in length; five of them ascending; the sixth deflexed.

The bulbs are carefully collected by the natives, and cooked between heated flones, when they assume the appearance of baked pears, and have an agreeable sweet taste. They form a great part of the winter flores of thee Indians. Though governor Lewis's party found them a pleasant sort of food, they could not be eaten, in any quantity, without causing bowel complaints.

QUAMCLIT, an Indian name, retained by Plumier and Tournefort as generic; but by Lamens used only as the specific appellation of a beautiful species of Ipomea; see that article.

QUAMEAGAN FALLS, in Geography, falls in America at the head of the tide on Newichwanoek river, which joins Piscataqua river, 10 miles from the sea: so called by the natives, because fish were there taken with nets. At these falls are a few saw-mills and others, and also a landing-place, where great quantities of lumber are rafted. Here the river has the English name of Salmon Falls river, from the number of salmon caught there. On many places from Quameagan to the pond, from which it issues, there are mills for boards and corn.

QUAM-TOM, a town of China, of the third rank,
in the province of Yunnan; 15 miles N.E. of Tchou-hiong.

QUAN, a town of China, of the third rank, in Chaung-tong; 22 miles W. of Tong-tchang.

QUAN, or Quan, in Ornithology. See Penelope Criptata.

QUANAMORA, in Geography, a town of Africa, in Upper Guinea, on the banks of the Scherbro', said to contain 5000 families. N. lat. 7° 45'; W. long. 10° 15'.

QUANDROS, a name given by writers of the middle ages to a stone to which they attribute great virtues, and which, they say, is found in the head of a vulture.

QUANG-LING, in Geography, a town of China, of the third rank, in Chin-fu; 15 miles W.S.W. of Ouei.

QUANG-NING, a town of China, of the third rank, in Quang-tong; 35 miles N. of Tchao-kung.

QUANG-PING, a city of China, of the first rank, situated in the northern part of the province of Pe-teche-li, between the provinces of Chang-tong and Ho-nan, which

has nine towns of the third class dependent upon it. All

its plains are well watered by rivers. Among its temples,

one is dedicated to that of the Confucian, who, as the Chines pretend, discovered the secret of rendering themselves immortal;

212 miles S.S.W. of Peking. N. lat. 36° 47'. E. long. 114° 29'.

QUANG-PUNING, a town of China, of the third rank, in Pe-teche-li; 17 miles N.W. of Tay-ming.

QUANG-SI, a province of China, situated between those of Quang-tong, Hou-quang, Koei-techeou, Yunnan, and the kingdom of Tung-kung; about 360 miles from E. to W., and 230 from N. to S. In commerce, as well as extent, it is not equal to that of the other provinces; and yet it abounds with rice, so as to supply, for fix months in the year, the province of Quang-tong, without which the inhabitants of this province could not subsist. The mountains with which it is covered, abound with mines of gold, silver, copper, and tin, and in this province is a singular kind of tree, containing a soft pulp, which yields a sort of flour, and of this flour they make a very good bread. Besides paroquets, hedges-hogs, and the rhinoceros, wild animals, curious birds, and uncommon insects are found here in great number. This province contains twelve towns of the first class, and eighty of the second and third. Its capital is Chei-ling. Groffier's China, vol. i.

The population of this province is estimated by Sir George Staunton at 16,000,000; its area comprehends 79,456 square miles, or 50,851,840 acres. The revenue transferred from it to the treasury at Peking, comprising land, salt, and taxes, is stated at 500,000 taels, or ounces of silver.

QUANG-TCHANG, a town of China, of the third rank, in the province of Chin-fu; 28 miles S. of Ouei.

QUANG-TCHEOU, or Quang-chou-fou, a city of China, of the first rank, in the province of Quang-tong, usually called by the Europeans Canton; which see.

QUANG-TONG, the most considerable of the southern provinces of China; bounded on the N.E. by Fokien, on the N. by Kiang-fu, on the W. by Quang-fu, and the kingdom of Tung-kung; the rift is washed by the sea. The country is diversified with plains and mountains, and the land is so fertile that it produces two crops every year. Trade and the fertility of the soil supply this province with everything that can contribute to the pleasures of life; it furnishes gold, precious stones, flax, pearls, eagles-wood, tin, quicksilver, fugar, copper, iron, steel, falkpetre, ebony, and abundance of aromatic woods, which are much valued. Besides Chinese and Indian fruits, it produces several that are peculiar to itself. All the coasts abound

with fish, and furnish great quantities of oysters, crabs, and tortoises of an immense size; of the shells of these the Chinese make several pretty toys. Tame ducks are reared in this province in great numbers; the Chinese are industrious in breeding them, and they hatch their eggs in ovens or dung-hills, though they do not seem to have derived this mode of breeding them from Egypt, where it is practised. They carry them on their backs in large flocks to feed on the sea-shore, where, at low water, they find shrimps, oysters, and other kinds of shell-fish. At the approach of night they are collected together by only beating on a bough, upon which they immediately form themselves into different flocks, and each returns to the vessel to which it belongs. The Chinese have a method of salting their meat without injuring its flavour, and they salt their eggs by enclosing them in a coat of clay mixed with salt. These salted eggs are said to be very wholesome, and even sick persons are permitted to eat them. Although the climate of this province is warm, the air is pure, and the people are robust and healthy. They are noted for their industry, and for a talent of imitation, which they possess in an eminent degree. As this province is at a great distance from court, its government is one of the most important, and it is the one of the most flourishing in the empire. Its vice-regal has also the command of Quang-fu, and resides at Cheo-kung, for the convenience of expediting his orders to either of these provinces. This governor always has a number of troops ready, properly posted, to check the incursions of robbers and pirates, who might otherwise interrupt and injure trade: for the same purpose, a great number of fortresses (most of them being cities provided with numerous garrisons) have been built along the coasts and in the interior parts of the country. This province is divided into 10 districts, which contain 10 cities of the first class, and 84 of the second and third. Groffier.

The number of inhabitants, according to Sir George Staunton's estimate, is 21,000,000; its area comprehends 79,456 square miles, or 50,851,840 acres. The revenue

remitted to the imperial treasury at Peking, and raised from land, salt, and taxes, amounts to 1,240,000 taels, or ounces of silver. The military force is said to amount to 50,000 men. Its capital is Canton; which see.

QUANG-YANG, a town of China, of the third rank, in the province of Quang-fu; 30 miles S. of Tien.

QUANG-YUEN, a town of China, of the third rank, in the province of Sencechou, seated on the Kialing; 50 miles N. of Paot-king.

QUANNEFIORD, a bay on the W. coast of Wett Greenland. N. lat. 62° 10'. W. long. 48° 5'.

QUANO, a town of Japan, on the island of Niphon, on the S. coast, 70 miles E. of Meaco. N. lat. 35° 58'. E. long. 136° 14'.

QUANTA, an island of Africa, at the mouth of the Zaire, celebrated for a silver idol, to which the neighbouring kings lend presents and other sacrifices.

QUANTAO, a town of China, of the third rank, in Chan-fung; 25 miles W.N.W. of Tong-tchang.

QUAN-TCHANG, a town of China, in Chan-tong; 13 miles N. of Po.

QUANTITE, Fr. This word in music, like profody, does not fix the number of notes or of syllables, but their relative duration. Quantity produces the rhythm, as accent produces intonation. Rhythm and intonation generate melody. Rouleau, See MELODY.

QUANTITY, Quantitas, anything capable of estimation or menuration; or, which is compared with another
other thing of the same kind, may be said to be greater or less than it; equal, or unequal, to it.

Mathematics is the science or doctrine of quantity.

Quantity is a general attribute, applied in a very different manner to things of very different nature; whence it is impossible to give any universal definition of it.

Quantity is applied both to things and to modes; and this either singularly to one; or pluraly, to several. In the first case it is called magnitude; in the latter multitude.

Quantity may be reduced to four classes; viz.

Quantity, Moral, which depends on the manners of men, and the free determination of their wills. As the prices and value of things; degrees of dignity and power, good and evil, merit and demerit, rewards and punishments, &c.

Quantity, National, arising from the operation of the understanding only. Such as the largeness or narrowness of the capacity of the mind, and its conceptions. In Logic, universals, predicaments, &c. In Grammar, the quantity or measure of syllables, accents, tones, &c.

Quantity, Physical, or Natural, which is of two kinds:

1. That which nature furnishes us with in matter, and its extension. And, 2. In the powers and properties of natural bodies: as gravity, motion, light, heat, cold, rarity, density, &c.

Quantity, Transcendental, as duration, the continuance of any being, existence, time, &c.

Quantity is also popularly distinguished into continued and discrete.

Quantity, Continued, or Continuous, is when the parts are connected together, and is commonly called magnitude. This again, is of two kinds: either successive, or improper, as time.

Quantity, Discrete, is when the parts of which it consists exist distinctly, and unconnected together; which makes what we call number or multitude.

The notion of continued quantity, and its difference from discrete, appears to some without foundation. Mr. Machin considers all mathematical quantity, or that for which any symbol is put, as nothing else but number, with regard to some measure, which is considered as one; for that we cannot know precisely how much any thing is, but by means of number. The notion of continued quantity, without regard to any measure, is indistinct and confused; and though some species of such quantity, considered physically, may be described by motion, as lines by the motion of points, and surfaces by the motion of lines; yet the magnitudes, or mathematical quantities, are not made by the motion, but by numbering according to a measure. Vide Phil. Trans. No. 447. p. 228.

Permanence quantity is farther distinguishable into length, breadth, and depth.

Wallis seems to give us a more precise notion of mathematical quantity, and its two species of discrete and continuous, however is referred to unity in the same manner as one right line to another, is what we call quantity; or number in general.

If, now, the thing be referred to a given unit, as 3, it is called a determinate number; if to unity in the general, or at large, it is called a quantity; which, on this principle, is the same with indeterminate number.

Thus, e. g. the breadth of a river is accounted a quantity: if, then, it be enquired how great it is; to conceive its quantity, we take some unit at pleasure, and fix the relation of the breadth to it; and according to the different unit assumed, we express the breadth of the river in a different determinate number.

Vol. XXIX.
by subtracting any real quantity out of nothing; e.g.

\[ a - 3 = -3 \] and \[ a - a = -a \].

For an illustration. Suppose when you are quite deflute of money, somebody gives you a hundred pieces; you have then a hundred pieces more than nothing; which pieces constitute a positive quantity.

On the contrary, suppose you have no money, yet owe a hundred pieces; you have then a hundred pieces less than nothing; for you must pay a hundred pieces to have just nothing. This debt is a negative quantity.

Thus in local motion, progress may be called a positive quantity, and regres a negative one; because the first increases, and the second diminishes the space passed over.

And in geometry, if a line drawn towards any part be accounted an affirmative quantity, another the contrary way will be a negative one.

Positive or negative quantities, therefore, are equally real with positive quantities, but opposite to each other, so as to take away each other's effect, in any operation, when they are equal as to quantity. Thus \( 3 - 3 = 0 \), and \( a - a = 0 \). However, though \( +a \) and \( -a \) are equal as to quantity, we do not suppose in algebra, that \( +a = -a \); because to infer equality in this science, they must not only be equal as to quantity, but of the same quality, that in every operation the one may have the same effect as the other. A negative quantity is said to be less than nothing, because it is opposite to the positive, and diminishes it when joined to it; whereas the addition of \( 0 \) has no effect. But a negative is to be considered no less as a real quantity than a positive. Quantities that have no sign prefixed to them are understood to be positive. See **Negative Sign**.

**Quantities, commenparable, compound, exponential, heterogeneous, like, rational, simple, transcendental, and variable.** See the adjectives.

**Quantities, Addition of.** 1. If the quantities denoted by the fame letter be affected with the fame sign, the numbers prefixed to them are added as in common arithmetic.

2. If they be affected with different signs, the addition is changed into subtraction; and to the remainder is prefixed the sign of the greater.

3. Quantities denoted by different letters, are added by means of the sign \( + \); as in the following example:

\[
\begin{align*}
4a + 2b - 2c &= 5d - 8 \\
5a - 2b + 6c &= 2d + 3g \\
9a + 4c - 3d &= 4g \\
&= a - b + c
\end{align*}
\]

See **Addition**.

**Quantities, Subtraction of.** See **Subtraction**.

**Quantities, Multiplication and Division of.** See **Multiplication**, and **Division**.

**Quantities, Combination of.** See **Combination**.

1. If a positive quantity be multiplied or divided by another positive quantity, the result is also a positive quantity.

2. If a negative quantity be multiplied or divided by a positive, the result is a negative.

3. If a negative quantity be multiplied or divided by another negative, the result is a positive.

4. If a positive quantity be multiplied or divided by a negative, the result is a negative quantity. See **Multiplication**.

**Quantities, of a Degree.** See **Degree**.

**Quantities of an Eclipse.** See **Eclipse**.

**Quantities of Seed, Sets, and Plants, in Agriculture,** the proportions of each, which are necessary for raising good crops of the different kinds. The ascertaining of the most useful and beneficial quantities, in the several cases, depends, in a material degree, upon a number of different circumstances, such as those of the situation, the nature and quality of the soil, the period of sowing, the state of the season, the manner of putting them into the earth, and several others.

A great deal more feed, sets, and plants, are requisite in late situations or backward seasons, heavy, wet, ffluff lands, and late sowings; than where they are more forward, more light and dry, and put in early. And far less quantities made use of in the drill and dibble methods of putting in the crops, than in that of the broadcast, or by the hand.

In most of white, or grain crops, the quantities are from two to five bushels per acre, being more in barley and oats, than in those of the other kinds, as from three to five in general.

In those of the pulse kinds, usually from six or seven pecks, to two, three and a half, and four bushels, being commonly the latter, or more, in some forts of beans.

In those of the small feed description, as the buck-wheat and turnip forts, from one to two and three pounds; but in the cabbage kind, only from six ounces to half a pound, and a quarter or half a peck.

In the tap-rooted crops, as the carrot, parsnip, mangle-wurzel, &c. from two to five pounds, and sometimes six.

In lettuce crops, in the field, from three to four pounds the acre.

In different sorts of plantation crops, as those of hemp, flax, wool, and teasel, &c. from two to three up to five or six bushels, in the three first; but only from two to four quarters, and from one to two pecks, in the two last.

The fets in the hop, madder, liquorice, and lavender kinds, are from six to seven hundred, and a thousand or more, in the first, and two last; but in the madder from fifteen to twenty thousand per acre. In the cabbage fort, from eight hundred to a thousand and more plants or fets to the acre. And in the potato the quantity of fets vary from eight to twenty or more bushels to the acre, according to the soil and manner of their being put into the ground.

The quantities of natural grain feeds which are generally employed upon the acre, are from two to four bushels and upwards. And those of the artificial grain kinds, in the crovess from ten to eighteen pounds; in fatnoff from three to four bushels; in lucern from sixteen to eighteen pounds; mashes from two to three bushels; trefoil, three pottles of cleaned feed, or two bushels of the uncleaned fort. And in chicory from eight to twelve pounds. See **Seed, Set, Plant, and Sowing**.

The subject is more fully explained in speaking of the culture of the different sorts of crops, and the most suitable quantities under different circumstances put down.

**Quantity, in Grammar,** denotes the measure and magnitude of the syllables; or that which determines them to be called long, or short; or, it is the measure of time requisite for the distinct pronunciation of a syllable.

This quantity is the object of prosody; and it is the regard to this that distinguishes verbs from prose.

The economy and arrangement of the quantities, i. e. the distribution of long and short syllables, make what we call the **number**.

The quantities are used to be distinguished among grammarians by the characters short and long.

The proportion between the long and short syllables may be generally fixed as that as between the crozet and quaver in music; viz. as two to one.

**Syllables are long or short, either by their nature, or by accident; that is, on account of the place where they are put**
QUANTITY.

put and the letters that follow them, which is called position.

In most languages, there are some syllables whose quantities vary, as the measure requires, which are called common; as in the English record and record.

Some authors confound the quantity with the accent; but the difference is very evident; the former being the length or shortness of a syllable, the latter the raising or falling of the voice.

From two quantities, viz., long and short syllables, arise all the varieties of poetic feet, which are very great. He race alone uses no less than twenty-eight. Yet the Greeks went vastly beyond the Romans in this respect. In effect, as many ways as two quantities may be varied by composition and transposition, from two to six syllables, so many different feet have the Greek poets contrived, and that under different names, to the number of 124. Though it is the opinion of some of the learned, that poetical numbers may be sufficiently explained from the feet of two or three syllables.

Tho' of three syllables are the monosyllabic, consisting of two long syllables; the psyllabic, of two short ones; the trochee, of a long and short syllable; and the iambic, of a short and long syllable.

The feet, formed by the ancients of the long and short syllables immediately, are the spondaic, consisting of two long syllables; the trochaic, of three short ones; the dactyl, of one long and two short syllables; and the anapest, of two short and one long syllable.

The English tongue admits of no feet above two syllables, though both the Latin and Greek allow of six.

Our heroic versification of five long and five short syllables intermixed alternately; though not so strictly but that the order may be dispensed with. Dryden varies them with admirable beauty; frequently his heroic verse begins with a long syllable followed by two short ones.

The truth is, the quantity of the syllables is but little fixed in the modern tongues; and there is still less regard had to it in the composition of modern verses. The want of feet, or rather the shortness and uniformity of our feet, makes great difference between the numbers of the ancient and modern verse. Our poets are fettered; and their fettlers are so short, consisting of but two poor links, that it is no wonder they can make no extraordinary motions.

The ancients sublimated by their quantities alone; so well were they distinguished, and such a variety and harmony did they afford! Our quantities make such poor music, that we are forced to call in the Gothic aid of rhyme to dilute our verse from prose.

Yet have attempts been made to settle our verse on the ancient and natural footing of quantities, in exclusion of rhyme, and with such success too (witness the immortal Paradise Lost) as seems to leave the practice of rhyming inexculpable. The French have likewise attempted the same in their tongue, particularly Jodellet, and after him Pafquier, Passier, and Rapin; but they have all failed.

On Quantity in the Greek Language.

Rules for the determination of quantity in the Greek language, chiefly relate to the doubtful vowels $a$, $e$, $i$, since $r$, $s$, are, by nature, or not affected by position, short; and $a$, $e$, are, by nature, or not affected by position, long.

Position.

1. A syllable in which a short or doubtful vowel precedes two consonants or a double letter, is long in every situation; as αὐδαί ζώον, σέλας, κατά πόδια, παντί, οἰκον. Hom.

2. A short vowel is sometimes made long before a single consonant, particularly before a liquid, as πολύ λεσπειρα, Hom.; πανορίμην, Hom.

Note.—Note.—In pastoral, elegiac, and epigrammatic verse, the syllable is more frequently short.

3. In dramatic poetry we may observe, 10, that a short vowel before a short or aspirate mute followed by a liquid, and before a middle mute followed by a, remains short. In tragedy the syllable, if not final, is often long. 20. A short vowel before a middle mute followed by $a$, or $u$, lengthens the syllable in all dramatic poetry.

4. When the syllable is lengthened before two consonants, the vowel in pronunciation affixes one of them, as βέλος, λαμπρός, κατά πόδια, παντί, οἰκον. Hom. When the syllable remains short the vowel conclusions it; as πανορίμην, τρόποι.

A short vowel is sometimes made long before a single consonant, particularly before a liquid, as πολύ λεσπειρα, Hom.; πανορίμην, Hom.

Note.—It is generally long before $e$, which with its aspirate appears to have been doubled in pronunciation; as πανορίμην, Hom. This licence is not confined to one liquid; as τοῦτο, ἐν κόλασι. Hom.

5. A short syllable is often made long when the next word begins with a digrammatized vowel, as ἀξίωσε, for ἀξίωσεν. Hom. Μάλιστα ἄνων for ἄνων, Hom. Οὐδὲν οὖν ἄνων. Hom.

6. When three short syllables come together, it is necessary, on account of the measure in heroic verse, that one should be made long; as ἄλατον, Ἐπιμέλης.

Note.—This takes place even where the three syllables are in different words; as ἀλάς, Ἔνα, Hom.; ἔδωθ' ἑρμα, Ilyc.

7. A vowel before another does not suffer elision, as in Latin, at the end of a word, unless an apostrophe is substituted.

Note.—The elision of diphthongs takes place in verbs only: real influences of this are to be found only in the fragments of the new comedy.

8. A long vowel, or a diphthong, is generally shortened at the end, and sometimes at the beginning, of a word, before a vowel; as ὅτι, Hom.; οὖν, Soph.; ὅτι δὴ, Theocr.

Note.—A long vowel, or a diphthong, may be considered as consisting of two short vowels. If the latter is supposed to suffer elision, the former will of course remain short; as ὅτι δὲ.

Cras, or Contraction.

7. A contracted syllable is always long; as ἀμιος, Ἱος; ἰδίας, ἰδίας.

8. Two successive vowels, forming two syllables, even in different words, frequently coalesce in poetry; thus ὅς becomes a monosyllable, κρασία a diphthong, and in ἄλατον, ὁ οὖν ἄλατον, Hom.; οὖν are pronounced as one syllable.

Composition and Derivation.

9. Compound and derivative words follow the quantity of their primitives; as κεφαλή from κεφαλή, κέφαλος from κέφαλος; δικαίος from δικαίος.

Note.—Grammarians have sometimes complained that "non tener huius regulam fidemur." But Dr. S. Clarke affirms:—"Derivation pro eo, quae prius usitata semper in usum vel praecedens vel postea corri-"

10. Α', privative, is short, as ἄδεια; but long in ἄδειον.

11. 'Αργ. ἔλε, ἔλε, ἤλε, ἦλε, in composition, are short; as ἔλεος.

Of the Increments of Nouns and Adjectives.

12. The penultimate increases, Α', of nouns and adjectives is short; as Μαρτυρίας.

1. Except nouns in οίκοις; οίκοι, οίκοις.

2. And the Doric genitive; as Αριστείας, μετωπίς for μετωποῖας.

3. Αλήθειας, ἀλήθειας, κρίμας; κρίμα, κρίμας; κρίμα, κρίμας; κρίμα, κρίμας.

4. Αἴλου, άλος, αἰλοῦ, αἰλοῦ; άλος, αἰλοῦ; άλος, αἰλοῦ; άλος, αἰλοῦ.

5. Αἴνιος, άινίος, άγάμος, άγάμος; άγάμος, άγάμος; άγάμος, άγάμος; άγάμος, άγάμος.

6. Αἰνίας, άινίας, άγάμης, άγάμης; άγάμης, άγάμης; άγάμης, άγάμης; άγάμης, άγάμης.

7. Αἴνιος, άινίος, άγάμος, άγάμος; άγάμος, άγάμος; άγάμος, άγάμος; άγάμος, άγάμος.

8. Αἴνιας, άινίας, άγάμης, άγάμης; άγάμης, άγάμης; άγάμης, άγάμης; άγάμης, άγάμης.

13. The penultimate increases, Ι', of nouns and adjectives is short; as ἱστος, ἱστος.

1. Except in words of two terminations; as ἄβιβα, ἄβιβα, ἄβιβος.

2. And monosyllables; as θῆς, θῆς; but Δί, Δί; οί, ωί, οί; τί, τί, τί, οί, ωί, οί; τί, τί, τί.

3. Αλήθειας nouns making οί; of οί; as κρίμα, κρίμας; κρίμα, κρίμας; κρίμα, κρίμας.

4. Nouns in οί, οίος, or οίς; as μάστος, μάστος; μάστος, μάστος; μάστος, μάστος.

5. Monosyllables in Ι, ιτος; as ιτε, ιτε.

14. The penultimate increases, Τ', of nouns and adjectives is short; as της, της.

1. Except in words of two terminations; as βηβες and βηβες, with ιτε, ιτε, ιτε.

2. Γρή, γρής; γρής; γρηθής; γρηθής; γρής, γρηθής.

3. The doubtful words before ιτε are long; as τηςτικος, τηςτικος.

21. In the first aoríst participle, οιτε is long.

22. In the imperative of verbs in μι, μι is short in polysyllables; as καινος, but long in diffyllables, as καινός.

23. In the first future, ιτε, and μι followed by οιτε are short; as τηποτε, τηποτε; τηποτε, τηποτε; καινος, καινος.

24. But οιτε is long before from verbs in μι preceded by a vowel, or in μι, as μις, μις; μις, μις. ιτε and μι are long from verbs in μι pure; as της, της; γρηθής, γρηθής.

The Quantity of doubtful Vowels in the First or Middle Syllables.

25. Α': i, i, before vowels, are generally short; as ἠθέος, ἠθεώς, ἠθεός. Helioc.
QUANTITY.

1. Except that as α is long in circumflexed words, and in oxytons masculine; as μαχα, μαχει.
2. These adverbs, ἄπαξ, ἀραζόν, λέγοντες, may possibly be long; and the accusative of the first declension, whose nominative is long; as Αἴανα, ἀλών.
3. τι is long in words of two terminations; as ἄδηλος and ἀδηλίζοντας.
4. Ἠμι and ἠμί when circumflexed; τις Doric for τα.
5. τα is sometimes long in Homer.
6. Υπό is long in words of two terminations; as ἀγών and ἀγώνων.
7. Accusatives from τα long; as ἀφός, with τα; though τον the elicit short is short; as τον του.
8. The imperfect and second aorist of verbs in ταί; as ἄδεικνυμι, ἀφέω.
9. Except that γας and αντας are sometimes long in Homer.
32. Ας final is short, τα final long; as Νικταῦξ, αὐτας; ἀπός ταυτας.

On Quantity in the Latin Language.

As the proisy of the Latin language is considered to form an efficiencral part of a clacbyial education, we shall, therefore, devote the moe peculiar attention to this part of the subject. In the course of which some rules will be given on the quantity of syllables usually said to be long or short by authority; which, we believe, have never yet been collected by any writer, ancient or modern. Perhaps, therefore, in particular for this, and for such other reasons as the cadence of impalpable diacritic shall discover, we shall not incur the censure of having been too fanciful, should we have indulged the hope of being enabled to offer the most complete syllarem on Latin proisy that has hitherto been presented to the public.

GENERAL RULES.

A Vowel before a Vowel.

1. One vowel preceding another, in the same word, is short; as πέπερ, εργεία.

O Meliboe, Deus nobis hunc in fascem. Virg.

2. The same happens, though an h intervene; as nihil, ahenus, déhico.

De nihilō nihil, in nihilō nihil poele reverti. Pers.

Note—H is generally considered only as a note of aspiration or breathing; though some ancient grammarians considered H as a consonant, and ranked it with the semi-vowels. See Terentianus Maurus, de syll. § 11.

1. Except...
QUANTITY.

1. Except the i of sio is long, when it is not followed by e and r; as siam, sieban, flat.

Omnia jam sunt, sibi quie possit negabam. Ovid.

2. The e of the genitive and dative of the fifth declension, when it comes between double i, is long; but it is short in fpē, and long and short in rei and sīdei.

Ventum erat ad Velia, quartam jam parte dēi. Virg.

3. Genitives in ius have the i long in prose, though in poetry it is common: as unus or unus, illius or illius: except the i of alius, which (formed by crasis from alius) is always long, and the i of alterius, mostly short.

Novius, inaudund! similis, unus ob iram. Hor.

4. The penultimate is long in aurā, alāi, and other antique genitives of the first declension, and in such vocatives as Pompei, Caì; because these were originally written with a double i; thus, Pompei, Caì.

5. In obie, in (whether interjection or proper name), and in Diana, the first syllable is common.

Ole! jam fatis ed, ibe, libelle! Mart. 

6. In many Greek words a vowel is long, though immediately followed by another: as Achāia, Achēliaus, Lāerēs, Lāodeice, and other words compounded with λαος; Latūs, Enyō, Panchāia, Threicēus, Tāygetus, Trōas, Trōīus, Galātia, &c.

Eurubis Mavors, averqua rīt Enyo. Claud.

7. Thofe words which are written in Greek with the diphthong eu, and in Latin with a single e or i, have that e or i long; as Aēneas, Macrēm, Dāirus, Thalās, Clio, Elegia, Orēdas, &c.

Et parvō potens, et Thēsīla contumax. Lucan.

8. Most adjectives in eus, formed from Greek proper names, have the e long; and it continues so, when resolved into ei.

Oppida tēmēto Pælopolis marte vigentur. Claud.

Note.—1. Thofe which contain a cheme (") in the two syllables immediately preceding the penultimate, were more frequently formed, for the convenience of furnishing a dactyl, with the penultimate short; as Hērōtērus, Nērōtērus, Agōnōtērus, Antēnōtērus, &c.

9. In imitation of the Greeks, we use in Statius, the adjective Tērētēus.

10. Names of towns, temples, or monuments in ca, iā, or eum, formed in the Greek manner, from the proper names of persons, most commonly have the penultimate long; as Laodīcēa, Apatēmēa, Cæfarēa, Alexandria, Antiochēa, Maurokēm.

Terrarum medius Apaneæ menia clara. Prisc.

11. Academia, Chorea, Platea, Malea, have the penultimate common.

In Latium ipsum, Academiam migrat Athenes. Claud. 

Atque Academiam celebrat, cum nomine illius. Laur. Tol.

12. Greek genitives and accusatives from nominatives in eus have the penultimate short, according to the common dialect, long according to the Ionic.

O of Diphthongs.

3. A diphthong is long; as aurum, fœnus, audio, aitās, penitent, Æneas, Lūs, Grauis, Cāius, Pompeius, Prœmītus, &c.

Theōtīrōs, ignotum argoni pandus et Æris. Virg.

1. Except pra, immediately before a vowel in a compound word, is generally short.

Nec tecta tamen ille præter iam veniendum. Virg.

Note.—Pra, originally being pra or pra, by the elision of the latter vowel before a following one, the words became pra±sutra, pra²cium, &c. Status, however, (Theb. 6. 519.) and Sidonius Apollinarius (carm. 23.) prefer the AE long.

2. A diphthong is once short in a line of Virgil, out of composition; thus,

3. The eu of Greek proper names in eus (genitive eus) becomes a diphthong.

Parvo dilixit pater Minōda Thēsōs. Propert.

4. Τι is also a diphthong in Greek names, such as Orthiāia, Thithiāia, Harpyia, Aγyeus, &c.

Orthiāia amans fulvis amplectitur alis. 

Et patrio infantes Harpypae pellere regno. Ovid. 

A Vowel before two Consonants.

4. A vowel is long by position, when it immediately precedes two consonants, one or both of which being in the same word with it; as ārma, Errabāt silva in magna.

Pācrea spērit oves, dōnābant dicere ārmen. Virg.

5. Also, a vowel is long by position, when it immediately precedes a double consonant (X or Z), or the letter J; as axiās, patrīco, cūjus.

At unō, Fāx alna, veni, ſpērque tenēto. Tibell. 

It Sthenelus, qualum Maurantia vidit Amīna. V. Plac. 

Causa parecimone non hinc poter erit. Ovid.

Note.—In reality the J or I makes a diphthong with the preceding vowel; as maior, pējor, are from mai-ōr, pēi-ōr; and in Miās, Mīus, Bī-x, Troī-x, Aī-x, Bī-uit, Cā-īt, Ćī-us, and Grāz-ī-us, diphthongs. Hujus and cūjus were, like illius, originally triphthongs, of which the first two, by synalepsis, condensed into one.

Except the compounds of jugum, which have the i short before j; as bījūs, quadrījūs.

Martis equi bījūs, et magni currus Achillis. Virg. 

Note.—The word which in England we pronounce jugum, is in reality i-ōgum or y-ōgum, as the Germans at this day pronounce it. And in the meeting of two vowels, the former is tinctly elided, leaving the words bīgus, quadrīgus.
QUANTITY.

6. If the former of two words end in a short vowel, and the next begin with two consonants or a double letter, the vowel often remains short.

Note.—Virgil, however, who has adopted such licences as fultus Hyacintho, and qui amant, has lengthened the short syllable but in one line; ' etre cito terram, date odio, facunda muros.' Many of these, which at the end of a word are found long before two consonants beginning a following word, are lengthened by the ex Beca; as ' Aeneidis apat, et plures de pace triumphis.' Juven.

Of a Vowel before a Mute and a Liquid.

7. A vowel naturally short, followed by a mute and a liquid, is common, though always pronounced short in prose:

as agris, pharcera.

Note.—1. To produce this kind of position, three things are requisite:

1. That the mute precede the liquid; 2. That the mute and the liquid be both in the following syllable; or otherwise this rule cannot take place; as in ab-bag, where the two consonants cannot be founded in the latter syllable; 3. That the vowel preceding the mute and liquid be short by nature. Hence the a in stiris and mater is always long, because the a in mater and mother is always short.

in Latin words, / and r are the only liquids preceded by a vowel and a mute; in Greek words, /, /, and /, /, have the same effect as Cykleps, Té-cennis, Da plane.

3. H is not, neither in this, nor the following rule, to be deemed a consonant. Joined with any of the consonant s, it has not the power of lengthening a preceding short vowel; nor even with two consonants (i.e. a mute and a liquid) in the following syllable, as

Of Crafts, or Contraction.

8. Every syllable formed by the contraction of two syllables into one, is long; as cógo for có-ag; the genitive allus for allius.

Note.—This is a rule of very extensive application. We are told that the ancients expressed a long syllable by a reduplication of the vowel, thus veni for the perfect verba. And it will be found that in many words the long syllable arises from the contraction of two vowels. Thus we write tibi for tih; ambages for ambages; biga, trige, for biga, trige; junior for juvenil; bônis for bôbis; it for ist; mi for mihi; and mälo for magis volo.

Of Derivatives.

9. Derivatives usually follow the quantity of their primitives; as ánimum, ánima, animal, animalis, animofus, innam; from lègö; lègebant, lègorn, légam, &c.; but from lègö; lègeram, lègerem, léger, &c.; tóalis from tóitus, and tóitis from tót. 

Nece lüa pars, homo terrae quota tóitis unus. Lucrat.

1. Except deitative verbs in aris, which have the short, although formed from the participle in aris, that has a long; as nuptiö from nuptiö. 

2. Prequentative verbs, formed from the second supine of the first conjugation, by changing ánti into ánte, have the short; as clamito, volito. 

3. There are other long derivatives formed from short primitives, and short derivatives formed from long primitives.
2. Rē is short; as rēmitto, rēpello, rēfero. But re (which here is supposed to be the ablative of rex) is long in the imperf. verbal refert, it concurs.

Propellit hōres; zulus et unda refert. Ovid.

Præterea nec jam matutin pulchra refert. Virg.

13. Pro, when used as a Greek preposition for ante, is short; as prōpheta, prōlogus, prōpontis; but pro, a Latin preposition, is generally long; as prōdo, prōveho, prōmitto.

Mītis in his suis longi Prīncipis aquae. Ovid.

Quae tam icta dixit, ut refert princeps terrae.

Except prōfundus, prōfugio, prō fugus, prōnepos, prōnepticus, prōfugius, prōfugus, prōticus, prōfanaus, prōfecto, prōcellicus, prōcurvus, and prōpago, figura longa, but prōpago, figure short, is long.

Note.—Notwithstanding such diminutions, prose, where figuratio is always radically the same, may be considered among the doublets; to which class propontis is likewise added by some. But when the remarkable irregularity of pro is considered, without the slightest apparent reason to determine why it should be short in one word, long in another, and common in a third, it seems most probable, that it was in reality every where common, and that we should, doublets, and it so, had we enough of the ancient poetry extant. The word being derives borrowed from the Greek, in which it was written as an αἰκών, we might form for that reason expect to find it invariably short; but the Latin final o in other cases more generally long, we might, on this account, as naturally expect to find pro usually made long, by those at least who were acquainted with Greek. The press seem to have availed themselves of this convenient ambiguity by making pro long or short, as proved most suitable to their purpose.

By the final Vowels of first Words in Composition.

14. If the first member of a Latin compound word end in A, that vowel is long; as traedo, tráno, quare, quăpropter, quātusus: but in Greek compounds the A is sometimes short; as ádipos, sometimes long, as Nópolis.

Quare agit o propriis generatim ducit cultus. Virg.

Exstinguhit faxum promus, cui nomen ádipus. Trif.

Ambrum medio proctó Nópolis arcm. Avienus.

Except cædam, unless it be the ablative.

Non edēm arboribus pendent vindemia notitas. Virg.

15. If the first member of a compound word terminate in e, that vowel is short; as in all syllables of néfas, néfandus, néque, trédécem, trécenti; in the second of válica, madéfaco, múpæfaco, treméfaco; and in the third of hujuefemod, ejufemod.

Except 1. The E is long in words compounded of se for sex, or for sem: as sedécem, sémeltris, sémudius; (but in libellum it is short.)

Sémishamnus Coci fames, quam dira tegebib. Virg.

Argentum libris mittebat: sects álotin oil. Mart.

2. It is long also in něquæ, něquæcum, něquam, něquita, něquando, vidélicet, and vénæquæ.

Něquæcum feros equest renotus canus. Virg.

3. Liquefaco, tepaeéfaco, and patefaco, have the e of the second syllable chiefly short, though sometimes long; rarefaco and rareföe have the e generally long.

Sic mea perpetua liquifant pécora curus. Ovid.

Tres liquifatis, tendens ad ferae palmaris. Ovid.

Ex ræfinit cælo maxime vapore. Virg.

Introitum, múraque fium patræcæ aquarum. Ovid.

Atque patræfæt, quæ ante iudicium at. Lucr.

Note.—Virgil observes that Virgil introduces the e in such words, and

that Lucretius and Catullus longed it, the former without reason; indeed it is probable that in their words it was generally considered common.

16. If the first member of a compound word terminate in e, that vowel is short; as bivium, trivium, triceres, sigüem, faticidus, agricola, vaticinum, signifio, architectus, dímeuter, trimèter, Iphigenia, &c.

Jane bireps: amn incita labam inago. Ovid.

1. Except those compounds in which the e is changed in declining; as quīvam, quīvus, quīlibet, quīventis, quanticunque, tantídem, uníque, eídem, repíublica, quâmque.

2. The final i is long in those compounds which may be separated without destroying the meaning; as ludi, lūdī, lūdīmagitus, or ludi magitus; pārvipendu, or pāri pendo; lucrīfación, or lucrī facio; sīquis, or sī quī.

3. Those words which in joining undergo a crasis or syncope, are long; as hisbib,—for hisbib; bigae, trīgus, &c. for bigius, trijus, &c.; ficæ for ficæ; bīcibem for bicibem; fundum for fundum; which has suffered neither, is short by the general rule.

Ricit ignis exad summus : quī quaque vento. Virg.

4. Ídem masculine. The word, is long; but in the neuter, it is short.

Adsumus identidem has the penultimate short.

Vindicat qui fortunat, ideo faciat quodcum. Hor.

Qui edens adsumus identidem e. Catul.

5. The final i of the formercompound word, is long in nīmirum, ubique, utrobum, ibīdem.

6. As the i is common in ubi; so it is in ubicunque and ubivis.

Clamant: iō marres audite ubicunque Latins. Virg.

Servor, ubicunque est; ubi mea grudia fero? Ovid.

7. The compounds of dies have the final i of the first word long; as biduum, triduum, meridies, prīdie, postrīdie.

Si solus tibi triduo laget. Mart.

Note.—1. Postrīde and postrīdie are long by exception 3, being prior dicī, and poterit etc.

2. Quidcumque and quintcumque are said to have the i sometimes short; but this is not strictly so. Dexterly sustained, since the lines added in proof may, by the figure synsiis, be differently measured: thus

Conjugis in culpa flagravit quidquidam. Catul.

* Or, nisi quid si quis, it must be confessed, however, that thus read the line is hard, and is unnecessarily rendered pointless.

3. Trigitas, tridímus, trivium, and tricere, are not considered as compound words, in which the trī is short, as it is in all the real compounds of trīs, trīpes, trīplex, trīfimīna, trīuos, trīcentias, &c. &c. for trīgintas cannot with propriety be called a compound word, since trīnta is only a termination. At all events the trī in trīgintas, &c. is ever long.

17. If the first member of a compound word terminate in o, it is short; as Argōnauta, Arctōphylax, arēopus, philōsophus, sērcōnuctus, duōdecem, hodie.

Non nutus purum vos, sed Argōnautas. Mart.

Non dies bīde, quærum hic tam putatis tandem — Hor.

1. Except words compounded with intro, retro, contrō, and quando: as introducto, intrōmitto, introceredó, controverfus, quandōque, &c.; but quandōquiem has the o short.

1. ἰδω τρικέςς τε και πολλοίς πρώτος ὀρα. Ovid.

2. Alfo sliquim, utróque, euteroquin, utróbiique;
and the compounds of quō; as quōmodo, quōcunque, quōminus, quōcitra, quōvis, and quōque the adjective; but quōque, the particle, has the short.

Mendæci est natura. alēgnum recta, vehut il. Hor.

3. Those words which in Greek are written with an o-mega, have the long; as geometria, geographia, miniatura, lagopus. Virg.

Si mensurati gaudet lagopode Furtun. Mart.

18. U and Y terminating the first member of a compound word, are short; as, in Thrasylalus, Eurypylus, Polypus, ducet, duxendum, centuplex, Trojanæa, cornipeta, Polydorus, Polyphemus, &c.

Nam fuit hoc vitiosus: in horis epeæ dicitæ— Hor. Virg.

Except jūdico, which in its first syllable is, by syncope, long.

Et spīt, et meem femt, et Jove jīdentur, aqua. Hor.

Of the first Syllable of Diffyllable Preterites.

19. Preterites of two syllables have the first long; as vēni, vidi, vici.

Except bibi, tūbi, dēdī, fētī, fētī, fētī from lēcindo, (for abfētī is long from abfētī, and abfētī short from abfētī, ) fūdī from fūno, (for fīdi and confidī from fido are long.)

Of the two first Syllables of Reduplicated Preterites.

20. Preterites doubling their first syllable, have that syllable and the following both short; as tētīgī, pēpūli, pēpēri, didici, tūtīdī, ecīdi from cādo.

Si mēnītā fuerant tibī quaestor, Elia, deteun. Lāter. Virg.

Except ecīdi from cādo has the second syllable long; and likewise those preterites, in which that syllable is followed by two consonants; as fēfēlli, mōmordī, fīpōndī.

Ebrīus et petulans, qui nullum fors cōctī. Junen.

Vatum fōpōndīt: nulla poder me fango. Senec.

Quæ Deum īpe īvis intermissa fortibus fōpōndīt. Prud.

Note.—From the authorities here quoted, it is evident that fōpōndī is the classical orthography, not ḥpōndī, which would have the first syllable long by position, before ap, as we may invariably observe in compound words: as rēspō, respicio, respōndes, respīro, respīgo, &c.

Of the first Syllable of Diffyllable Supinæ.

21. Supines of two syllables, and the perfect participle formed from them, have the first syllable long; as sīlum, mātum, clēm, fētum, vītus, mutus, &c.

Terribilēs sē mitā fornā, letumque, laboraque. Virg.

Quōs ego—sed nōtos prātā componere flātūt. Virg.

1. Except the first syllable is short in dātūm, rītum, fātum, iitum, lītum, quītum, situm, rītum, and futūm, from the oblique, quo, whence we have fātūrūs.

Cui dātūs inter eam cōtus, curticque regebat. Virg.

2. Cītum from cīo of the second conjugation has the short; but cītum from cīo of the fourth conjugation has the long.

Corripit fēcē, et teclis cītus extulit alīs. Virg.

Unde nānto sē mitā pectus mundi. Lucan.

3. Statum is common: hence we find flātūrūs, conflātūrūs, obflātūrūs, flāmen, flātus—um, flātus—us, &c.: the former of which are said to come from flō, the latter from flīto.

Hier flītus in cōdo multos permutat in annos. Ovid.

Dannavit multō, flāturus languit Marty. Mart.

Inflōtus impēris, caepo fainōto honemum. Claud.

Non pref rétās fīli prætār naturā ferī suos. Prop.

Confignifātur fīt Megalēnsis purpurā centum. Mart.

Of the first Syllable of Poly syllable Preterites and Supines.

22. Preterites and supines of more than two syllables have the same quantity in their first syllable as the present; thus vōcavi and vocātum have the short; because the first of vōcō is short: clāmavi and clamātum have the first long, because the first of clamō is long.

Si vīrōt officinam turbā cædenre vehérat. Juvan.

Induit, implesvitus mero, divolque vēnīvit. Virg.

Except pōtūi, pōtūtum from pōno; gēnūi, gēnitum from gignon; pōtūi from potūm, fōlūtum, volūtum from folvo and volvō.

Of the Penultimate of Poly syllable Supines.

23. Supines of more than two syllables, in ātum, ānum, and ātum, lengthen the last syllable but one; as amatūr, delētum, minūtum.

24. Supines in ītum, from preterites in iei, also have the penultimate long; as cupiūt, cupiūtum, petiūt, petiūtum; quaśiūt, quaśiūtum; poliūt, poliūtum; but the compounds of cō, abīmo excepted, have the penultimate short.

25. Supines in ītum, from any other preterites, shorten the penultimate; as cubiūt, cubiūtum; moniūt, moniūtum; aboliūt, aboliūtum; agnobiūt, agnobiūtum; creditūt, creditūtum; recensūtum of recenfeo is long, on account of its origin from the oblique cenfо, cenfī.

Namque fortun laevel Cyenum Phæbontios anātī. Virg.

Dēlictus Volcūrīm aēs; ececlīde Camillam. Virg.

Sulūtī exītīs vinīlis ad fidera palmas. Virg.

Sæpe incœsum prōbris, gladiāque petitīs. Virg.

Cendamus Pheeb, et moniit meliora sequeamus. Virg.

Prīca recensuīt evolvē fæcūla fātīs. Claud.

Of the Penultimate of Participles in Rūs.

26. Participles in rūs always lengthen the last syllable but one; as amatūtur, habītur, lectūtur, auditūtur.

Tarda venit, feris pūtāra nepotibus umbrae. Virg.

Increment of Nouns.

Note.—1. If the genitive case singular do not contain a greater number of syllables than the nominative, that noun has no increment, as pecunia, pænis, caro, carnis. But if the genitive contains more syllables than the nominative, the penultimate of the genitive is the increment; and whether that syllable be long or short, it prefers the same quantity in all the oblique cases singular and plural. If bōbus or bōbus be an exception, we should recollect, it is for syncope and crafts from bōvībus. Aufōnius, contrary to the practice of better authors, has an example of bōbus short, as if it had been formed by simple syncope without crafts. See Aulīn. Epig. 62.

2. Nouns fīldōn have more than one increase in the singular: iter, ier, (when its genitive is jecinoris), fīpelle, and the compounds of caput, ending in ps, have two increments. The aitive and ablative of the third declension have two; of the aforementioned words, three increments. They are reckoned in the retrograde order, beginning with the penultimate, for the last syllable is never considered as an increment.
Of the Increments of the Singular Number.

Of the first, second, fourth, and fifth Declensions.

27. In the first, fourth, and fifth declensions, there is no increment in the singular; except the ancient increment of the first declension, by the resolution of the diphthong ai into au, in which the a is long; as

Deus equum, dives pueri velit et uiri.

28. The increments of the second declension are short; as

pueri, viri, fatuiri, tenerti.

O pueri! ne tanta animis affecte bella. Virg.

Except Iber, Ibéri, and its compounds Celtiber, Celtibéri, which lengthen the penultimate; as

Quique ferors movit. Ser orios exul Térras. Lucem.

Vir Celtibéri non tacende genus.

Increments of the third Declension.

29. Nouns in A shorten the genitive penultimate; as dogma-atís.

Non quivi videt immobiles poenitenta judex. Hor.

30. Nouns in I, compounds of meli, shorten the genitive penultimate; as hydromeli, hydromelitis.

31. Nouns in O, increasing in Ínis, shorten the genitive penultimate; as cardo, cardinis, imago, imaginis.

32. Ínis and Íonis, from ou, are long; as anio, anionis; ferreo, fermonis.

1. Except gentiles in ou generally shorten the increment; as Macedo, Macedonis; Saxo, Saxonis. To which add Lingonis, Seuones, Tentones, Vangiones, Vafcones. Some lengthen the penultimate; as Successiones, Vettlenes, Burgundiones, Eburones. Juvenal shortens Britones; Martial lengthens it.

2. Nouns in on, from the Greek on, which sometimes drop the Ío, preferre in Latin the same quantity which they have in the original; as Agamemnon or Agamenno, Agamemnonis; Demiphon or Demipho, Demiphônis.

33. Nouns in EC lengthen the genitive penultimate; as halcat-ecís.

Halocem feó quem protinus ipsa veret. Mart.

34. Nouns in D shorten the genitive penultimate; as David, Davidis.

Eredo indulget Davidis origine lunem. Juven.

Note.—Ecclesiastical writers often lengthen the penultimate of David.

35. Masculines in AL shorten the genitive penultimate; as Hannibal-ális; fal-ális (masculine or neuter).

36. Neuters in AL lengthen ális; as animal-ális.

Vela dabant levi, et frumus sólis are rubant. Virg.

Promaque cum ópportunis animum alta terreus. Ovid.

37. SOL lengthens sólis; and also Hebrew nouns in EL lengthen the genitive penultimate; as Daniel-élis.

Regia sólis erat sublimibus alta columnis. Ovid.

38. All other nouns in L shorten the genitive increment; as vigil-élis, consil-élis, exúl-élis.

Aut uriam, aut puellas, his nam plebeius guadet. Hor.

39. Nouns in EN shorten the genitive penultimate; as crimen-énis, flumen-inis.

Quoque magis mirum est, nescorem eriminis hujus— Mart.

40. No certain rule can be given for the quantity of the increment of nouns ending in ON. Many lengthen the genitive penultimate; as Chiron, Demipho, Agon, Helicon, Lacon, Sicyon, Solon, Simon: many shorten it; as Acteon, Agamemnon, Amazon, Jafon, Memnon, Philémon, Orion, Sido, Sindon: and Ægeon has the common penultimate.

Credit, et excludit famos Hécules putris. Hor.

Et volet abstinent certa Academia clamat. Ovid.

Ægöebus nás inimnias terga incursis. Ovid.

41. All other nouns in N lengthen the genitive penultimate; thus Titan-ánis, Siren-énis, delphin-ínis, Phorcyn-ýnis.

Conétas iratus validus. Titónis in arma. Ovid.

Orpheus in sylvis, inter dôhplices Atóon. Virg.

42. Neuter nouns in AR lengthen the genitive in Íaris; as calcari-áris.

Seu Ípmanis equi fóderat calcabiros armos. Virg.

But these neuters shorten áris; bacchar, jubar, nectar-áris. To which add par-páris, and its compounds; as impart-Íapáris; dissipispáris, &c.; also hepar-áris.

Pugnavere páres; succubuerce páres. Mart.

43. But masculine nouns in AR shorten áris; as Cæsar-áris, Hamilcar-áris, lar-láris.

Except Car and Nar; as, Ládibus immodicís Gáres in alta terram. Mart.

Salióres pavoit Sparmánum Náris ad unam. Ína.

44. Greek nouns in TÉR lengthen the increment; as crater-érís, charáccter-érís, spinther-érís; except ather-érís.

Indulgent vino, et vertunt craterés ahenos. Virg.

Quiscumque illi levem fujus focet aesthëru penicil. Virg.

45. Nouns in OR lengthen Íoris; as amör-óris; timor-óris.

1. Except neuter nouns; as marmor, aquor-óris.

2. Greek nouns in OR; as Hécor, rhetor-óris.

3. Arbor-óris, and memór-memóris.

4. Ador forms adorí or adorís, whence adóres in Virgil, Horace, and Claudian.

Inter spem curamque, títures inter et íras. Hor.

Praetéra fuit in tétudes de murosque templum. Virg.

Finiet, ante graven que legius arboris fólen— Hor.

Mox ador, atque adorís de polline púlficium far. Hor.

Emitit in nubes adorís. Prís.

46. The following nouns lengthen the increment; fur-fúris, ver-véris, Recímer-címerís, Byzer-Byzéris, Ser-Sérís, Iber-Ibérís, (as well as Iber of the second declension.)

Vellérque ut foliis dependant ténus Sérís. Virg.

47. Other nouns in R, not mentioned, shorten the penultimate; as aer, aéri; melíer, éris; cadaver-érís; iter, itinérís; verbis, verbéris; cultír, úris; mumar, úris; fémur, rubor, jecer, ébur-óris; martyr-ýris.

Si nigrum obsuro compredérit aëra cornu. Virg.

Aphex, venite occiduntur marmurís narae. Virg.

48. Latin nouns in AS lengthen the increment; as pietas-átis; Mæcenas-átis; vas, valis, a vellic.

Foréignum pictáte virum tot adhære labores. Virg.
QUANTITY.

Except anas, anatis; mas, maris; and vas, vados, a secuery.

Tyrtaeique naro animos in martis bella. Hor.

49. Greek nouns in AS shorten adis, atis, and anis; as Pallas, lampas, adis; artocreas, atis; Melas, anus.

Hater nars equos divinae Polides arte. Virg.

50. Nouns in ES shorten the increment; as miles, militis; feges, fegetis; praefes, presidis; obles, obdis; Ceres, Ceris; pes, pedis.

Metri fe quemque suo modulus se plude, v. rum ell. Hor.

Except locuples, quies, manufnes, etis; hares, merces, edes; also Greek nouns which have etis; as lebes, Theales, tapes, magnes, etis.

Atoniums fermentum, et ipsa hortis fuli. Virg.

Virgini fulvis operosae ex ore florentem.

51. Nouns in IS shorten the increment; as lapis, Phyllis, idis; cinis, cris; langes, inis.

Immodi et penam (feleato ex fangulae suntu. Virg.

1. Except glis, gloris, and vire the plural of vis, which lengthen the increment.

Scanimolos ille portigii gloses. Mart.

Sic fanus validis ingeniius hortis habet — Virg.

2. Latin nouns which have itis, as dis, itis; lis, litis; Quiris, Saumis, igitis; but Charis, a Greek noun, has Charitis short.

Infrequens tamen hunc, et hortis moraris iniqua. Hor.

Tres fuerant Charitis, fed dum nos Lelha visce — Aufon.

3. Crepis, Crenidis; Nefis, Nesidis; Pfiophis, Pfiophidis, lengthen the penultimate; but Pfiophis shortens it once in Statius.

Sylvaque, que hunc pelago Nisidae coronat. Stat.

Utque futi Orchaenon, Epiphidaque Cylleneca. Ovid.

4. Greek nouns in it, which have also the termination in it; as Salamis, or Salamin-itis.

Tilurus umbra tui, Tenebr Salamatian putremque. Hor.

52. Nouns in OS lengthen the increment; as nepos, odis; floes, floris; os, oris; cultos, cultoûis; rinoceros, ôtis; Tros, ois; heros, ois.

Qui legitis floros, et humi incertissima fraga. Virg.

Egregii optatis potuerunt Troes arrea. Virg.

Except bos, bovis; comos, impos, odis; which increafe short.

53. Nouns in US shorten the increment; as lepus, corpus, oris; villus, eris; tripus, odis.

Ut canis in vicum lopeum cum Gallicus arvo. Ovid.

1. Except those nouns which have udis, uris, or utis; as incus, incudis; tellus, telluris; salus, saltatis. But these are short; Liguris, from Ligur or Lignus; pendis, from the obsolete pecus; and intercitis, from intercurs.

In medio; Surri tripodes viridesque corouac — Virg.

Fas et jure finitum: rivos deducere nulli — Virg.

Non ego in Ligurian ductor fortissime belle — Virg.

2. Comparatives in us lengthen the genitive penultimate; as melius, meliores.

Perfe, deceat, forian maiores meliores sequentur. Virg.

54. Nouns in YS shorten the increment ydis and ydos, and lengthens ynis; as chlamys, ydis or y'dos; Trachys, ynis.

In medio, chlamyde, et pientis contextus in armis. Virg.

Herculea Trachynis jube, lib imaginis reque. Ovid.

55. Nouns in S, preceded by a consonant, shorten their increment; as calebs, igitis; flaps, flapi; Lulaps, apis; Cecrops, Dolops, opis; aepees, euples; hienas, crimis; also aneeus, bieees, cipits, and similar compounds of caput, in which both increments are short.

Ad matres primo ancipites, ouulique malignis — Virg.

Hic Dolopes manus, hic ferves tendatbro Achilles. Ovid.

Except Cyclops, opis; feps, fe pes; grumps, yphis; Cecrops, opis; plebes, plebis; hydrops, opis; and genitives long by position; as excors, excordis; pars, partis.

Fortunam, et mores antiquae pellis, et idem — Hor.

Antiquatae memoriae immutante Cyclopis. Ovid.

56. Nouns in T shorten the penultimate of itis; as caput, igitis; finciput, fincipitis; occuput, occupitis.

Magna fuit quondam capitis reverentia cani. Ovid.

57. A noun in X shortens the vowel before gir; as harpax, agis; grex, grexis; aquilex, ligis; biturix, ligis; Styx, ygis; Allobroxi, gigis; conjux, ugis. Phryx, ygis.

Quingue grises illi balanum, quinu redundunt. Virg.

Ad Sjyo Tamariit et atheist decockian port. Ovid.

Except lex, legis; illex, exlex, legis; rex, regis; cocoxy, ygis; malix, igis; and frugis, from the obfolete frux.

Omnis sub leges mors vocet atra fusa. Ovid.

58. A noun in EX shortens icis; as vertex, icis; pontificex, icis; vibex (rather vibix), istic excepted.

Qualem virgineo dememium politice florem — Virg.

59. But EX having icis, lengthens the increment; as vexcex, ecis.

Verbecum in patria, criblique sub areo matic. Juven.

Except neces, vicis, and precise, wanting nominatives; allo famines; refex, ecis; and supplex, ecitis.

Quam ecises articlcs arte perire fusa. Ovid.

60. And all other nouns in X generally lengthen the increment; thus nouns in ax; as pax, paces; fornas, aesis.

Except abax, similax, Atrax, dropax, fax, Atax, elmax, panax, opponax, ilurax, colax; the compounds of phy lax and corax; as Arcophylax, Nomophylax, nythicorax, phlaecorax, aecis.

61. Thus words in IX; as radix, felix, eicatrix, nutrix, victrix, altrix, perdix, cortunae, perinis, lodix, icis.

1. Except appendix, chaenis, cozenaxis, clix, calix, fornix, filix, hilrix, larix, pit, falix, varix, icis, and frix, fritis.

2. Nix, nivis; malix, ichis, a gum.

Ecce coturnae inter sua praelis virtut. Ovid.

Et fitches curvis inviain polcit aratra. Virg.

Et lfriges inventa per bufa jacentia plumex. Proper.

Jam fastis terris nivos atque dira. Hor.

Contrimque simul cum matilce confer anerium. Seren. Sannon

B b 2 62. And
QUANTITY.

62. And words in Ox; as vox, vocis; velox, ucis. Except Cappadox; praecox, oxis.

Condimus et magna suprema uoce ciuus. Virg.
Mancip is locuplet, et uis Cappadicion res. Hor.

63. In UX; as lux, luuis; Pollux, luis. Except dux, drx, nux, trux-ucis.

Reellit Arnea, claraque in lucre refulit.
Confedero dices, et uolgi stante corama. Virg.

64. In YX; as bombyx, ycis. Except onyx, ycis; Eryx, ycis; calyx, ycis; Naryx, ycis. But Sandyx and Bexy have the increment common.

Nec faus Arabico facet bombyce parilla.
Haque plena, vel it, fauciis amitula.
Interad, Lycybo facuntur, fauciis pinze.
Vexuis et Scylli lice, praecord inclementia faci.

65. The plural increments, A, E, O, are long; as musarum, ambabus, animabas; rerum, rebus, horum, quorum, regnum.

Tuque, heram interprete curuam, et consil, Juno. Virg.
Solicet in nobis rerum natura novat e: Ovid.
Rerum in angulius facile eit contemnere vitam. Mart.

Projectis? O Latin captat heram et eaft multuram. Ovid.

66. The plural increments I and U are short; as quibus, tribus, monitius, veribus, labitus.

Except bobbis or bobs, which, on account of its contraction from bovibus, as already explained, is long.

Necel tribus nodis ternos, Amarylli, colores. Virg.
Non qipibus mentis hominem curaque levatur. Tibul.

Pars in fructa feemt, verbisque tenebris figurat. Curi.
Cum super eadix, labidibus deminit; et illud: Ovid.
Et tumur labiriti curvatis arcibus orgonis. Manil.
Et Thibes nostris advena bobs ort.

Increment of Verbs.

Note.—1. When any part of a verb exceeds, in the number of syllables, the second person singular of the indicative passive, the third person is considered as the increment. As in nouns, the last syllable is never reckoned the increment; so also in verbs; and, therefore, when there is only one increase, it must be the penultimates.

2. Thus amat, amant, amas, amem, amas, containing, like amas, only two syllables, have no increment. A mas, a-matis, tis, tis, de hasta, mas, have one increment, because they exceed, by one syllable, amat, alas, fis, fis, and das. A-mata-mus, a-ma-bis, have two increments, because they exceed amas by two syllables. A-ma-ve-sis has three increments. A- di-e-ba-mi-ni has four, because it has four syllables more than uis. In determining the increments of the dependent verbs, an active voice may be supposed; thus, conerat has one increment; con-a-bat, two; con-rr-e-mi-ni, three; because con of the fictitious active voice has but two syllables. Or their increments may also be regulated by other verbs of the same conjugation and number of syllables, which have an active voice.

67. A is long in the increments of verbs; as albam, flares, prooperamus, doccebamur, audiembnii.

Serius aut citius fedem propemus ad uum. Ovid.
Pugnabunt armis, que post fabricarenter uos. Hor.
Et conturb pare, et redponde navi. Virg.
Contemplator stem, cum fa nur plurima filius. Virg.

Except that de, and its compounds of the first conjugation, have a short in their first increment; as damus, dabunt, dare; so circumdamus, venendabo, &c. But in any other increment do, like its compounds of the third conjugation, is long; as dabamus, derederatis, circumdamus, credamus.

Hic lacrimus vitam damus, et ni rebus ultros. Virg.
Taurino quantum potent circumdamus tergo. Virg.
Nam quid continuit, aut quam toruias debatur? Virg.

68. E is long in the increments of verbs; as sbbam, rebas, ambris, doccebas, legierunt, amemus, amaremus, amavemus, regedebat, audibab, &c.

Sec equidem duce Domino, virilique suum. Virg.
Ne juvenis celebrat multo termum, casu. Tibul.

Except 1. E before R is short in the first increment of all the present and imperfect tenses of the third conjugation; as leges or legere, the indicative present passive; leges, the infinitive perfect active, and imperfect passive; leges and legere, the imperfect subjunctive active and passive. But reis and rere are long; as amaberis, amabere; docere, docere; regere, regere; audiere, audiere.

Parere plonim, dii de vel. Mart.
Sec fendas Pelen, fi moreurem, crn. Ovid.
Cuius confirmatus dedituris capis, Ovid.
Nebes, neque ad fatex victor vehemus. Virg.

2. Ebris and ubere are every where short; as amaberes, amabere; monerebres, monerebe; and among the ancients, largebres, experibere of the fourth. Excepting where the belongs to the termination of the present; as feriebres and scribere of the future passive being long by the general rule.

Sanguine Trojano et Rutulo datavere, virgo. Virg.
Seriores Varo torus, et hoffium— Hor.

3. E, before ram, rim, ro, and the persons formed from them, is short; as amavaram, amaveram, amavero; monure, monurem, monureo; rexarem, rexere, rexere; eram, fueram; potero, potere, &c.

Vincere, nec duro potere convellere ferro. Virg.

4. By syllable, the poets sometimes shorten before runt; as

Oblupae deterrautque cume, et vaca fusitus haeve. Virg.
Di tibi dividias delitum, artemque frondre. Hor.

69. In every increment, (whether the first, second, third, or fourth,) I is short; as amabimus, doccebimini, regituris, regimis, audibimini, audibamini.

Mora tanta mente cedat; simulic, sequimini. Catul.
Vemimus; et latoi indagine ciauimis ago. Ovid.

Note.—In such verbs of the fourth conjunction as have in the first person plural of their present and perfect indicative, the same words, in regard to spelling, there is a distinction by the quantity; the penultimate of the former being long, as venimus, reperimus; and that of the latter short, as venimus, reperimus.

Except 1. These have i long; simus, velimus, noimus, with the other persons coming from them and their compounds; as sitis, velitis, volitis, volite, volitote; malimus, malitis; posimus, positis, &c.

Ne nimium simus, flutorum mere, molesti. Mart.

2. I before vi in preterites is always long; as petivi, quaesivi, audivi, and in its derivative persons; as petivi, quaesivi, audivimus, &c.

Coffi e fubbato montem genitore positi. Virg.

3. The first increment of the fourth conjugation is long; as audimus, auditis, audir, audio, audirem, fecimus, feire; and in auditbam, as it is sometimes con-
tract'd; and in ibam and ibo, from co. But when a 
vowel follows, it is short by position, as audibem.

Naturale tenet immutabiles ubera labris.
Levibus tecta vulnera morta finis.
Tu ne cede multis; fed commio sedio tor.
Famulentus hujusque de tenebris, et testa fulmis.
Quo non editet, tu turi festis tabulis.

Note.—Inms in every präterite, and in that of the fourth conjugation 
also, is short; as juvenus, virumus, fecumnus, venunus, amarnus, 
adolevinus, perpercimus, mununvus.

4. Rimus and ritis in the subjunctive präterite are 
short.
Egerimus notit; et minimum memínisse necesse est. Virg.

5. Rimus and ritis in the perfect future subjunctive are 
common.
Quas ob res, ubi siderinus nil poëte creari.
Lucr.
Nec mi acrum pocto, nec mi pretium dederitis.
Enn.
Puderit tules ille, ubi circius axem.
Ovid.
Dein cum multi multa fecernimus.
Catal.
Oderimus magis in culpam parenque creatur.
Manl.
Cum parvis locis transferimus aquas.

Note.—We have innumerable examples to prove that rimus and 
ritis in the perfect future subjunctive is common; but concerning 
the quantity of rimus and ritis in the präterite subjunctive, 
grammarians are not agreed. A difficulty in this investigation arises 
from the similarity of the two tenses; the latter having not un-
frequently been mistaken for the former, and vice versa: for the 
perfect of the potential seems to be both part-perfect con-
gent, and future-perfect contingent. The perfect future has 
also gone to great an affinity to the präterperfect potential, that often 
a word may, consistently with the tense, be supposed to belong to 
either. As these tenses are usually interpreted in English, there 
is a great resemblance in their structure, as well as in the ideas 
which they express. Both are composed of verbs in perfect 
time, the one a verb of present liberty, or the like, the other of 
present intentius or obligation; of an infinitive denoting subsequeit 
or dependent position; and a participle significant of the perfection 
of the action denoted by the verb: thus, I may have written, 
I shall have written. 2 We find by A. Gallius, 18, 5, that it 
was a subject of dispute at Rome, whether the tense in rim ought 
to be considered as part or future, or both. Such disputes may, 
perhaps, have arisen from the accidental circumstances which are 
implied, besides the immediate action of the verb; in the same 
manner as, in English, two forms, precisely the same in their 
structure and exact in their meaning, have been considered by 
certain grammarians under different times, viz. I may write, 
and I shall write, the former being named, from the accessory idea, a 
pretense, and the latter, from the depending action, a future, while, in 
reality, if we apply the same criterion to them, they are both 
präterit, or both future. Indeed it has been contended that 
the future had the termination rim, as well as so; so that 
it is reckoned not improbable that both may originally have 
been but one tense, which had both a past and future refer-
cence. It is evident that this is a consideration by no means 
sirelevant, but indispensably necessary, before we can, with 
certainty, determine the quantity of rimus and ritis in the 
subjunctive präterite. In addition to the authorities for reckoning 
rimus and ritis common, there is likewise sufficient example from 
Horace, Martial, Ovid, Seneca, Tibullus, and Plautus, to consider 
ris of the future, at least as common; and this is an argument 
founded on the analogy of other tenses between the quantity 
of the final syllable in the second person singular, and the 
present 

timate of the first and second persons plural, for considering the 
following rimus and ritis also common.—Ris, rimus, and ritis, 
are usually accounted short; but it is exceedingly probable that, 
whether referred to the präterite or perfect future, they still 
might be used as common.

70. O, in the increase of verbs, is always long; as 
amota, facitote, Æote.

Cumque loci posuerit, matrem facitote falutet. Ovid.

71. U, in the increase of verbs, is short; as sūmus, 
postiumus, volūmus, malāmus.

Discer, Pierides: non omnis pofcamus onmes. Virg.

Note.—For U in the penultimate of the future in rēs, see the 
rule.

SECTION II.—On the quantity of the penultimate and ante-
penultimate syllables, and on the quantity of such as are usually 
short to be long or short by authority.

Note.—It is very well known that the prosodial rules, hitherto ex-
tant, determine not the quantity of every syllable of the Latin 
language; but of those of the most important, viz. the quantities 
from the circumstances of position, derivation, prefixes, suffixes, 
increment, and final syllables. Consequentially, in the greater 
number of instances, the inquiries of the student are at a stand 
until he can appeal to that observation, which would be more 
aptly employed in confirming his previous acquisitions. And 
throughout but particular and complete in their derivation, and 
are applied at but mere intimation, the first stage of his progress, 
at the time when he unquestionably might achieve the second, the 
facts and practical illustration of his previous attainments. If we 
depend on practice for the first principles of our knowledge, we 
lose his bell and happiest effect. Practice will always evidence its 
moral prevalence in itself, when its force is alone to bear the superstructure 
of the basis of regular system and theory, and not to attempt the 
caval and fortuitous task of laying a transitory foundation, and that 
too on a vacuum, the baleful texture of ignorance, not admitting 
that analogy and arrangement, that reciprocal and corroboration 
illustration, which so frequently and effectually improve 
sound and permanent improvement. The part which follows is an 
attempt to fulfill this dejideratum. It was obtained by four con-
secutive analyses of the language, in which every word and syllable 
pulled under minute and decisive consideration. This investigation 
was undertaken in consequence of its being subjected, that since it 
is a general rule in the Latin language, that a vowel before two consonants, &c. is long, that a law exists, directly 
the reverse of this, and of not less extensive influence; viz. that a 
vowel before a single consonant is short; though each of these 
general and very extensive rules, may have, in special cases, their 
exceptions. The refuit justified the expectation, and proved, that 
principally with the addition of another general rule, the prosodial 
system might become so comprehensive, as to include and provide 
for the whole language; and consequently, for all those syllables 
usually used to be long or short only by authority. The exceptions 
to this general principle are chiefly included in the rules for the 
penultimate and antepenultimate syllables. And though some of 
these have appeared in former treatises, yet from their enlarge-
ment, the additional exceptions, the other general rules, and its some 
special exceptions, which have arisen from the repeated analyses 
we have undertaken, it will be easy to perceive, that we have in 
this part some claim to originality. In the preceding rules, and 
that to which we now intend to add, we have had much 
influence from the works of our predecessors, and yet we are 
indispensible on us to avail ourselves of the valuable references of preceding and contemporary 
profesions. And the originality of this section places us under 
the obligation of devoting peculiar attention, especially to the de-
omatic part, that every rule and exception, which we now 
first offer, might not appear to roll over on our bare assertion, but on 
the only legitimate warrant, poetic illustration. And thus, perhps, 
we have now the opportunity, for the first time, of offering the 
only complete collection or system which determines the quantity 
of every syllable, at least of pure and Augustan Latinity, that has 
hitherto been pretended to the public.

1. Masculine patronymics in ades or ides usually shorten 
the penultimate; as Priamides, Atlantiades.

Atque hic pristamides lanitiam corpora toto. Virg. En. 6. 494.

1. Except those thome from in nouns in us; as Pélides.

2. Ału. Amphiaratides, Belides, Japetionides, 
Lycurgides.

1. Par ìbi Pélides; nec inania Tarutra sentit.
Ovid. Met. 15. 619.
Ovid. Ep. 2. 43.
Verg. Aeneis 1. 32.
Ovid. Met. 16. 632.
5. Quoque Lycurgides lethet, et arboris natum.
Ovid. In B. 525.

2. Patronymics and similar words in adēs, rēs, and us, 
lengthen the penultimate; as Achāis, Prolemais, Chryscis, 
Æneas, Minōs, and Latōs.

Proterus Ægeides, rapī Minōide, Dian. Ovid. Met. 8. 274.

Except *Thebāis and *Phoicas: *Nercis is common. 1.
Words ending in *acus, ius, and idus*, shorten the pe-

cnitutate; as *Aegyptiacus*, *barbarius*, *candidius*.

1. *Aegyptiacus* is frequenter notabilis ab Aevus—

2. 1. Thei curvus, 1. he multea antiquus illum—

3. Vatis faltitare, ceceint quum prima futurus.

4. Utque famam, quos *collus* utilibus accipit. Ovid.  

1. *Except Mericicus, opacicus, amicicus, lapidicus, anticus, ficicus*, *mendicicus, politicus, pudicus*, *sobolificus, vicus*.

2. *Allo *h*idus, *idus*; *fidos, infidus*: but *pervidus* (from *per and filus*), follows the general rule.

1. *Ah! perent quicunque merito repertur  

2. Continui montes, nisi duodecim opus.*

3. Et tibi magnum, *Xelecnum, vidaret animus*  

4. *Quodque opus* in colubris uva colorum.

5. *Et tue* opus* in frontes imaginis cranes*.

6. *Cum me ficitur alia, cum patior dulces avis.*

7. *Nec neque* neque harto barbae frugi.

8. *Occipi caeco, poficce occurrere fumus.*

10. *Nec umbilicis quaecumque decorus et cedro.*

11. *Et tua patricia cum ultima rica habet.*

12. *Ore ferunt, dolo multa antiquitas acem.*

13. *Nec metuens, cari tenebant et sidera verum.*

15. *Diffidum etiam spatulā, perfidis tamen.*

Words ending in *imus or iunus*, shorten the pe-

cnitutate; as *finitus, maximus, thyimus, fortissimus.*

Thus animus, decimus, finus, acimum, anonimus, 

callionymus, and all adjectives and superlatives in *imus* 

shorten the penultimutate.

1. *Emell horum quoniam fortissime trahis.*

2. *Pervit opus, redactaque thymi tragiuncta mella.*

1. *Except iunus, iinus, minus, opinimus, quadrimus, simus, trimus.*

2. And two superlatives, *imus* and *primus*.

1. *Sum vitulos, bimn curvans, jam cornus fronte.*

3. *Sciripere fias esse imitantis turpis minus.*

4. *Ant simplici ego jam rapias fundabore opinimus.*

5. *Inicopus quadrannis Sabini.*

7. *Quae, velut latis extra trimn campo.*

1. *Traduis u sicce radix elongatia ligno.*

2. *Grandis tollens cratulina, maxima ruribus.*

4. *Et lur cum primam terris fe cratulina reddet.*

5. *Deliciae et panus cum ombulins omnibus uti.*

Except *repentinus, matutinus, vepertinus.*

1. *Inque repentinis convivis veris tumultus.*

2. *Matutinus primum cautos jam fragula mordent.*

3. *Nec epertinus circumgnetis utris ores.*

1. *Except asinus, cominus, dominus, eminus, facinus, sinus, terminus.*

2. *Susectus Asino fugere, ne polet capi.*

3. *Cominus cense fert; Jacu candidu simul is.*

4. *Tom caput ipsi aperit dominus, tramucunque reliquit.*

5. *Nemum Juditiam facinus mortale fugaret.*

7. *Quaeque miles tenuis omnibus oblitit.*

1. *Vix primos inopia quiue laxaverat artus.*

2. *Except asinus, cominus, dominus, eminus, facinus, sinus, terminus.*

3. *So ancile, bovile, bulae, capitale, crinale, focale, foliile, incile, mixtale, mantile, ovile.*

4. *And alae, anilia, aprilis, civilis, carduelis, curulis, crudelis, conjugalis, dotalis, exilis, sidelis, herlis, miles, patrichis, proles, quintilis, subtilis, factilis, &c. with many others.*

7. Adjectives in *inus* derived from nouns signifying *trees, plants, and stones*; also from *adverbs of time, or from sublativas signifying the four seasons of the yeer, shorten the penultimutate; as *faginus, thymus, adantis, cinnamum, diutinus, perdingus, chimerinus, amnotinus, hornotinus*; to which add *bambycinus, elephantinus*, which seem rather to refer to the filk and ivory, than to the animals themselves.

8. All other adjectives and words ending in *imus* lengthen the penultimutate; as *caninus, binus, trinus, fennius, Latius, medallitus.*

Vix primos inopia quiue laxaverat artus.*

Viet

Except *asinus, cominus, dominus, eminus, facinus, sinus, terminus.*
QUANTITY.

num, vânum, and many others; for the nouns and adjectives comprised by this rule are numerous.

Except galbânus, mânsus, ocênsus, "platânus, "tympanum; "chênsus, "pênsus, "tênus, "Vênsus; hó-
nus, "ônsus, "pônsus, " tônsus.

1. Fucêres colorés, Galbânus habet mares.
2. Et mouâres in gremio languâd fasâ fect.
3. Quid tantam ocênö propterì fe turgere foles.
4. Non fiiamnati platânus, bastato foress.
5. Hinc radios transe rotes, hinc tympanum fultritis.
7. Hinc âe tertum, âci, id gênus et hominem penîsum.
8. Et quådquâm füdâs, ãi non sonâr ãhrâ.
9. Sic Tênsus; et t'arvis courâ sc fîlùs otus.
10. At hôina pars procemium tacito libâbat acerâ.
12. Omnibus audìtur. Êônsus eit, qui vivit in illâ.
13. Æcia dulcisônis ucefar illâ ônsus.

10. Words ending in ino or inor shorten the penultimâte; as lîno, fulminio, termîno.

So sóno, inquino, coinîquo, circîno, fêmeno, grandîno, germinio, emînor, procralîno, comperîndio; the compounds of cûno, as concîno, and many others.

Nunc sinûs, el plagium lati compositâ fadus. Virg.

Except 'divîno, 'omniôno, 'propîno, 'supîno; alo 'clîno, and its " compounds, as acclîno, inclîno, pro-
clîno, reclîno.

1. Hec ãóvinâ, natamque tuli. Ovid.
2. Non impuls mi, hec nunci âominâ ut credere. Terence.
5. Quares etiam, etiam etiam plum et nivale nöcre. Lucret.
6. Inclinat eufus; et eadem circinat ausus. Ovid.

11. Other vowels before final na or nor are long; as mâno, exarêno, pôno, ãûno.

So plâno, trâno, ferênó, ãono, cônor, and several others.

Hec te nos fragli dònamus ante cêatu. Virg.

Except 'cânô, 'rêno, 'hônor, 'sôno, and 'tônó.

2. Sed jurnemus in hæce; fœnus max taxa cénâvût.
4. Te leya pulsa man, te carmina noitra sînumut. Ovid.
5. Cum ônöst, examine primo quoque murmure calli—Juven.

12. A vowel before final na is long; as lâna, vêna, ãpina, nôna, Lûna, râna, arêna, arvina, carina.

Hec régina gravem geminö naurque popoleit. Virg.

1. Non tanem hophos ebris, nec jam petas advena dici. Mart.
3. Concurrent trepide comites, domingamque recentem—Virg.
5. Praefâque flammea rumpatur fêcina eluta. Cel.
6. Femînae palantes agi, atque âce ãêmna verit? Hor.
7. At hacc in murrecta ãet meoche muros. Hor.
8. Quam ubi que Vâri pretcipitât pagina nomen. Ovid.
10. Êbria nos maddis rumput tibëcîna buccis. Virg.
11. Si volâte, hac leges in trutina pauper etiam. Hor.

13. A vowel before final 'ne, 'ni, 'nax, 'nis is long; as mâne, sêni, mânes, fînis.

So bulbinë, amenône, conûine, ãênë, bâni, lucâni,
anteûlädni, ãinûni, fëptêni, octônë, novôni, dêni, vicënë,
ducëni, and other numerals in ãëni; so fûni, aëclîni,
inclins, inâns, commûns, immûns, communis, immûns,
&c.

1. Et que ãùnë refert, et quë furgenithus âfri. Virg.
2. Bis dêmax ãlato textumn robore naves. Virg.
4. O curs homînus! O quælim el in rebus ãûnë! Perp.

Except 'bëne, 'sine, 'pênes, 'cânës, 'cîns, 'ju-
vëns; and ãouns derived from ãosquæs, as lîppô-
nës, trichománes.

1. Vivitur parvo bûco, cui parentum—Hor.
5. Fec chîs, ãe verâ 3, under the above rule. Juven.
6. Chamnus jucumhum pater exequi; acceo cœras. Hor.
7. Hippomônes, quod sapit male legerâ noverces. Hor.

14. A vowel before final 'ne, 'nax, 'nax, 'nix, 'nix, and 'nôm is long; as lîne, cânëno, mûnëno, pûno, favônëo, fêrûmëin.

So arëna, gâneo, declînëo, dèlineo, lîneo, cicônia,
ìnâns, ìbôna, colônìa, aclêdonia, ìcûnìa, quërimonìa,
dêlëno, cûxînëo, ñînëo, ìnànsîo, mùnûo, conûfinium,
patrimûnium, vadîmonium, and many others.

1. In feribus laxos fusae pandit arënae caffer. Virg.
5. Primum refutátur vero favônî. Hor.

Caflënsæ molles, et prepì complect. Virg.

1. Aut lineus odes tacitus inermes. Hor.
2. Quo Dana: Aut quod me succit flânuâm. Hor.
3. Indicata mâenti in eadem prodita partem. Lucret.
5. Utque vâs ãâmnes, multoque errore traharis. Ovid.
9. Quin libitum mundum; tanta est àediciâ frater. Ovid.
10. Momento cita mors vivit, aut victoria letâ. Hor.

15. A vowel before final do is long; as vâdo, cêdo, fîmîdo, rôdo, testûdo.

So râdo, crêdo, akëdo, dûceâdo, cupidôdo, nódo, cêdo, lûdo, altitûdo, beâtîudo, and many others; for the nouns and verbs comprised by this rule are very numerous.

Poëf putus illes fisco freta rûdore paffin. Ovid.

Except 'câdo, 'divido, 'trepîdo; and 'rûdo, which is common; and 'cêdo, to eat; cêdo, to declare, publi-
îce, &c. (the preposition ê being long,) follows the above rule.

1. Molta remücentur, que jam ecciderë, cêdâtque. Hor.
5. Incluâmque cavo fâxo, atque inflecta vâlentum. Hor.
6. Ut verb è expliâ quoties; fortì arder èndì. Ovid.

16. E before final râs, rûs, is short; as mûrûs, he-
dîra, castrum.

The nouns and adjectives comprised by this rule are numerous.

It domus fatue, venit Hobînus, ice capela. Virg.

1. Except
QUANTITY.

2. And though of anthera, canothóra, flatóra, there is no poetic function, they are long by derivation from *ánthera, *cañóthera, and *flatóthera (Virg. _En. 8._ 1450.) from *sár.

1. Qui voles antheras estet ferre viros.
2. Ena manu, salquisque lópi de pellac gátdra.
4. _Sérus_ in auctóndia redúctio deleone.
5. Cum fit tráe habitu, vulgacque et velé _sérurum._
6. _Vérum_, quid fáciis? Ut homo est, ita morès geras.
7. _Prés_ impont Jupiter nobis dux.
9. Exe recumdant; ne pars _fíncérus_ trañatur.

17. Other vowels before final _r_ as _ra, ra, rum_ are long;

as cárus, múrus, mórus, múrus; _hára, fpíra, óra, natura, lórum, &c._

So ára, tiára, íra, líra, hóra, aúrora, lóra, tanti-córa, próra, captúra, _figura, censúra_; allo the nouns, adjectives, and participles in _rus, rás_ &c. are very numerous.

1. Exúltam corem laté dispérit _amurrum._
2. Vela legunt fóci, et præces ad lítura torqueant.
3. Púnicócos tingent _múra_ color.

3. And the following in _rum, rum_ suppuram, _gárum, _párum._
4. Alfo the compounds of _vós, as_ carnivóres, omnívóres; those ending in _phórus and phóra, from_ _ságne_, as amphóra, canephóra, echóphóra,olphóphórus, cítophorus, &c.; and the derivatives of _appagó, as_ hydrárgýrum, lithargýrus.

1. _Archárus_ hic ego sum, quia non intelligor uli.
2. Sed tibi dimidio confrénues Cántumvis ovo.
3. _Pés etam et canemis_ hirta fùb cornibus aures.
4. Et gravis attrit pendebat _canthóris_ ands.
5. Doctus et Phíbus charis, et _Dame._
7. Si quí tibi nítrus est, qúia est tibi fals, voces.
8. Vino ornamentos opipfíriques opúluis.
10. Agrostódia manus armat _frícaris_; vertitur _ípce._
11. _Tartára_ Panthóden iterum _orco._
12. _Prominis ut virízante tóro_ confrédata herbóe.
13. _Aujóna_ jam notáram non tenet uá latus.
15. Troja cadet; sed erit notóri mórre longa habris.
16. _Per hóc inane purpurás deces precor._
17. Difíligat nexe _phóri_ corone.
18. _Indícumque formam, aut populi tabulacri viát._
19. _Suppira_ nudatos clúngit anguila lacertos.
20. _Præfiter cella, gáro de funeis piéto litéri._
21. _Matiría púrínæ caude jam frízara mordet._
22. Mittere _canthóris_ peribui phalæ mandat.
23. _Pholphóre_ rolde diem, quid gaudia notra mezzorin._
24. _Amphóra_ non meruit tu prætori mort._

18. E before final _ro_ or _ror_ is short; as _féro, géro, tério._

So tempéro, áfero, blatóro, cætério, capério, seléro, confidéro, défidéro, fecéro, propéro, _séro_ (to _sow_), quècor, &c.

Verum, quid _fácies? ut homó est, ita mórere._

Except *séro; *avevéro and *pervevéro from _ve-rus, and_ the adverb _séro_ from _serus; for _séro_ to _sow_ is short.

1. _Spérit idem, sedet auctóndia fráuelque lúber._
2. _Próteahur, jurabit, offícuari._
3. _Póet manes tumultuoso persequet._
4. Verum. _Age_ modo _hodie: _séro quosquidem voles._

19. Other vowels before final _ra_ or _ror_ are long; as _váro, _fpíro, _óro, _úro._

So _liro, tiro, inquiri, acquiri, consigni, plóro, labóro, autótero, ignóro, cáro, figúro, lúro, dúdo, and many others.

Delicis et panicum _hómblicuyus oris._

1. Except _séro, _cáro, _fúro, _hilario, _infóro, _móró, _fpíro, _stúro, _úro._
2. Alfo the _ derivatives from genitives increasing short in _oris or _uris_; as _deóró, murróro, from_ _decus-óris, murrur-óris._

So memóro from _memor-óris; corporó from _corpus-óris; robóro from _robús-óris; exaugórro from _augúris; fulgórro from _fulgúris; expectóro from _pecú-óris._

1. _Litius árant, Rutulóque exsercer vóctor cölles._
2. Sed malé _viv_ a _cáro_ et. _Lambduo mater in artus—_ Ovid.
3. _Quid fúce?_ Aut quamquam nocti tibi _cura recoll te._
4. Hoc ubi facendo tu vos _hilitorum ort._
5. _Lictére in_ _urare, ft _incomitare non lícet._
6. _Quid vitam _mórór inviam, Pallante percutio._
7. _Umbris, et caele defundere linga pénit._
8. Quo _fatbrot Calibus culta Galésis aquis._
9. _Optima_ _valvarum interea, pehque perhab._
10. _Et validas auget viros, et robérét tútum._
11. _Locrut._

20. Words ending in _átus, _étus, _otus, _átus, lengthen the penultimé; as _probátus; cáttus, tótus, títus._

So _grátus, facétus, bolétus, pótus, agrótus, argútus, áfuitus, brúsus, hírusus, mutus, and many others; allo participes in _átus, _étus, _ótos, _atós; as _man- dátus, decréctus, nóctus, minútus, metútus, confínutus, volútus, etc._

1. _O fortunátus minimu, fui _bona morári._
2. _Tu_ _rem impéxim et _pérdatim rellactus?_ _hem! quo _feitus sum._
3. Facié _omnes, cum _valémus, _recta _conília, _agreótis damus._
4. _Titia_ _mani_, medii _Tálius_ futuat in undis._

1. Except *cátus, _látius-éris, _látius-ús; _impétus, _métus, _véctus; and _antídótes._
2. _Venétus_ is short by derivation from _Vénétie._
3. _Quóstus_ _from quóct; _tótus_ (fo _great_), from _tót_; for _tótus_ is long; and _arbóres_ from _arbor-arbóris._

3. Of _mocúrum, and _sudomórum from _autómolum, there is no poetic authority._

4. Except allo the plural _genitives of nouns_ ending in _má-mátis; as _póemátu._

5. And the participles _dátus, rátus, sátus, fátus;_ for which see the rule concerning _diffylicial fugines._

1. Me _plus _hópe quum vos, _cedeor vénis confrémis cárum._
2. _Impulit in _átus, et venit, velet _agnim factio._
3. _Et enim veró quoniam formam cephusius in me et _Rúlum, Plaut._
4. _Aéquora; _se illam _intimátus ipse volám._
5. _Necum _et illi _darid, _dum _métus incubat amens._
6. _Et _tetricus obdité _referi foris._
7. _Et vendereris fölo _autótermom._
8. _Sic Venétæ _flamnante Páde, fúxque Bruninnus._
9. _& 10. _Nec _bós _par homo terraí, quidca _bósus unus._
10. _Inferiur _veró _ex _ánum _nucis _arbitús herida._

21. Words ending in _átus lengthen the penultimate; as _auritis, cínruitis, invítus, perítus._

Fac _cum tu, _praco, _nunc omnem _auritum populum._

1. Except
QUANTITY.

2. Also 'all adverbs in itus; as humanitus, penitius.
3. 'Blitum is not derived from the termination itus, but from Elatos, and therefore threatens the penultimate.
4. Also polyyllabic participles in itus, not derived from preterites in roi; as habitus, exercitus-a-sum, and nouns derived from them; as habitus-is, and exercitus-is.
5. And the participles from the verb eo, and its compounds; as transitus-a-um, and their derivatives; as transitius-is; the participle ambitus is, however, long, and the noun ambitus-is short.

2. Apud me juia et elemens fuerit eritius. Ter.
3. Dum messor ipse mei, dum füritus hos regit artus. Virg.
6. Apponunt rumicem, braficam, betum, Plaut. Plaut. For the 4th and 5th exceptions, see the rules for polyyllabic finites.

22. A vowel before final 'men, 'mens, 'mentum, is long; as levamen, clemens, clamitum.

So acutem, crimen, flamen, flumen, grámen, jurgámen, volúmen, argumentum, jümentum, ætramtum, and many others; the nouns comprised by this rule being numerous.

2. Ego canne elementum vitam, urbanum, atque ortum. Ter.

2. Alfo 'alimentum, 'docúmen or documentum, 'emolumentum, 'monumentum or monumentum, 'regimen, 'expémen, 'tégimen or tegumen and integumentum.
3. And such verbs as frémo, gémó, &c. will naturally shorten the penultimate of frémen, gémens, &c.

Note.—The irregularity of such words as monumentum, documentum, &c. has been considered as arising from the paine of the second or third conjunction; which originally, before the effect of syncope, is $pp$ and to have generally been in it is and as monoe, monoeu, monœsum, doce, or doce, dokúmum, and by füre dokumum or doctum; whence documentum or documentum, &c. But if these verbal nouns were primarily deducible from their finites, many of them must have sufficiently afforded the characteristic of the infinitive present, as the g of regimen and tegumen will testify. See Salmon's Statimmat Latinitatis on the terminations men and mentum.

1. Sed témen idem alium curru faccendae fueri.
2. Bum cullum, fulvum, colómen verb familiar.
4. Dóctores, elementum velit ut dúce própra. Hor.
5. Atque ipsæ virtus sunt aliména vices. Ovid.
8. Hic habet, nères monœsum non teque retur. Hor.
11. Iliæ ego mihi tempe habui atati tegiimentum me. Plaut.

23. A vowel before final 'ma, 'mes, 'mis, is long; as hâma, limes, sublimis.

So agéma, dâma, fâma, plûma, poëma, ríma, rûma, sîma, füqua, füpium, fríuma, fèmes, trèmes, illímis, cómis, sèmes, déplûmis, décrîmis, quadriquirémis, quinquerémis, infâmis, and many others in each of these terminations.

2. Exciit invioládam admodó füqua flamman. Lucan.

24. I or Y, or a vowel derived from the short increment of the genitive, before final mo or mor, is short; as animo, ætimo, docimo, lacrýmo, and luémo from hiemis-émis.

Quo redit ad falsos, et virtutem efficit annis. Hor.

Except 'limo and 'rimor.

1. Limó non odio obcurò morafique venenat. Hor.

25. Other vowels before final mo or mor are long; as clámo, némò, prómo, súmo.

So fámo, füquámo, témò, démò, poérimo, fúmo, immo, fipúmo, rúmer, &c.

Excít et longe lapsum témone reliquiab. Virg.

1. Volum in émtane novum; vellem, quod émorum abhófet. Ovid.
3. Atque omne deam, flamà crepantia, crémari. Ovid.
5. Si quis éntat chiphas, emptas commort in unum. Ter.
8. Hémo summar; humani nihil à me alienum puto. Hor.
9. Ignócis; prémite ille graves interritus iras. Hor.
10. Tempellas concussa trémite, frémítique moverunt. Lucr.

Note.—Coméere follows the general rule; but cómo-ère, is verb fóldem addid, thomsen the penultimate: both are derived from córa.

26. A vowel before final lo or lor is long; as cálo, célo, piló, sólo.

So hâlo, málo, vélo, sîlo, nólo, pâlor, sólor, pèculor, and several others.

Except, ac felleos opibus sólatus amicis. Virg.

1. Except 'álo, 'célor, 'célor, dólò (noun or verb), 'dólor, 'mólò, 'ventílo, 'vélo, and 'célo-ère, to cultivate, but 'cólo-are, to filter, follows the general rule.
2. Alfo the penultimate of 'consúlo is short, from confun-ális; so 'gélò from gélu, and 'assimilo from similis.

C c 3. Except
3. Except alfo verbs in uto or utor, which are generally derived from diminutives in ulus; as circulo, circulor, from circulus.

1. Tuttius et peninus minus suius mater ildit.
2. Et color extremus primo cum furgere mixtus.
4. Pilul massa, favoque gerunt in bello divinum.
5. Materienique dierum, kareve ac radoe tigna.
7. Magnitudem utique in jupiter; vulgandum; habendus

5. except

6. Et Cambrium cotit vitioi materi vollas.

Except 'culex,' silex, and 'rumeix.'

1. Tota abit hora. Mali volvex, ranque paludex.
2. Spem graphe ab silve in malo centum sequatur.
3. Apparnet rumeix, brachus, betum, blatum.

Note.—Ales, in the bell authors and editions, is read Ale, and is therefore no exception to this rule.

30. A vowel before final 'per' and 'ter' is short; as supér, arbitér.

So àper, cæper, iter, lâter, accipiter, dimâter, pâter, Jupiter, Dis, Philr, and all verbs in ter; a-
sliter, amplifier, acriter, celeriter, and many others.

1. Dum magna monita òper, flavus dum pisces, amabil
2. Non locus esti hie maiori arbité, auctem.

2. Uter-tra-trum follows the general rule; but
տeter-tris, a bag, lengthens the penultimate.

3. Alfo no sòter from swort, of which the poets give
no example, except through its derivative sòteria.

1. Nune hue remuit nuper 6d me epistolam.
2. Calculus immuner demittitur òr in uram.
3. Cum volct, importunit eburn; ñtés, patcr, addc.
4. Cum mâter melius feu teble obvia fylia.
5. Turn òper unciales magnum criterum coroné.
6. Nam òfectores on nos ìmum licentia.
7. Tôr òper immunde carnis abreri dor.
8. Mollibus in pratis uniformibus quercem òfere.
9. Nam quoties fugit, sòteriam pòles amis.

31. A vowel before final 'bat,' 'bo,' 'pa,' 'po,' is short; as fâba, bibo, sâpa, muncûpo.

So jûba, jûlla, cibô, próbo, glôbo, cûbo, ar-
hâbo, fôbo, sâpa, lâpa, pôpa, uþpâla, alâpa, crîpa, legièrèpa, metôpa, crîpo, itôpo, cûpo, occúpo, emancipo, partícipo, antécipo, &c.

1. Dona jûbo, et dâali jûca recumbrar in armo.
3. Et Lurectane nigra lîgâna áppe.

Except 'gêba,' 'scriba,' 'feribo,' 'libo,' 'nûbo,' 'bûbo,' 'cêpa,' 'râpa,' 'fôopa,' 'clêpo,' 'fîpo.

1. Liquitur, et Zephyro parsit le gêba fêdor.
2. Liquinum, infamis fidic eteza praemia fîria.
3. Sumne materiae vestris, qui fêdostis agam.
4. Purpuræace necunì flores, et ñamne libant.
5. Is ñobatum, et illos ducere cendo hae lex jubet.
7. Cædonis et habert erata cepû meus.
8. Hæc tibi hrammi gaudentia frigere râpa.
10. Qui hé habent confilis; ubi data occatio eë, rape.

Note.—Cûpa, frâpa, and pûpa, are sometimes more properly espelled cupâa, rupâa, püpa; since this latter orthography designates their quantity, and is therefore more confident with their derivation from sucela. (French cuppe,) sîpes, &c. Cèpa and cêpo seem corrupted readings for cupo, which the more accurate editions substitute.

32. A vowel before final ga is long; as fiégâ.

So auriga, biga, quadriga, collâga, sâga, cygra, rûga, fangüîsaga, folîpûga, &c.

At Novis collega grado poit me ledeto uno.

Except 'calliga,' 'offîriga, 'töga,' and the 'derivatives of fugio, as fugâ, perfugâ, lucifuga, lucrîfuga.

1. Calâr
QUANTITY.

2. Adcepit aures, atque offlgeris, meretrigece, marium. Lucret. 7.
3. As nematiques, ficaga tua, mens quarta. Mart. 7.

33. A vowel before final go is long; as imago, origo, indigo.

So arugo, rugo, aurigo, fuligo, campago, carti
gago, condilgo, caligo, fugo, rigo, helperigo, sigo, sulfargo, &c.

Adjutate meus, primumque a origine mundi.

1. Except 'ego, 'fugo, 'harpago, ligo ('noun or verb'), 'rego, 'rigo, 'slio, 'rigo, 'tego.' 2. Allo 'congrego is short, from grex-gregis; and 'jugo, from jugum.

3. 'Lego-ere of the third conjugation shortens the penultimate; but 'leco- are of the third, lengthens it.

4. Except allo 'ago, and its 'compounds; as nego, navigo, litigo, mitigo, &c. It is to be observed, however, that when the 'compounds has been formed by fyncope or crafts, the penultimate, according to the rule for contracted syllables, becomes long; as fatigo, from fatum or affatin and ago; midago, from inde and ago; farrago, from farre and ago; vertigo, from vertendo and ago; caligo, from calatum and ago; dego, from de and ago, &c.

8. Sacerdes, id fusa; atque aquam hinc de proximo rogabo. Ovid. 6.

11. Inde ea comprehendunt inter se, cumque rigrantur. Lucret. 6.
15. Hec etiam 'eris pectorale mali fugit. Hor. 6.

34. A vowel before final 'gus, 'gum, or 'gus, is short; as palaugus, jugum, navium.

So alpargus, catalogus, confragus, naufragus, offfargus, dialogus, epilogus, ethologus, elegus, inci
gus, indignus, nocevagus, mages, rogus, the noun sagus or sagus; conjugium, elongium, fortlegium, naufragium, prodigium, diffugium, perfugium, horas
gium, remigium, sacrilegium, aquilegium, configium, &c.

2. Allo 'contagium, 'faltigium, 'suffragium, 'vef
gium.

3. And 'choragio, 'choragium from 'xogio, 'xogio

1. Tierye, tu tabulae recumbatur sub termini fti
gi. 7.
3. Anti bonum, 'frigis erit, as molles in umbri. Virg. 7.
4. Quid si me terra laboris nihil posse. Virg. 7.
5. Ipsa nolendo 'sagis chasoroner alien. Ist. 7.
7. Amagens; fed fumma fequar 'fugitione rerum. Lucret. 7.
37. Words ending in 'aris or 'are lengthen the penultimate; as alaris, altaire.

So agricolaris, peculiarius, naris, alvare, capillare, plantare, quaere, and many others.

1. Suspiens, patulis capavt narius auras.
2. Suspiit exigit letum plantaribus horit.

Except hiliaris, bimarius, cantharius, capprarius, mare, and dare.

1. Oderunt hillisem tristes, tristemque jecoci.
2. Aut Ephylum binatrie Corinthi.
3. Cantharium fuccos, dante parente, bibas.
5. Anto nare et tellus, et quod teget omnis celum.
6. See, for the versal increment in a.

38. Words ending in elis, elus, elas, elum, ofus, adus, ator, utor, lengthen the penultimate; as adulis, phaselus, fuadis, pruflus, fumodos, sudus, orat, utor.

So crudelis, carduelis, patruelis, candelis, loquela, querdla, corrupela, cicindela, cindelis, mutelia, ntelis, Philomela, parallellis, polymelus, aremosus, formosus, lucofus, perniofis, nusis, crudus, ludos, sudus, and many others.

1. Nuncum et fidulis cum potente facietas.
2. Et cervus velibus vehit runa phala phala.
3. Qualis populca marcas Philomela sub umbra.
 
4. & 5. Curvis phaselis formis dergi laelis.
6. Quis Nero tam sumava, cruditeque tyrannide fecit?
7. Hinc alta sub rupe camet jomador ad auris.
8. Nec feola fecit; utor tamen et fapiens. Quo?—Hor.

39. Words ending in nor, nor, or nor, lengthen the penultimate; as Octobor, salubor, papaver.

So fuber, tumer, uber, huber, puber, cadaver, &c.

1. Te taceo, Octiber femere dixit aoros.
2. Quaeque frequentur herbs et textiles abore campus.
3. Lillas purpureas milia papaveribus.

Except coluber and ruber.

1. Inque prumo colobor dilectum arvo.
2. Crines ruber, iner ore, brevis pede, lumina lasus.
3. Quo fugiit.

40. Adverbs in tim lengthen the penultimate; as oppidatim, virtim, tributum: except trematim.

1. Et velut abdentem certatim Alcirona clamant.
2. Nec spernat auris, nec tamen credat fretum.

Note.—Nofira Lexicon, Graduque ad Parnas. Penultimam adverbium, effimum, longa apice signant. Nec eo incipis in quoque degeneris Latinitatias eam producit. Vide tamum Lexicon Focillati, qui hanc observationem invenit, Aquilan poetam, quod divitiam eum depretit, Dominus l. 7. c. 7. 8. 9. 10. in Acropoph. v. 326. verum non est hoc falsis, ut conus philosophum uim productum fit.

41. Words ending in final quas are compounded with aquas, and therefore lengthen the penultimate; as antiquis, inquas, obliquas.

Terra antiqua, potens armis acque ubere globor.

Except relquias, which is not derived from aquas, and is therefore excepted.

Texitum reliquas telas palette ubi.

Note.—Though the real case of the penultimate of inquas, antiquis, &c. being long, is the contraction of the ae, of aquas, from which they are derived, itor, which is therefore long, according to the rule we have given for contractions; yet since the above may be a more obvious distinction than a late penult, we have not thought it improper to add it. And thus this remark is applicable to some other terminations and examples, noticed in this analysis, it is sufficient here, once for all, to give the general safter.

42. Words ending in pola, or polium, being derived from polis, lengthen the vowel before i; as bibliopola, cenopola.

So myropola, myropolum, propola, pharmacoepola, &c.

1. Sed qui me vendit Bibliopola putat.
2. Nam omnem plateas persequi, gymnasum et myropolum. Plaut.

43. Words ending in areo, arius, erium, orius, lengthen the antepenultimate; as paereo, cibarius, acrotetium, meposuros.

So areo, areo, cordaeus, sextarius, librarus, mercanearius, herbarius, capilltarius, dicetarium, ecclestetium, nicetetium, fexhretetium, adulatetium, cenforium, and many others.

1. Vm geminam funt, peregrek inscruta doctus.
2. In hanc dicit jam tuum fam mercanereos.
3. Omnibus arride, dicitelis dictis in omnes.
4. Queus cenforius cum meo fero.

1. Except aexo, varius, and nectareus, from neetar-aris.
2. Allo defidetrium, from defidetoro; magetetium, from magifetor; and minifetetium, from minifetor.
3. And the 7 derivatives of genitives increasing in short oris; as aequoeres, arboreus, calibreus, corporeus, eboreus, marmoreus, luscereus, roboreus, from aequororis, arbororis, caulororis, corpusoris, eburneis, marmoreis, luscereis, roboreis.
4. Except allo fome 3 derivatives from om (omieron), as aires, antibeuris, hypoboreus, from phaeos.

1. Scleiet et morbis et debilite cereba.
2. Et veters usus mediae extesunt artes.
3. Arthur niectedebum turbati mella felentum.—Hor.
4. Roma, domumque subit, defectioneque horatium.
5. Varum, id sicetum, ute, et magni etc. tetro.
6. Felis minifetetius mulcs, repergique labor.
7. Arborece frondes auto radiat eis cornes.
8. Vt probat patria per gentes ubi saco Boreis.

44. Words ending in aceus, aeous, aceus, eucus, eusus, lengthen the antepenultimate; as teftaceous, cæsus, subitaneus, ahénes, idoneus.

So arenaces, hederaces, Hordeæcæs, refinaecæs, cretaceus, arineus, conditaneus, rejeçtaneus, collectaneus, bipedaneus, and many others.

1. Herbus untius argilicetorum tera.
2. Pinnus et ingrate premactus catus urbi.
3. Nec nemulam noque, neque ararıis tenuis lina.
4. Si recte facies: hoc maris ahénes eto.
5. Opportnus ut est si fite et idoneus æter.

1. Except callaneus, from callanea.

Cajfetaceasque naeles, me quas Amaranis ambas.

45. Words ending in icius, ietium, or ius, shorten the antepenultimate; as patricius, xedifictium, xedilium.

Patricius omnes opibus eum provocet unus.

So gentlicius, tribunicius, adventitius, faticius, aufiplicium, judicium, artificium, arufiplicium, maleflium, beneficium, opificium, extifpicium, harruflcium, sacrifìcium, indicium, officium, paneuficium, and many others.

1. Except unovicius, or novitius; and those which come from long uipines; as eflifatius, from effluius, iri, ivi, itum.
2. Alto convicium, libicium, and nutricium, from nutrix-icis.

1. Jam fedit in ripa terraque novicibus horatet.
2. Neeve in me flolibus convicibus funere lingue.
3. Et presel domitare boues, et tifica teles.
4. Omnibus legatam mixta nutritia turba —

46. Words
So pluvitilis, plicatilis, definitudo, crematio, balbitio, and many others.

1. Calvarela pedes, nec habis aquatilus Aufer.  
2. Labirin occulit, fallique uatulatbus exus.  
4. Scletha hic sunt aedes, impia el hablatuito.  
5. Balbrito fur存ram, pravis fuulte mali tales.  

Hor.

 Except some ending in maticus, from neuters in ma-atis; as aromaticus, from aromaticus; rheumaticus, from pocu-vocatru; grammaticus, from γραμματικός; and hepaticus, from hepaticus.

Grammaticus ambris tribus; et pulita dignor.  

47. Abilis lengthens the antepenultimate; so does ibilis, when from long preterites in i vi; otherwise it shortens it, as amabilis; expetibilis, from expeto, ivi, itum; terribilis, from tercco, ët, itum.

Aeciupiam, nunclique meum l&ubie latum.  
Territo et innotare Cares; cui plurima mento—  
Ving.

1. Palaica parva regens, nulloque loquacibus eis.  
2. Omnibus transformat femt in ueracita rerum.  
3. Aut urum, aut pugiles; his nam peltatae gaulet.  
4. Quam ex hunc fustulato suntante mumer.  

Hor.

Hor.

Hor.

Larret.

Except *periculum, and *forme long by derivation; as lacidiculus, from haledé; redimiculum, from redimio, ivi, &c.; loricula, from loria; polliciculum, from politicul; nutricula, from nutrix-icis.

1. Sed tibi vexata per multa pericaula vitae.  
2. Et turice manious et habet redinicaula mitra.  

Prop.

49. Words ending in *acium, *ela, *fariam, lengthen the antepenultimate; as mendiacium, pittiacium, contumelia, multifarum.

1. Imperfecta pi a mendacium fraudat labem.  
2. Quod quam inquinantibus omni contumelia.  
3. Ut difpatriam chomau hic effaviam.  

Plaut.

Ovid.

50. Numerals ending in *ni, lengthen the penultimate; in *gindi, *ginta, *gits, and *gimus, the antepenultimate; as bini, seni, vecini, duceni, viginti, octoginta, nonagies, ocdogen, vigesimogen, mulctigenus.

So quino, qeponi, qeponi, noveni, undeni, duoden, tredeni, &c.; quadranginta, quinquaginta, &c.; quadragrasies, quinquagies, &c.; trigesimal, quadragesimus, &c.

1. Bis dina Inx io taxumus rebore nes.  
2. Vignits tuorum magnus horusculum centum.  
3. Tringita magnos volvendos mensibus erbes.  
4. Phocbus nonagies illicueci polam uramuram.  
5. Bis jam pene tibi confal trigesiogins infact.  

Mert.

Mert.

Ving.

51. Words ending in *ates, *ites, *otis, *ota, and *eta, lengthen the penultimate; as vates, vites, caroyitis, diota, meta.

So crites, penates, mitis, chalcitis, pleuritis, amplitatis, arthritis, capitis, mephitis, caryota, celritera, beta, creta, cofmetia, cometa, poeta, seta, &c.

1. Calvolea, clari quiu suo podate penates.  
2. Contuderio utes, cleamie monomerit asias.  
3. Et metis caroabdios theatris—  
4. O Tbalarche mirum dulio.  
5. Quantum abente faci? cretile an carbole notandi? —  

Hor.

Hor.

Hor.

Plaut.

Hippere.

52. Last; the following final syllables lengthen the preceding vowel, *nur, *cul, *gal, *nal, and *tal; as laclinar, pulvinar, cervical, vetitgal, Bacchali, minital, and some others.

1. Med residiem in domo lacunari.  
2. Tinge esputum pasti, cervicis del.  
4. Bacchanal te exercuisse, quem qui fais, alium rogites?  
5. Heftenum festitus medio ferevem minitiat.  

Hor.

Hor.

Hor.

Plaut.

Juven.

53. Alfo, whatever terminations are naturally derivable from any of the preceding final syllables, lengthen or shorten, according to their primitive termination, their penultimate, or antepenultimate syllable; as masculines ending in *arius, may form feminines in *auris, and neuters in *aurum; fo *arious, *aurium; etc., as arerius, belonging to copper or brass; araria, a copper mine; arerimus, a treasury; hence rosarium, pomarium, muscarium, meridarium, quercetum, rosatum, palmatum, &c.,

Note.—1. And it should be recollected, that since compounds and derivatives follow the quantity of their primitives, the compounds and derivatives of such words as form exceptions to any of these rules, will follow the general rule for the quantity of derivative words.

2. And it may be here necessary, finally, to remind the young prodigio of the same rule, since the quantity of many words is explicable solely by this law, and requires no other direction; as additius from *abditis, abnegans from alienus; contradictio from contrari; aliquastus from aliquis, &c. Hence adjectives ending in *ex-*exes form derivatives in *axis, *acicu; as capax-acis, capaxica, capaxica, audax-icis, audaxia; in the same manner genitives increasing shorter, shorten the corresponding vowel of the derivative; as carrilago-icus, carrilagineus, carrilagineus.

Thus preterites and future forms their penultimate long, lengthen accordingly the derivative vowel; as donito from dormio-ivium; conditio, constitutio from condi-tum-ivium; fo condito, conditus, conditor from condom-i-ditium: hence aririo, aririor, auditio, definition, are from rhodo-ri-ri-rum, &c. Thus words ending in *ius may form derivatives in *iatis, *iabitas, *iiber, *iitias, *ilius, *ilius; hence redialis, equilialis, carialis, carialis, arine from the primitive termination *alia; and thus nouns in *aio have their derivatives in *aistitia as *aistificicio, *aiisticinius, &c.

54. I * before or * after r, is long; as *ari, fricinum.

1. Ira furos brevis est. Animam rege, qui nifi parat— Hor.  
2. Mixtare *idaei coloribus fandare seclant.  

Ving.

2. Alfo, *i followed by *r is short; as frico, Africu, fabrico, lubrico, curricula; yet *ibricius, *rbica, *trica, and its derivative *extrico, and *ti-rica, follow the general rule.

3. And *i followed by a vowel, is short by the rule "a vowel before another," &c. as penuria.

QUANTITY.

Note.—The above verses not only furnish the words relating to rule 62, but also, to unite two objects in one, they at the same time afford a specimen of the Horatian metre, which, to the critical student, may prove a useful compendium. It is, probably, only the second production of the kind in print. The first is quoted by the two editors of Horace, Cramer and Baxter, and, if its fulness had been as ample as its design, the reprint would have been superseded. For a definition of the Horatian metres composing this specimen, the reader may consult Lane’s Latin Primer, (edit. 4th) page 216, or VERSIONIFICATION, in the sequel of this work. The following, however, are the Horatian metres, as exemplified in the above lines:—1. An Adonic. 2. A dactylic prothomimer. 3. A Pherecatan tripod. 4. A Glyconic choricor. 5. Dactylic tetrameter. 6. An hexameter; 7. Labicus dimetro acrophalus; 8. Labicus dimeter; 9. Labicus hypertrachelic; 10. Labicus tristipestic; 11. Labicus trimeter; 12. An anarhyd; 13. A Saphic hendecasyllable; 14. A great Alcaic; 15. A small Alcaic; 16. Alcaic choricor; 17. Chorographie dimeter; 18. Epichorhabtic tetrameter; 19. Ionicus minori trimeter; 20. Saphic ionic; 21. Ionicus minor tetrameter; 22. Dactylic heptameter; 23. 2nd elegiac Archilochian; 24. 2nd elegiac Archilochian. The remaining lines alluded to by rule 62, are comprised by the following hexameters:

Note.—1. To confine the preceding rules to limits as short as possible, till, the preceding rules and their exceptions relate only to words of pure or Augustan Latin. 2. Some terms of very rare occurrence, chiefly the names of plants, herbs, fishes, &c., near 300 in number, are omitted, as matters of occasional reference, rather than of constant attention or grammatical rule.

2. We have now, after four consecutive analyses of the language, for the more complete information of the student, accomplished a task, perhaps never achieved before, nor, so far as we are acquainted, offered to the public, in any professed system. And we can vouch for the accuracy of the rules of this section, that any person well acquainted with common prudery, and the rules of the preceding, will not, within the precincts of Augustan Latin, find a single word, except the few of rare and infrequent occurrence mentioned above, whose quantity is not regulated or accounted for by the rules now given. Thus, for the first time, we have succeeded in determining the majority of Latin quantity, by all preceding prodians referred to a course of observation and practice alone, to a regular classification and system. Would our limits permit, we would here, for the sake of exemplification, take the words composed by any letter of the alphabet, and account for the quantity of each by the principles and criteria we have here considered.

3. It is almost necessary here to add, that the quantities of syllables are marked with very frequent inaccuracy in most of our common dictionaries. The poets are the only satisfactory test.

SECTION III.—On final Syllables.

1. A final, in words declined by caes, is short; as fama, regna, lampada. Anchors de prorsus: final litorei puppae. Virg.

1. Except the ablativ singular of the first declension; as hac mufa, hoc Amie.

2. The vocative singular from Greek nouns in -a; as O Pallia, O Athia.

1. Prospicio, famam plicam caput extulit ustris. Virg.

2. A final, in words not declined by caes, is long; as amn, ultra, praetera.

1. Litus ad and levand artingu sine palmata caetera. Virg.

2. Interma magna miferi murmure postare. Virg.

1. Except ita and eia short, and pollea common.

2. Quia is generally short, but since Phedrus lengthens it, we may pronounce it to be common.

3. Some prodigions quote puta, with the short a, from Periuss, 4. 9. But the best editions have puto, a reading evidently preferable, in point both of sense and grammar.

4. Though numerals in ginta are sometimes found short, approved authors lengthen the a; yet it may be well to recollect, that the Greek termination KONTA, whence the Latin ginta is evidently borrowed, has the final vowel short; as

The à óm àm mander KONTA miimus, miimus. 
[See many other instances in this B.]
2. Tum ac aeger regem, atque ita turbibus inhev. Virg.
5. Si sufficiat, quid quid divinitus ilia. Virg.
QUANTITY.

1. Except the i of Greek vocatives; as Alexi, Amaryllis, Thetis, Parth, Daphnis; but Simoni, or such as belong to nouns having enio in the genitive, are long.

2. Greek datives singular of the third declension, from nouns increasing, are varied. Minodit and Sethy in Catullus, and Palladi in Statius, are short. Theseit in Catullus, and Paridi and Tyndaridi in Propertius, are long; but Greek datives formed by contraction are always long; as Demotheni, metamorphosi; also thos which come from the first declension in Greek; as Orfei, Euripidi.

3. Neuters in i are also short; as gymnii, meli, finapi.

4. Datives and ablatives plural of Greek nouns in i (in a before a vowel) are short; as herois, Troasi.

5. Mihii, tibi, fibi are common. Alfo ibi, nifi, ubi and qua; but these last are more frequently short.

*Note.—These may be long by poetic licence, or by position: for the i of Greek cats is naturally short. Orphé may be considered as a dactyl in Virgil, ed. 4. 57; and by synæresis it is a pænus in the Georgics, 4. 353 and 353.

6. U final is long; as vultu, cornu, Panth, dièthi, diù.

5. O final is common; as quando, Cato, leo, ambo, oculo, amo, doceto.

1. Arma aemus rapitis, nec fat rationes in arma. Virg.

2. Non ambe te, Clidi; nec prom prom ducere quae. Mart.

1. Except i monosyllables, which are long; as o, pró, dò, fò, and pró, b not being accounted a letter.

2. 'Greek feminines ending in o are long; as Didè, Sappho, Clis.

3. O final in ' datives and ablatives of the second declension, is long; as fonnò, to which add another ablative, as ergò, for the sake of, ergò therefore belonging to the rule.

4. Alfo ' Greek caes, written in the original with omega; as Androgoo, Atho.

5. 'Adverbs formed from nouns have the final o long; as lubito, merito, multo; and illò, quò, có, and their compounds. Alto citò, inìro, retrò, utro. But the following are sometimes found short, denoò, idecò, fero, profècto, 'poltremo, the conjunction 'verò, 'porro, to which some add fedulo, crebro, and mutuo. 'Modo (ufed adverbially,) and its compounds are short; as quomodo, dummodo, pòlmodo.

6. Though the final o of verbs, occasionally by writers of a secondary clas, and more rarely by those of the Augustan age, has been made sometimes short, yet its derivation from the Greek omega, and the more general practice of the principal poets, make it long; the o of ficio, aecicio, puto, cito, and of the imperative cedo, only, are generally short.

7. The gerund in do, in reality, being nothing else than the dative or ablative of the second declension, is, accordingly, by all authors of the Augustan age, made long: the exceptions to this rule are very few, and only by writers of an inferior clas.

8. 'Ambo, duo, imo, illico, ego, generally shorten o final.

1. Péri moli viola, pre purpureo nacido. Virg.

5. Uque, aleœne times, quem tu facis ino tempus? Ovid.

15. Dicerò quò id ino, focietes, hoc mihi pertus. Ovid.

16. Sc ubi ubi quis Lyca co gente vicinam. Hor.

17. Quò noti, modibus velis modiciter menti. Hor.

18. Plautus diò nec tutti mihi valle repeti. Hor.

1. Indò
QUANTITY.

1. Indú manu validís potus est moderanter habéns. 
Laur. 

2. Nóns quum ubi contra conflabre leones. 
Laur. 

Enn. 

7. Y final is short; as Molý, Típý, Chelý, Tethý. 
Molý vocant superí.

Except when y is a contraction, as in Tethý, instead of Tethý, the dative, it is long by the general rule for cæsí.

Quam Tethý longinqua dies, Glanuco repétánum. 
Val. Flac. 

8. Latin words ending in B short the preceding vowel; foreign words lengthen it, as āb, ob, Jób, Jacob. 
Magna ēd integro fecííorum náctíor órda. 
Virg. 

9. Final C lengthens the preceding vowel; as ēc, sic, hic, (adverb), dúe, illúc, &c.
Sic cóllus, sic ille manu, sic ora ferébat.
Virg. 

1. Except that nec and donec are short, as also the imperative fac. 

2. Hic and hoc of the nominative and accussive, are common.

* Two passages quoted from incorrect copies of Ovid, to prove fac long. in better editions appear jucundus and factus; so that, according to the opinion of Alvarez, it is safer to consider fac as short.

1. Parē, ré, invédeo, fine me, liber itis in urbem. 
Virg. 

2. Dúce eris félio, mātus numerábilis animó. 
Ovid. 

3. Sigüa rarius, aut fémel fác illud. 
Mart. 

4. Híc vie, híc oll, tibi quem promití fœtus audís. 
Virg. 

5. Híc gládio fidés, híc acer et ardubus habít.
Virg. 

10. Final D in Latin words, shortens the preceding vowel; in foreign words it lengthens it; as quíd, ad, apud, illud, séd, David. 

Ipse decet quid agam. Fas est et ēb hoste doceri. 
Ovid. 

11. Final L shortens the preceding vowel; as mel, fel, pol, simul, femel, nihil, consúl.

Innócui venient: procil hinc, procil impius ello. 
Ovid. 

1. Except that Hebrew words are generally long; as Daniel, Nabíl, Saul. 

2. Sél, fél, and nihil, are long. 

1. Non sál, eoxperum cepheve. 
Stat. 

2. Omnia sub pedibus, quá sál unrumque recurrent. 
Virg. 

Claud. 

12. Final M was, anciently, short, and was not, as now, elided when followed by a vowel. 

Inignitas féré tum milliá miltimís oás. 
Enn. 

It is short in circínēm, in composition with words beginning with a vowel, as ‘circuméno, ‘circunago. 

1. Cuhus non hederae circunérère caput. 
Propert. 

2. Quo ce circunágus? quae aut utrimum posu? 
Juven. 

15. Final N lengthens the preceding vowel; as cá, plén, quin, nón, sín, ren, Pán, Salamín, Orión, Titán. 

Mérit et aderentés Orinon surrías. 
Manil. 

1. Except nouns ending in -en, which have inis, short, in the genitive; as carmén-inis, teqmín-inis. 

2. Allo nouns in -en of the singular number, from the Greek ο (omicron), and which, in Latin, are of the second declension; as Ilión, Pylon. 

3. N is short in the accusatives of Greek nouns, having the final syllable of their nominative short; as Majaín, Eginán, Orpéon, Alexín, Ibín, Chelýn, Itýn. 

Vol. XXIX. 

4. Allo ān, in, forbán, fortún, tamén, attamén, veruntamén, vidém, fatín, have a short. 

1. Addunt et titulam; tituló brevem carmn habebat. 
Ovid. 

2. Lácabunt alií clarum Robídon, at Múylen. 
Herc. 

3. Fanlque nos animó eí, libis hac æcstas, dixit. 
Ovid. 

4. Múttis; forsás et hæc òlim meminisse jussa. 
Virg. 

5. Forbátan et, Priami forunt quisque fatitas, requirás. 
Virg. 

Virg. 

14. Final R shortens the preceding vowel; as vís, puer, tís, timóre, cáler, Hámillar, annuamur, audíntur. 

Tum pár omnipotents millo perfregit Olympum. 
Ovid. 

1. Except 1 Greek nouns, and 1 such as have ēris, long, in the genitive; as cratér, flátér, vér, Recímer, 1 Iber-éris; but 2 Célíiber, the compound of Iber, has the penultimate common.

2. Allo ār and æther, though they increase short in the genitive. 

And 1 ār, 1 lár, 1 nár, 1 cůr, 1 fur, and 1 pár, with its 12 compounds, compár, impár, dispár.

1. Crátei aurâs forgit cælios ab alta. 
Manil. 

2. Fér erat aeternum, plácidique tepemís auris. 
Ovid. 

3. Si tibi durus Hér, aut ti tibi terrá decipí. 
Lucan. 

Catul. 

5. Ducit ad foras quod me fállo Célíórrn orás. 
Mart. 

6. Inde marc, inde áér, inde adhíc ígitur ãpte. 
Lucrèt. 

7. Fúr erat, et púri lucida nigia folis. 
Ovid. 

Ovid. 

Ovid. 

10. Nusta quidem dixi, eír executus abíren. 
Hor. 

11. Callidus eíftaíx normos fúr autercr utr. 
Hor. 

12. Ludere pír, tugurí, equivate in aroundo lundí. 

Note.—Cor long is attributed to Ovid, but the line in which it is said to be thus found, is read differently in corrected editions; the same remark is applicable to wís; as 

1. Móle meum leviufque eír eft violábilis telís. 
Ovid. 

2. De gréce nunc tibi vís, nunc de gréce nunc hábendís. 
Ovid. 

Thus corrected, wís is long merely by position.

15. Words ending in AS, lengthen the final syllable; as mís, vís, crás, fás, amás, farás, pietás, Thomás, Mufá. 

Híis autem terrís, Italique hancurrió oris. 
Virg. 

1. Greek nouns in as are short, which make the genitive in, ados or adís, as Arcas, Pallas, Lampas, Íllas; to which add the noun Anás, and Latin nouns in as, formed after the manner of Greek patronymics; as Appás.

2. Allo the final as of Greek accusatives plural of the third declension is short; as cráteras, lampadás, Trósás, Cyclopás, héroás, heroídás, Hекторás, &c.

Ovid. 

2. Et pliás amós enovata pennis. 
Petron. 

3. Aýpás exséfis óra pulsát aquis. 
Ovid. 

4. Návibus his venam, que nuncquam arefcrete pollet—- 
Ovid. 

16. Words ending in ES lengthen that syllable; as rís, spés, vulpés, qués, herés, eísés, Anchiés, totíés, locúples. 

Vulpés alaeam dictae chiroinum. 
Phaedr. 

1. 'The nouns and vocatives plural of Greek nouns increasing (not in all) short in the singular, are short; as Amazónes, Arcádes, Delphínés, Náiadés, Gryphés, Phrygés. 

2. To which may be added Greek vocatives singular in as, coming from nominatives in es, not formed from ies of the Doric dialect, and having their genitive in en; as demoíthenés, Socratés. 

Dd 3. En.
QUANTITY.

3. * Exe, in the present tense of *cum, and its compounds, is short; as ades, abes, prodes, potes, &c.; and in the preposition penes.

4. - Latin nouns of the third declension, in *es, increasing short in the genitive, are short in the final syllable; as hebês, aedes, pedes, hemês, obsês. * But *es is long in these following: Cerês, paries, aries, abies, pês, and its * compounds, as bipes, tripes, alpês, sini- pês; to which form add *areti, a derivative of *arepet.

1. Tramès; et patrie famamia tecta reliquum.
2. Quicquês, fr. affinis sine jam omnino Graia.
4. Vivitur ex rapto; non 4066s ab hopite tuteus.
5. Flava Cerês aetépeque spectat Olympo.
6. Creditor: ipse aries etiam non velles fecétor.
7. Dictor Auga rotor pês immutéat areti.

*Note.* - 1. Th 20 *es, in the present tense of *cum and its compounds is short; it is not in any other tense, nor in the final syllable of *effec, (as has been asserted), as

*Psiss in tanto vivere flagilis?
Effes luni tecta pellas maris.
Propret. Propret.

2. Whenever parus, aries, and ahes are found long, there happens to be a sub固定; and, perhaps Ceres and pes are long by dint of: Au- sions shortens bipes and tripes; and Popons observes that alpês and sines are likewise short; though the contrary appears in Virgil, Lucan, and Horace, yet some of the above-mentioned words could not be introduced into heroic verse with the influence of a figure to lengthen their final syllable. *Proper*, which comes not from pes, but from *pereas*, is short in Virgil. (Aen. 5. 254.) Tigres, ascribed to Ovid, is, by the bell critics, rejected.

17. IF final is short; as bis, is, quis, cis, magis, turris, militis, creditis, Thelas.

Tum bis id occultam, bis, fe convertit ad orutam. Ovid.

1. Except plural *cases in *is; as nobis, vocis, ("quis for quibus") musis; the plural * accustivis *omnis, *ubis, &c.

2. The nominative in *es is long, when the genitive ends in *itz, inis, or *init long; as lis, Samias, Salamis, Simois.

3. Is is long in the adverbs *gratis and foris; in the noun *glis, and in *is, whether noun or *verb.

4. Alit second *persons singular in *is are long; when the second *persons plural have *itis long; as *cis, *isi, *abes, *aides, *velis, *nolis, *posis, &c.

5. *Ris of the perfect is commonly shared short, of the *future, common; fo are the penultimates of *aesus and *axis; ris and *ritis of *zero and potero are more frequently short.

1. Inducenda rota est: das nolês ulle manus
2. Ouid ante parum Trojan sub manus altis.
3. Non omnis arbuit juvant, numineque mirace.
4. Add tot exse notis, ex speculique lucem.
5. Sed dix erit dii de tribus capitilis.
7. Ignea convexa ris et sine pondere celli.
8. Si ris effe dijquis. Probatis laudatur et alget.
9. Gratias inhakans, multa agens, nol est agens.
10. Dixeris egregie aetatis et culuis verum.
11. Quas gentes fustum, non qua non araeus arbus.
12. Da mihi te placidum; delebas in carmine vivis.
13. Est romanes, tu nunc ris alter abillo.

18. *OS final is long; as rós, vos, nós, mós, fós, trós, arbós, honós, cultus, nepós.

Or hominis sublimé dedas, eunomique tuert.

1. Except Greek *genitives in *es; as Arcadós, Téthys, Tereós, Orphés.

2. Alit *compós, impós, and *és-offis, with its compounds *esós have the final *yllable short.

3. *Greek nominatives and vocatives of the second declension have *es short; as Clarós, Tenedós, Letbós, Atropós. But those nouns of the *Attic dialect, having their genitives in omega, are long, as Androgóes, Atlós: also *es-offis of the *former dialect, which have changed *bádis (2a54s) into *les (2a54s), as Penelesó, Mel- nés.

4. Greek *neuters in *es are short; as Argós, epós, chaús, melos.

2. Inque re, et voix postmodus compós crís. Ovid.
3. Exidos est esqueuis umbos purpurae oris. Lucræ.
4. Dum, cum tritus est, defens eis hostis arma. Ovid.
5. Quadrum Atlós, aut quarto Eryx, aut ipse carúrus. Virg.

19. Last final is short; as terés, litiit, penitit, intus, Ambobus, Montibus, Amantus.

Inipsa: potentes servabant Tithérus Æceos.

Virg.

1. Except *monosyllables in *is; as grús, plús, rús, thús, jús.

2. Alit the *genitives of feminine nouns in *es as Clías, Sappliús, Mantús.

3. *Genitives singular, and nominatives, accusatives, and vocatives plural of the fourth declension, (all being contracted,) have *is long; as frúsctis, manus.

4. *Alit nouns increasing long in the genitive; as palús-tidís, virtús-úris, tellús-úris, Opís-úntis.

5. *Us is long in the * compounds of *au1 (denoting the genitive in podis or podos), as Tripús, Melampús, Cedipús, Polypús.

6. *Alit *those nouns which have *au in their voca- tives; as Panthús, O Panthu.

7. Finally, *a1 (t子公司) has the final *yllable long.

2. Dolés atque sum miserrimi fanguine fanguine. Varo.
7. Et cælo et terris ventrando nomine Jofis.

20. *YS final is short; as Capys, clefys, chlamys.

At Capys, et quantum mellor contentus ventur. Virg.

Except *nouns which form the nominative in *au alio; as Gortyís, Phoréys. To these add contracted *pluralis; as Erymmys, for Erinýys, or Erinmyás.

21. Final *shortens the preceding *vocalis; as *capy, *amyt.

Veram hæc cantum alias aliter; capyt est uterque urbé. Séneca.

1. Quamcumque in *is is long by *craftis; as *redit for *redit or *reditiv.

22. The *yllable of every *veris is considered common; that is, if the *yllable be naturally long, it may be accounted short; or, if it suit the *veris, *vice verée.

Gens inimica mihi Tyrhœnum navigat asquar. Virg.

1. In the *is of these *examples, *is, naturally short, forms the *yllable of a *speaker; in the *is, a *Sapphic *veris, the word *aué, which is naturally a *sponde, forms a *trochee.

2. "The grammarians that displease Dr. Clarke, (see Clarke's Homer, libid A. v. 34,) by saying that the *yllable of a *ver is common, only mean, that the *local quantity superides the natural quantity of the *yllable."

For the last principal head of *prosody; see *Versification.

QUAN-TSOM, in Geography, a town of China, of the third rank, in Pe-tche-li; 32 miles *of Chunte.
QUANTUM Meruit, called also an _assumpfit_, in Law, an action upon the cafe, grounded upon a necessity to pay a
sum for doing any thing so much as it deserves or merits.

This valuation of his trouble is submitted to the deter-
mation of a jury; who will affe6 such a sum in damages as
they think he really merited.

Quantum Solvabat, or an implied _assumpfit_, is where
goods and wares fold, are delivered by a tradesman at no
certain price, or to be paid for them as much as they are
worth in general; then _quantum solvabat_, or an action on
the cafe, lies, and the plaintiff is to aver them to be worth so
much; so where the law obliges one to furnish another with
goods or provisions, as an inn-keeper his guests, &c.

QUANTZ, John Joachim, in _Biography_, chamber
musician to Frederic II. king of Prufia, to whom he had
been flute-master before his accession to the crown. Quantz
was born at Oberfecheden, a village in the electorate of
Hanover, in 1697. His father, who was a blacksmith,
obliged him to work at the anvils before he was nine years
old; which must have afforded him an early opportunity of
making the famous Pythagorean experiment, mentioned by
Jamblischus (De Vit. Pythag.), and by all the musical writers
of antiquity. Indeed, the ear of our young Arelus had been
already formed, in his exercitons with his brother, a
village musician, who used to play about the country on
holydays and festivals, whom he accompanied upon these
canesions, on the bafe-viol, when but eight years old, and
without knowing a note of music; but this performance,
bad as it was, pleased him so much, that he determined to
chose music for his profession; though his father, who died
when he was only ten years of age, recommended to him,
on his death-bed, to continue in the honourable profession
of his ancestors.

Quantz, after losing his father, had no other friends to
 depend upon for counsel and protection, than two uncles,
who lived at Merfburg in Saxony; and these, finding for
him, gave him the choice of their several professions, the
one being a tailor, and the other a kunftpfeifer, or town-wait.

Upon this occasion, the passion for music in the young
Quantz overpowered all other considerations, and, prefer-
ing the fiddle-stick to the anvils or shears, he bound himself
apprentice to his uncle, the musician, for five years; but
this unclc dying three months after, he was transferred to
his son-in-law, Fleichhacker, who was of the fame profession;
and was under him that he first practifed the violin, an
instrument to which his inclination at this time impelled him,
preferably to any other.

Soon after this, however, he practifed the hautbois, and
the trumpet, with which instruments, and the violin, he
chiefly filled up the term of his apprenticeship; but as a
ttrue town musician, in Germany, is expected to play upon
all kinds of instruments, he had been obliged, occasionally,
to apply himself, during this period, to the fackbut, cornet,
base-viol, French horn, common flute, bagfioon, voif da
gamba, and the lord knows how many more. These were
in the way of bufinefs, but for pleasure, he now and then
and took leifons on the harfpcord, of the organif Kiefewetter,
who was likewise his relation; by which he laid the first foun-
dation of his knowledge in harmony, and love for composition.

Luckily for Quantz, his master, Fleichhacker, was not,
like other country musicians, fond only of old, dry, stiff,
and tallowy compositions, but had sufficient discernment to
chose his pieces out of the newest and best productions of
the times, by Telemann, Melchoir, Hofmann, and Heine-
chen, which were published at Leipzig; from the perufal,
and practice of which, our young performer derived great
advantage.

The duke of Merfburg's band not being very numerous,
the town-waits, at this time, were often called in, to affit
at the musical performances, both of court and chapel.
Here Quantz frequently heard foreigners play and sing, in
a manner far superior to any professors whom he had hitherto
met with, which excited in him a flrong desire to travel.
Drefden and Berlin were at this time the most renowned
cities in Germany, for the cultivation of music, and the
number of able musicians. He eagerly wished to visit one
of those cities, but was delibed of the means. However,
he now began to feel his strength, and trusting to his feet
and his fiddle, he boldly set off for Drefden.

It was in the year 1714 that he arrived in that city. His
first entrance was not auspicious; being wholly unable to
procure employment; on this account, he made an excursion
to Radeburg, where a journeyman fiddler being wanting, he
entered into the service of the town musician, Knoll; but
alas! he was soon driven from this port, by the fatal acci-
dent of the town being burnt down by lightning. Again
reduced to the state of a fugitive, and a wanderer, he levied
contributions round the country by the power of his violin,
which was now his principal instrument, till he reached
Pirna.

Here, defined till to be ferous ferverum, he could pro-
cure no other means of exercising his profession, than by ac-
cepting the office of deputy to a fick journeyman musician
of the town. It was during this time, that he first saw
Vivaldi's concertos for the violin, which were so congenial
to his own feelings and ideas of perfection, that he made
them his model as long as he continued to practise that in-
strument.

Still regarding Drefden as his centre, he eagerly accepted
an offer that was made to him, of being temporary affistant
there, to one of the town-waits, who was then ill; an em-
ployment which he preferred, for the opportunities it af-
forded him of hearing good music and good musicians, to
the more honourable post of being the best of bad musicians
at Berenburg, where he might have been appointed first
violin, with a good salary.

His second arrival at Drefden was in the year 1716,
where he soon discovered that it was not sufficient for a
musician to be able to execute the mere notes which a com-
poser had fet on paper; and it was now that he first began
to be sensible of the existence of taste and expression.

Augustus II. was at this time king of Poland, and
elector of Saxony, and the orchestra of this prince at Dref-
den was in a flourishing condition; however, the style which
had been introduced there, by the concert-master Volumer,
was French; but Pfendel, who succeeded him, introduced
a mixed taste, partly French, and partly Italian, which he
afterwards brought to such perfection, that Quantz declares,
he never heard a better band in all his future travels.

No orchestra in Europe could now boast of so many able
professors, as that of the elector of Saxony, among whom,
were Pfendel and Verdeinini, on the violin; Pantaleone He-
bentreit, on the pantalone; Weiffs, on the lute; Richter,
the hautbois; and Buffardin, on the German flute; not
to mention several excellent performers on the violoncello,
bagfioon, French horn, and double-bafe.

Upon hearing these great performers, Quantz was filled
with fuch wonder, and polelfed of fuch a rage for improve-
ment, that he laboured incessantly to render himself worthy
of a place among fuch honourable associates.

For, however prejudiced he may have been in favour of
his own reputable calling of kunftpfeifer, he began now juft
to think it poifible for him to be prevailed upon, to relin-
quift that part of it, at leaft, which required him to play

D d 2
country dances, though in itself so jovial, plesant, and feftal
an employment.

He continued, however, to be the künstpfeifer’s deleg-ate
in this city, till the death of Augustus II.’s mother,
in 1717, at which time, the general mourning procrisbing
the use of every species of convivial music, he again, in his
usual manner, commenced traveller, and fiddled his way
through Silia, Moravia, and Austria, to Vienna; and in
the month of October, of the same year, returned through
Prague to Dresden; which journey, he thinks, contributed
more to his knowledge, in practical geography, than in any
other art.

The jubilee of the reformation, brought about by Dr.
Luther, happening to be celebrated soon after his return,
he was called upon, among others, to perform a part upon
the trumpet, at church, where the chapel-maister Schmidt
having heard him, offered to prevail on the king to have him
regularly taught that instrument, in order to qualify him
for the place of court trumpeter; but Quantz, however
ardently he might have wished for an office at court, de-
cided the acceptance of this, well knowing that the good
tale to which he aspired, was not to be learned upon that
instrument, at least as it was then played in Dresden.

In 1716, the Polish or royal chapel was instituted; it was
to consist of twelve performers, eleven were already chosen,
and a hautbois player, only, was now wanting, to complete
the number. After undergoing the several trials, and giving
the requisite proofs of his abilities, he had the happiness
to be invited with that employment, by the director, baron
Seyfried, with a salary of 150 dollars, and a lodging.

This was an important period in his life, and in the exer-
cise of his profession. The violino, which had hitherto been
his principal instrument, was now laid aside for the hautbois,
upon which, however, he was prevented from distinguishing
himself, by the seniority of his brethren. Mortified at this
circumstance, he applied himself seriously to the German
flute, upon which he had formerly made some progress with-
out a master; but his motive now for refuming it, was the
certainty of his having no rivals in the king’s band, as
M. Price, the first flute, had no great passion for music,
and readily relinquished to him his place.

In order to work upon sure ground, Quantz took lessons
at this time of the famous Buffardin, with whom, however,
he only played quick movements; in which this celebrated
flute-player chiefly excelled. The scarcity of pieces, com-
posed expressly for the German flute, was such, at this
period, that the performers upon that instrument were
obliged to adopt those of the hautbois, or violin, and by alter-
ing or transposing, accommodate them to their purpose, as
well as they could.

This stimulated Quantz to compose for himself; he had
not as yet ever received any regular instructions in counter-
point, so that, after he had committed his thoughts to paper,
he was obliged to have recourse to others to correct them.
Schmidt, the chapel-maister, had promised to teach him
composition, but delayed keeping his word from time to
time, and Quantz was afraid of applying to Heinichen, his
colleague, for fear of offending Schmidt, as these maisters
were upon bad terms together. In the mean time, for want
of other assistance, he diligently studied the scores of great
maisters, and without feeling from them, endeavoured to
imitate their manner of putting parts together, in trios, and
concertos.

About this time he had the good fortune to commence a
friendship with Pifendel, now appointed concert-maister, in
the room of Volumier. Quantz is very warm in his praises
of Pifendel, whom he calls a profound theorist, a great per-
former, and a truly honest man. It was from this worthy
concert-maister that he learned to perform an adagio, and to
compose in many parts. Pifendel had in his youth been
taught to sing by the famous Piffacchi, and had received
instructions, on the violin, from Torelli; however, having
travelled through France and Italy, where he had acquired
the peculiarities in the taste of both countries, he so blended
them together as to form a third genus, or mixed style of
writing and playing, which was half French and half Italian.
Influenced by his example, Quantz declares, that he always
preferred this compound style, to that of Italy, France, or
the national style of his own country.

At the marriage of the prince royal of Poland, in 1719,
several Italian operas were performed at Dresden. Lotti,
the famous Venetian maestro di capella, together with the
most celebrated fingers of Italy, male and female, were
engaged thither upon this occasion; there were the first Italian
operas which Quantz had heard, and he confesses, that the
performance of them gave him a very favourable idea of the
genuine and found Italian music, from which he thinks later
times have too much deviated.

After describing the talents of the fingers who will have
their place in our alphabet, he informs us that this famous
opera at Dresden, was broken up by a quarrel between
Henichen, the king of Poland’s chapel-maister, and Sene-
dino, who this same year, 1719, went to England for the
first time.

Nothing very interesting occurs in the life of Quantz
from this period, till 1723, when he took a journey with
Weils, the famous lutentia, and Graun, the composer, to
Prague.

Quantz, not long after the coronation of Charles VI. at
Prague, went to Italy in the suite of count Lagnafco, with
the consent of his royal master, the king of Poland. He
left Dresden in May 1724, and, when he arrived at Rome,
he found that Vivolli had just introduced the Lombard Ryle
in that city, with which the citizens were so captivated, that
they would hear no other.

During his residence at Rome, he took lessons in com-
position of the famous Gasparini, who was at that time seventy-
two years of age; and after studying counterpoint with him,
which he calls music for the eye, he went to work for
the ear, and composed foles, ducts, trios, and concertos;
however, he confesses, that counterpoint had its use in
writing pieces of many parts; though he was obliged to
learn many things, in practice, which theory had taught him,
in order to avoid that dry, and stiff Ryle, which too close an
adherence to rules is apt to produce; upon this occasion,
he very judiciously observes, that invention is the first
require in a composer, and that it behoves him to pre-
serve a friendship between harmony and melody.

In 1725 he went to Naples, where he met with his
countryman Haffe, who then studied under Ale. Scarlatti.
Haffe had not, as yet, distinguished himself by any com-
positions for the flage; however, it was at this time, that a
considerable Neapolitan banker employed him to set a fere-
nata for two voices, which he did in the presence of Quantz;
the singers who performed in it, were Farinelli and Teif.
Haffe gained so much reputation by this production, that
it paved the way to his future success, and he was soon after
appointed composer of the great opera at the theatre royal.

Quantz intreated Haffe to introduce him to his maister,
Scarlatti, to which he readily consented; but upon men-
tioning him to the old composer, he said, "my son, you
know I hate wind instruments, they are never in tune." How-
er, Haffe did not cease importuning him, till he had
obtained the permission he required.
In the visit which he made to Scarlatti, M. Quantz says, that he had an opportunity of hearing him play on the harpsichord, which he did in a very learned manner; but observes, that his abilities on that instrument were not equal to those of his son.

Before his departure from Naples, M. Quantz frequently heard concerts at the duke of Lichtenstein’s, in which Halévy, Farinelli, Tevi, and Francheschello, were employed.

In 1726 he was at Venice, during the performance of two rival operas, “Sisace” compiled by Porpora, and “Siroe,” by Vincen; the latter was most applauded. The Cav. Nicolini, a contralto, La Romanina, a deep soprano, and the famous tenor, Pa’aita, were the principal singers in these dramas.

San Martini, the celebrated performer on the hautbois, who afterwards established himself in London, was now at Venice, as was Vivaldi.

At Turin he met with Sonnis, under whom, Le Claire was at that time a scholar on the violin.

From Turin he went to Paris, which, with respect to music, was going from one extreme to another.

His character of French singing in the former part of the last century, is very just and characteristic.

“I was displeased with the French taste now,” says M. Quantz, “though I had heard it formerly with patience. The old, worn-out, second-hand thoughts, and palliages ill-expressed, disgusted me now, as much as a stale dish warmed again. The resemblance between recitative and air, with the affected and unnatural bowling of the fingers, particularly the women, shocked my ears.”

M. Quantz was the first who applied an additional key to the German flute, in order to correct its imperfections; and it was in the course of this year, 1726, that he made the discovery.

In 1727 he arrived in London, where he found the opera in a very flourishing state, under the direction of Handel. The drama of “Ariadne” was now in run, of which, he says, the music was grand and pompous. Senefo performed the first male part, and Cuzzoni and Faustina were the principal women.

He then gives a character of the singers, state of the opera, and of music in general in London, very correctly.

Upon his return to Dresden, he was established in the king’s chapel, with an addition to his former salary of 250 dollars a-year. He now entirely quitted the hautbois, supposing it hurtful to the embouchure of the flute, which, from this time, he made his sole study.

In 1728 he went to Berlin, with baron Seyffritz, in the suite of the king of Poland; where he was obliged, at the command of the queen of Prussia, but with the permission of his royal master, to remain for some months. Pfeudel, Weiß, and Buffardin, were, by the same favour, called thither. After he had had the honour of playing before the queen two or three times, he was offered a place and pension of 800 dollars a-year. He was very willing to accept of them, but the king his master would not grant his content: however, this prince gave him a general permission to go to Berlin as often as he was desired.

This year, 1728, the prince royal of Prussia determined to learn the German flute, and M. Quantz had the honour to teach him. On this account, he was obliged to go twice a year to Berlin, Ruppin, or Reinsberg, the several residences of his royal scholar.

After the death of the king of Poland, in 1733, his son, Augustus III, not choosing to dimish M. Quantz, raised his appointment to 800 dollars, and confirmed the permission which had been granted by his royal father, for his going occasionally to Berlin.

In 1734 he published his first folio; but he does not acknowledge the sonatas, which were printed under his name, in Holland, about that time.

In 1739, M. Quantz finding a great scarcity of German flutes, undertook to bore them himself for the use of his pupils; an enterprise which, afterwards, he found to be very lucrative.

In 1741 he was again invited to Berlin, in order to enter into the service of his royal scholar, then king of Prussia, with offers of an annual pension of 2000 dollars for life; a separate payment for compositions; 100 ducats for every flute he should deliver; and an exemption from playing in the orchestra, or any where else, but in the king’s chamber, as well as from dependance on any other commands than those of his majesty; which terms, as the king of Poland was too gracious longer to refuse his diffusion, M. Quantz was unable to refuse.

In 1752 he published his “Art of Playing the German Flute;” and it was this year that he invented the new joint for the upper-piece of the flute, by which means, without drawing out the middle piece, and without hurting the tone, the instrument may be raised or lowered half a note.

And now, having traced our industrious musician through the troublesome mazes by which he arrived at the temple of fortune, we had hopes that we should have left him to the enjoyment of that retable sale, that atium cum dignitate, to which every artist in years aspires; but alas! this eminent musician and worthy man died at Potsdam in less than a year after we had seen, heard, and conversed with him in that summer residence of his royal disciple and patron! A complete lift of his works is given in Gerber.

QUANUSE, in Geography, a town of America, in the Tennessee government. N. lat. 35° 12’. W. long. 84° 28’.

QUAPÁ, a town of Louisiana, at the confluence of the Akanas with the Mississippi. N. lat. 33° 48’. W. long. 91° 23’.

QUAPACTOTOTL, in Ornithology, a name under which Nieremberg has described a bird, which, he says, imitates the human laugh. He says its body is eight inches long, and the tail as many; the beak of a blue-fish-black, and bent and crooked; the breast grey, and the belly black; the tail of a brownish-black; and the wings, neck, and head, of a yellowish-brown.

This is the Cuculus ridibundus of Gmelin, the Cuculus Mexicanus of Brilliant, and the Laughing cuckow of Latham. It is found in New Spain.

QUAPIZOTL, in Zoology, the name given by Hernandez to the Tajaça of Maregrave, the Pecari of Buffon, and the Mexican hog of Pennant. See Sty Tajaça.

QUAPOYA, in Botany, Aubl. Guian. v. 2. 897. t. 345. 344.; a barbarous Caribean name. See Xanth.

QUAR, in Agriculture, a term occasionally employed, in a provincial manner, to signify a small sort of quarry of any kind, but more especially of the lime-stone, free-stone, flag-stone, or slate-stone nature. It is much used in some of the more northern districts of the country. See Quarry.

QUARANTAIN, in old Law Books, written Quarantein, and Quarantena, denotes the space of forty days.

“Quatuor carucatas terrae arabilis, continentis in longitudine: 8 quarantenas, & 8 quarantenas in latitudine.”

“Quarantena in London, ponetur pro respectu habend. 40 dies potf summationem per breve regis, it confulant, &c. si ibi viderint expedire.” MS. de Temp. Ed. III. The
The term is borrowed from the French quarantaine; and is sometimes used for the time of Lent.

Quarantain of the King, in France, denotes a truce of forty days appointed by St. Louis, during which time it was expressly forbidden to take any revenge of the relations or friends of people who had fought, wounded, or affronted each other in words.

Quarantain, or Quarantine, is more particularly used for the term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves before they come into port.

By the Stat. 26 Geo. II. cap. 6, explained and amended by 29 Geo. II. cap. 8, the method of performing quarantine, or forty days probation, by ships coming from foreign countries, is put in a much more regular and official order than formerly; and matters of ships coming from infected places, and discharging the directions there given, or having the plague on board, and concealing it, are guilty of felony without benefit of clergy. The same penalty also attends persons escaping from the lazaretto, and officers and watchers neglecting their duty, and persons conveying goods or letters from ships performing quarantine. See Plague.

In cases of insurance, before the risk on a ship can be said to be completely ended, the same not only have been 24 hours moored at anchor in her port of deputation, but the same have been during that time in good safety, in the fullest sense of those words. If, therefore, the ship be obliged to perform quarantine, this does not end the voyage. The voyage only ends when the ship is arrived at her port of deputation, and is there moored 24 hours in good safety. Accordingly, if the ship, before the 24 hours are expired, be ordered to the proper place for performing quarantine, the risk continues, though she do not leave her moorings till long after the 24 hours are expired. See Risk.

Quarantain also denotes certain duties imposed upon ships, for the purposes of quarantine.

Quarantine, Quarantine, or Quarantines, Quarantena, in Laws, denotes a benefit allowed by the laws of England to the widow of a man dying seized of land; by which the same challenge to continue in his capital messuage, or chief manor-house (so it be not a cattle), for the space of 40 days after his decease; during which time her dower shall be assigned. The particular lands to be held in dower must be assigned by the heir of the husband, or his guardian. Co. Litt. 3a. 35.

If the heir, or any other person, attempt to eject her, she may have the writ de quarantena habenda; which lies for a widow to enjoy her quarantain.

Quarantain is also used for a measure or extent of land, containing 40 perches.

Quarantaria, in Geography, a high mountain between Jerusalem and Jericho; which, as tradition says, is the mountain to which our blessed Saviour was taken by the devil, when he tempted him with the visionary scene of all the kingdoms and glories of the world. This is, as St. Matthew styles it, an exceeding high mountain, and not only difficult, but dangerous, of ascent. It has a small chapel at the top, and another about half-way of its ascent, founded upon a prominent part of the rock. Near this latter are several caves and holes in the side of the mountain, made use of by the hermits, and from time to time, for places in which they kept their Lent; in imitation of that of our blessed Saviour. In most of these groves Maundrell found certain Arabs quartered with fire-arms, who obstructed his ascent, demanding 200 dollars for leave to go up the mountain. He and his companions, says the traveller, departed without farther trouble, not a little glad to have so good an excuse for not climbing to dangerous a precipice. Maundrell's Journey, &c. p. 86.

Quarantain, in the Venetian Polity, a court of judicature composed of forty judges.

The Venetians have an old civil quarantain, a new civil quarantain, and a criminal quarantain.

The criminal quarantain takes cognizance of all crimes except those against the state, which belongs to the council of ten. The new civil quarantain judges of appeals made from sentences made by judges out of the city. The old civil quarantain takes cognizance of appeals from sentences of municipal judges in that city.

Quararibea, in Botany. See Myriodia.

Quare ejet infra terminum, a writ which lies, by the ancient law, where the wrongdoer or ejector is not himself in possession of the lands, but another who claims under him. As where a man leafeth lands to another for years, and, after, the lessor or reverfioner entereth, and maketh a presentment in for, or for life, of the same lands to a stranger; now the lefsee cannot bring a writ of ejectiune for this ejectment, against the feoffee; because he did not eject him, but the reverfioner; neither can he have any such action to recover his term against the reverfioner, who did oult him; because he is not now in possession. And upon that account this writ was devised, upon the equity of the statute. 2do. e c. 24. as in a case where no adequate remedy was already provided. And the action is brought against the seoffee for deforcing, or keeping out, the original lefsee during the continuance of his term; and herein, as in the ejectment, the plaintiff shall recover so much of the term as remains; and also shall have actual damages for that portion of it, whereby he has been unjustly deprived. But since the introduction of fictitious oulters, whereby the title may be tried against any tenant in possession, (by what means ever he acquired it,) and the subsequent recovery of damages by action of trespas for male profits, this action is fallen into disuse. See Ejectione Firma.

Quare impedit, a writ which lies for him who has purchased an advowson, against him that disturbs him in the right of it, by presenting a clerk to it when the church is void.

It differs from the affize of darrein prezentment, ultima prezentationis, which lies where a man, or his ancestors, formerly prezent; this other bying for him who is the purchafer himself. Where a man may have the affise, he may have this writ; but not contrariwise.

In contentions presentations, upon the first delay or refual of the bishop to admit his clerk, the patron usually brings his writ of quare impedit against the bishop, for the temporal injury done to his property, in disturbing him in his presentation. And if the delay arises from the bishop alone, as upon pretence of incapacity, or the like, then he only is named in the writ; but if there be another presentation set up, then the pretended patron and his clerk are also joined in the action; or it may be brought against the patron and clerk, leaving out the bishop; or against the patron only. But it is most advisable to bring it against all three: for if the bishop be left out, and the suit be not determined till the six months are past, the bishop is entitled to present by lape; for he is not party to the suit: but, if he be named, no lape can possibly accrue till the right is determined. If the patron be left out, and the writ be brought only against the bishop and the clerk, the suit is of no effect, and the writ shall abate; for the right of the patron is the principal question in the cause. If the clerk be left out, and has received
ceived institution before the action brought, (as is sometimes the case,) the patron by this suit may recover his right of patronage, but not the present turn; for he cannot have judgment to remove the clerk, unless he be made a defendant, and party to the suit, to hear what he can allege against it. For which reason it is the fæver way to infert all three in the writ.

The writ of quare impedit commands the disturbers, the bishop, the pseudo-patron, and his clerk, to permit the plaintiff to present a proper person (without specifying the particular clerk) to such a vacant church, which pertains to his patronage; and which the defendants, as he alleges, do obstruct; and unless they so do, then that they appear in court to shew the reason why they hinder him.

Immediately on the filing out of the quare impedit, if the plaintiff sues out that the bishop will admit the defendant's or any other clerk, pending the suit, he may have a prohibitory writ, called a ne admissit; which recites the contention begun in the king's courts, and forbids the bishop to admit any clerk whatsoever till such contention be determined. And if the bishop doth, after the receipt of this writ, admit any person, even though the patron's right may have been found in a juven patronatus, then the plaintiff, after he has obtained judgment in the quare impedit, may remove the incumbent, if the clerk of a stranger, by writ of facias jure factas; and shall have a special action against the bishop, called a quare incumberit; to recover the presentation, and also satisfaction in damages for the injury done him by incumbering the church with a clerk, pending the suit, and after the ne admissit received. But if the bishop has incumbered the church by instituting the clerk, before the ne admissit issued, no quare incumberit lies; for the bishop hath no legal notice, till the writ of ne admissit is served upon him. The patron is, therefore, left to his quare impedit merely; which now lies (since the statute of Welfyn. 2,) as well upon a recent usurpation within six months past, as upon a disturbance without any usurpation had.

In the proceedings upon a quare impedit, the plaintiff must set out his title at length, and prove at least one presentation in his name, his ancestor, or those under whom he claims; for he must recover by the strength of his own right, and not by the weakness of the defendant's; and he must also shew a disturbance before the action brought. Upon this the bishop and the clerk usually disclaim all title; save only, the one as ordinary, to admit and institute; and the other as a benefice of the patron, who is left to defend his own right. And, upon failure of the plaintiff in making out his own title, the defendant is put upon the proof of his, in order to obtain judgment for himself, if needful. But if the right be found for the plaintiff, on the trial, three farther points are also to be inquired; 1. If the church be full; and, if full, then of whole presentation; for if it be of the defendant's presentation, then the clerk is removable by writ brought in due time. 2. Of what value the living is; and this in order to affc the damages which are directed to be given by the statute of Welfyn. 2. 3. In case of plenary upon an usurpation, whether fixed calendar months have passed between the avoidance and the time of bringing the action; for then it would not be within the statute, which permits an usurpation to be divested by a quare impedit, brought infra tempus semelire. So that plenary is still a sufficient bar in an action of quare impedit, brought above six months after the vacancy happens; as it was universally by the common law, however early the action was commenced.

If it be found that the plaintiff hath the right, and hath commenced his action in due time, then he shall have judgment to recover the presentation; and, if the church be full by institution of any clerk, to remove him; unless it were filled pendente lite by loan to the ordinary, he not being party to the suit; in which case the plaintiff loses his presentation pro hac vice, but shall recover two years' full value of the church from the defendant, the pretended patron, as a satisfaction for the turn lost by his disturbance: or, in case of infolvency, the defendant shall be imprisoned for two years. But if the church remains void at the end of the suit, then whichever party the presentation is found to belong to, whether plaintiff or defendant, shall have a writ directed to the bishop ad admissionem clericum, reciting the judgment of the court, and ordering him to admit and institute the clerk of the prevailing party; and, if upon this order he does not admit him, the patron may sue the bishop in a writ of quare non admissit, and recover ample satisfaction in damages.

Besides these possessory actions, there may be also had a writ of right of advowson, which resembles other writs of right: the only distinguishing advantage now attending it being, that it is more conclusive than a quare impedit; since to an action of quare impedit a recovery had in a writ of right may be pleaded in bar.

There is no limitation with regard to the time within which any actions touching advowsons are to be brought; at least none later than the times of Richard I. and Henry III.: for by statute 1 Mar. R. 2, c. 5, the statute of limitations, 32 Hen. VIII. c. 2, is declared not to extend to any writ of right of advowson, quare impedit, or alias of darrein presemtment, or jus patronatus.

In a writ of quare impedit, which is almost the only real action that remains in common use, and also in the alias of darrein presentation, and writ of right, the patron only, and not the clerk, is allowed to sue the disturber. But, by virtue of several acts of parliament, there is one species of presentations, in which a remedy, to be sued in the temporal courts, is put into the hands of the clerks preferred, as well as of the owners of the advowson. We mean the presentation to such benefices, as belong to Roman Catholic patrons; which, according to their several counties, are vested in and secured to the two universities of this kingdom. And particularly by the statute of 12 Ann. R. 2, c. 14. § 4. a new method of proceeding is provided; viz. that, besides the writs of quare impedit, which the universities as patrons are entitled to bring, they, or their clerks, may be at liberty to file a bill in equity against any person presenting to such livings, and disturbing their right of patronage, or his esle ay que truyf, or any other person whom they have cause to suit; in order to compel a discovery of any secret trusts, for the benefit of Papists, in evasion of those laws whereby this right of advowson is vested in those learned bodies: and also (by the statute 11 Geo. II. c. 17.) to compel a discovery whether any grant or conveyance, said to be made of such advowson, were made bona fide to a Protestant purchaser, for the benefit of Protessants, and for a full consideration; without which requisites, every such grant and conveyance of any advowson or avoidance is absolutely null and void. Blackst. Com. b. iii.

Quare incumberit, a writ which lies against the bishop, who, within six months after the vacancy of a benefice, confines it on the clerk of any one, while two persons are contending at law for the right of presenting. This writ lies always depending the plea. See the preceding article, Presentation, Assise of darrein presemtment, &c.
QUARE non admisit, a writ which lies against the bishop, for refusing to admit his clerk, who has recovered in a plea of advowson, on pretence of lapse, &c. See QUARE impedi.

QUARE non permissiti, is a writ that lies for one who has a right to present for a turn against the proprietary.

QUARE ostreata, a writ that lies for him, who, having right to pass through his neighbour's grounds, cannot enjoy the fame, because the owner has fenced it up.

QUARENTINE. See QUARANTAIN.

QUARERA, or QUARATIA. See QUARRY.

QUARITZ, in Geography, a town of Silesia, in the principality of Glogau; 8 miles W. of Gross-Glogau.

QUARKEN, or QUERKEN, a cluster of small islands, in the gulf of Bothnia, near the call coal. N. lat. 63° 16'. E. long. 21°.

QUARLES, Francis, in Biography, an English poet, born in 1592, near Rumford, in Essex, was son of James Quarles, esq. who held an office at the navy board in the reign of queen Elizabeth. The subject of this article was educated at Christ's college in Cambridge, and was afterwards entered a student in Lincoln's Inn. He obtained the place of cup-bearer to the queen of Bohemia, daughter to James I.; and upon his return, he was appointed secretary to archbishop Usher in Ireland, from which country he made his escape; on the breaking out of the rebellion in 1641, after the loss of his property. He had before distinguished himself by some works, chiefly on religious subjeets, in consideration of which he had a pension from Charles I. About this time he had the post of chronicler to the city of London. On the commencement of the civil wars, he gave great offence to the parliament by a work, entitled "The Royal Convert;" and when he actually joined the king at Oxford, he was plundered of his elates, his books, and manuscripts. These losses he did not long survive. He died at the age of 52, in 1644. Of his numerous writings, as well in prose as in verfe, the most celebrated, and indeed that by which he is almost entirely known, is his "Emblems," a set of designs exhibited in prints, and elucidated by some lines attached to each. Considerable part of the work is borrowed from the "Emblems" of Hermannus Hugo, but his verses are his own. For a considerable time they excited a large portion of public admiration in the religious world. They then fell into contempt; but we believe a new edition has of late years been given to the world. Quarles is thus characterized by an able critic: "He is by no means without his beauties; and his verses, which are generally smooth, afford occasional burks of fancy, and stokes of pathos, which show real genius, though overrun with fable taille. Mr. Jackson of Exeter, in his "Letters on various Subjects," endeavoured to recall the public attention to this neglected poet, and pointed out with much feeling some of his brilliant passages; but though curiosity may be amused by hunting for his scattered beauties, he can never regain a place among the English classical poets."

QUARLESVILLE, in Geography, a poft-town of America, in Brunswick county, Virginia; 204 miles from Washington.

QUARNAMELA, a town of Sweden, in the province of Smaland; 23 miles S. of Wexio.

QUARNERO, or CORNERO, Gulf of, a part of the Adriatic, between 17thia and Moracliia, anciently called "Sinus Fanaticus." It is subject to sudden storms and hurricanes, which render its navigation dangerous.

QUARRE, Fr. In old French munie, B quart was the term for Bq. See QUADO.

QUARRE les Tombes, in Geography, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Avalon; 6 miles S. of Avalon. The place contains 2007, and the canton 7257 inhabitants, on a territory of 1924 square, and 9 comunnes.

QUARREL, in the Old French time-table, implied a breve, or square note, equal to two semi-breves. See TIME-TABLE.

QUARREL, QUERELA, in Law. See QUERGY.

Quarrel seems proper to relate to personal actions, or to molt to mixed ones, wherein the plaintiff is called querens; and in all declarations of trefpafs, it is laid, queritur.

Yet if a man releace all quarrels or quercles, (a man's own deed being taken molt strongly against himself,) a quarrel includes all actions; and accordingly all actions, both real and personal, are hereby released.

Quarrels or affrays in a church or church-yard are esteemed very heinous offences, as being indignities to him whose service those places are consecrated; therefore mere quarrelsome words, which are neither an affray nor an offence in any other place, are penal here. See AFFRAY.

Quarrel between the French and Italian fingers at Rome, in the time of Charlemagne; for which we refer to our article CHARLEMAGNE. See also Roufeau's Dict.

Quarrel, in Armoury, a bolt, or square-headed arrow, to shoot out of an arculin, or cros-bow.

Quarrel of Glass. See QUARRY.

The word is formed, by diminution, from the Latin quadratum, or the French quarré, square; or, perhaps, immediately from the Italian quadratto, little square.

Quarry, in Agriculture, the common name of an opening, pit, drift, or shaft, which is dug into the earth or ground, and from which are to be raised ores of various kinds, different sorts of stones, &c., and other materials of similar natures. It is remarked by the writer of the work on "Landed Property," that the more useful and advantageous materials and substancess that have at different times been dug and raised out of quarries in this country, are chiefly those of the iron ore kind, lime-stone, and other calcareous matters, materials for building, such as slates, flags, stones, and substances of other sorts, matters for the constructing and repairing of roads, as sand, gravel, and others of the same nature, earthy-substances for the purposes of different manufactures, such as clays, &c., moulds and vegetable earthy matters, and coals, with other articles for use as fuel. There are, however, occasionally raised from openings of this nature, a few other kinds of substances, such as will be noticed below.

It has been farther supposed by the above writer, that the substances which he has here mentioned, may with truth be said to be of more real use and value to mankind than all the mines of precious metals in the world; and that the eyes of the managers of landed estates should constantly be turned towards and fixed upon the discovery of the hidden valuable treasures and productions of this nature, wherever there is a probability or likelihood of their being to be met with. It is also suggested, that it would be highly beneficial and advantageous if mineralogists, and those who are acquainted with such substances, were to turn their attention towards the appearances or accompaniments which point out such useful concealed matters; for it might greatly facilitate the search for them, and frequently lead fortuitously to their discovery. The methods which are practised in searching for and ascertaining the presence of different sorts of materials...
Quarry.

The mohl sands/methods of working and managing different forts of quarries, are in general, in molt places, tolerably well understood and regulated, by such quarriers as are confidently employed in the hufines; but a circumstance which they commonly neglect very much, or are in a great degree inattention to, in very many cases, is that of making good the ground below, by means of the turf or foil which is call'd from the top, or upper parts; and that of keeping the mouths of the openings sufficiently clear and free. Another common difficulty incident to them, is that of draining, and freeing their bottom parts from injurious water. This may be effected in various ways, as by the use of different forts of machinery worked by wind, water, and steam, and by some other means. See Quarries, Pits, &c. Draining of.

In many of the more southern districts of the kingdom, and still more in those towards the north, and in Wales, there are quarries, from which substancess of some of the following kinds are raised and used in their neighbourhoods, or sent away to a distance, in a very extensive manner; such, for instance, as those of the fliny kind, as iron-stone or ore, lime-stone, marble, chalk, granite, free-stone, grit-stone, flag-stone, white, grey, purple, and blue slate, sandstone, sand, gravel, clay-stone, eythe-stones, tile-stones, &c.; different ochres, plumbago or black lead, calcimine, gypsum, marble, pipe-clay, alum-earth, fuller's-earth, peat-earth, chalk, coal, cannel, salt-rock, &c. These quarries and pits are wrought, and the materials got up from them, in several different ways, according to circumstances and convenience, as well as the particular nature, kinds, qualities, &c. of the different articles themselves; all of which are mostly well known, and capable of being performed by the workmen of their respective neighbourhoods, who are commonly employed in them, and very expert in their management.

Stony substancess which bear a great variety of different names, and which poffefs equal variety in their qualities and useful properties, are met with, and dug up from quarries and pits, in many different districts and situations, in almost all parts of this island, in order to be converted to purpofof improvement and utility in a variety of different ways and intentions. Iron-stones and ores abound more in the northern parts, though they are occasionally found in some of the southern ones. A considerable quantity of highly rich iron-stone is got up and sent annually from the vicinities of Combemartin in Devonshire, to the iron-works of Mr. Raby at Lenethy in South Wales. A large portion of it is also found on the borders of the Orcheston river, and diffirded throughout the whole district, as well as in other parts of the same county.

Iron-stone is likewise met with in Suffex in large quantities, imbedded with lime-stone and sand-stone, that which rises near to the surface being the best, the others having a coarser and more dull appearance, working heavier in the furnace. The very best is frequently interfecied with thin stripes of soft matter. Iron-stone, to a great extent, existis on the estates of lord Dudley, and many others in Staffordshire, and contributes much to the employment and prosperity of the inhabitants. But, in the northern part of Lancashire, in the district of Low Furnace, stone and ore of this fort are perhaps found in the largest quantity, of the best kind, and in the most general manner, of any where in the kingdom. There are numbers of shafts, quarries, and pits for raising them from, on Lindal Moor, Whithrig Moor, and Crosses Gates, in the vicinity of Dalton, as well as in some other places. In the former, the working is usually effectuated at the depth of from twenty to forty-five feet, but it has been done at less as well as greater depths. The whole of their cavities are chambered with wood, and coft from a guinea to twenty-five shillings in finking each fathom, without the wood. The ore runs in veins or beams between the rocks on the north and fouth, being in breadth from about forty to fiftty yards. And it contantly dips towards the fouth-eaft at the rate of about a foot in five or fix. The better ore is that which has the mofl greasy appearance, and it is raifed with lesf difficulty, working fels hard, requiring fels flux, and forming a more fopt iron. It is raiied from the shafts or pits by machinery of the gin or windfrafe kind, the men employing picks, punches, and hammers in diggins it up. It was formerly got, in fome places, by driving levels into the fides of the hills, and conveying it out on railways, in small wagons; but now the other way is mostf employed. Four men get about fourteen tons in the day, in fome situations; but in others, double the number are required for getting the fame quantity. It is wheeled to dillant heaps, from which much of it is fent in small catts to the port of Old Bawree, from whence it is shipped to different parts of England, Wales, and Scotland, at the expence of about fourteen to thirty fhillings in freight; and the fett converted into pig-iron by the furnaces in the neighbourhood. Iron-stones and ores are also met with in fome other counties more to the north of the kingdom, where there are pits and quarries for raiing them from.

Lime-stone is a very general fort of stone raiied from quarries and pits in many different parts of this country; as in Devonshire, Suffex, Kent, &c. towards the fourth, where it lies in vall beds, from which it is dug for ufe; in the more midland counties, as in Glouceftershire, Shropshire, Derbyshire, Staffordshire, and others, where it exists and is employed to a fift greater extenfive; but by far the mofl extenfive in thofe farther to the north, as Lancashire, Wellmoreland, Yorkshire, Cumberland, and fome districts of Scotland. In many parts of the county of Lancalifer it is dug and raised from quarries, where it lies in a ftratified manner at no great depth from the surface, being got up without much difficulty or trouble; while in other places it is forced from the fold rock, with great labour and ex- pense. This is likewise the cafe in many other districts. Wherever it is met with, it is almost conftantly a quarr material of great value, and which affords much employment to labourers.

In the county of Kent, the banks of fome of the large rivers are scoopen out into stone quarries in a remarkable manner, fome of them worn out and diffured, others in the flate of being wrought. It has been observed, that this is the nearest ftone county into which water-carriage can penetrate from the metropolis; and that the original London
was built, as well as the modern one chiefly paved, by materials from this district, such as the rag-stone, and the large pebbles gathered on the sea-shores, before the Scotch granite came into use. In the neighbourhood of Maidstone there are the appearances of many abandoned and neglected quarries of this nature; but the most considerable ones, which were lately worked in that vicinity, are those of Farleigh and Fant. In each of these, blocks of flones, of different kinds, and of every form and size, are met with, being separated by seams, and large irregular masses of earth of various qualities: among the red, brick-earth of the belt quality. In some places, the flones are buried several feet under these earthy materials; in others, the rock rises to the surface. After this, the quarrymen worm their way; following it, with irregular windings, leaving behind them refuse in greater quantity than the useful materials which they raise.

The flony substanfes which are principally met with in them, are of two very different kinds: the one hard, and of a strong texture, provincially denominated rag, or Kentish rag; the other of a soft crumbly nature, provincially termed baijock. The quarrymen are in the practice of dividing the firft fort into two kinds: what they call the common rag, and the cork-stone, the latter being their principal object in these immense works. It has in its general appearance much resemblance to the strong grey lime-flones which are found in different parts of this country; but when minutely examined by means of a glafs, its fracture and contexture have the characters of the Devonshire marbles; except that the grain of this fort of flone is somewhat coarser. In colour, too, it differs from these marbles, having a greater resemblance to the Yorkshire lime-flones. It is used for different purposes; much of it is sent to the neighbourhood of London, where it is burnt into lime, for the use of the sugar-bakers; who, for some reafon or other, chiefly employ lime, burnt from this material, or flone, instead of that of chalk. It is likewise made use of as a building material; and, particularly in pedeflars, for the polfs of cattle-sheds and other farm-offices. It is hewn with flone-masons’ axes, working with tolerable freedom.

It is very durable, as some part of the baseament of Weftminster Abbey appears to have been built with the flone from these quarries. In this cafe, it seems to have been drefsed smooth; and the surface still remains with little alteration; having withftood the attacks of time with great firmnefs; it being even now difficult to detect a loofened splinter in the work.

The common rag-flone comprehends all the different kinds which are met with in these quarries, except that of the above, and that which is of the hallokey nature; though the true unmixed rag is a distinct fort, having characters different from any of the others. In the colour, it inclines more to the red or liver colour, than that of the cork-flone, but otherwise resembles it considerably. Viewed with a glafs, its grain is finer, and the fracture flint-like.

Its use is, however, but few. Some of the best and most regularly-faced flones are sometimes laid aside for paving materials; but the large pieces are mostly reserved, in order to be sent by water to the district of Romney Marsh, for the purpose of forming the hard materials of the embankments and jetties, which are there made against the sea. The smaller forts are, in general, converted to use as a road material.

The hallokey flone appears to the naked eye to be of a soft, white, sandy quality; and its fracture is the fame. But under the glafs, its grain is fine, its contexture uniform, and so thickly interperfed with small seed-like granules, of a dark or black colour, as to give it a grey appearance. Sometimes bearing evident impressions of shells. Its texture is ftrong and brittle; crumbling cafly between the fingers into a coarfe hand-like powder. It will not burn into good lime, although it is almost wholly calcareous.

Its principal use is that of forming a flone frable fort of rubbly fulb-fol, in some places, which is admirably suited to the growth of fainfom, and fome other crops of the plant as well as the fruit-tree kinds.

The quarries in several other counties contain floney materials of these different kinds, which are wrought and applied to a variety of different ules in these and other ways.

Quarries of marble are wrought in several districts in different parts of the country, and afford great advantages in various ways. In Suffex they have a marble, which, when cut into slabs, is used for ornamenting chimney-pieces, and many other purposes. It is equal in quality and beauty to mofl forts when highly polished. For square building and paving it is also a material scarcely to be exceeded. By burning, it likewise affords a very valuable manure, equal, and, by some thought inferior, to chalk, being cheaper to thofe who are near the places from which it is dug. It is found the moft perfect about Kirfford, at the depth of from ten to twenty feet underground, in flakes nine or ten inches in thickness, and called the Petworth marble. It was much employed in building the cathedral at Canterbury, the pillars, monuments, vaults, pavement, &c. being formed of it. And the archbishop’s chair is one entire piece of it. Marble is gotten in fome of the counties in the middle of the island, as Derbyshire, Nottinghamshire, &c. At Beacon-hill, near Newark, a blue flone for hearths is got, which approaches to marble, and is capable of burning into lime. And in the county of Derby much good marble is raised in different places. In Lancashire there are quarries of fine black marble, and of flones, which approach to, and take on the polish of marbles. In many of the western and northern parts of Yorkshire, marble of various kinds is found, some much resembing, and others superior, in clofenes of texture and diftinctness of colours, to that which is wrought in Derbyshire. Also a flone, which greatly resembles the marble of that county, and which is capable of receiving much such a polish, and is nearly of the fame colour, mixture, and appearance. On the fide of the river Kent, near Kendall, a vein of beautiful marble has been lately discovered in the property of D. Wilton, eq. of Dallam-Tower; and a main quartry opened upon it. Marble has also been met with on the opposite bank.

In the county of Invernes, likewise, marble of the greateft variety of colours, and of the moft beautiful fhades, has been met with in Benson, on the property of Mr. Camerton; and inexhauffible quarries of it lie untouched in the islands which belong to it.

Besides, this fort of material exists in immense quantities, in quarries, in many other parts of the kingdom.

Chalk is a material which is raised from quarries and pits, mostly in the southern parts of the country, as in Suffex, Surrey, Kent, Essex, Berkshire, Hertfhorshire, &c. It exists in vaft ranges and tracts in mofl of thefe districts, whence it is dug up from quarries, at different depths, according to circumstances, exposed in fles for dry, when wet, and then converted into lime for various ules, by means of fire, or employed in its broken and powderly state, without undergoing the above procefses, by merely digging it out of such places. In fome parts, as in Kent, and the neighbouring districts, it is often dug and raised from considerable depths, from beds of very great thicknesses. And near Reading, in Berkshire, there is a stratum of this fubstance,
Quarry.

Flint, which is thirty feet in thickness. It is there used and dug out for manure, and occasionally as a building material, for the latter of which purposes it is very durable. The remains of the abbey of Hurley, and of the ancient chapel, now the parish church, built wholly of chalk, in the reign of William the Conqueror, are, it is remarked by the writer of the corrected Agricultural Survey of the district, still as fresh and found as if they had been the works of the last century. Chalk, when once indurated by the air, has a remarkable property in retarding the action of the weather.

Granite is a stony substance, which is found to exist in some of the southern parts of the country, as well as in those of the north, but it abounds much more in the latter.

In the western parts of Cornwall it is great plenty in the districts of Penwith and Kierri, presenting itself in large flabs on all the rocky hills or tors, as well as in the walle moors and vallies; and appearing in detached spots, even in the stony flat tracts. It is of different colours and textures, being adapted to a great variety of uses and purposes, as those of building, and being wrought into columnar masses, eight or ten feet in length, for supports to sheeds, out-houses, &c.; and as gate-poles, and bridges over brooks, rivulets, &c.; as well as in the forming of rollers, melting, faltling, and pig troughs. It is also an article of commerce to different parts. It is suppose to be exactly of the same nature with the original granite; and there are five ferts of it, which are distinguished by their colours, the white, the duny, or dove-coloured, the yellow, the red, and the black, most of which are charged with a brown and bright flivery matter.

The county of Inverness has a great deal of this fort of flone, and there are numerous quarries in it for raising and working of it. The common granite abounds in all the different districts of it. In many places the whole rocks are compos'd of this kind, which is uncommonly useful for all ordinary purposes. By natural fissures, which run in straight lines, and generally at right angles, it is formed into all sized portions and shapes, having uniformly a plain surface. And, by means of cutters or tranverfe lines, these flones are easily quarried, and found in the greatest plenty everywhere. They are remarkably beautiful, being almost as smooth and regular as hewn flone, and of course well suited for various forts of building work. The bell buildings of the county-town are of a dark kind of granite, which is very hard and durable, but which has few or no fissures. It is generally found in large blocks, and in many of these parts, there is no other material for building or adding ornament with. The manner of giving it the polish it admits of at the quarries, is by means of small picks, or pick-axes, which are, in fact, hammers with sharp points at each end, in the manner of those employed by millers in preparing their grinding flones. It is a very heavy, compact flone. There is a mixed fort, denominate peazy granite, which consists of white, black, and grey spots, that sparkle beautifully in the sun, and is very ornamental, as well as much used for different purposes, as flairs, doors, and windows. Though this is very solid, and almost without natural fissures, it splits very straight, by means of iron wedges, set in a line, and struck alternately, with a hammer of great power.

A great deal of this kind of flone is imported into the metropolis and other large towns, for paving the streets, &c. It is on the whole a very advantageous fort of quarry material in various parts of the kingdom.

Quarries of free-flone are wrought in a great number of different places. In the more southern parts is found the Portland flone, which is so famous and useful in building. A fort of this kind of flone, which much approaches to it in quality, is also met with in Cornwall. Some likewise exist in Devonshire and Gloucestershire. The Cotswold quarries in the latter, afford free-flone of an excellent quality, particularly those at Painwick, Lodbury, Lockhampton-hill, &c. It abounds more, however, in Cheshire, Lancashire, Wellmoreland, Cumberland, and some of the still more northern districts. Several excellent quarries of free-flone are carried on in the first of these, as those at Runcorn, Manley, &c., where much valuable flone of this nature is raised. The second county also affords equally valuable quarries in many different places, from which vast quantities of the flone are raised, and employed, or sent away to a distance. Those about Ormskirk, Up-Holland, and Wigan, as well as those on all the eastern side, are in general of a very good quality. And in the vicinity of Lancaster there are some excellent ones; that on the moor or common, close to the town, is very extensive, and affords a free-flone that admits of a fine polish. In this district, this fort of flone is met with of a whitish-brown, yellowish, and reddish cast, but the firt is by much the most esteemed. In the eastern parts of Wellmoreland, as about Hutton Roofes, and some other places, a good fort of free-flone is dug up from pits and quarries formed for raising it. This fort of flone exists and is quarried almost over all the counties of Cumberland and Northumberland; and prevails occasionally in others, where it is wrought to advantage. A grit-flone, somewhat of this nature, is met with in some districts, as in Shropshire, &c., which is raised from quarries, and used as a building material. And a sand-flone exists to considerable extent in others, as in Suffolk, &c., that is sometimes dug up, and made use of for common buildings, &c.

In Cheshire, on the rights near Macclesfield, about Kerridge, a fort of sand-flone is met with, which is particularly well fitted to the making of flags, and whetting tools, as well as to the forming of slates, for which it was formerly much employed. Near Pott-Shrigley, also, a fine sand-flone is found, that admits of a good polish. The quarry has not, however, been wrought for some late years, as from the extreme hardnes of the flone, the expense of getting it is very considerable. There are several other quarries of excellent free-flone wrought in the same neighbourhood.

There has been great abundance of free-flone wrought, time immemorial, in the low parts of the county of Perth, and quarries of a greater or smaller grained flone of this fort appear almost in every place, with the exception of the caries. In the lowlands, and near to the eastern sea, the pores and grain of it are greater; but as the mountains are approached, the pores are less, and the grain finer, by which these flones admit a smoother polish. The quarry of Tul-lyalan parish, called Long-amat, affords a flone of a very excellent quality. It has a white colour, admits of a smooth polish, and refits the influence of the weather. Some of the principal houses in that part of the country, as well as some of the most magnificent public buildings in the capital of Edinburgh, as those of the Exchange, the Infirmary, and the Register-office, consist partly of this flone, and those found at hand. And farther, in some instances it has been carried to the continent. But the quarry of Kingoodie, in the carse of Gowrie, belonging to Mr. Mylne, of Mylnefield, is unquestionably the finest of this kind of any in the county. Altonishing blocks in great number are raised there, fifty feet in length, sixteen feet in breadth, and three feet in thicknes. Such is the demand for this flone, both at home and abroad, that four vessel are employed in exporting it from this quarry. The work is, however, on the de-
The quarries of the kind become flate-flone, and furnish the white, grey, and brown flate, wherever the flone lies in thin layers, or strata, which are able to be raised and separated from each other with convenience and facility. They exist in most of the above tracts, and are plentiful in some of them, especially those towards the north. The Lancashire and Yorkshire quarries, in many places, supply the white and grey fmits in great abundance, and of good qualities. Those of Westmoreland, Cumberland, and Northumberland, also afford them in many instances of a valuable nature. And they are equally good in the hillier northern districts. There are numerous quarries of different colours of them in Clydefdale, Perthshire, Argyllshire, and the county of Inverness, from which vast supplies are constantly raised for home and other ufe. This fort of flate has, however, moftly the disadvantages of being very porous, heavy, lefs durable, and of requiring more and stronger timber to support it, than fome other kinds; being only fit for exposed climates and situations.

The quarries of the lighter and thinner kinds of flate, of the blue, green, purple, and other colours, formed from other forts of flone, only exit in fome particular districts, as those of Wales, the northern part of Lancashire, and the adjoining counties, and in a few places in Scotland. The flate quarries of the Welsh districts supply fveral kinds and colours in large quantities, and of good qualities, but the dark and longer purples are the moft prevalent fmits in moft of them. In Lancashire the quarries of this kind are very numerous in the part to the north of the fands, as about Goffawaite-common, Kirby-moor, Coniflon-hills, and Tilberthwaite-fells, &c.; and from which very large supplies of the blue, green, and the dark purple fmits of flate are raised, and fent away for exportation, or confumed at home for different purpoles. They are wrought, and the flate prepared in somewhat different manners in different places. The Goffawaite quarries have the flate dug out from the fide of the hill, and carried away. But in fome on Kirby-moor, a level is driven through the ground from below, the metal being conveyed away by small four-wheeled wagons on iron rail-ways. Thofe about Coniflon are mostly worked into the hills, and the metal raised and carried out from them. Some of the Tilberthwaite quarries are wrought by blaffing the flate-flone, and collecting and carrying it out of them on flanting roads, in small carts or trucks constructed for the purpose, the level being below the hills, but not nearly fo low as the bottoms of the quarries. Others are wrought by draught roads from the bottoms of them. One man will raife eighteen or twenty hundred weight of flate in one day, where the metal rides well, but lefs in other cafes. In furnace it is dug out by one ft of men, fhift by another, and frormed into flates by a third, for which purpoles, flat crow-bars, flate-knives, and axes are employed. The flate is divided and fifted into three forts, or fmits, fconds, and fours, of London, country, and town. In the firft, or Goffawaite quarries, the flate has a dark fhit purple, or black cafl, and is worth from forty to forty-four fhillings the ton. In the Coniflon it has a fine fhit and green appearance, and is much thinner and lighter than the other fort. The Tilberthwaite flate, in fome inftances, is very flat, thin, and light, but does not cover fo far as thofe of the Goffawaite and Kirby quarries. This flate is worth from forty-eight to fifty fhillings the ton. In fome quarries a fhort of rent is paid per ton, on the flate which is raifed, as ten fhillings for the fift, eight fhillings for the fconds, and fixpence for the f-thirds. In others a certain rent only is paid for the liberty of the royalty, and not a tonnage duty. Thofe rents or duties on the workers of thofe quarries, are probably higher than they will bear, and have enabled the Welsh flate dealers to underfell thofe of this county.

Welshmoorland and Cumberland, in fome inftances, afford good blue and green flates. In the latter, fome of an excellent quality are gotten in the quarries of Borrowdale, and inferior forts in fome of the neighbouring mountains.

The county of Argyle, in Scotland, in fome parts abounds with flate-quarries, as the tracts about Efdale, from which five millions of flates have for some time been annually sold at the rate of twenty-five fhillings the thousand. Quaries of the fame kind are also wrought in many other parts, with great benefit to the inhabitants.

Slate-quarries are formed in many parts of the highlands of the county of Perth, but none in the low. The flates in fome are of a purple colour, in others of an azure blue, and in a few of a muddy, fandy, brown complexion along the cutters. It is well known where the different sorts are quarried. The veins of flate-rock feem to run from Drum-dale, in the parish of Aberfoil, in a north-eaft direction to Dunkeld; and may be traced beyond the limits of the county both ways. The azure coloured are the beft metal, and rife of a greater fize than any of the other kinds. Many of the buildings in different places are flated with this beautiful covering. Into the lower districts of the county, flates are imported from Efdale, and the other quarries on the west coaft of the county of Argyle.

Quaries of grey flate exit in many different parts of the county of Inverness, in which the quality is very good, and well fitted to the climate. In fome places these flates are much preferred to blue ones, as the latter are more expensive in procuring, and though nailed on the roofs ever fo firmly, are apt to be loftened by high winds, unless belded in lime, which circumstance renders repairs difficult.

There are numerous quarries of fland and gravel to be met with in almost every district of the kingdom, which are wrought either for the purpose of supplying domestic ufe, or of repairing roads, &c. Thofe of the former fort, which contain the fine white, red, and yellow sands, are by far the moft valuable, and wrought to the greatest extent, the materials being mostly dug out from the fides of banks and other places, and but rarely got by finking the
the quarries into the more level parts of the ground, though
this method is sometimes practised. The matters are com-
monly raised simply by digging and sapces; and thrown
into the carts, in many cases, from the quarries and pits
themselves. Numerous quarries and pits of this nature
exist and are wrought to a very great extent in the neigh-
bourhoods of the metropolis, and most other large towns,
all over the kingdom, for the purpose of sale for various
domestic uses.

In the gravelly kinds, those quarries which abound with
the sharp, coarse, flinty, and pebbly sorts, are the most
proper and beneficial for the making and repairing of all
sorts of roads and carriage-ways. They are occasionally
formed by working into banks and steep places, but more
frequently by openings in the plain surface. Their depth
is sometimes considerable, the materials being raised after
being screened, the work, of course, very laborious and
troubledome. In other cases, the carts are filled from the
quarries or pits without much difficulty or trouble.

Quarries of clay-lime, stone-tiles, fleyce-tiles, and some
other sorts, are found of good qualities in different districts.
In Gloucestershire they have quarries of blue clay-lime at
different depths, lying in beds of the same coloured clay,
dispersed in layers of from four to ten inches in thickness.
The lime in new quarries is estimated by the effects which
the atmosphere has upon it from some exposure. The
belf fort is a very useful material for several purpoaes.
Quarries of stone-tiles principally exist, and these articles are
raised from them, in different part of the Cotswolds. The
belf are prepared about Mifedune, Beverlone, Charlton, and
Hampton-field, the colour of which is red or grey; but another fort, which is red grit, is dug up about Iron
Aston, and some other places, but which is more valuable.

There are quarries of fleyce-tiles in many parts of Lan-
cashire, but the belf are obtained from those about Rain-
ford, where they are well wrought and prepared for use.
In several other districts, quarries of different sorts of
whetting-tiles likewise exist, and are wrought to ad-
vantage.

Ochres of different kinds are met with in different places
in quarries formed for the purpose of raising them. In
the county of Devon, formerly large quantities of various
shades between red and yellow, were raised and manufact-
ured in those about East-Down. Umbre, in the parish of
Combehart, excists in a pretty large body. The work-
ning and preparing of these are, however, now much less
attended to than heretofore.

In Suffolk there are quarries of red ochre about Graff-
ham, and in various places contiguous to the sea, as near
Chidham, &c. where much is raised, prepared, and sent to
London. Ochre quarries also exist in many counties
more to the middle and north of the kingdom, from
which great quantities of this substance are procured and
prepared for use in different sorts of arts and manufactures.

Quarries of plumbago, or black lead, are likewise occasion-
ally found and wrought, in different situations, in dif-
terent districts of the country. This substance has been
met with and raised near the borders of the Bovey river,
in Devonshire, in some quantity, and prepared to be sent to
Exeter for sale. Quarries of black lead are also found and
wrought in Borrowdale, in Cumberland, near to the town
of Keswick, to some advantage. And they exist in some of
the middle tracts of the island, affording great benefit
unto the proprietors of them. In the county of Inverness,
there are some appearances of black or pencil lead about
Glengary, but they have not yet been turned to any usefull
account.

In some districts, in the middle parts of the country,
quarries of calamine, or lapis calaminaris, are met with, and
much of this substance raised from them to great profit.
It abounds in the Mendip-hills, in Somersetshire, about
Rowbarrow, Shipham, Wilton, and on Broadwell,
&c. It is sometimes found within a yard of the
surface, and seldom wrought deeper than thirty fathoms.
In some places its quality is excellent. It is present in
other neighbouring mountanious tracts, and raised with equal
advantage.

Quarries of gypsum present themselves in many different
parts, and are wrought in some with considerable benefit.
In the county of Devon, it lies between the frats of red stone,
marl, and chalk rubble, about Salcombe, Banacombe, and
Beer, being useful for various purpoaes. Gloucestershire
and Derbyshire have quarries of this nature, where there
are fine beds of it. Theofe of Ault Cliff in the former,
have it not so good, however, as that which is met with
in the latter county. In Nottinghamshire it is of an ex-
cellent quality, especially that got near Newark and at Red-
hill. Cheshire has some, but not turned to much account.
Welfordland and Cumberland have good quarries of it,
in some places, where a great deal is gotten up, and made
use of. And it abounds in different parts of the county of
York, where it is raised to advantage.

Marl is an article that is met with in pits and quarries in
a variety of different situations, and of several different
kinds and qualities. It is found and dug up for use in many
places in Suffolk, and the counties more to the centre of
the country; but it prevails in the greatest plenty in the
county of Lancaster and some others, in which it is raised
or worked out from large openings on the sides of hills,
high banks, or in the plain surface, and lying thinly
upon the land. The getting or digging of the material out
of such places, is usually performed by means of strong
iron mattock, crowes, fpasde, and wooden spiles; large pieces
being in some cases forced down, not without danger to
the workmen, by driving in the spiles or piles from above.
This method is called jailing. The work is extremely fe-
vere, and commonly done by the rod. The large elods thus
forced down, break into small pieces, and are then filled into
carts for the purpoe.

Shell-marle, though it is not much attended to in any part
of England, is frequently met with and dug up from va-
rious parts of Scotland, and employed on the land in great
quantities, with much success. The pits and quarries of this
fort are commonly wrought with much more facility than
those of the others.

Pipe, and other kinds of fine clays, are dug and raised
from a fort of pits or quarries, in large quantities, in many
different counties. Near Wear Giffard, in Devonshire,
muich of the flinty fort is dug and sent coastways, though not in
such quantities as formerly. Brown potter's-clay is also
raised and sent away in great abundance from the neigh-
bouhood of Fremington. These forts of clays are like-
wise found in much abundance in Berkshire, and fill more
fully in some of the midland districts, where the pits of them
are wrought to a vail extent. They are articles of great
importance and utility in several forts of manufactures, and
for which there is great demand in many inns.

Alum earth is a kind of stratified matter, which is met
with and raised from pits and quarries in a number of dif-
cerent situations, and various parts of the kingdom. In some
they are wrought to very considerable extents and advan-
tages, but in others in far less degrees, and with much less
success.

The frats of this earth are dug and got up in different
manner.
manner under different circumstances, but mostly by means of strong crows, picks, and other tools of a similar kind, being wrought in somewhat the same method as in the coal-mine. The business is usually executed by common labourers.

Fuller's-earth is another material of this nature, which is dug out of the ground from pits and quarries at different depths in several parts of the country. In some it is very abundant, and of a rich good quality, as in those of the middle and more northern parts of the island, forming an article of great use and demand in several branches of business. In others it is of much less valuable nature, being far less in request. That which is found about York, in Yorkshir, is consumed in the neighbouring fulling mills. The mills of this sort in Yorkshire, and other parts also, consume immense quantities. The material is raised from the places in which it is found in much the same way as many other earthy substances, but it seldom requires so much digging, as it is a hard earthy matter.

Fuller's-earth was formerly got up from pits and quarries in the neighbourhood of Maidstone, in Kent, and much ground brought over; but the beds of sand by which it is covered are of such depths, as to render the works of little value or importance.

Quarries and pits of mineral peat-earth are found in some districts, and much of the material dug up from them, and made use of when prepared upon land. The vale of Kinet, in Berkshire, contains vast quantities of it, as well as some other parts. It is a stratified substance which is dug up from under the surface at the depth of from one to fix feet, laying below strata of small thills and calcareous matter. In raising it, a peculiar kind of spade is made use of, which cuts it in long pangs, something like soap, which, when dry, are burnt into ashes and laid on the land. This substance is found to contain the oxygen of iron, gypsum, and the muriates of sulphur and potash, in the proportions of forty-eight, thirty-two, and twenty parts to that of one hundred.

It is suggested by the writer of the work on "Landed Property," that in most mountainous districts, and many low sandy counties, immense collections of vegetable mould or peat-earth lie in a state of neglect; even in places where they might be converted to valuable purposes not only as sources of fuel merely, but as manure, either using the vegetable matter in its raw state, or after being reduced to ashes. In all these situations it might be readily dug up from different places, and applied to different uses in each of these ways, the pits or other spots containing it working in a very easy manner. The ashes of it are only employed on any large scale in the above county.

Culm, coal, and cannel, are articles of the fuel kind, which are found in a vast number of places, all over the kingdom in pits, mines, or quarries, and which are of the greatest importance in many of them. Speaking of coals, the author of the work on "Landed Property," considers them as rising in the minds of men far superior to other productions and subterraneous matters, whether they are held in the light of agriculture, manufactures, or national defence. It is asked, if they were not for the colliers of this country, how many hundreds of thousand acres of its land, which are now appropriated to cultivation, would be required for the production of fuel? How many manufactories, especially those of iron, which are so valuable to civilized society, would be cramped, retarded, and stopped, in their progress and operations? And how many hardy seamen would be wanting to its navy? Surely, in his opinion, an indigenous production and material, on which the prosperity of the country so greatly depends, is entitled to the guardian care of its government; to anticipate the present expenditure, and the probable block which is remaining. Let us not, it is remarked, play the spendthrift, and, by the fables of a day, entail centuries of want on generations to come, and the curses of millions on the memory of the present times.

In endeavouring to find these sorts of sublimacies in parts where pits of them have not yet been wrought, the searchings, it is supposed by the same writer, should, in general, be done by the land proprietors of the particular places, in a conjunct manner. There are, however, certain instances, in which individuals may prosecute the search with propriety, and in the most beneficial manner. In doing which, the principal things to be guarded against are those of misjudgment and impugnation. Hence the necessary prudence of endeavouring to procure performers of skill and integrity for making such searchings; which are, in the first place, to be attempted by a close investigation of superficial appearances, and then where those are favourable in their nature, by the use of the boring rod or tool. It is supposed that, at present, there are none who are equal to such undertakings, except those who have been long conversant with the business of coal-work; men who have an interest in the exciting colliers or works of that kind. On this account it is thought to become a matter of common prudence, in a given situation, to endeavour to procure an undertaker or overlooker from a distant work; or such a one as can have no counter-interest to that of his employer; and then, closely to connect and bind them in one common interest. After having had different occasions for considering the subject, and for bellowing no small thought upon it, the writer is of opinion that the most eligible plan of proceeding, in such cases, is that of agreeing with an overlooker, or undertaker, to pay him reasonably, but not extravagantly, for his time, and for his actual expenses in prosecuting the necessary searchings; and, further, to agree to give him, in the event of success, a reward sufficient to call forth his best exertions; such reward to be payable, not on finding coal, but whenever the work, to be established in consequence of the discovery, shall have cleared the amount. In this way the proprietor will feel himself secure, while the person employed has the most powerful stimulus to industry, attention, and the accomplishment of the object of the undertaking.

Culm and coal have been met with and wrought in some degree, in Devonshire, Suffel, and some other of the southern parts of the island; but they exist much more plentifully in the midland and more northern districts, as well as in some places in Wales and Scotland. In Gloucestershire, coal abounds in most parts of the forest of Dean, and its vicinities, and probably to within a small distance of the county-town, as at Newent and Painsley, where pits are established. Tho' of a forest tract are very numerous, but not fully wrought for want of sufficient draining. Pits of this kind also exist in many places, in the lower vale part of the county. In this district, however, the coals are no where of the best quality.

In the counties of Salop and Somerfor, coals also prevail very much, various pits of them in both, being wrought to considerable extent. Tho' in the northern part of the latter district, have strata of them which form an inclination of the plane of about nine inches in the yard; and are in the number. They are seldom wrought where less than fifteen inches in thickness, but they vary from ten inches to upwards of three feet. The working is performed at considerable depths, especially since the establishment of improved machinery, and other means for raising them. The
coal is of the first quality, being pure and durable in burning, and from its firmness, largeness, and strength of grain, capable of being conveyed to any distance without injury. At present the quantity raised in these pits, is from fifteen hundred to two thousand tons weekly, but much greater supplies could be afforded, if they were wanted. The works are twenty-six in number, some of which afford a good profit.

The pits in the southern part are upon a more limited scale of work. In them the strata of coal form an inclination of the plane of from eighteen to thirty inches in the yard; but in some it is destroyed, and they descend in a perpendicular manner. There are, in number, twenty-five, which are in thicknesses from six inches to seven feet, being rarely wrought under eighteen inches. The depth of working is middling, but will be increased. The quality of the coal not the best, but tolerably good. The quantity now raised from these pits is from eight hundred to a thousand tons in the week, which might be easily extended. The working profits are by no means great. There are pits in other parts, but they are not many, or much wrought.

Against the apprehension of pits of this nature being exhausted or worn out in these places, it is contended that more than treble the present quantity is capable of being raised from the works already carried on, and that this increased quantity might be supplied for several hundred years to come.

The works and quantities of coals contained in the counties of Stafford, Derby, and Nottingham, are likewise very great, and mostly of good kinds; pits of them being carried on in many places to vast extent.

Cheffhire, too, is a coal district, in which a great variety of works for raising it are established in different parts, and much of it, which is of a very good quality, gotten up. The strata of coal here in many cases are several feet thick; and Wirral the seam is five or six feet thick, and the works extensive under the channel of the Dee. In some works the beds of coal lie at the depth of from seventy to one hundred yards below the surface of the ground, and are of different thicknesses to ten feet or more.

In Lancashire, coal of good sorts is most abundant. The beds of it run across the county in somewhat three different parts, as towards the north, nearly in the middle, and on the north-eaft part. Thole in the two first are of considerable breadths and thicknesses in different parts, but the third is much less broad and very thin in many places. They all run, in some degree, from the north-eaft to the south-well, constantly keeping somewhat the same direction, though occasionally branching out in a lateral manner to some extent. The works on each of these different lines of coal strata, especially the two most towards the north, are very numerous, and, in different inlines, of very considerable extent. There are some also established on the northern line, but they are of a far more limited nature. The layers or strata of the coals are of various widths, from a few yards to a very great distance, and their depths or thicknesses from a few inches to fix or seven feet. They lie at very different depths from the surface of the earth, according to circumstances and situation; on the eastern side of the county they sometimes nearly appear on the top of the ground, while in the middle, and towards the south-west, they are often a considerable number of yards deep. All about most of the large towns in the southern parts of the district very extensive works are established, where immense quantities of coals are raised for home use, as well as being sent coalways, and, in some cases, for exportation. They are a sort of material which is of vast importance to the manufacturing state of the county, and which contributes greatly to its prosperity. The quantity is so great, when considered as a whole, that they would seem to be almost inexhaustible.

The cannel coal, which is a sort that has some resemblance to fine black marble, is principally found and raised in the tract about Haigh, near Wigan, which is not more than a few miles square. It lies in pretty thick strata, at the depth of from five to seven or eight yards from the surface. It is of a very fine, hard, inflammable quality, being got up by sharp picks, often with considerable labour, and for which there is much demand, for domestic use, in the neighbourhood.

Coals also abound in the neighbouring counties of Cumberland and Northumberland, being found in many parts of the ealern mountains, and, with not many exceptions, all along the tract, which extends in different degrees of breadth, from Sebergham to Whitehaven, and along the coast to Maryport, forming and comprehending a district of about one hundred square miles, in the former. And they are met with in great plenty throughout the greatest part of the latter county, particularly in the lower district of it; being of the best quality, and the most numerous, and thickest seams, in the south-east quarter; whence those vast quantities are exported which supply the great consumption of the London market, as well as the coaling and foreign trade. A trade which is the foundation of the commerce of the country, and the principal source of its wealth, as well as a never failing nursery for some of the best seamen of the British navy. The former county has likewise works which supply prodigious quantities, both for home consumption and the coalways and export trade. Cannel coal is also raised in this district in pretty large supplies in the neighbourhoods of Caldbeck and Bolton.

Large portions of this article are likewise raised from the works in the county of Durham, which in some parts are carried on with much spirit and enterprise.

Coals are found, and raised in full supplies, in many places, in most of the counties of Scotland, so far as Perthshire; but they have not been met with any farther towards the north in any sufficient quantities. Where they exist, to any extent, in these situations, they are generally of good kinds, and capable of being got up without any great difficulty, seldom lying at any very great depth below the surface.

It has been contended by some, that the coals in the pits and other places, in this country, are inexhaustible, while others maintain the contrary to be the case; as the matter relates to the county of Northumberland, we have the following calculations, on the authority of the writers of the Agricultural Report of that district. And they may perhaps equally apply to others. It is supposed, that towards elucidating this point, it may be of some use to estimate what number of acres are wrought yearly in the county to supply the necessary consumption. In order to accomplish this object, the thickness and number of workable seams of coal must be first ascertained; for which purpose they have been favourably with sections, exhibiting the thickness and depth of the various strata, in some of the deepest pits in the county, one of which has a depth of two hundred and seven yards, with sixteen seams of coals; the other a depth of two hundred and forty yards, with fifteen seams; consequently, if the medium be taken between the two, it will be nearly fix yards thick of workable coal; from which may be formed, it is thought, a calculation of the quantity of coal in an acre of ground, supposing the aggregate thickness of the various seams amount to fix yards.
An acre of ground contains 4840 square yards, which, multiplied by the thickness 6 yards, gives 29040 cubic yards in an acre.

From which deduct 31 for waste and the parts or pillars necessary to be left in working

there remains 19360 cubic yards to be wrought.

And as three cubic yards of coal, when wrought, afford a Newcastle chaldron, therefore

19360 = gives 6453 Newcastle chaldrons per acre,

divided by 3

The coals exported yearly from the rivers Tyne and Wear, with Hartley and Blyth, amount to about 825,000 chaldrons, which, with the home-consumption of the two counties of Northumberland and Durham, will make the quantity of coals raised yearly about 1,000,000 chaldrons.

And the chaldrons raised yearly 1,000,000 = gives 155 acres nearly divided by the chaldrons per acre 6453 coal fix yards thick.

And by eliminating the breadth occupied by the caking coals to be on the average eight miles broad, and twenty-five miles long in the two counties, it is found that there will be about two hundred square miles, or 128,000 acres of coal proper for exportation.

From Newcastle 510,000 chaldrons.

Sunderland 315,000 ditto.

In all 825,000

Then the whole area 128,000 = 825 years. The time yearly consumption 155 before this space will be wrought out.

It is, however, suggested, that there are some reasons to suppose that a thickness of seam equal to fix yards will not be obtained all over an extent of two hundred square miles, probably not more, on an average, than four yards; in which case the coal will be exhausted in five hundred and fifty years. And if the aggregate thickness of the seams to be obtained should prove only three yards, then little more than four hundred will be the term of continuance; but it is probable, it is thought, that before the half of that time be elapsed, the price to the consumer will be considerably increased from the increased expense of obtaining them, and the increased length of carriage from the pits to the rivers; this last, it is presumed, may be reduced in some situations, by adopting canals instead of waggon-ways, which, it has often been wondered at, have never yet been attempted. From this investigation, it is suggested, that the apprehensions of exhaustion are not so chimerical as they have been supposed and represented to be by some persons. When, however, the vast extent of the working and unwrought tracts, in the different parts of the country, are considered, there cannot be any grounds for fear, in this respect, for a vast length of time yet to come.

Pits, some what of the quarry kind, are wrought in one district of this country, that of Cheshire, for the raising of rock-falt, in some of which large quantities of this material are procured, from different depths, and different thicknesses of the strata of it. In the getting of it different means are employed, as those of blasting, picking with implements, for the purpose of roofing, the using of hores, and machinery wrought by steam, for forcing up the sub-

stance, and some others. The digging, raising, and working of this article, employs a great number of labourers, and it is of much importance to the county in many points of view.

But though this sort of material is found in several different parts of the county, pits, or shafts of it, are at this time only wrought in the vicinity of the town of Northwich. This arises from a great many different causes, but principally from that of the want of water-carriage for the conveyance of the material from them. The number of pits or shafts, which there are at this time in work, for the purpose of raising this article, are about a dozen. They are by much the most commonly made in something of the square form, being secured on the sides by means of strong timber, but they have occasionally a round form, and are walled on the sides with bricks.

The beds of this material, that are to be raised, are wrought at various depths, the deepest being in general the most pure, and they vary equally in their thickness and directions, as suggested above. In some cases the beds are of the greatest thickness, the more they approach the north-east, decreasing in a gradual manner, in their course to the south-west; and in some instances they incline from north-west to south-east, dipping at the rate of about three feet in twenty-seven or thirty.

The Ilrata, which are passed through in getting at and working the rock-falt, lie in a very regular manner, and consist, in general, of a hard clayey sub stance and a part of gyppus material in mixture in various ways and proportions, that of the latter kind being the most predominant as the pit or shaft approaches the rocky saline substance. In working, the clayey matter is designated by the name of metal of the several different colours belonging to that part of the substance, and the other material by that of palest. These Ilrata are mostly of a solid compact nature, but occasionally broken in particular places, when the metal is termed flanny by the workmen.

In the buffets of working the pits, and raising the rock-falt, the rocky beds are reduced into pieces of proper sizes for the purpose, by means of blowing them with gunpowder, and those of splitting and dividing them with hammers and proper wedges for such uses; a good security headway or roofing being constantly provided in the first place, to the opening from which the falt-rock is to be taken, which is effected by the use of small sharp picks, carrying on the work in a plain fimple chambering manner.

The workings are funk from these chambers to different depths, as the nature of the beds of rock, and the quantity of the purer kind of rock-falt, or Prussian rock, as the workmen term it, may direct; but commonly about fifteen feet. Occasionally the roofs or headways of the pits or shafts are supported by considerable square pillars disposed in a somewhat regular manner, but in other cases they are wrought out in a fort of long openings, according as the workmen are inclined.

In getting the rock-falt, the workmen are paid by the ton at the rate usually of about two shillings, they finding the gunpowder and other tools.

In raising the falt from the pits or shafts, hores were formerly entirely made of, but within these few years, recourse has been had to the improved steam-engine, as already noticed, though it is not yet generally employed at every pit. See ROCK-SALT, ROCK-SALT Pits, SALT, and SALT BRINE SPRINGS.

It is evident from the above account, that in whatever way they are considered, the quarries of different kinds in this country are of very material importance to its prosperity.
QUARRY.

prosperity and convenience; contributing largely to the carrying on of different sorts of works and improvements. Without them much useful labour must be wholly at a stand; a variety of necessary business be incapable of being carried on; and the effects of it upon various arts and manufactures, be much too serious to be thought upon. In short, the numerous substanices of different kinds, which are taken from the bowels of the earth in this country, constitute one great source of our national wealth and prosperity.

Quarries, Pits, &c. Draining of, the proper, most convenient, and appropriate means of rendering all such forts of works dry, free from water, and in a fit state to be wrought with ease and advantage. In the effectual performance of all kinds of undertakings of this nature, there is occasion for the application of the same principles, which are spoken of and explained in considering the nature of draining land in general, and the particular manner which is necessary to be pursued in the practice of spring draining. See Draining of Land, and Spring-Draining.

There can be no doubt, indeed, but that the having recourse to such principles, and the modes of practice resulting from them, will be equally expeditious, beneficial, and successful, as well as in many situations of very material importance, in the various cases of this fort, as in those which have been mentioned; by leading to and introducing the most ready and easy means of diminishing the quantities of water, which are frequently met with in the course of working them, and which not unfrequently obstruct and hinder in a very high degree, but sometimes wholly put a stop to the work which is carrying on in them. Such, at least, is very often the case in quarries of the freestone, lime-stone, flag-stone, marble, and other kinds, as well as in pits of the coal and other forts. The want of this fort of knowledge, of course, is one great cause why such a number of quarries and works of that kind, in different parts, often lie altogether, or for a great length of time, in an unworked state; which might otherwise be wrought to very great advantage.

As it is now well understood, that most springs and subterraneous collections of water are formed and supplied from such grounds or lands as lie higher than that of the places where they are found or met with, which, on account of their being of an open or porous nature, admit that of rain and other forts of moisture to filtrate and pass freely through them, which sinking and descending to very great depths, through such open materials of the rocky, sandy, gravelly, and other loose qualities, before it becomes impeded and obstructed by some fort of impenetrable stratum or layer of an earthly or solid flinty nature, such for influence as those of pure flint or clay, or compact rock; it may happen, that in many such cases, in sinking pits or shafts for flint, coal, or any other kind of subterraneous material near the bottoms of hills or high grounds, beds of quicksand will be met with, and dug into, which are so full of water, that to pass through them becomes a most troublesome, difficult, and expensive piece of work, and sometimes impossible to be performed, but which, from knowing that the water proceeds from the porous ground that lies above, it may often be practicable to intercept and cut off the greater part of the water, before it reaches such sand beds in the quarries, pits, and shafts, by the means of boring into and tapping the water at the tail of the banks of this nature, provided that the ground naturally declines lower than the place where the sand is found in the quarries, pits, &c., and the whole or most of the water be drawn off, and diverted from them at a comparatively trifling expense to that which is employed as the common remedy in such cases and circumstances.

In order to accomplish this intention, it will be necessary, in ascending from the quarry or pit, to carefully examine and ascertain, if at any place higher on the declivity, any porous stratum, bed of rock, sand, or gravel, tails out, which may conduct and convey the water contained in it to the sand bed, which is below in the works; and where any such bed is found, to cut or bore into it in such a manner as to form a drain, that is capable of carrying away the whole or the greater part of the water, and of course to clear, or diminish the quantity contained in the quarry or pit, which would otherwise have continued to descend through such porous fabrikata or beds, and have continued to fill the sands, or quarries and pits.

But although this part of the business may have been accomplished, and the supply of water from the higher ground entirely cut off, a sufficient quantity to injure, hinder, and inconvenience the working of the quarries or pits, may yet continue to drain and ooze from the sides of the sand beds, notwithstanding they should happen to dip towards the lower ground, in which cases, however, that water may readily and with great ease be commonly drawn off at some particular point in it.

In order to effect this, and thereby remove the inconvenience of this filtering water, in descending from the quarries or pits along the declivity, it should be endeavoured to discover and ascertain, at what particular point or place in the low ground, the sand terminates or tails out, which is most likely accomplished by means of proper levelling; and if there should be there any appearance of the waters having a natural outlet, it may, by means of making in it a deep drain, be far more readily and effectually drawn off and removed; as springs, for the most part, naturally pass and flow through narrow, winding, convoluted openings, or perforations; of course, whenever the orifices or galleries are opened, enlarged, or made lower than before, the discharge of water becomes greater and more expeditious. Where, however, there happens to be a deep imperious layer or covering of clay, or other matter of a similar nature, placed above or upon the termination or tail of the sand, the drain need only be cut down to it or a little way into it, as by means of boring through it, or the remaining portion of it, a ready and easy outlet or passage may be given to the whole of the water, that may be contained in the sand-bed or other porous stratum.

This mode of draining quarries and pits may often be of great utility, advantage, and convenience, as it will also, in a great degree, remove, or at any rate relieve, the trouble and difficulty that would afterwards have attended the sinking the quarry, pit, or shaft; as the water thus drawn or cut off, must of necessity diminish and reduce the quantity, which would have been found at a greater depth, the fame body of it probably falling downwards from one stratum to another, as far as they continue to be porous, or capable of admitting it. Therefore, it is of very material importance to drain and lay dry all such ground as is situated higher, but contiguous to quarries, pits, or other deep subterraneous works of the same kind, for the above stated reasons. And it may, in general, be accomplished with but little trouble, difficulty, or expense, by adopting the same principles, and the same means.

But in regard to the removal of the water found and contained in the bottoms of such quarries, pits, or deep works, it must be drained off and got rid of in quite a different manner, as the level of the ground may probably be, or decline, nowhere lower than the mouths or openings of such quarries, pits.
pits, &c. as it is solely and particularly on the supposition, and in such cases as where the direction of the different strata and sand-beds have a dipping position with the natural inclination of the surface of the land, or lie nearly horizontally, that the method of proceeding which is stated above is practicable, or capable of being employed with any fort of advantage. But should they, for instance, lie in a reverse or contrary direction, there is but little possibility or chance of accomplishing the object, the removal of the water, unless by uncovering or hitting on their terminations, somewhere on the opposite sides of the hills or elevations, which in some cases may very nearly or exactly be found out, by ascertaining the precise inclination or direction of the materials of the quarries, pits, &c. and by a careful and exact notion of the level. But this will be much better comprehended, and a more clear, full, and perfect notion of its nature be afforded, by the section figure in the plate on draining quarries, pits, &c. in agriculture, as given by Mr. Elkington, in his work on that subject.

This is the manner which is to be pursued in preventing the effects of water, or cutting off that which is met with in sinking the quarries, pits, shafts, or other similar works, before reaching or arriving at the stone, coal, or other fort of material that may be wanted; but that which is found in the bottoms of these various kinds of undertakings, of which proceeds from the rocks or their sides, or in other ways, in the course of working them, is commonly got quit of by means of some fort of machinery, as that of the engine or other kind of pump, in order to afford in working of which, the water gained by cutting the drains already noticed may be particularly useful, especially where the usual stream for that purpose is insufficient in favoring the great expense of working such machinery by the power of steam. But without the aid of a natural stream, which is capable of being converted to this purpose, it is rarely possible to find, by means of drains, or in any other way, a quantity of water sufficient to drive such weighty machinery, in a situation of proper height, to have the full and necessary command of it. However, in many cases it may be an acquisition of great utility and value. It is explained at figs. 2, in the same plate.

In some situations, where a full and proper command of water can be had, and where the entrance to the quarry, pit, shaft, &c. is also suitable for the purpose, the use to which it may be converted and applied is still more important and advantageous, as the driving of machinery for bringing out the various kinds of materials, and at the same time working an engine-pump, in order to clear the works of the subterranean water which flows from the cavities of the rocks, which are met with in working these forts of pits, &c.

It has been remarked in Mr. Elkington's work on draining, in these cases, that the duke of Buccleugh's coal-works, near Langholm, in the county of Dumfries, afford a striking example of this, as well as of the superior powers of water and machinery, when properly combined, where a command of the former can be had, and when the latter is conducted on proper principles, and conducted with that care and ingenuity which are requisite in such difficult undertakings.

In working quarries of lime-stone, free-stone, and other forts of materials, it not infrequently happens, that at a certain depth, part of the rock or other body, which contains the water, is bit up, by which they are soon filled with it, as completely to put a stop to the work proceeding any deeper, where the bed and often the greatest part of the stone is situated. In all such cases, the most usual remedies have been, either the removal of a windmill pump, to draw out part of the water, as the whole cannot be taken away by such means, or the opening of a new quarry or pit contiguous to the other, which at the same depth most likely meets with a similar obstruction, or the bringing up of a very deep cut, often at great expense, under the level of the water, from the nearest declivity or hollow that can be met with. However, by the following method, all quarries of lime-stone, free-stone, marl, or other materials of the same nature, which are liable to such fort of obstruction, may be completely and effectually cleared of the water at but little expense; while, at the same time, the drain which is made may serve the double purpose of that, and the laying of the wet ground, caused by the spring contained in the rock, which is found contiguous to it, or dry.

There commonly lies, immediately under the rock, a bed of strong, stiff, retentive clay, which upholds all the water received and retained by that rocky stratum, and which being, at the same time, bound round on each side by a covering of the same fort of clayey material, or other stiff earthy substance, is not able to discharge itself, and of course constantly remains or stands full in the rock, so as to prevent the working or taking out the stone from the bottom.

In such cases it is necessary, in the first place, to endeavour to find to what depth the rock dips or inclines, which, in general, may easily be ascertained by the appearance of the surface, in examining the surrounding ground, and the aid of a proper level. When this has been discovered and fully ascertained, a suitable drain must be cut through the clayey covering to the rock, by which the water will be drawn off, which, for want of a proper outlet, formerly stood up in the hollows and cavities of the stratum or body. This is further and more fully explained by figs. 3 and 4, in the same plate.

But, in some cases, this fort of evil or inconvenience may be removed and remedied in a different way. As it frequently happens that a bed or body of the same stone, which has a close, compact nature or quality, is found lying under one which has a more open porous texture, with fissures and cracks in it, that are amissible of water, which obliterates and keeps up the water in the upper bed or layer, in such a manner, that not any of it can pass or filtrate through it to an inferior, or still deeper open stratum or bed; and on sinking or cutting through this compact bed of stone, another layer is met with, which is of so open and porous a nature, as to admit the reception of any water from the above one, which may come upon it.

And sometimes a bed of gravel or sand is found under that of the close stone, which being still more capable of absorbing or taking up any water that may be let down to it, is far better and more properly suited for the purpose of clearing the upper bed of stone from water, than a stratum of open stone itself.

Therefore, when this is discovered and ascertained to be the case, and the water is kept up by the second bed of stone, so as to be injurious and hurtful to the working of the upper bed, and which will be equally so in working the second; the work may be greatly freed and relieved by boring through the close bed of stone, and letting down the water into the more porous one below, or into a stratum or body of dry sand or gravel, should there be such a one underneath it. But in place of boring, the sinking of small pits through the close stone is a more effectual method of letting down the water, though a much more difficult one in the execution. The methods of digging and boring, even in the bottoms of quarries, pits, and shafts, where pumps and other machinery of the same nature are made use of, as has been noticed above, may, in some cases, not only be practicable, but advantageous for letting down the water which they contain into an inferior open stratum.

That
That of boring has been practised with complete success in the case of a colliery in the county of York, which had been wrought many years, and in which the water was raised about sixty yards by a steam-engine: the proprietors of which, on boring down from the bottom of the pit next to the engine-pit, to the further depth of about ten yards, in order to ascertain the depth or thickness of a seam of coal, which was supposed to lie below those then wrought; the workmen, on taking out the boring rods, found that the water from the works, which usually ran across the bottom of this pit to the engine-pump, now ran down the holes they had made. And that the steam-engine pump, on being set to work, contained little or no water, it having escaped through these holes, and continued to run through the same ever afterwards, rendering the pump inefficacious. It is remarked, that this instance of water at so great a depth from the surface, finding a passage at a further depth of ten yards, or less, and immediately below, is extremely singular and striking in its nature. The situation was much higher than the nearest contiguous valleys, or the level of the sea. Trials of this fort can seldom be made, therefore the cafes are rare, uncommon, and curious. But in extensive tracts of level land, where lakes or morasses have been formed, and which cannot be laid dry by cutting open drains, or driving levels through rocks, except at an expense for which the lands, when drained, would never compensate, the above instances warrant the trial of experiments with boring rods, which, if not attended with success, can be made at little expense.

In the county of Lancashire, about the town of Ormskirk, as well as in some other parts, flote quarries are cleared of water exactly in the manner which has been already pointed out, but which fig. 5, in the plate will explain much better.

The success of the practice has likewise been farther shown by the late T. Eccleston, esq. of Scarisbrick-hall, an ingenious and extensive proprietor of land in the same neighbourhood, who remarks, that in these quarries thereabouts, wells or pits are occasionally sunk to the open bed, which have proved serviceable. This mode was practised in a flotet dell near the above town in a very beneficial manner. But in order to lay the dell more effectually dry to a greater depth, Mr. Elkingston, on viewing the surrounding ground, marked out where he thought the rock terminated, or tailed out, and at the lowest level let a drain to be cut and carried up to the rock, part of which work has been executed, and a very considerable flow of water comes from it; but on account of its great depth, sixteen feet, the whole will not be finished before he has seen the work again. The drain he has thus laid out is about ten feet lower than the bottom of the flote quarry, and when completed, will lay the head or body of flote dry lower than the present floor. All rocks, for the most part, where they terminate, are succeeded by broken loofe flotes of the same nature as the rock, and they are frequently, nay almost always, succeeded by land, which, when in a thick bed, and of a running nature, such as quickflond, often cause great expense in cutting through to the tail end of any rock. This is more fully explained in speaking of the manner of draining in hilly lands, and where the rocks are of a mixed nature. See Spring-Draining.

Therefore, in all such cafes as this, where there is any danger of meeting a quickflond, boring or sinking pits through the bed of close flote, is by much the most advisable, and at the same time the least expensive method that can be purveyed.

The situations of marle pits are for the most part such, that they require very extensive cuts to be made through some parts of the surrounding banks or sides of them, in order to carry or convey off the superabundant quantity of water which prevents their being dug or wrought to advantage. This business might frequently be effected in a much less and more expensive manner, by the method of letting the water down by means of sinking pits or openings through the retaining and upheaving flotam underneath the bed of marle, into some absorbent porous body of materials lying still deeper, which is capable of receiving it. Where the space of ground that is occupied by the marle is of considerable size, several pits will be required, in order to effeetually carry off the water; and where it is necessary that they should be so deep as to be in danger of falling in, they ought to be walled round the sides, or filled up to near the top with loose flotes, through which the water can settle and find its way. And any such cuts or drains or cuts as may be necessary for the purpose of collecting the water must be so formed and conducted as to lead into the pits. But in many cafes the water may be removed and got rid of in a still more easy manner, especially where the situation of the ground is favourable and suited to the purpose.

In instances where the surrounding banks decline or fall on the opposite sides lower than the water, by cutting drainings into them, and boring with an horizontal auger into the tails of the strata containing the water, it may be drawn off and brought down to a level lower than that of the bed or body of marle. And as this water is not unfrequently supplied by a spring which rises in some part of the higher ground, and descends into the place where the marle is found, it will be necessary, in all such cafes, to cut off the source of it, and divert the flow of water into some other channel; by which means the quantity of water below will be silenced, and more easily and readily carried off by the pits or drains which may have been formed.

Mines and shafts, for the purpose of raising different sorts of metals, are often much impeded, or wholly prevented from being worked by the water which is brought into them from a distance, by various kinds of mineral strata. In many such cafes, the water flowing in this way may be intercepted, by making cuts up to the lowest banks of them, from some neighbouring water-course, or other convenient outlet, and then boring or digging pits in the bottoms of such cuts, when the metals to such depths or levels will be rendered free from water, and capable of being wrought. This will, however, be more amply shown in considering the manner of draining, in some cafes of wetnels, caused by springs arising in this way. See Spring-Draining.

In removing the water, or freeing the bottoms of quarries and pits from it, where machinery is required, the writer of the work on "Landed Property" has remarked, that in cafes where flat-bottomed drains are found to be impracticable, wall-drains and pumps become necessary, and are the most proper; as they may be wrought by water, where streams can be conducted to them; or by wind in high exposed situations; or in works of consequence, where fuel is moderately cheap, by small steam-engines. However, in instances where large bodies of water are required to be raised and discharged at the height of a few feet only, marsh-mills, such as are made use of in low marsh-land districts, are found the readiest and most useful kind of machinery for the purpose.

In some cafes of this nature, the bottoms of quarries, pits, and mines, may be cleared from water, simply by forming openings into them from some parts of the neighbouring ground where it falls lower than the levels of them, at sufficiently short distances, without any other more expensive works being undertaken for the purpose. This should always be fully considered before any means are reorted to
for laying them dry, as it may occasionally be the saving of much labour, trouble, and money.

Quarry, in Glascory, a pane, or piece of glass, cut in a lozenge, or diamond-form.

The word seems formed by corruption, from quarrel, (which see) unless we will suppose it to come immediately from the French квар. Qjure.

Quarries, or quarrels of glass, are of two kinds; viz. square and long, each of which is of different sizes, expreßed by the number of pieces which make a foot of glass; viz. 8ths, 10ths, 12ths, 15ths, 18ths, and 20ths; but all the sizes are cut at the same angle, the acute angle being 77° 19' in the square quarries, and 67° 22' in the long ones.

Quarry, in Falconry, is the game, or fowl, which the hawk is in pursuit of, or has killed.

Quarry, among Hunters, is sometimes used for part of the vêcera of the beat taken; given by way of reward to the hounds.

Quarry-Cart, a name commonly given to that fort of cart which is principally employed in the work of quarries, and which is generally of a low, compact, strong kind, in its nature, form, and manner of construction, in order to sustain heavy weights, and receive them without difficulty, or the danger of being destroyed. Carts for this purpose should always be made of well-seasoned wood, be well put together, and have sufficient strength of timber in those parts where the main stress of the load is placed. See Cart.

Some quarry counties have well-formed carts of this nature, as many of those towards the northern boundaries of the kingdom.

Quarry-Wagon, or Truck, a small carriage of the low-truck kind, which is much employed in the business of quarries, especially those of the flate kind, for the purpose of holding and conveying the rough materials, which have been blown from the large mafy rocks, or separated in other ways, out of or from the quarries and pits in which they are situated and contained, to the places where they are to receive their different preparations and shapes.

It is generally of iron, and constructed on a frame somewhat familiar to that of the common barrow, and mounted on two low light iron wheels on the fore part, having two feet behind, projecting from the frame, bent something in the manner of the letter S, and of sufficient length to let it stand or roll in a horizontal position while it is in the act of being loaded. These feet are usually made of iron, but they may be formed of other materials. A sort of inclined plane is formed from the bottoms of the quarries or pits, up which it is forced, with great ease and facility, by the workmen, or small animals of the horse kind, after being filled with these forts of heavy materials. It is a very useful and convenient machine in this application, being met with in most of the flat quarries in the northern part of Lancashire, as well as in those of many other districts of the kingdom.

Quarrying, the business of directing and conducting the nature and management of sinking the different kinds of quarries, pits, and shafts, as well as of the different forts of work which are necessary to be undertaken, carried on, and performed, in the several different descriptions of them; such as those of separating, getting up, and preparing the various forts of materials for use in the arts, or in other ways. It is a practice which requires considerable knowledge and experience, to be fully master of it in all its different bearings and intentions. See Quarry, and Quarrying Slates and Stones.

Almost every fort of quarrying-work requires a different kind of management, not only in the opening and sinking the quarries and pits in the grounds at first, but afterwards in the methods and practices of working them, and getting up the various forts of materials from them, as well as in the modes of preparing, trimming, and arranging them, after they have been raised. They are, however, mostly well known and familiar to the quarry-men and pit-men who are usually engaged in works of the several different kinds.

Quarrying Slates and Stones, the methods of preparing and lifting them for their different uses and applications at the quarries and pits where they have been raised. The former of these articles, particularly those of the blue, green, and purple or blackish kinds, undergo several different forts of preparation in the quarrying, according to the purposes to which they are to be afterwards applied. They are separated and divided into very thin pieces or plates, where light, neat coverings are required, or in much demand; but for more strong and heavy coverings, in exposed situations, or other places, they are split into much thicker sheets, layers, or plates, and are, of course, much smaller in their appearance.

Each fort in the business of quarrying is wrought in a separate manner, and packed up by itself; the different forts having appropriate names, as has been already seen.

The white or brown slates are never divided and prepared in to fine a way as the other kinds, but separated into much thicker flakes or laminæ, in this intention. The blue, green, and purple or darkish sorts, are, for the most part, found capable of being split into very thin laminæ or sheets, but those of the white, or brownish free-rock kinds, can seldom be separated or divided in any very thin manner, as the layers of the large mafes of the flones are of a much thicker nature, and consequently form heavy, strong, thick coverings, proper for buildings in exposed climates and situations, and of the more rough kinds, such as bars, slates, and other forts of out-houses.

In the different operations and process of this fort of quarrying, slate knives, axes, bars, and wedges are chiefly made use of in the different intentions of splitting and cleaning the sheets, they being separated into proper thicknesses by the axes, bars, and wedges, and afterwards chipped into their proper forms and shapes by the knife. All the different inequalities which may appear upon any part of them, are likewise removed by this last fort of implement.

In the quarrying of the latter sorts of materials, or those of flones, the work is usually performed in such a manner as to suit the different uses for which they are intended. Where flags are to be formed, they are split or riven into suitable thicknesses, and squared to different sizes, so as to be adapted to different applications. These operations are executed in rather a rough way, as they are afterwards to be finished by the flone-mason. When for flags, they have the proper breadths and depths given to them in a sort of squaring manner, being left to be completed as they may be wanted for particular uses and applications. Gate-pots are, for the most part, quarried so as to have from about a foot to a foot and a half or more in the square. Trough-flones have the quarrying performed so as to be formed into various proper-fixed squares or other forms, in a rough manner, being left in these states to be afterwards hewn and hollowed out, in the intended parts, by the flone-masons.

Stones for building purposes are usually raised and quarried out roughly into something of the square shape, being left in that state for the builders, who afterwards fit them so as to suit their own purposes and intentions.

In the quarrying of flones, the quarrymen commonly make use of large hammers, with cutting ends on one side, the other being formed in a plain manner; strong, sharp, crow-bars,
bars, and broad, sharp, iron wedges; by which means these matters are, from the constant practice of the men, split and torn into such forms as are wanted with great ease and facility. See Quarry.

Quarrying tools, the different sorts of implements which are employed or made use of in the different works of this kind, as in the raising and preparing the various sorts of materials of this nature. They are principally such as those which have been noticed already, and different descriptions of picks, mattocks, and jumpers, or boring implements, for the purpose of blasting the various kinds of stone, and other hard materials. These tools are individually described under their particular heads. See each of them.

Quarryings, the small pieces which are broken or chipped off from the different sorts of materials which are found and wrought in quarries, while they are undergoing their different preparations for various uses. These substances, where they are of the hard kind, such as those of the blue and lime-flint, as well as some other sorts, are extremely well calculated for the purpose of forming and repairing roads, as they are nearly, if not quite, in a state fit for immediate application in this way. Materials of these kinds ought, therefore, where they can be conveniently had, never to be neglected by those who have the care and management of roads, as they will save much expense and trouble, in a great number of instances. See Roads.

Quart, q. d. fourth, in Music. See Quarte.

Quart is particularly used for a diminutive measure, containing one-fourth, or quarter, of some other measure; which see.

The English quart is a fourth of a gallon, or two pints; the Roman quart, or quattuorarius, was the fourth part of their congius.

The committee appointed for examining the standards of weights and measures, and ascertaining those that shall be used in this kingdom, delivered it as their opinion, in their report to the House of Commons, A.D. 1814, that the gallon ought to contain 10 pounds of pure water, or 276.48 cubic inches; that the quart, or quarter of the gallon, ought to contain 40 ounces of water, or 69.12 cubic inches; and that the pint, or half of the quart, ought to contain 20 ounces of water, or 34.56 cubic inches.

The French, from whom we borrow the word, besides their quart, or pot of two pints, have various other quarts, distinguished by the whole of which they are quarters; as quart de muid, and quart de bouteille. See Muid, and Bouteille.

Quart of Butter, in Rural Economy, a name given to a lump which contains the quantity of three pounds; and which is a mode of selling it that is peculiar to some districts, it being carried in this state to the markets.

Quart de Soupir, in Fr. Mufic, is a rest equal to a semiquaver. By a 4th part of a soupir is meant an equivalent to a double croche, or two quavers in French, and one crochet in English. See Time-table, and Value of Notes.

Quart de Ton, Fr., a quarter of a tone, an interval introduced into the enharmonic genus by Aristoxenus. We have neither ear nor harmonic calculations that can furnish us with the exact interval or ratio of a quarter-tone; and when we consider what nice geometric operations are necessary to fettle it on the monochord, we are very apt to suspect that this true quarter-tone never has been nor ever will be produced exactly in tune either vocally or instrumentally. Musicians, however, call the difference between Aₚ and D₀, a quarter-tone, an interval which, though in nature, is annihilated by temperament.

This quarter-tone is pretended to be of two kinds; the enharmonic major, in the ratio of 576 to 625, which is the complement of two minor semitones to a tone major; and the enharmonic minor, in the ratio of 125 to 128, which is the complement of the same two minor semitones to the minor tone. Rouffeau.

Quartan, in Medicine, an ague or intermittent fever, the paroxysms of which occur every third day, leaving two intervening days without fever. This is vulgarly called a third-day ague; but in medical language it is termed quartan, or fourth-day ague, because if we reckon the day on which the disease commences as one, then the second paroxysm is on the fourth day, which again becomes one in relation to the succeeding paroxysms. See Fever, Quartan, and Ague. See also tertian.

Quartarius, a measure among the ancients, being the fourth part of a sextary, and nearly equal to a quarter of a pint of our wine-measure.

Quartaro, in Commerce, a liquid measure at Venice. The amphora, which is a wine-measure, contains 4 bigoncioli; a bigoncio 4 quartari, 16 fecchie, or 256 lb. Pefo groppo; but a bigoncio of brandy is only 14 fecchie, or 56 lb. Kelly's Un. Cambia.

Quartation, in Metallurgy, is the separation of silver from gold by means of aqua fortis or nitric acid; which is an operation that has something singular in it. If silver and gold are mixed together into a mass, and the gold is not less than one-third part of the mass in weight, the beet aqua fortis poured upon it is not at all capable of dissolving the silver; but if you add more aqua fortis to this mass, by melting it again in the fire, with such a necessary addition of that metal alone as should bring the gold in the mass to the proportion of less than one-third of the whole, and suffer it to cool, then aqua fortis poured on it will corrode the silver from it; this is also by so much the more strongly performed, as the quantity of gold is less than in the proportion of one-third of the whole mass; but experience has taught us, that aqua fortis dissolves silver mixed with gold quickly enough when the gold constitutes but one, and the silver three parts of a mixed mass of them; and in this case, if the solution is not too impatiently performed, the gold usually remains in such a proportion, in the fame figure that the whole mass had before the separation of the silver by this menstruum; so that, in this case, there is no reason to apprehend the gold's being torn into minute particles, and dissolved in some measure; though this can hardly be prevented when the silver exceeds the three-quarter proportion, in regard to the gold in the mass. The artificers, therefore, always make it their study to observe very exactly this proportion of the gold being one-fourth part of the mixture; and thence it is that the operation itself has been called quartation.

In order to ascertain nearly the proportion of gold and silver in a mass, the allayers rub this mass upon a touch-flone, so as to leave a mark upon it; and they then make marks upon the flone with some of these needles, called touch-needles, the colour of which they think comes nearest to that of the mass; by comparing the marks of these needles with the mark of the mass, they discover nearly the proportion of the gold and silver in the mass. The mass of gold and silver to be quartered ought previously to be granulated, by melting it in a crucible, and pouring it into a large vessel full of cold water, while at the same time a rapid circular motion is given to the water by quickly stirring it round with a thick or broom. The vessels generally used for this operation are called parting-galles. The aqua fortis must be purified for this purpose, and should be so strong as to be capable of acting feebly on silver when cold, but not too strong as to act violently. If it be very strong, and the vessels well...
well cloathed, a small quantity of the gold will be dissolved along with the silver, which is to be guarded against. Little heat ought to be applied at the beginning, the liquor being apt to fizzle and rise over the vessel; but when the acid is nearly saturated, the heat may be safely increased. When the solution cools, which may be known by the discontinuance of the effervescence or effusion of air-bubbles, the liquor is to be poured off. If any grains appear entire, more aqua fortis must be added, that all the silver may be dissolved. If the operation has been performed slowly, the remaining gold will have filled the form of distinct masses, which are to receive solidity and colour by putting them into a retort under a muffle, and making them red hot. If the operation has been performed hastily, the gold will have the appearance of a black mud or powder, which, after five or six washings with pure water, will be melted. The silver is usually recovered by precipitating it from the aqua fortis by means of copper vessels, into which the liquor is poured, or of plates of copper, which are thrown along with the liquor into glass vessels.

A considerable heat is required to accelerate this precipitation.

Dr. Lewis observes, that when the aqua fortis has been perfectly saturated with silver, no precipitation is occasioned by plates of copper, till a drop or two of aqua fortis is added to the liquor, and then the precipitation begins, and continues as usual. The precipitated silver must be well washed in boiling water, and tufed with some nitre, the use of which is to fecify any cuprous particles which may adhere to the silver.

Here we may add, that silver and gold may be parted from one another by the vitriolic acid, as effectually, though not so commodiously, as by the nitrous. If the compound be reduced into grains or thin plates, and boiled in about twice its weight of oil of vitriol to dryness, the silver will be so far corroded, as to be easily washed off by a little more of the acid; or if the mafs, after the corrosion, be melted in a crucible, the gold will separate and subside, the silver forming a scoria above it. Gold may be purified in the same manner from several other metallic bodies. M. Scheffer says, that this is the most direct way of separating tin from gold. Lewis’s Com. Phil. Techn. 95. 149, &c. See ASSAYING, DEPART, and GOLD.

QUARTA, in Commerce, a wine measure in some parts of France: thus, at Blois, 3.74 quarts are equal to 100 English gallons, and each of them contains 6183 cubic inches; in Burgundy, 3.68 quarts are equal to 100 English gallons, and each contains 6175 cubic inches. Kelly’s Un. Cam. A

QUARTE, Fr., Quarte, Ital., the 4th in music, and the third consonance in point of perfection, according to the order in which concords are generated.

The 4th is a perfect concord; its ratio is 3 to 4. It is composed of three diatonic degrees, formed of four sounds; whence it has its name of fourth. Its interval is composed of two tones and a half: a tone major, a tone minor, and a major femitone.

The 4th may be altered two several ways: 1st, by diminishing its interval a femitone, and then it is called the diminished 4th; 2dly, by augmenting it a femitone, and then it is called a tritone, or superfluous 4th. (See Tritonus.) The diminished 4th is never used in harmony, and only touched now and then in melody as an appoggiatura, or note of refinement.

The 4th in thorough-bass is accompanied by the 5th, and called by some the chord of the 1st.

Another chord is called the superfluous 4th, or tritone, by the French; which is what we call the chord of the 7th, or 5th, in which the dissonance is in the base; but it is not the chord of the tritone, unless the 4th is sharp. See CHORD, and ACCOMPANIMENT.

The succession of two perfect 4ths is allowed in composition, even in similar motion, provided they are accompanied by the 6th; but these are passages that must not be abused, or pulled too far, as they are not authorized by the fundamental base. The Italians call a regular succession of chords of the 6th falsa bordone; for which see FOURTH.

QUARTELL, in Commerce, a measure for train-oil at Hamburg: it contains 2 tonnes, or 64 rubgens, and is reckoned at 2 centners, or 224 lbs. net weight. Kelly.

QUARTELOIS, CARTELOIS, or Coriace, furcots, or upper garments, with coats of arms quartered on them, worn by the ancient knights in their military expeditions.

QUARTER, the fourth part of a whole, or integer divided into four equal portions.

In working of fractions, the quarter is expressed by ¼; three quarters by ¾.

QUARTER, as a Weight, is a fourth part of the quintal, or hundred-weight.

The quarter is 28 pounds avoirdupois.

The quarter is also a dry measure, containing of corn eight bushels, or two facks, being that by which corn is generally sold in the London market, and in large quantities in some districts of the country; and the quarter of coal is the fourth part of a chaldron, called a vat.

"Quartierum fragmenti conflat ex octo buffellis." Flata, lib. ii. This seems to have signified originally the fourth part of a ton in weight, or capacity. See WEIGHT.

quarter, in Astronomy, the fourth part of the moon's period, or lunation, which is divided into four stages, or quarters; containing each from seven to eight days.

The first quarter is from the new moon to the quadrature; the second thence to the full moon, &c.

Quarters, in Heraldry, is sometimes used for an escutcheon, or coat of arms.

In this sense there are sixteen quarters required to prove nobility, in companies, or orders, where none but nobles are admitted.

The word quarters, required as a proof of nobility, is derived hence, that they used anciently to put the coats of arms of the father, mother, grandfather, and grandmother, on the four corners of the tomb of the deceased.

In Flanders and Germany we frequently see tombs that have eight, sixteen, and even thirty-two quarters.

Quarter is also applied to the parts or members of the first division of a coat that is quartered, or divided into four quarters. See QUARTERING.

The king of Great Britain, in the first quarter, bears gules three lions paffant or, &c. In the second quarter he bears azure three fleurs-de-lis, &c.

Quarter, France, is a quarter single, or alone; which is to poise the one-fourth part of the field.

This makes one of the honourable ordinaries of a coat. See ORDINARY.

Quarter, in Law, Quarterium Anni, is the fourth part of a year.

Hence the days on which these quarters flately commence, are called quarter-days.

Quarter-days are the 25th of March, called Lady-day; the 24th of June, called Midsummer-day; the 26th of September, called Michaelmas-day; and the 25th of December, or Christmas-day.

Quarter, Fr., in old counterpoint, was proceeding in ditant by a succession of 4ths; which was called, in barbarous
barous Latin, dextrarum; of which we have instances in the "Micrologus" of Guido.

Quarter, in Navigation. A quarter of a point, wind, or rhumb, is the fourth part of a cardinal point, wind, or rhumb; or of the distance between two cardinal points, winds, &c.

The quarter contains an arc of 11 degrees 15 minutes.

The quarter is what Welling, with regard to the other divisions, calls a secondary point of the second order.

Quar'ter of a Ship is that part of the ship's fide which lies towards the stern; or which is comprehended between the aftmost end of the main chains and the fides of the stern, where it is terminated by the quarter-pieces. Although the lines by which the quarter and bow of a ship are determined, with respect to her length, are only imaginary, yet experience appears sufficiently to have ascertained their limits; so that if we were to divide the ship's fides into five equal portions, the names of each space would be readily enough exprefl. Thus the firt, from the stern, would be the quarter; the fecond, abait the midship; the third, the midship; the fourth, before the midship; and the fift, the bow. Falconer.

Quarter, On the, in Sea Language, may be defined an arc of the horizon, contained between the line prolonged from the ship's stern and any dillant object, as land, ships, &c. Thus if the ship's keel lies on an efl and west line, the stern being westward, any dillant object, perceived in the north-west or south-east, is faid to be on the landboard or ftrord quarter.

Quarter is also used for a canton, or divifion of a city; confifling of several ranges of buildings, &c. separated from other quarter by a river, a great ftreel, or by other boundary.

Such are the twenty quarters of the city of Paris. Ancient Rome was divided several times, under its several augmentations, into quarters, which were called regions; as may be observed in the topographies of Aurelius Victor, Onuphrius Panvinius, Marilian, Pyro Ligorio, Doffard, and other antiquaries.

In many cities there are collumbs of the quarter appointed to look to the policy of them. The prior of the Caporions accounts him of the chief and colonel of the fourteen regions, or quarters, of Rome. Muc. Carat. p. 134.

Quar' ters, French of. See Franchise.

Quarter, in War, the place allotted to certain forces to live, lodge, and encamp upon, during a siege, or the like. See Camp.

The general's quarter, called the head-quarters of an army, is that where the general lodges and encamps in person. They used to make lines of communication, to join the several quarters together.

Quar' ters at a Siege, are the encampments on the principal paffes about a place; serving to flop the avenues, and to prevent relief and convey.

Quarter is also used for any lodgment made in the field, or champagne, out of a siege. Thus they fay, the general has extended his quarters a good way; the enemy coming by, made him contract his quarters.

Quar' ters, Intrerected, denote a place fortified with a ditch and parapet, to secure a body of troops.

Quar' ters, Winter, the place allotted troops to pass the winter season in. Wherein these differ from garrisons, see Garrison.

Winter quarters, when cold or moist, are productive of inflammatory disorders, particularly hard coughs, with inflammations of the pleura or lungs. See Barracks.

Quar' ters, Winter, are also used for the time the troops continue in this lodgment; and for the advantage the captains make of it.

In Spain they have also summer quarters.

Quar' ters of Affed'ue, is the place of rendezvous, where the troops are to meet and draw up, to march in a body.

Quar' ters of Refrefmen, denote some well provided, fertile spot, to which troops, that have been much fatigued and harassed, are sent to recover their strength, or health; even during the season of the campaign.

There are also quarters alligned for the bucketers, and their equipage.

Quar' ters also denotes the safety and good treatment promised to perfons or troops that surrender, and lay down their arms. Thus we fay, the enemy begge quarter.

The plarfe took its ride from an agreement ancietly made between the Dutch and Spaniards, that the ransom of an officer, or folder, should be a quarter of his pay. Hence, to beg quarter was to offer a quarter of their pay for their safety; and to refuse quarter was not to accept of that condition for their ransom.

On an enemy's submitting, and delivering up his arms, the victor cannot with justice take away his life. In a battle, quarter is to be given to those who lay down their arms; and at a siege, a garrifon offering to capitulate are never to be refu’d their lives. If sometimes, however, in the heat of action, the folder refuses to give quarter, it is always contrary to the inclination of the officers, who eagerly interpose for saving the lives of such enemies as have laid down their arms. Nevertheless, there is one cafe, in which life may be denied to an enemy who surrenders, and also capitulation refused to a place. This is when the enemy has been guilty of some enormous breach of the law of nations, and particularly if it be at the same time a violation of the laws of war. This denial of quarter is no natural confefion of the war, but the punishment of his crime; a punishment which the injured party has a right to inflict; but that the punishment may be just, it must fall on the guilty. When the war is with a savage nation, which observes no rules, and never gives quarter, it may be chastifed in the perfons of any that are feized or taken, among the guilty; fo that by this rigour they may be brought to conform to the laws of humanity. But wherever severity is not absolutely necessary, clemency is to be used. Corinthus was utterly destroyed, for having violated the law of nations towards the Roman ambassadors. However, that severity has been cenured by Cicero, and other great men. He, who has even the moll just caufe to punish a sovereign as his enemy, will always incur the reproach of cruelty, if he should cause the punishment to fall on the innocent people. There are other methods of chastifing the sovereign; as the depriving him of some of his rights, taking him towns and provinces. The evil which a whole nation suffers is the participation inevitable to the members of a political society. The learned Vattel exprefies his aflumption that, in a knowing age, it could be conceived that it is lawful to punish with death a governor who has defended his place to the last extremity; or who, in a weak place, has professed to make a stand against a royal army. Yet, even in the 17th century, this notion was so common as to make an article in the law of war; and, at a later period, it is not wholly exploded. What a thought! to punish a brave man for having performed his duty. Very different were the principles of Alexander the Great, when he gave orders for sparing some Milesians, "on account of their courage and fidelity." It is in vain to object, that an obstinate defence, especially in a weak place, against a royal army, only causes a great effusion of blood to no purpose; for this defence may save the flate, by delaying the enemy some days longer; and,
and, besides, courage supplies the want of fortifications. It is urged farther, that by threatening a commander with death, you may shorten the bloody siege, spare your troops, and gain a valuable opportunity. The answer is, says Vattel, that a brave man will delibe your menace; or, provoked at such ignominious usage, will fell his life at a dear rate, make you pay for your injustice, and bury his-.

self under the ruins of his fort. Besides, the menace of an unjust punishment is unjust in itself; it is an insult and an injury. But to execute it, would be barbarous and hor-

rible; and if it is not to take effect, it must be allowed to be vain and ridiculous. Nevertheless, just and lawful means may be used for inducing a governor not obstinately to re-
duce himself to the last extremity; and this is at present done by all wise and humane generals. A governor is summoned to surrender, and in the progress of the siege an honourable and advantageous capitulation is offered him, with an intimation that if he stays too long, he will be ad-
mitted only to surrender as a prisoner of war, and at difcre-
tion: if he perfists, and is at length forced to surrender at difcretion, all the severity of the law of war may be used, both against him and his troops. But this right never ex-
tends so far as to deprive an enemy of life, who lays down his arms, unless he has been guilty of some proportionate crime towards the conqueror. See CAPITULATION, PRISONERS OF WAR, and REPRISALS.

Quarters, in Building, those flight, upright pieces of timber, placed between the pannels and posts; used to lath upon. They are of two kinds, single and double. The single quarters are fawn to two inches thick, and four inches broad; the double are four inches square.

Quarters in a clock, are little bells, which found the quarters of an hour.

Quarters, in Sea Language, the several stations of a ship's crew in the time of action. See Quartering the Men.

Quarter, in the Manger, to work from quarter to quarter, is to ride a horse three times upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second; and so to the third and fourth, always changing hands and observing the same order.

Quarters of a Saddle, the parts or pieces of leather, or fluff, which are made fast to the lower part of the sides, and which hang down below the saddle.

Quarters of a Horse, and other Animals, the four prin-
cipal parts of the animals; the fore-quarters consist of the shoulders and the fore-legs; the hind-quarters, of the hips and the hind legs.

In the horse, the fore-quarters or shoulders should al-
ways fall in a neat manner backwards, where they join with the breast, and the hind-quarters be suitably long and well shaped towards the rump. Something of a simi-
larly of shape should likewise prevail in the quarters of neat cattle, sheep, and swine, but they should be much more fleshly downwards as they approach the thigh and leg parts. See Live-Stock, Horse, Sheep, and Swine.

Quarters of the Foot, in horses, are the sides of the coffin, comprehended between the toe and the heel on both sides; the inner quarters are those opposite to one another, facing from one foot to the other; those are always weaker than the outside quarters, which lie on the external sides of the coffin. A horse is said to have a false quarter, when the hoof has a kind of cleft occasioned by the clefting the quarter and getting a new one, for then the horn becomes uneven, and also lofter than the rest of the hoof; and the foot should be fixed with some nicety. But if the cleft be considerable, and take up a fourth of the hoof, the horse is worth little afterwards for any purpose.

Quarter-Cut, among horses, is when for any disease in the coffin-bone or joint, one of the quarters of the hoof is cut off, and when thus cut, the reproduction of a new hoof or part takes place. It is a common occurrence among some horses.

Quarter-Evil, among domestic animals of the next cattle,

kinds, is an affection which sometimes takes place in the glands of the udders, and sometimes in different parts of the feet.

Quarters, in Gardening, the large divisions of garden grounds, or those parts of them which are situated be-
tween the different walks, at a distance from the small, nar-
row portions on the fides usually termed borders, and which form or constitute the principal spaces or compartments for the cultivation and growth of the various sorts of the more useful culinary vegetables which are raised in large quan-
tities; such as peas, beans, cabbages, cauliflowers, broccoli, early potatoes, and many others.

It is necessary to have the quarters of garden grounds formed and laid out in such a manner as to favour the
growth of early and late crops of the several different sorts, as much as possible; those for the former having a southerly, or south-western exposure, and those for the latter, an easterly or north-easterly aspect. By these means, early crops are, in some measure, rendered more forward and fine, and those of the more late kinds, in some degree, prevented from being injured or burnt up and destroyed by too full an exposure to the heat of the sun.

It is usual during the winter season to have the large quarters of garden grounds laid up in high ridges, in order to be exposed to the influence and effects of frost, by which the earth may be rendered more light and mellow, and be in a more fit rate for sowing or planting in the spring months, on throwing them down and rendering them level for the purpose.

The large quarters of gardens should likewise be kept as free and open as possible, not being inclosed and choked up, as is too frequently the case by planting fruit-trees and shrubs on their sides, either in the manner of espaliers or otherways, as by such means the growths of the plants are much promoted, and they are prevented from being drawn up in a weak manner. See Garden.

All forms of garden grounds are found, except that of the square, to derange the regularity of the quarters, and, of course, to render them highly troublesome in digging and cropping. Where they are very large they may be subdi

vided into suitable fizes, as one hundred feet in breadth, &c.; but their length does not signify, as it is may be varied in different ways, as by rows of trees, bushes, or which, in many cafes, are preferable, by trodden walks and the modes of cropping.

Quarters of a Garden, the several divisions into which it is formed for the purpose of cultivating the different kinds of vegetables, fruits, &c. Thus, there are parts or quarters destined to the growth of kitchen vegetables, fruit, and other trees, forcing, &c.

Quarters of a Field, or Farm, in Agriculture, are the particular parts of them, which are under, set apart, or intended for any fort of crops, or peculiar modes of cul-
tivation and management. Farmers are frequently in the practice of dividing their lands or farms into different quar-
ters or parts, according to the different sorts of husbandry which they are proper for, and the manner and succession in which the various kinds of crops are to be grown upon them, and the same is often the case with large fields; four, five, six, and more divisions or quarters, being common in such instances.
instances. This plan of proceeding is supposed to give cafe, facility, and dispatch, to the work which is afterwards carried on, as well as to have several other advantages and conveniences. See Farm.

QUARTER-Bill, in Sea Language, a roll or list, containing the different flations, to which all the officers and crew of the ship are quartered, in the time of battle, and the names of all the persons appointed to those flations.

QUARTER-Bullet, a bullet quartered into four or eight parts.

QUARTER-Chord, in Mining, seven yards and a quarter, which the miner hath cros-ways of his vein on either side, for liberty to lay his earth, flones, and rubbish on, and to wash and dres up his ore.

QUARTERS, Close, in a Ship. See Close-Quarters.

QUARTER-Cloths, are long pieces of painted canvas extended on the outside of the quarter-netting from the upper part of the gallery to the gang-way. They are generally decorated with martial instruments, or allegorical figures.

QUARTER-Day. See Quarter.

QUARTER-Deck of a ship, is aloft the quarterage, reaching to the round-house; or that deck in ships of war which extends from the main-mast to the forecastle, next above the upper-deck.

QUARTER, Fat, in a Ship, denotes the fame with broad.

Thus, if the trifling in, or tack of a ship's quarter under water be deep, they lay, the hath a fat quarter.

QUARTER-Gallery, a fort of small balcony, with or without balustrades, on the quarter of a ship; which generally communicates with the gallery on the forecastle, by means of a door palling from one to the other.

QUARTER-Guard. See Guard.

QUARTER-Gunner, is an inferior officer under the direction of the gunner of a ship, whose he is to affit in every branch of his duty; as keeping the guns and their carriages in proper order, and duly furnished with whatever is necessary; filling the powder into cartridges; scaling the guns, and keeping them always in a condition ready for service. The number of quarter-gunners in any ship is always in proportion to the number of her artillery; one quarter-gunner being allowed to every four cannon.

QUARTER-Netting, is a fort of net-work, extended along the rails on the upper part of a ship's quarter. In a ship of war these are always double, being supported by iron cranes, placed at proper distances. The interval is sometimes filled with cork or old sails, but chiefly with the hammocks of the sailors, so as to form a parapet to prevent the execution of the enemy's small arms in an engagement.

QUARTER-Pieces, substantial pieces of timber, moly of fir, that form the outboundary of the forecastle, and connect the quarter-galley to the forecastle and tofiffel.

QUARTER-Point of the Compofts. See Point.

QUARTER-Rails, in a Ship, are narrow-moulded planks, generally of fir, reaching from the top of the forecastle to the gang-way. They are supported by flanchons, and serve as a fence to the quarter-deck, to prevent the men from tumbling into the sea by the rolling of the ship, particularly in small vessels.

QUARTER-Round, in Architecture, is a term used by the workmen for any projecting moulding in general, whose contour is a perfect quadrant, or quarter of a circle, or which approaches near that figure.

The architects usually call it ovolo; and Vitruvius, the tectum.

QUARTER-Session, General, Court of. See Court of General Quarter-Session, and Sessions.

QUARTER-Staff, a long staff, or pole, borne by foresters.
of soldiers against their wills; it is also enacted by the 31 Car. II. c. 1, that no officer, military or civil, nor any other person whatsoever, shall presume to place, quarter, or billet any soldier on any subject or inhabitant of this realm, of any degree, quality, or profession whatsoever, without his consent; and every such subject or inhabitant may refuse to furnish or quarter any soldier, notwithstanding any command, order, warrant, or billeting whatever. The present mode of quartering our troops is settled by the Mutiny Act, renewed annually, with little or no alteration. Accordingly by the mutiny act, 49 Geo. III. c. 12, f. 41, the constables and other chief officers and magistrates of cities, towns, villages, and other places, and in their default or absence, any one justice inhabiting in or near such place, and no other, shall and may, during the continuance of this act, quarter and billet officers and soldiers in inns, livery stables, alehouses, victualling houses, and the houses of sellers of wine by retail to be drank in their own houses or places thereunto belonging, (other than publicans' cellars held under the authority of the commissioners for the affairs of barracks, and other than persons who keep taverns only, being free of the vintners' company in London,) and all houses of persons selling brandy, strong waters, cider, or methyglin, by retail to be drank in houses, (other than the houses of distillers who keep places of distilling brandy and strong waters, and of shopkeepers whose principal dealings shall be in other goods than in brandy and strong waters, and who do not permit tipping in their houses,) and no other, and in no private houses whatsoever; nor shall any more billets be ordered than there are effective soldiers; which billets when made out shall be delivered to the commanding officer present; and if any constable, or such like officer or magistrate as aforesaid, shall presume to billet any such officer or soldier in any private house without the consent of the owner or occupier, such owner or occupier shall have his remedy at law against such magistrate or officer, for damages; and if any military officer shall take upon him to quarter soldiers otherwise than by this act, or shall offer any menace or compulsion to any mayor, or other civil officer before-mentioned, tending to discourage any of them from doing their duty, he shall on conviction before any two justices by the oath of two witnesses be ipso facto cashiered and disabled to hold any military employment; provided the conviction be affirmed at the next quarter sessions, and a certificate thereof be transmitted to the judge advocate, who shall certify the same to the next court martial. And if any person shall be aggrieved by having more soldiers billeted than in proportion to his neighbours, on complaint thereof to one justice of the division, &c. where quartered, or if the person so billeting them be a justice, then on complaint to two justices they may relieve him.

Note.—The clause above recited, relating to shopkeepers, might as well be now omitted out of the act; for that by the 17 Geo. II. c. 17, no shopkeepers, as such, are allowed to retail any spirituous liquors, but only those who keep taverns, victualling houses, inns, coffee-houses, or alehouses.

By l. 45. No justice, having any military command, shall be concerned in quartering soldiers under his immediate command; but all things done by him therein shall be void.

By l. 50. of this act, an officer taking money for executing the quartering, shall be cashiered.

By l. 51. If any high constable or other officer or any person whatsoever shall neglect to quarter any officers or soldiers, provided sufficient notice be given him before their arrival, or if he receive or agree for any reward in order to excuse any person from receiving such officer or soldier, or if any victualler, &c. having any officer, &c. billeted upon him, refuse to receive him, or refuse to furnish him as herein provided by this act, and shall be thereof convicted by one justice of the county, &c. where such offence was committed, on confession of the oath of one witness, he shall forfeit not more than $5. nor less than 40s. to be levied by distrefs; which sum shall be applied first to satisfy such officer for the expence thereby occasioned to him, and the remainder to the overseers of the poor of the parish where the offence was committed.

By l. 52. If any officer, military or civil, shall quarter any of the wives, children, or servants of officer or soldier, in any house, against the consent of the owner; if he be an officer, he shall on proof made thereof to the commander in chief of the army or judge advocate, be ipso facto cashiered; and if a civil officer, he shall forfeit to the party grieved 20s. on proof thereof to the next justice by distress.

By l. 53. Officers and soldiers, billeted as aforesaid, shall be received and furnished with diet and small beer, paying for the same as hereafter mentioned, out of their subsistence-money.

By l. 54. If any person shall choose rather to furnish non-commissioned officers or private men, with candles, vinegar, and salt, gratis, and allow them the use of fire and the necessary utensils for dressing and eating their meat, and shall give notice thereof to the commanding officer, and shall furnish the same accordingly; in such case they shall provide their own victuals and small beer, and the officer who receives their pay shall pay the sums after mentioned out of the subsistence-money for diet and small beer to them, and not to the persons on whom they are quartered.

By l. 55. Every officer receiving the pay or subsistence-money, either for a regiment, or particular troops and companies, or otherwise, shall immediately, upon receipt of each sum, give public notice thereof to all on whom officers or soldiers are quartered; and shall also appoint such persons to repair to their quarters, at such times as they shall appoint, for the payment of the said pay or subsistence-money to the officers or soldiers, which shall be within four days at the farthest after the receipt of the same, as aforesaid; and such persons shall then and there acquaint such officer with the accounts or debts between them and the officers and soldiers quartered; which accounts the said officer is to accept of, and immediately pay the same, before any part of the pay or subsistence be distributed; provided the said accounts exceed not, for a commission officer of horse being under the degree of a captain, for such officer's diet and small beer, per diem, 2s.; nor for one commission officer of dragoons, being under the degree of a captain, for such officer's diet and small beer, per diem, 2s.; nor for one commission officer of foot, under the degree of a captain, for such officer's diet and small beer, per diem, 2s.; nor for one foot officer quartered under this act, for hay and straw, per diem, 6d.; nor for one light horseman's diet and small beer, per diem, 7d.; and hay and straw for his horse, per diem, 6d.; nor for one dragoon's diet and small beer, per diem, 7d.; and hay and straw for his horse, per diem, 6d.; nor for one foot soldier's diet and small beer, per diem, 5d.; and if such officer shall not give notice and shall not immediately upon producing such account stated satisfy the same; upon complaint on oath by two witnesses, at the next quarter sessions for the county or city where such quarters were, the paymaster of the guards, garrisons, and marines, are authorized (upon certificate of the said justices before whom such oath was made, of the sum due upon such accounts and the person or persons to whom it was due);
fons to whom the same is owing) to pay the said sums out of the arrears due to the said officer, upon pain of such paymaster forfeiting his place, and being incapacitated from holding it again. The act then states what course is to be pursued if there be no arrears due, or no subsistence-money remitted, and is directory of the course to be pursued by the paymaster.

By f. 47. And where any horse or dragoon shall be quartered upon any person who hath not stables, upon his complaint to two justices of the division, &c. and his making such allowance as such justices shall think reasonable, they may order the men and their horses, or the horses only, as the case may be, to be removed and quartered upon some other person who hath stables, and may order and settle a proper allowance to be made by the person having no stables, in lieu of his quartering such horse or dragoons, and order payment thereof to the person to whom the removal is made, or to be applied for the furnishing of quarters for such men and their horses.

By 49 Geo. III. c. 37. It is enacted that every non-commissioned officer and private soldier who shall be furnished with diet and small beer by the persons on whom they are quartered, shall pay for the same 12. 3d. per day, in like manner as by the first act is enacted as to the 7d. per day.

By f. 2. Where the innholder, &c. furnishes certain articles in lieu of diet and small beer, as in the former act mentioned, he shall have one halfpenny per day for each non-commissioned officer, &c.

By f. 3. 12. 3d. per day is to be paid for each horse, instead of 6d. per day.

By f. 4. The provisions in the former act relating to the dieting on a march or recruiting are repealed.

By f. 5. All non-commissioned officers and soldiers shall receive their diet and small beer at the above rates while on the march and on the day of arrival at the place of their final destination, and on the two subsequent days, unless either of the two be a market day for the place where billeted, or within two miles thereof; in which case the innkeeper, &c. shall discontinue on and from such market-day the diet and small beer, and furnish in lieu thereof the articles in the said former act specified, and at the rate in this act prescribed.

By f. 6. If any person liable to have soldiers quartered on him shall pay any sum to any non-commissioned officer or soldier on the march in lieu of the diet and small beer, he may be proceeded against and fined as if he had refused to furnish according to the former act the things to be furnished to non-commissioned officers and soldiers to quartered as aforesaid.

By f. 7. The provisions of f. 5. are extended to halting on a march.

By f. 8. But if the halt be for longer than one day, and the day after the arrival be market-day as aforesaid, there is to be no discontinuance of diet and small beer.

By f. 9. Non-commissioned officers and private men employed in recruiting, and the recruits by them raised, shall, while on the march, and for two days after the day of their arrival at any recruiting station, be entitled to the same benefits as before provided for troops on the march; but no recruit enlisted after the two days subsequent to the arrival of the party at their recruiting station, shall be entitled to be supplied with diet and small beer at the rate herein-before prescribed, except at the option of the party where quartered. Provided that in case any recruiting party, with the recruits by them raised, shall remove from their station, and after a time shall return to the same place, they and the recruits shall not be again entitled to the diet and small beer for two days, unless the time of absence exceed 20 days. This act to continue to 25th March 1810.

By f. 52. Any justice within his county, &c. may command any contable or other officer who shall billet any soldiers, to give an account in writing to him of the number of officers and soldiers billeted by them, and the names of the persons on whom quartered, and an account of the place where they dwell, and of his signs, if any. See Martial Law, and Soldiers.

But by the 50 G. III. c. 96. f. 1. it is enacted, that after the 25th of June 1810, every non-commissioned officer and private soldier who shall be furnished with diet and small beer within the parts of the united kingdom mentioned in the 50 G. III. c. 28. by the innholders or other persons on whom such non-commissioned officers or private soldiers shall be quartered and billeted by virtue of the said act, shall pay and allow for the same, the sum of eight-pence per diem instead of one shilling and four-pence per diem, as in the said act specified; and that for such allowance of eight-pence, the innkeeper or other person shall furnish one meal; vide locutus, a hot dinner if required in each day to each non-commissioned officer, trumpeter, drummer, and private soldier quartered and billeted on him, to confit of such quantities of diet and small beer as shall be specified and fixed in and by any regulations made or to be made from time to time by his majesty in that behalf, but not to exceed one pound and a quarter of meat previous to being dressed, one pound of bread, one pound of potatoes or other vegetables previous to being cooked, and two pints of small beer, and vinegar, salt, and pepper.

And by f. 2. of the same act, the mutiny act, and the said 50 G. III. c. 28, shall be applied for the enforcing such regulations as to the diet of soldiers and the payment of and accounting for the allowances for the same.

Quartering of Traitors, in Law. See treason.

Quartering, in the Sea Language. When a ship under fail goes at large, neither by a wind nor before a wind, but, as it were, betwixt both, she is said to go quartering.

The term is also used when a ship fails with quarter-winds.

Quartering the Men, the disposing of the ship's company at the time of an engagement in such a manner, that each may readily know where his station is, and what he is to do; as, fume to the miter, for the management of the sails; fume to assist the gunners to traverse the ordnance; fume for plying the enemy with small shot; fume to fill powder in the powder-room; others to carry it from thence to the gunners in cartridges, &c.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are in general as follow, when the ship is well manned, to as to fight both sides at once occasionally:

<table>

The lieutenants are usually stationed to command the different batteries, and direct their efforts against the enemy. The master superintends the movements of the ship, and whatever relates to the sails. The boatswain and a sufficient number of men are stationed to repair the damaged rigging: and the gunner and carpenter whatever may be found necessary, according to their respective offices. The marines are generally quartered on the poop and forecastle, or gangway, under the direction of their officers: although, on some occasions, they affit at the great guns, particularly in distant cannonading. Falconer. See ENGAGEMENT.

QUARTERING, in Gunnery, is when a piece of ordnance is so furnished, that it will shoot on the same line, or on the same point of the compass, as the ship's quarter bears.

QUARTERING, in Heraldry, the act of dividing a coat into four or more quarters, or quarterings, by parting, coupling, &c. I. e. by perpendicular and horizontal lines, &c. See QUARTER and QUARTERLY.

The king of Great Britain quarters with Great Britain, France, Ireland, Brunswick, &c.

Colombarie reckons twelve forts of quartering; but other authors give us more—viz. party per pale, dividing the escutcheons from to bottom. See PALE.—Party per crofs, dividing it from side to side. See CROSS.—Party of six pieces, when the escutcheon is divided into fix parts, or quarters.—Party of ten; of twelve; of sixteen; of twenty; and of thirty-two; when there are so many partitions respectively.

Others give the divisions in another manner as—Party per crofs—per pale—per chief—per pale inclave—per bend Dexter—per bend sinister—per chevron—barry bendy of eightys—paleways of six pieces—barry of six pieces—barry of eight pieces—bendy of fix cheeky—fully, or lozenge—pale bendy, or bendy lozenge—barry bendy lozenge, or bend lozenge—gyronny—barry lozenge counterchanged—waved of five pieces—barry nebule of five pieces—party per faltier—and party per pale in point. See farther under their respective articles.

Counter-quartering a coat, is when the quarters are quartered over again, or subdivided each into four. See COUNTER-QUAR TERED.

There are counter-quartered coats which have twenty or twenty-five quarters.

QUARTERING is also applied to the partitions or compartments themselves, that is, the several coats borne on an escutcheon, or the several divisions made in it, when the arms of several families are to be placed on the same shield, on account of intermarriages, or the like.

Colombarie observes, that thirty-two is the greatest number used in France; but that the English and Germans some times extend to forty: as a testimony of the truth of which, he fays he saw the escutcheon of the earl of Leicester, ambassador extraordinary in France in the year 1639, divided into the number of forty: and fome, he affirms, do go on to sixty-four several coats.

But a multitude of quarters make a confusion; and, accordingly, all the writers of armoury exhain as an abuse. The first instance of quartering, of which we have any account, is said to be in the arms of Rennatus, king of Sicily, &c. in the year 1435, who quartered the arms of Sicily, Arragon, Jerufalem, &c.

William Wickeley observes, that fuch quarterings are much more proper for a pedegree, to be looked upon in a chaff, and occasionally produced as an evidence for the clearing or afcertaining of alliances of families, and titles to lands, &c. than to be borne as a cognizance.

In blazoning, when the quartering is performed per crofs, the two quarters a-top are numbered the firft and fecond: and thofe at the bottom the third and fourth; beginning to tell on the right fide. When the quartering is by a faltier, &c. the chief and point are the firft and fecond quarters, the right fide the third, the left the fourth.

QUARTERING is sometimes alfo used for the dlinifying of younger brothers from elder. See DIFFERENCE.

QUARTERIZATION, QUARTERING, part of the punishment of a traitor, by dividing his body into four quarters.

"Walkingham, in Ric. II. Auditum et confellium turpis fima federea trahitionis, fupredio, decollationis, exenterationis, et quarterizacionis judicacit."" QUARTERLY, in Heraldry, a perfon is said to be quarterly, when he bears arms quartered.

The king of Great Britain bears quarterly of four; in the firft quarter gules, &c Great Britain; in the second, azure, &c Ireland, &c.

QUARTER-MASTER, an officer in the army, whose buiffines is to look after the quarters of the foldiers; their clothing, bread, ammunition, firing, &c. Every regiment of foot and artillery has a quarter-master, and every troop of horfe one, who are only warrant-officers, except in the blues. Whereof there are feveral kinds; viz. the;

QUARTER-MASTER General, whose buiffines is to provide good quarters for the whole army.

QUARTER-MASTER of Foot, he who is to provide quarters for a regiment of foot.

QUARTER-MASTER of Horfe, he who is to provide quarters for a troop of horfe.

QUARTER-MASTER, in a Ship, is an inferior officer, appointed by the master of a ship of war to attend the mates in their feveral duties; as flowing the ballast and provisions in the hold, coiling the cables on their platforms, overlouking the fteerage of the ship, and keeping the time by the watch-glass.

QUARTERN, QUARTERON, a diminutive of quart, signifying a quarter of a pint, as a quart does a quarter of a gallon.

QUARTER, in Commerce, a liquid meafure in Germany, which, according to a regulation of 1713, made in Hanover, muft hold 2lbs. of spring water, and the contents of which are 49 French, or 5¼ English cubic inches. A fuder of wine contains 4 exhiofs, 6 ahms, or 15 emers; an ahm, 4 ankers, 40 rubgens, 80 kannes, 162 quarters, or 320 noffels. Hence 36 rubgens, or 144 quarters, = 37 English wine gallons. A fad of beer at Lubeck contains 42 rubgens, or 168 quarters. Kelly's Un. Cambilt.

QUARTILE, an aspect of the planets when they are three signs, or 90 degrees distant from each other. The
The quartile aspect is marked thus □. See Aspect.

QUARTILLO, in Commerce, a liquid measure in Spain. At Barcelona, 138 quartillos are equal to 32 quater-
ers. (See Quarters.) A moyo of wine contains 16 ar-
robas; an arroba 8 zumbres, or 2 quartillos. The ar-
roba of wine contains 34 lb., of river water (Callilian weight),
and measures 1 237½ Spanish, or 98½ English cubic inches;
and hence four such arrobas are equal to 17 English wine gallons.
The arroba of oil measures 966½ Spanish, or 771 English
cubic inches; so that three such arrobas correspond to 10
English gallons: this arroba is divided into 4 quartillos, or
100 quar-teneros, or panillas. A Spanish botta contains 30
arrobas of wine, or 384 of oil; a pipe is 27 arrobas of
wine, or 343 of oil; thus the botta = 127½ English gal-
lons, and the pipe = 114½. Kelly. See Tab. XXXII. of

MEASURES.

QUARTO, or 4vo. a book whereof four leaves, or eight
pages, make a sheet.

QUARO, in Commerce, a money of account in Spain.
See Real.

QUARTO DELL TORRI, in Geography, a town of Naples,
in Capitanata; 12 miles W. of Salpe.

QUARO die poß, in Law, denotes the fourth day inclu-
sive beyond the return of a writ, in which those that are
summoned are allowed to make their appearance. See
Essoinz day of term.

QUARO-DECIMANS, QUARO-DECIMANI, in Ec-
clesiatical History, an ancient sect in the church, who main-
thained, that Easter was always to be celebrated, conformably
to the custom of the Jews, on the fourteenth day of
the moon in the month of March, wherewith that day fell out.

And hence their name Quarto-decimani, q. d. Four-
teenethers.

The Almatex were mightily attached to this opinion, pre-
tending that it was built on the authority of St. John, who
was their apostle; and pope Victor could never bring them
to obedience in this article, though he was upon the point of
excommunicating them: but it is more probable he contented
himself with menaces. See Easter.

QUARVM par constrinens, in Anatomy, a name given
by Spigelius and some others to the muscle called by Albi-
nus and Riordanus orbicularis oris; and by Cowper and some
others, contrictor labiorum.

QUARVTUS hydrids musculus, a name given by Vefalus,
Fabricius, and many other anatomists, to a muscle now gen-
erally called the coracohyoideus.

QUARVTUS scopus movens, a name given by Vefalus to one
of the muscles of the eye, called by some rectus inferior, and by
others humilis.

It is the depressor oculi of Albinus, being one of the
quatuor recti oculi of that author.

QUA, in Mineralogy. No substance in the mineral
kingdom is more abundantly distributed than quartz.

Quartz generally compose a considerable part of the
fands on the sea-shore, and of the sand-rones of the se-
condary strata. Rolled pieces of quartz, or pebbles and
boulders, are widely scattered over alluvial districts. Quartz
is disseminated through granite, gneifs, mica-flate, and other
compound rocks which constitute the loftiest mountains on
the globe; it also forms veins of vast extent interfacing these
mountains, and sometimes entire simple rocks are composed
of this mineral. Quartz has a considerable degree of hard-
ness, always striking fire with flint when the fragments have
sufficient solidity to resist the blow. Powdered quartz feels
hard, and, when rubbed on polished flint, or on glass,
ferchets the surface. Quartz is infusible by the common
blowpipe. These two qualities, hardnes and infeasibility,
are the essential characters of all the varieties of quartz,
whatever forms or colours they may present, whether masive
or crystrallized.

Quartz has most commonly a conchoidal fracture, but
sometimes the fracture is undulated, foliated, or splintery.
The luntil is vitreous. Quartz has various degrees of
transparency; from a perfectly pellucid colourless plate, it
pales by different gradations to opacity; but all the varieties,
except simplex, admit light through the very minute frag-
ments. The colours are various, owing to the impregnation
or intermixture with foreign substances. The specific gra-
avity of quartz is from 2.58 to 2.65. It yields a phospho-
refeunc light when rubbed, and is not soluble in any of the
acids except the fluoric. According to Vauquelin, pow-
dered quartz gives a green colour to tincture of violets.
Crystrallized quartz presents the phenomenon of double re-
fraction, when an object is seen through one side of the py-
ramid that terminates the crystal, and the opposite side of
the hexagonal prism on which it is placed, in the most con-
mmon variety of the secondary forms of these crystals.

The subflances found imbedded in quartz are, ores of ti-
nanium, antimony, gold, silver, copper, and lead, arsenic,
and maccaceous iron ore, with chlorite, hornblende, felspar,
garnet, and flato of lime. It is also penetrated by fibres of
albitus, and by minute lamines of mica and epidote; the
latter subflance is sometimes fo intimately diffused through
quartz as to give it an homogeneous green colour. This va-
riety of quartz is called prae.

Quartz crystralizes dillinctly; some of the crystals are of
considerable size.

In the imperial cabinet of Vienna, there is said to be a
crystal of quartz seven feet in length. The forms of cry-
ystaline quartz are various; they have been reduced by modern
mineralogists to fix or seven principal varieties. The most
common is a fix-sided prism, terminated by a fix-sided py-
ramid, or two fix-sided pyramids joined at their bases. The
sides of these pyramids are icofoeles triangles, having the
vertical angle 45°, and each of the angles at the base 90°.
The sides of the upper and lower pyramids are inclined to
each other at an angle of 104°. According to Haiy, the
primitive form of the crystal is a rhomboid, varying little from
the cube, the angles being 94° and 86°. The primitive
rhomboid is rarely found in nature; it occurs sometimes in
red hematite, coated with that mineral, and in chalcedony.

Bubbles containing air, water, and bitumen, are some-
times seen in quartz crystals, and have given rise to much
speculation respecting their formation. Silicious earth, of
which these crystals are composed, is infusible in water, by
artificial means; but in the great laboratory of nature, its
solution is effected probably by the effect of heat and com-
pression, as flex exifts in the boiling fountains of Iceland
and the Azores, and in the hot springs of Bath, Italy, and
various parts of the world. It has been supposfed that the
flicous earth was held in solution by foda; but Klapproth,
who analyized the waters from the Reikum, in Iceland, thinks
the quantity of alkali too small to have dissolved the flex.
One hundred cubic inches contained nine grains of flexes,
three of carbonate of foda, eight of common salt, and five
of sulphate of foda. If rock crystals were formed in an aqueous
solution greatly heated and compressed, it would not be
difficult to conceive how volatile matter might be involved in
the subflance of the crystal during its formation; but our
knowledge of the subterranean operations of nature is at
present too limited to enable us to ascertain, or even to form
any rational conjecture in what manner some of her more
mysteries proceses are effected. Thoese who have frequent
opportunities of exploring mines, will not be disposed to
deny that silicious fl-actions, and crystals, are now forming
at the common temperature of the earth, as they are ob-
erved.
QUARTZ.

served on the roofs and sides of artificial excavations, and plications which have been undisturbed for some years. According to Chantil, a quartz of a siliceous paff on ferruginous rocks at Chamon, near Planches les Mines, in Franche Comté, and where this is washed and deposited by water, rock cryftals are formed. Siliceous falsafites have not unfrequently been seen coating the wood which has been left in mines.

Pseudomorphous cryftals of quartz, or falf cryftals of this mineral, are frequently found in mines; they are tarnished and opaque, and their edges are blunted. They afume the forms of cubic cryftals of fluor, and the pyramidal and other forms of calcareous and other cryftals. These falf cryftals are evidently moulded in the cavities which the former have once occupied. Quartz also occurs filling up the cavities of shells in a similar manner, and the pores of wood and other organic fubstances.

Cellular quartz with polyhedral cavities, appears to have been formed round cryftals of other minerals which are sub- fiently decomposed. The internal cryftals are ffreely those of the metallic sulphurites. Brongniart fays this conclufion is founded on direct obfervation, as the re- mains found in these cavities are sulphur, native gold, and oxyd of iron, all fubstances which originally formed part of the decomposed sulphurites. Such is the cellular quartz at Schenmitz in Hungary, and Joachimthah in Bohemia. The cellular quartz at Berezof, in Siberia, is fo porous that it is lighter than pumice.

Rock cryftal, or Mountain cryftal, is the purest variety of quartz, differing from common quartz by its tranparency, and the more regular form of its cryftals; the fracture is also more perfectly conchoidal. According to some analyses, rock cryftal contains 98 parts of filex, with 2 parts of water. Bergman found in one specimen only:

Silex - 93
Alumine 6
Lime - 1

Amethyst is a purple variety of rock cryftal. See Amethy.

Caingorum flones are rock cryftals, from the mountains of Caingorum, in Scotland. They are valued by jewel- lers on account of their purity and colour. Clove-brown quartz cryftals are known by the name of the smoke topaz. According to Kailen, the specific gravity of this variety is 2.85. Coloured rock cryftals lose their colour, when carefully exoed to a gentle heat, but retain their tranparency. The yellow and orange-yellow varieties are the most esteemed.

Milk quartz, called by some mineralogists rofe quartz, and by others the Bohemian ruby, as it is frequent of a beautiful rofe-red colour, which it derives from manganite. By eposure to the light the intensity of its colour is diminished. It is used in jewellery, and takes a good polish; it is sometimes sold for the ruby, but is less hard, nor has it the tranparency and brilliancy of that gem. Rose quartz is found at Rabenstein, in Bavaria, in considerable masses, and in a vein of manganite which traverses a coaf-grained granite. It occurs also in Sweden, Greenland, Saxony, in the ifland of Coll, one of the Hebrides, and in Ireland. Some varieties are of a milk-white colour, others pearl-grey.

Iridescent quartz, Quartz hyalin iriif, presents on its su- face, or in its interior, the various colours of the rainbow; it sometimes derives this property from a thin pellicle of metal f oxyd which covers the surface, and sometimes from minute fuffures in the subfance of the cryftal. These colours may be given to quartz by heating it and exposing it sud- denly to a cold temperature.

Avanturine quartz (see Avanturine) owes its brilliancy to minute particles of mica diffiminated through it, and fometimes to minute fractures. Avanturines may be formed artificially, in some varieties of quartz, by heat.

Blue quartz, Quartz hyalin saphir, has been found in Spain, Bohemia, and Bavaria.

Black quartz is found, mixed with carbonate of lime, in the department of Ifere in France, in Bohemia, and at Cappe Nuova, on the road to Sienna. Brongniart Mine- ralogie.

Cat's-eye, Quartz hyalin chatoyant, so called because it re- fects a pearly variety of colours, according as the light falls upon it in different directions; this property is owing to the fibrous texture of this mineral, which may be observed in the well characterized specimens. It contains 95 parts of filex, and according to Brongniart is a variety of quartz, and ought not to be clased with fipar. The geological fiation of this flone is not known. The cut and polished specimens feen in cabinets come from Malabar and Ceylon. It is faid, also, to occur in Egypt and Arabia.

Green quartz, Praef, Quartz hyalin verde ifeaf. The colour is a leek green; it is seldom cryftallized; the form of the cryftals are fthose of common quartz. Praef has been faid to owe its colour to an intimate intermixture with actyno- lite, but Klaproth is of opinion that this is not well ascer- tained.

Sinele is claffed, by some mineralogists, with quartz. It is of a deep blood-red colour, and perfectly opaque, or barely tranmits light on the edges. It refembles red jasper, but has a vitreous luflre, and conchoidal fracture, and is fometimes cryftallized.

Ferruginous quartz consists of small cryftals, or of granular quartz, intimately mixed with oxyd of iron, and has a brown ochre-yellow, or red colour. From the iron which it contains it becomes magnetic when heated. It is harder than pure quartz.

Certain properties, beside colour, have given names to some varieties of quartz.

Fat quartz is fo called because it has a greasy appearance, as if the surface had been rubbed with oil.

Etched quartz differs from common quartz, by emitting an odour, when rubbed, like that of sulphuretted hydrogen gas. When this odour is heated below a red heat, it lofes its etched odour on cooling, and when plunged into water becomes transparent. When etched it is nearly opaque. It is found in the vicinity of Nantes and Chantilou, in the department of Haute Vienne, forming a confluent part of the granitic mountains of that district. It occurs also in the ifland of Elba.

Elastic quartz is a flicefue fand-flone, found in the Bra- zils, composed of oblong laminate of quartz, arranged in one direction, and fo interlocked together as to form a kind of hinge with each other, from whence it poififes a certain degree of pliability, like that of a flif piece of leather. In appearance, elastic quartz resembles some of the flaty fand- flines in the northern counties of England. According to Klaproth its confluent parts are

Silex - - 96.50
Alumine - - 2.50
Oxyd of iron and lofs 1

The use of quartz in the arts is principally confined to the manufactures of glafs, enamels, porcelain, and earthen- ware. The finer cryftallizations are employed by the jewel- lers, and before the discovery of glafs, ornaments and veifels of great value were made by the ancients from rock cryftal. Stones in which quartz forms the principal ingredient, are bell fitted for purpofes of durable architecture, and in the economy
QUA

Economy of nature this mineral gives stability to the solid fabric of the globe, enabling those rocks and mountains in which it abounds to resist the decomposing effects of air and moisture, and to brave for ages the impetuous fury of the ocean. For the properties of silica, of which quartz is composed, see SILEX.

QUARTZ, Rock, in Geology. Entire rocks and even mountains are composed of quartz in various parts of the world, in the vicinity of granite districts. The quartz is granular, and sometimes intermixed with a small portion of mica. Werner classes quartz rock as a distinct order of primary rocks, but it would be perhaps more consonant with a natural arrangement, to consider this rock as a constituent of granite on a large scale, certain caules having lepaped the quartz, mica, and feldspar into distinct masses. Entire mountains of these three sublunaries are laid to occur in the Urbian chain, presenting the materials of granite on a large scale. Quartz rocks are met with in Scotland. In the highlands the summits of some of the mountains are formed of white quartz, and appear as if covered with snow. The two beautiful conical mountains, called the Sugar-loaves, in the vicinity of Dublin, are composed of granular quartz, of a familiar kind to what forms veins in the gneiss and mica slate of the surrounding mountains nearer Dublin.

QUARTZOLE, in Mineralogy, a term applied to these rocks or minerals which are principally composed of quartz.

QUASHING, in Law, the overthrowing and annulling a thing. Thus, pleas in abatement (which fee), when the suit is by original, conclude to the writ or declaration; by praying judgment of the writ, or declaration, and that the same may be quashed, called, made void or abated; but if the action be by bill, the plea may pray judgment of the bill, and not of the declaration; the bill being here the original, and the declaration only a copy of the bill. See Plea, Dilatory Pleas, and Certiorari.

QUASI-CONTRACT, in Civil Law, an act which has not the strict form of a contract, but yet has the force of it.

In a contract there must be the mutual consent of both parties; whereas, in a quasi-contract, one party may be bound or obligated to the other, without having given his consent to the act by which he is obliged.

For an example: I have sold your business in your absence, without your procurement; and it has succeeded to your advantage; I have then an action against you for the recovery of what I have disbursed; and you an action against me, to make me give an account of my administration, which amounts to a quasi-contract. See Contract.

QUASI-CRIME, or QUASI-DELECT, the action of a person who does damage, or evil, involuntarily.

The repetition of quasi-crimes confits in making good the damages, with interest.

QUASI-MODO SUNDAY, Law EASTER-SUNDAY, or the next tunday after Easter; thus called from the initial words of the introit of the mass for the day, Quasi modo geniti infantes.

In the ancient deeds these words are signified by q. m. g.

QUASS, the name of a liquor in Russia, which serves the natives not only for drink, but also for sauce to a number of dines; and is the basis of the favourite cold foup of the North, which is made by adding cold meat cut in pieces, with cucumbers salted after a peculiar manner, or with onions, or garlic, to a bowl of this subacid liquor. The common Russian quain is prepared by putting into a large pot full of cold water as much rye-flower as will make a thin dough; this is then placed in an oven moderately heated, for three hours, and afterwards taken out and thrown into a tub of cold water; the mixture is worked with a machine like a chocolate mill till it froths. To this liquor are added two hafons of the grounds of old quafs, leaven, or a piece of their four bread; and the tub is covered with a cloth, and laid by till the liquor has acquired a fourth taste, which marks its being ready for use.

There is a better fort of quaus, which is prepared as follows. Take a chetereck (about 35 pounds Ruff, or 30 pounds Engl.) of barley-malt, two or three handfuls of rye-malt, and a like quantity of unboilt rye-meal; mix them all together in earthen potts, then pour boiling water upon it, and stir the whole till it acquires the confidence of a thin pap. The pots must be full to within an inch of the brim. Upon this mixture milk now be poured about an inch in height of the huks of oats, from which groats are made. Set the pots in a heated oven, in which some glowing coals are still remaining, which must be heaped about the pots. This done, close the oven, and leave the pots in it four-and-twenty hours. This time being claped, take them out; again pour boiling water in till they are brimfull, and stir all well together. Now pour it all into a wooden vessel or tub, provided with a lpggott and follet, first cover the bottom with a layer of straw, as is usually done in brewing beer; then add warm water, more or less, according to the quantity of quafs you want; let it stand an hour, and afterwards draw it off into vessels. In every vessel a slice of coarfe rye bread must be put, in order to make it ferment. Set the vessels in a cellar, and after four-and-twenty hours the quafs is fit for drinking.

In making quafs, barley-malt alone may be used. The rye-malt is added only from necessity, when the former, by itself, would be too poor, and not be sufficiently sweet. But the rye-meal is absolutely neccesary.

From the quantity of malt and meal above stated, is obtained about fix or seven kilderkins, or two ankers of quaus. The Russions in the summer season put the velvets of quafs immediately in the cellar, but in the winter they let them stand a whole night in a warm room, for the quafs to ferment.

QUASSE, in Geography, a town of Africa, in Benin. N. lat. 6º 20'. E. long. 3º 30'.

Gen. Ch. Col. Perianth inferior, very short, of five ovate, permanent leaves. Cor. Petals five, filide, equal, lanceolate, elongated, obtuse, converging. Nectary of five ovate villous scales, attached to the inside of the filaments at the base. Stam. Filaments ten, thread-shaped, equal, the length of the corolla; anthers oblong, incumbent. Fis. Receptacle fleshy, elevated, orbicular, broader than the germs. Germs ovate, composed of five separate ones; style thread-shaped, with five furrows, the length of the flaments; stigma with five angles. Peric. Drupas five, distinct, horizontal, ovate, oblique, splitting into two parts, all standing on a fleshy pentagonal receptacle. Seeds solitary, globose or oval.

Obf. Some flowers have abortive germs, others imperfect anthers.
QUASSIA.

This is the true original Quassia, whose wood is more powerful than that of the other species; but being very rare, and of small bulk, its place is said to be usually supplied by *Q. excelsa* hereafter described.

2. *Q. Simarouba.* Wing-leaved Quassia. Linn. Suppl. 234. Willd. n. 2. Ait. n. 2. Woodv. Med. Bot. t. 76. (Simarouba amara; Audb. Guian. v. 2. 859. t. 331. 332.)—Flowers monocious. Leaves pinnate; leaflets alternate, not quite fiddle; common falk naked. *Clutters* panicked.—Native of various parts of the West Indies, in a fandy soil, flowering in November and December. It was sent to Kew in 1787, by Mr. Alexander Anderson, but has not as yet bloomed there. This is a tall and f stout tree, whose wood is hard, white, without any peculiar flavour. *Leaves* alternate, with *five* or seven, or eight alternate obovate, rather narrow, entire, flaked leaflets, two inches long, white beneath; their common falk simple, roundish. *Flowers* yellowish-white, much smaller than the preceding, either monocious, or, as some fay, dioecious, in branched or panicked clutters. The bark of the *root* is bitter, and much celebrated as a cure for the dyfenter. Dr. Wright has given a full history of the plant, with a plate, in the Tranfactions of the Royal Society of Edinburgh, vol. ii. It is known in Jamaica by the name of Mountain Damfon, Bitter Damfon, and Stave-wood. In that island, according to Dr. Wright, the male flowers are never found on the fame tree with the female.

3. *Q. excelsa.* Lofty Quassia. Swartz in Stockh. Transf. for 1788. 302. t. 8. Ind. Occ. v. 2. 742. Willd. n. 3.—Flowers polygamous. Stamens five. Leaves pinnate; leaflets opposite, flaked; common falk naked.—Native of rather mountainous woods, in Jamaica and the Caribbean islands. The English commonly call it bitter wood, or bitter ash. The *tree* is lofty, with a very ftrait trunk; the wood whitifh, moderately clofe-grained, very bitter; frequently foled by the druggifts for the true *Quassia amara,* and found uffel in intermittent fevers, debility of the stomach, worms, dropy, and chlorofis. It is also ufed for making cabinets, for preferving ifects, or other natural curiosities; this wood being fuppose incapable to worms. The *leaves* are larger than the leaf, and compofed of from four to fix pair of opposite, elliptical, pointed, firm, entire, smooth leaflets, on short partial falks. *Clutters* panicked, bearing very numerous, small, pale flowers, some male, the reft hermaphrodite, in the fame clutter. Swartz describes the *nectary,* of five minute villus fcales, contrary to the remark of Willdenow, under his *Zwingeria,* Sp. Pl. v. 2. 569, where it is faid to be wanting in this fpecies of *Quassia.* The *flamen* are mostly five, rarely four or fix. German from two to four.

*Quassia Amara,* bitter quassia, in the *Materia Medica.*

The *root,* bark, and wood of this tree are all comprehended in the catalogues of the *Materia Medica;* and it is obferved that the leaves, flowers, &c. posfe similar qualities. The roots, being perfectly ligious, may be medically confidered in the fame light with the wood, which is now moft generally employed, and foems to dilfer from the bark in being lefs intenfly bitter; fo that the latter is thought to be a more powerful medicine. The wood is sent to this country from Jamaica and the Caribbean iflands in billets; and is reduced to chips, or rapsed by the druggifts. *Quassia* has no feenable odour; its taffe is that of a pure bitter, more intense and durable than that of any other fubftance. It imparts its virtues more completely to water than to spurious medicinal, and its infufions are not blackened by the addition of martial vitriol. When the infufion is evaporated to dryness, it leaves a brownifh-yellow, somewhat tranparent, brittle extract, which has been regarded as a vegetable conftituent of *Quassia,* and named the bitter principle. (Edinb. Phil. Tranf. iii. 207.)

The infusion is rendered muddy by nitrate of silver, and a hot, flaky, yellow precipitate is formed; acetate of lead occasions a copious white precipitate; and hence it has been inferred that these falks are incompatible in formula with it. The watty extract is of a fith to a ninth of the weight of the wood; the spirituous about a twenty-fourth.

*Quassia* derived its name, as has already obferved, from a negro named *Quass* (by Fermin written Coifo, and by Rolander, *Quals,* who employed it with uncommon fuccefs as a reftor in the malignant, endemic fevers, which frequently prevailed at Surinam. In conquence of a valuable confideration, this reftor was difclofed to Daniel Rolander, a Swede, who brought specimens of the *Quassia*-wood to Stockholm in the year 1756; and since that time the effects of this drug have been very generify tried in Europe, and numerous testimonies of its efficacy published by many refeptable authors. Its antifeptic powers have been submitted to various trials, from which it has been concluded, that it has coniderable influence in reftoring the tendency to putrefacion; which, in thefe reftor, cannot be attributed to its fensible qualities, as it posfees no astringency whatever, nor to its bitternefs, as gentian is much more bitter, but lefs antifeptic. The medicinal virtues ascribed to *Quassia* are thofe of a tonic, fumatric, antifeptic, and febrifuge; it has been found very effectual in reftoring the tone of the fomatich, producing appetite for food, affihling digeflion, expelling flatulency, and removing habitual colifienes, produced from debility of the intestines, and common to a feptenary life. Dr. Letfom obferves, that in hystorical atony, to which the female fex is fo prone, the *Quassia* affords morve vigour and relief to the fystem than the Peruvian bark, espeffially when united with the vitriol album, and still more with the aid of fome abortifant. In dyspepsia, arifing from hard drinking, and also in diarrheas, he exhibited the *Quassia* with great fuccefs. Although he does not concur in opinion with Limaeus, who fais, "me quodem judice chinchanam longe superat;" yet he has met with feveral infufions of low remittent and nervous fevers, the symptoms of which the bark uniformly aggravated, though administered in intermiffions the moft favourable to its fuccefses, in which *Quassia,* or *snake-root,* was fuccefffully fubstituted. In fuch cafes, he moftly obferved that there was great congeftion in the hepatic fystem, and the debility at the fame time defcouraged copious evacuations. And in many fevers, without evident remissions...
remit to warrant the use of the bark, whilst, at the same time, increasing debility began to threaten the life of the patient, the doctor found that quaffia, or snake-root, finely or combined, upheld the vital powers, and promoted a critical intermission of fever, by which an opportunity was offered for the bark to effect a cure. Dr. Cullen says, (Mat. Med. vol. ii. p. 174.) "I believe quaffia to be an excellent bitter, and that it will do all that any pure and simple bitter can do; but our experience of it in this country does not lead us to think it will do more; and the extraordinary commendations given of it are to be ascribed to the partiality so often shown to new medicines." It is said to have been given, combined with nitric acid, with evident benefit in typhus, and also in fever. It may be given in infusion, which is the best form of administering it; or in pills made from the watery extract. It may also be given in substructure of doses of from grs. x to 3 j three or four times a day. The official preparations are the "infusio quaffae" of the London Pharmacopoeia, and the "tinctura quaffae" of that of Dublin. The infusion is prepared by macerating for two hours in a lightly covered vessel a scuffle of quaffia-wood, chopped, in half a pint of boiling water, and straining. In febilities, this may be combined with purgatives and tincture of valerian; in atomic gout, with aromatics; and in dyspeptic affections, with chalybeates, sulphate of zinc, or mineral acids. The dose is from j to 3 j, given twice or thrice a day. The tincture is prepared by digesting for seven days an ounce of chips of quaffia-wood in two parts of proof spirit; and then straining. This may be used in the same cafes as the infusion.

It is asserted that the brewers have, of late years, used quaffia-wood instead of hops. Beer made with it certainly does not keep, says Thomson, but soon becomes muddy and flat, has a mawkish taste, and runs into the acesce fermentation. It is consequently less nutritious and wholesome than that which is properly hopped. Wood. Mat. Med. Thomson's Lond. Difp.

QUASSIA SIMARULA. See SIMARUBA.

QUACHEOU, in Geography, a town of Affia, in the country of Hami; 30 miles E. of Tchel-techeou. N. lat. 40° 28'. E. long. 94° 27'.

QUATER-COUSINS, QUATRE-COUSINS, fourth cousins, or the half degree of kindred.

Hence, when perfons are at variance, it is said they are not quarter, or other-cousins.

QUATERNA FOlia, among Botanists. See LEAF.

QUATO, in Zoology. See SIMIA PANICUUS.

QUATORZIEME, Fr., the 14th, or double octave of the 7th. It is called the 14th, because 14 sounds must be formed to pass diatonically from one of its terms to the other.

QUATERTOMOMI, in Ornithology, the name of an American bird of the wood pecker kind, having a red crest on its head, and two white lines running down the sides of the neck to the breast. It is called by Nieremberg Pius inermbratus; for which see.

QUATOZTI. See TANAGRA LOUROEOPHALUS.

QUATRE FACARDINS, Frs., in Geography, four small islands in the South Pacific ocean, so named by M. Bougainville, in the year 1768. S. lat. 18° 40'. W. long. 140° 30'.

QUATREFOIL, a decoration resembling a rose with four leaves, which constantly occurs in pointed architecture.

QUATRE-NATIONS, q. d. Four Nations, the denomination of a college founded in 1661, by cardinal Ma-azarin, for the education and maintenance of sixty children, natives of the four countries conquered by Lewis XIV., viz. fifteen for Pignerol and Italy, fifteen for Alfrass, twenty for Flanders, and ten for Rouffillon.

QUATRICHROMA, in the Italian Music, is what we call a demi-femi-quaver, thirty-two of which make a bar in common time. See TIME, and TRIPLE.

QUATRO CASE, in Geography, a town of Italy, in the department of the Mincio; 17 miles S.E. of Mantua.

QUATROL, a small island in the gulf of Siam, near the coast of Camboja. N. lat. 10° 13'. E. long. 103° 25'.

QUATROS, CORONADOS, LERI, an island in the Pacific ocean, discovered by Quiros in 1606. S. lat. 18° 40'.

QUATTRINO, in Commerce, a copper coin at Florence; also a money of account, 60 quattrini being equal to 12 cia, 15 paoli, or 2 lira. At Rome, the feudo is divided into 3 telfoni, 500 quattrini, or 1000 mezzi quattrini; so that 5 quattrini make 1 paolo, and 3 paoli 1 tefrone. See Scudo.

QUAUTOR, Lat., a name given to any musical composition, vocal or instrumental, in four parts, and in dialogue, or a parte equali, when each have four parts alternately. The Italians sometimes call a quartet, but more frequently quartetto, and the English quartet.

A vocal quartet, says Rousseau, is more difficult for the poet to write, as well as for the composer to let, than a trio or chorus.

In the vocal quartet of a musical drama, four distinct characters should be supported both in the words and music, according to the situation and state of mind of the several persons who have petitions or complaints to make, or answers to give.

The instrumental quartets of Haydn have been the delight of all that have performed, or heard them performed, for full 30 years, and bid fair to continue to afford delight for at least 30 years more.

QUAUTOR PRINCIPALA ARTIS MUSICAE, the title of a MS. in the Bodleian library at Oxford (Digby 90.), which has been ascribed to several authors. Anthony Wood gives it to Tewkebury, to whom it is likewise ascribed in the Oxford Catalogue of MSS., with very little foundation. Bishop Tanner has honoured Dr. John Hambois with this production, a writer on music, who flourished more than a century after this MS. was finished, as appears from the testament of the former himself.

There is, however, at Oxford, among the MSS. another volume of Musical Tracts (Bodl. 515.), which had not been sufficiently examined by any of the cataloguers who have mentioned it, for, on a careful perusal and collation, we found in it, besides two other tracts by Simon Tunifede, or Tuffede, a duplicate of the Quatuor Principala; and as no doubt has been thrown upon Tunfede having been the author of the two first tracts in the volume, it seems as if we might venture, without doubt or hesitation, to affign to him this ampler, and, for the time when it was written, excellent treatise. That Simon Tunifede was a man of science, and an able musician, as well as a doctor of divinity, appears at the end of MS. Digby 90. After saying that the book was finished in 1531, we have the following pafage: "Ille autem anno regna crat inter minores Oxonie fratres, Simon de Tunifede, doctor facro theologio, qui in musica pollebat, et eciam in septem liberalibus artibus. Pits, Bales, Tanner, and all our biographical writers, speak of him as a learned musician; and Pits enumerates the Quatuor Principala among his writings. (De Illust. Angl. Script.) Simon Tunifede, a Franciscan friar, born at Norwich, was in such favour for his learning and piety, as to
be unanimously chosen provincial master of all England. He died at Brizard, in Suffolk, in 1369.

The title of the tracts in the Oxford Catalogue of MSS. has occasioned the great diversity of opinions about the writer of the Quatuor Principia; for No. 515 is entitled "De Musica continua et differens, cum Diaphragmatibus, per Simonem Tunate, A.D. 1351." However, in the beginning of the volume, the author propounds to treat "De quatuor Principibbus in quibus tocinus Musica radices confitit," &c. which exactly agrees with the other MSS.; and there is no difference from the beginning to the end, except in the omission of a kind of prologue, or argument to the work, which appears in the tract ascribed to Tewkeber (Digby 90.), beginning "Quemadmodum inter Trinitatem," and is omitted in that to which the name of Tunate is prefixed. Bodl. 515.

What the author calls the "Four Principals of Musick," will both appear from his own manner of dividing the work. In the first part or principal, containing nineteen chapters, he treats of music in general, its constituent parts and divisions. II. Of its invention, intervals, and proportions, twenty-four chapters. III. Of plain chant, and the ecclesiastical modes, fifty-eight chapters. IV. Of measured music, or time; of diastems, and their several divisions. This last principal is divided into two sections, of which the first contains forty-one chapters, and the second forty-nine. The whole treatise fills a hundred and twenty-four folio pages; the diagrams, which are very numerous, are beautifully written, and illuminated with different coloured inks; and it seems to be in all respects the most ample and complete work of the kind which the fourteenth century can boast.

Quatuor Principia. See Preface.
Quatuor Viri, in Antiquity, frequently written III. Viri, a Roman magistrates, who had three colleagues joined with him in the same administration.

To the quatuor-viri was committed the charge of conducting and letting the colonies sent into the provinces.

Upon unlucky accidents, and other dangerous affairs, it was usual to create quatuor-viri, with commission to take care se quid detrimenti republica caperet, that the republic were not prejudiced.

There were also quatuor-viri appointed to inspect and take care of repairs, &c.

Quauchochopitili, in Ornithology. See Picus Tristis.
Quaver, in Musick, a measure of time, equal to one-half of the crotchet, or one-eighth of the demi-breve.

The quaver is marked by the character

The English quaver makes what the French call crochut, crotchet, because of the hook at bottom. See Crotchet.

The quaver is divided into two semiquavers, noted and four demisemiquavers, marked See Characters.

Quaivering, the art of trilling, or shaking; or the running a division with the voice.

Quauhayahtli, in Botany, a name by which some authors have called the tree, whose fruit is the calla inflata of the shells. Hern. p. 87.

Quauhchilui, in Ornithology. See Merops Cinereus.

Quauhioyamatl, in Zoology. See Sus Ta-
Quebec.

Flight walls are a sufficient defence; and in some places, where the rock is inaccessible, no walls are necessary. Here, however, are several redoubts and batteries. The principal battery, which points towards the bason, consists of twenty-two 24-pounders, two French 36-pounders, and two large iron mortars; this battery is flanked by another of fix guns, that commands the pâlès from the lower town. On the land side the fortifications are stupendous. When general Wolfe attacked this place, he thought it a vain attempt to make an allout on the side of the town which lies towards the water, where the rock is so steep, and so easily defended. In order to carry on the attack on the land side, he first attempted to land his troops some miles below the town, near the Falls of Montmorency; but here he was repulsed by a large division of the French forces with loss. Foiled in his first attempt to get on shore, the brave Wolfe formed the bold design of ascending to the top of the banks above Quebec, commonly called the Heights of Abraham. After previous preparation, the soldiers clambered up the heights with great difficulty, and the guns were hauled up by means of ropes and pulleys fixed round the trees, with which the banks are covered from top to bottom. At the top the plain commences, and extends close under the walls of the city. Here the memorable battle was fought, in which the much lamented general fell, at the moment when all his noble exertions were about to be crowned with thesuccess which they so eminently merited. The spot where the illustrious hero breathed his last is marked with a large stone, on which a true meridian line is drawn. Although the great Wolfe found it so difficult a task to gain possession of Quebec, and it has been rendered much stronger since his time, the people of the United States imagine, that, in case of a rupture with Great Britain, it might be easily taken; and yet at the close of the year 1775, and the commencement of 1776, an attempt was made by American troops, under the command of Arnold and Montgomery, without success. On this occasion Montgomery fell, and Arnold’s attempt, on the practicability and success of which he had previously boasted, proved fruitless. St. John’s gate, which he endeavoured to force, and the adjoining walls, are stupendous; and the mere sight of them may convince any person, that an attempt to form them must be altogether inefficacious, without the aid of heavy artillery, with which the Americans were not provided.

Independently of its fortifications, and situation on the summit of a rock, Quebec owes much of its strength and security to the long duration and extreme severity of the winter; as in that season it is wholly impracticable for a besieging army either to carry on any works, or to blockade the town. Mr. Weld says, that 5000 folders are necessary to man the works at Quebec completely. A large garrison is always kept in it, and abundance of stores of every description. The troops are lodged partly in barracks, partly in block-houses near Cape Diamond, which is the most elevated part of the point, and is reckoned to be upwards of 1600 feet above the level of the river. The Cape is strongly fortified, and may be considered as the citadel of Quebec; it commands the town in every direction, and also the plains on the outside of the walls. The evening and morning guns, and all signals, are fired from hence. Notwithstanding the great height of the rock above the river, water may be readily obtained even at the very top of it, by sinking wells of a moderate depth; and in some particular places, at the sides of the rock, it gushes out in large streams; and the water is of a very good quality. It is supposed, says Mr. Weld, that including the upper and lower towns and suburbs, there are at least 2000 dwellings; and the number of inhabitants, allowing fix to a house, may be estimated at 12,000. Mr. Heriot says, that, in 1806, the number of inhabitants amounted to 15,000; and if this statement be correct, the increase must have been very rapid, for, in the year 1784, Quebec contained only 6472 inhabitants. About two-thirds of the inhabitants are of French extraction. The society is agreeable, and very extensive for a place of its size, which is owing to its being the capital of the lower province, and therefore the residence of the governor, different civil officers, principal lawyers, &c. The large garrison always maintained in it contributes to make it gay and lively.

The lower town is mostly inhabited by the traders who are concerned with the shipping, and it is a very disagreeable place. The streets are narrow and dirty, and, on account of the height of the houses in most of them, the air is much confined; and in the streets next the water, there is an intolerable fench from the shore when the tide is out. The upper town, on the contrary, is extremely agreeable; from its elevated situation, the air is very pure, and the inhabitants are never oppressed with heat in summer; it is, however, far from being well laid out, the streets being narrow and very irregular. The houses are generally built of stone, and, except some few, built of late years, small and inconvenient. The chateau, in which the governor resides, is a plain building of common stone, situated in an open place, the houses round which form three sides of an oblong square. It consists of two parts. The old and the new are separated from each other by a spacious court. The former stands just on the verge of an inaccessible part of the rock; behind it, on the outside, there is a long gallery, from whence, if a pebble were let drop, it would fall at least sixty feet perpendicularly. This old part is chiefly taken up with the public offices, and all the apartments in it are small and ill contrived; but in the new part, which stands in front of the other, facing the square, they are spacious, and tolerably well finished, but none of them can be called elegant. This part is inhabited by the governor’s family. The chateau is built without any regularity of design, neither the old nor the new part having even an uniform front. It is not a place of strength, as commonly represented. In the garden adjoining to it is merely a parapet wall along the edge of the rock, with embrasures, in which a few small guns are planted, commanding a part of the lower town. Every evening during summer, when the weather is fine, one of the regiments of the garrison parades in the open place before the chateau, and the band plays for an hour or two, at which time the place becomes the resort of numbers of the most genteel people of the town, and has a very gay appearance.

Opposite to the chateau there is a monastery belonging to the Recollets, or Franciscan friars; a very few only of the order are now left. Contiguous to this building is the college belonging to the Jesuits, whose numbers have diminished even still faster than that of the Recollets.

The numeries are three in number, and as there is no restriction upon the female religious orders, they are all well filled. The largest of them, called L’Hôpital General, stands in the suburbs, outside of the walls; another, of the order of St. Ursule, is not far distant from the chateau.

The engineer’s drawing-room, in which is kept a variety of models, together with plans of the fortifications of Quebec and other fortresses in Canada, is an old building, near the principal battery. Adjoining to it stands the house
houe where the legislative council and assembly of representatives meet, which is also an old building, that has been plainly fitted up to accommodate the legislature.

The armory is situated near the artillery barrack, in another part of the town. About ten thousand fland of arms are kept in it, arranged in a similar manner with the arms in the Tower of London, but, if possible, with greater neatness and more fancy.

The artillery barracks are capable of containing about five hundred men, but the principal barracks are calculated to contain a much larger number; they stand in the marketplace, not far distant from the square in which the chateau is situated, but more in the heart of the town.

The market of Quebec is extremely well supplied with provisions of every kind, which may be purchased at a much more moderate price than in any town visited by Mr. Weld in the United States. It is a matter of curiosity to a stranger to see the number of dogs yoked in little carts, that are brought into this market by the people who attend it. The Canadian dogs are found extremely useful in drawing burdens, and there is fearcely a family in Quebec or Montreal, that does not keep one or more of them for that purpose. They are somewhat similar to the New- foundland breed, but broader across the loins, and have shorter and thicker legs; in general they are handlyome, and wonderfully docile and fagacious; their strength is prodigious. A single dog will draw a man for a consider- able distance, that could not weigh less than ten tons.

People, during the winter season, frequently perform long journeys on the snow with half a dozen or more of these animals yoked in a cariole or fledge.

An attempt was made in 1731 by the English and Americans, under the command of brigadier Hall, to surprize Quebec; but it proved abortive. In 1759 it was taken by the English, under the command of the valiant Wolfe, who sacrificed his life in the engagement; and by the peace, in 1763, it was ceded, with the rest of Canada, to the conquerors, in whose possession it has since continued.

The scenery that is exhibited to the view from various parts of the upper town of Quebec is surpassed for grandeur, beauty, and diversity, any other, as Mr. Weld says, that he has seen, either in America, or in any other part of the globe. In the variegated expanses that is laid open before you, stupendous rocks, immense rivers, trackless forests, and cultivated plains, mountains, lakes, towns, and villages, in turn strike the attention, and the scenes are almost bi- wiled in contemplating the vastness of the scene. Nature is here seen on the grandest scale; and it is fearcely possible for the imagination to paint to itself any thing more sub- limer than are the several prospects presented to the sight of the delighted spectator.

From Cape Diamond, situated one thousand feet above the level of the river, and the loftiest part of the rock on which the city is built, the prospect is considered by many as superior to that of any other spot. A greater extent of country opens upon you, and the eye is here enabled to take in more at once, than at any other place; but it appeared to Mr. Weld, that the view from the cape is by no means so fine as that, for instance, from the battery; for in surveying the different objects below you from such a stupendous height, their magni- tude is in a great measure lost, and it seems as if you were looking at a draft of the country, more than at the country itself. It is the upper battery that Mr. Weld alludes to, facing the baion, and is about three hundred feet above the level of the water. Here, if you stand but a few yards from the edge of the precipice, you may look down at once upon the river, the vessels upon which, as they fail up to the wharfs before the lower town, appear as if they were coming under your very feet. The river itself, which is between five and six miles wide, and visible as far as the distant end of the island of Orleans, where it loses itself amid the mountains that bound it on each side, is one of the most beautiful objects in nature, and on a fine still summer's evening it often wears the appearance of a vast mirror, where the varied rich tints of the sky, as well as the images of the different objects of the banks, are seen reflected with inconceivable lustre. The southern bank of the river, indented fancifully with bays and promontories, remains nearly in a flat of nature, clothed with lofty trees; but the opposite shore is thickly covered with bushes, extending as along other parts of the river already mentioned, in one uninterrupted village, feemingly, as far as the eye can reach. On this side the prospect is terminated by an extensive range of mountains, the flat lands situated between and the villages on the banks not being visible to a spectator at Quebec, it seems as if the mountains rose directly out of the water, and the houses were built on their steep and rugged sides.

Beautiful as the environs of the city appear when seen at a distance, they do not appear less so on a more close inspection; and in passing through them the eye is entertained with a most pleasing variety of fine landscapes, while the mind is equally gratified with the appearance of content and happiness that reigns in the countenances of the inhabitants. Indeed, if a country as fruitful as it is picturesque, a genial and healthy climate, and a tolerable share of civil and religious liberty, can make people happy, none ought to appear more so than the Canadians. There are, however, in the vicinity of Quebec two scenes, more particularly deserving of attention than any others: these are the falls or cataracts of the rivers Chaudière and Montmorency; which see respectively. N. lat. 46° 48' 38". W. long. 71° 4' 39". Weld's Travels, vol. i.

QUEBITEA, in Botany, a name which seems to have been whimsically extracted by Aublet, from the Caribbean appellation of this plant, Dasyphusites. Aubl. Guian. v. 2. 328. 1. 327. This has many creeping roots, and a twirled, decumbent, hairy stem, with alternate, elliptical, broad, entire, hairy leaves, three or four inches long, on hairy footstalks. Flowers minute, in short, dense, axillary, flaked spikes, with a small scale at the base of the flaks. Aublet did not investigate the structure of these flowers, but he suspects the plant to be nearly akin to Dracodium, under which genus it is accordingly noticed by Jullien. The roots, when chewed, are very acrid. The bruised herb is used externally, to cure the bite of serpents. It grows on the banks of rivulets in Guiana.

QUEBRANTAHUESOS, in Ornithology. See Proc- Cellaria Gigantea.

QUECALA, in Geography, a town of Mexico, in the province of Mechoacan; 105 miles S.S.E. of St. Luis de Potosi.

QUECHUA, in Literary History. See Perti.

QUEDA, a sea-port city on the W. coast of the peninsula of Malaca, the capital of a kingdom, tributary to Siam, with a good harbor, at the mouth of a river that will admit a vessel drawing 12 or 14 feet water on the springs over the bar, which is gravel and mud. The town contains about 400 houses, inhabited by Chinees and Malays. The environs are agreeable and fertile; the woods abound in elephants and other animals, and in some places are mines of lead, which supply large quantities of those metals for exportation to Hindoostan, Arabia, and Peru. The go-
vernument is monarchical, under a Malay Mahomedan prince, who, like many other Malay princes, engrosses almost the whole foreign trade of the port, excepting that of an annual Chinese junk, which pays a certain sum only as duty, and then has leave to trade freely with the inhabitants. This junk imports immense quantities of coarse China-ware, thin iron pans, and many other articles from that country, and exports biche de mer, called swallow, rhinco's fins, edible bird's nests, rattans, tin, rice, dammer, tortoise-shell, deer's skins and finews, bullocks and bullocks' hides and horns, jerked beef, and many other coarse articles. At Queeda there is great plenty of rice, bullocks, buffaloes, and poultry; but not such abundance of fruit and vegetables as at Acheen. The territory of Queeda is a flat country, favourable for the cultivation of rice; a hill north of the town and island, called the Elephant, favours the navigator's approach; also the small islands called Peers, 20 miles well of the bar, covered with trees, and good regular mudfoundings, a great way off, even by night, indicate the distance to the marinier; 300 miles E.N.E. of Acheen. N. lat. 6° 20'. E. long. 100° 18'.

QUEEDENAU, a town of Pruflia, in Samland; three miles N. of Königberg.

QUEDELINBURG, a town of Weftphalia, in the principality of Halberstadt, on the Boda, which divides it into the Old and New Towns. It has several churches, a hospital, and a college. Near this town is a prince's abbey, situated on a hill; it was founded by king Henry I. between the years 932 and 936, and since enriched by various endowments. In 1530 it embraced Lutheranism, and obliged itself, by solemn oaths, to maintain that form of religion. It lately confisted of four dignitaries, viz. of the lady abbots and three others, distinguished by the titles of provost, dean, and canon. In 1802, the abbey and its revenues were voted to the king of Prussia, as an indemnity; and by the treaty of Tilsit, transferred to the kingdom of Weftphalia. The town of Queedlinburg is seven miles S.S.E. of Halberstadt. N. lat. 51° 48'. E. long. 11° 20'.

QUEDLITZ, a town of Prussia, in the province of Ermeland; four miles S. of Wartenburg.

QUEECE, in Agriculture, a term sometimes provincially applied to the wood-pigeon, or birds of that kind.

QUEECHY, in Geography, a river of Vermont, which runs into the Connecticut at Hartford.

QUEEN, REGINA, a woman who holds the crown of a realm singly, and by right of blood.

The word queen is derived from the Saxon queen, uxor, the wife of any one, but applied, by way of excellence, to the wife of the king only; whence she was anciently called the king's queen; the West Saxons having no other name for a queen but the king's wife. (Alfr. de Aelfred, regibus, &c.) She was also called lady, in Saxon sealfige: jult as madamo, madamoifelle, were used in France, for the wife and daughter of the duke of Orleans.

The name queen is also given, by way of courtesy, to her that is married to the king; called, by way of distinction, queen consort. In respect of whom the former is called queen regnant, or regent.

The widow of a king is also called queen, but with the addition of dowager.

In the first sense, queen is, in all construction, the same with king; and has the same powers, prerogatives, rights, dignities, and duties that the king has. This is expressly declared by statute 1 Mar. 1. ft. 3. c. 1.

The queen consort is inferior, and a person distinct from, and a subject of, the king. In England, though the be a femme-covert, yet may she, and be sued, in her own name; and may make leaves, and grants, &c. as a femme-fide.

She has several other prerogatives. Though an alien, she may purchase lands in fee-simple, without either naturalization, or denization; she may prent to a benefice; nor is pleantry a bar against her more than against the king. She is also capable of taking a grant from the king, which no other wife can do from her husband; and she may have a separate property in goods as well as lands, and has a right to dispose of them by will. She pays no toll, and shall not be amerced, if she be nonsuited in any action; and may not be impleaded till first petitioned.

To confpire her death, or violate her chastity, is high treason. She has an ancient peculiar revenue, called queen-gold; besides a very large dower, with a royal court, and officers, distinct from the king's; and her attorney and fo-licitor-general are entitled to a place within the bar of his majesty's courts, together with the king's counsel.

Another ancient perquisite belonging to the queenconsort, mentioned by all our old writers, and, on this account only, worthy of notice, is this, that on the taking of a whale on the coast, which is a royal fish, it shall be divided between the king and queen; the head only being the king's property, and the tail of it the queen's. One reason of this whimsical division, as ascribed by our ancient records, was to furnish the crown's wardrobe with whalebone.

The queen dowager, as the widow of the king, enjoys most of the privileges belonging to her as queen consort. But it is not high treason to conspire her death; or to violate her chastity, because the succession to the crown is not thereby endangered. Yet still, pro dignitate regali, no man can marry a queen dowager without special licence from the king, on pain of forfeiting his lands and goods. She has also this particular, that the loves not her dignity, though she marry a private gentleman; as peeresses dowager do their peersage, when they marry commoners. Thus queen Catherine, widow of Henry V. being married to Owen ap Tudor, efq., maintained an action as queen of England. Much less does a queen regnant follow her husband's condition, or is subject to other queens; but she is sovereign to her own husband, as queen Mary was to king Philip, and queen Anne to prince George of Denmark; unless it be otherwise appointed by parliament. The husband may be guilty of high treason against her; but in the instance of conjugal infidelity, he is not subject to the same penal re-strictions. For which the reason seems to be, that if a queen consort is unfaithful to the royal bed, this may debase or baflarize the heirs to the crown; but no such danger can be conseqquent in the infidelity of a husband to a queen regnant.

QUEEN CAROLINE, in Biography, when princes of Wales, is told in the dedication of the opera of Julius Caesar to her royal highness, that the first musical founds which her highness heard, were those produced by the voice of the celebrated Piafio, the father of good taste, then in the service of his illustrious fire, at the court of Anspach.

Music doubtless was a serious part of her majesty's education, as it is, and has ever been, of all the princes and princesses of Germany; who have likewise frequent opportunities of hearing great performers and splendid performances; yet we do not recollect having heard that her majesty was a performer herself, or even an admirer or patron of the art. This princess died in November 1737.

QUEEN MARY. (See Mary.) During the short reign of this bigoted and intolerant princes, ecclesiastical music was again
again transferred to Latin words and the mass, both of which had been excommunicated during the reign of her brother, Edward VI. But metrical psalmody had not yet been generally received in our parochial churches. Mary was herself a performer on the virginal and lute, as appears by a letter sent to her by her mother, queen Katherine, after her separation from the king, in which she encourages her to suffer cheerfully, to trust to God, and keep her heart clean. She charged her in all things to obey the king's commands, except in matters of religion. She sent her two Latin books, the one 'De Vita Christi,' and the other the 'Ephesides of St. Jerom;' in them, (says the queen,) I trust you shall find good things. And sometimes, for your recreation, use your virginals or lute, if you have any."

Fuller tells us, that "eight weeks and upwards" passed between the proclaiming of queen Mary and her ascending the parliament; during which time two religions were together fet on foot, Protestantism and Popery; the former hoping to be continued, the latter to be restored; and during this interim the churches and chapels in England had a mongrel celebration of their divine services between reformation and superstitition. For the obsequies for king Edward were held by the queen in the Tower, August 7th, 1553, with the dirige fune in Latin, and on the morrow a maff of requiem, and on the same day his corps were buried at Westminster with a sermon service, and communion in English."

In October following the laws of her predecessor, Edward, concerning religion, were all repealed. And in November 1554, bishop Bonner "set up the old worship at Paul's, on St. Catherine's day; and it being the custom, that on some holy-days, the quire went up to the steeples to sing the anthems, that fell on that night:—and the next day, being St. Andrew's, he did officiate himself, and had a solemn procession."

After this period, during the subsequent years of Mary's reign, the public service was every where performed in the Roman Catholic manner, throughout the kingdom; and we may imagine that the numerous compositions to Latin words, which have been preferred of Dr. Tyt, White, Tallis, Bird, and the rest of our most eminent harmonists, were produced and performed at this time, while the Romish religion had the ascendant. And indeed it appears by a record, now in the possession of the Antiquarian Society, that the lit of Mary's chapel establishment contains nearly the same names as that of her brother Edward.

Queen Elizabeth. (See Elizabeth.) In speaking of music during the long and prosperous reign of queen Elizabeth, our nation's honour seems to require a more diffuse detail than at any other time:—for perhaps we never had so just a claim to equality with the rest of Europe, where music was the most successfully cultivated, at this period;—for indeed there was but little melody any where. Yet, with respect to harmony, canon, fugue, and such laboured and learned contrivances as were then chiefly studied and admired, we can produce such proofs of great abilities in the compositions of our countrymen, as candidates judges of their merit must allow to abound in every kind of excellence that was then known or expected.

Elizabeth, as well as the rest of Henry VIII.'s children, and indeed all the princes of Europe at that time, had been taught music early in life. For Camden, in giving an account of her studies, says, that she understood well the Latin, French, and Italian tongues, and was indifferently well seen in the Greek. Neither did the neglect music, so far forth as might become a princeess, being able to sing and play on the lute prettily and sweetly."

There is reason to conclude, that she continued to amuse herself with music many years after she ascended the throne. Sir James Melvil gives an account of a curious conversation which he had with this princess, to whom he was sent on an embassy by Mary, queen of Scots, in 1564. After her majesty had asked him how his queen dined? What was the colour of her hair? Whether that or her's was better? Which of them two was fairest? And which of them was highest in stature? "Then she asked, what kind of exercise she used?" I answered, says Melvil, "that when I received my dispatch, the queen was lately come from the Highland hunting: that when her more serious affairs permitted, she was taken up with reading of histories; that sometimes she recreated herself in playing upon the lute and virginals. She asked if she played well? I said, reasonably, for a queen."

"The same day, after dinner, my lord of Hunfen drew me up to a quiet gallery, that I might hear some music, (but he said, that he durst not allow it,) where I might hear the queen play upon her virginals. After I had hearkened a while, I took by the nape of the neck, that hung before the door of the chamber, and seating her back was toward the door, I entered within the chamber, and found a pretty space bearing her hand excellently well. But she left off immediately, so soon as the turned about and saw me. She appeared to be surprized to see me, and came forward, seeming to strike me with her hand;—alleging, she used not to play before men, but when she was solitary, to amuse melancholy. She asked how I came there? I answered, as I was walking with my lord Hunfen, as we passed by the chamber door, I heard such a melody as ravished me, whereby I was drawn in, ere I knew how; executing my fault of homelies, as being brought up in the course of France, where such freedom was allowed; declaring myself willing to endure what kind of punishment her majesty should be pleased to inflict upon me for so great offence. Then she laid down upon a cushion, and I upon my knees by her; but with her own hand she gave me a cushion, to lay under my knee, which at first I refused, but she compelled me to take it. She enquired whether my queen or she played better. In that I found myself obliged to give her the praise."

If her majesty was ever able to execute any of the pieces that are preferred in a MS, which goes under the name of "Queen Elizabeth's Virginal Book," the must have been a very great player; as some of these pieces, which were composed by Tallis, Bird, Giles, Farnaby, Dr. Bull, and others, are so difficult, that it would be hardly possible to find a master in Europe, who would undertake to play one of them at the end of a month's practice.

Besides the lute and virginals, Elizabeth was a performer on the violin, and on an instrument something like a lute, but strung with wire, and called the poliphant. A violin of a singular construction, with the arms of England, and the effigy of Dudley, earl of Leicester, this queen's favourite, engraved upon it, was purchased at the sale of the late duke of Dorset's effects. The date of its make, 1578. It is very curiously carved; but the several parts are so thick and loaded with ornaments, that it has not more tone than a nutlet, or violin with a fiddle; and the neck, which is so thick for the grasp of the hand, has a hole cut in it for the thumb of the player, by which the hand is so confined, as to be rendered incapable of shifting, so that nothing can be performed upon this instrument, but what lies within the reach of the hand in its first position. Playford tells...
QUE

tells us, that "Queen Elizabeth was not only a lover of this divine science (music), but a good proficient therein; and I have been informed, says he, by an ancient musician, and her servant, that she did often recreate herself on an excellent instrument, called the poliphon, not much unlike a lute, but strung with wire."

Among the Sloane MSS. in the British Museum, No 1520, there is a list of the officers of the court of revenue in this reign; in which is included the musical establishment of her majesty's household, about the year 1587.

Her majesty's chapel establishment was nearly the same, in number and salaries, as that of her brother and sister, Edward and Mary. Indeed, it seems as if the religious scruples of musicians had been considerably diminished by the severity with which Telford had been treated in the time of Henry VIII., and the peril into which Marbeck's zeal for reformation had involved him. For in comparing the chapel establishments of Edward, Mary, and Elizabeth, we find, that however the creeds of these monarchs differed, their musicians had constantly tuned their instruments to the court pitch: i.e. in perf. & unison with the orders of their sovereign, the supreme head of the church.

Camden says, that "the Roman religion remained a full month and more after the death of Mary, in the same state as before." For Elizabeth, who began her reign November 17th, 1558, had a solemn service performed for her sister Mary at Westminster, December 5th, and another December 28th, for the emperor Charles V.; and these, as well as her own coronation, were celebrated in the Romish manner.

Burnet says, that "Elizabeth had been bred up from her infancy with a hatred of the Papacy, and a love to the Reformation; but yet as her first impressions in her father's reign were in favour of such old rites as he had ill retained, so in her own nature she loved that, and some magnificence, in religion as well as in every thing else."

We have no other music printed expressly for the cathedral service to English words during the reign of Edward VI., than that of Marbeck, which was mere cantio fermo, without counterpoint; but the year after the publication of the English Liturgy by queen Elizabeth, the following choral work appeared: "Sustine nos in facto et in pace, ut sciamus, &c." We have no other music printed expressly for the cathedral service to English words during the reign of Edward VI., than that of Marbeck, which was mere cantio fermo, without counterpoint; but the year after the publication of the English Liturgy by queen Elizabeth, the following choral work appeared: "Sustine nos in facto et in pace, ut sciamus, &c." The authors of these compositions were Tallis, Cawston, John- fon, Oakland, Shepherd, and Taverner. In 1565, our ecclesiastical composers, encouraged probably by the reception of the former publication, and favour of the queen, printed another collection of offices, with musical notes, under the following title: "Morning and Evening Prayer and Communion, for four parts, to be sung in Churches, both for Men and Children, with versicles and responses, &c." The compositions of these were Tallis, Cawston, John- fon, Oakland, Shepherd, and Taverner. These two publications by John Day, fixed, for near a century, the style of our choral music; of which the movement was grave, the harmony grateful, and the contrivance frequently ingenious.

The great musicians of queen Elizabeth's reign were Dr. Tye, John White, Thomas Tallis, William Byrd, Dr. Bull, and Thomas Morley. And these, as ecclesiastical composers, were perhaps equal in learning and genius to the greatest contemporaneous contrapuntists on the continent of Europe.

We must not terminate our account of the cultivation and progress of music by queen Elizabeth and her subjects, without making honourable mention of her majesty's "Virgilian Book," and referring for a summary account of its contents to TAYLOR, W. In all our enquiries after musical curiosities throughout Europe, we have met with no pieces so elaborate and difficult for the harpsichord, as those by our ingenious countrymen.

This book, equally valuable for its antiquity and contents, was purchased by Burner at Dr. Pepusch's sale, 1762, whose property it was to the time of his death. After which it passed into the hands of vicount Fitzwilliams, in whose possession, we believe, it still continues.

It is a magnificent folio MS. curiously bound in red Morocco, with gilt leaves. There are nearly 70 pieces by Dr. Bull in this volume. The writing is small, but uncommonly neat, upon fixed lines. The compositions are in general extremely elaborate and difficult; particularly those by Bird, Dr. Bull, and Giles Farnaby, who have all contributed largely to the furnishing of this volume, which contains near three hundred pieces. The first movement in the book is an old English tune, called "Wallingham," beginning in C natural, and ending in A major, which Dr. Bull has varied in a most full and complicated style, thirty different ways. Signora Margarita, the wife of Dr. Pepusch, when she quitted the Opera stage, applied closely to the practice of the harpsichord; upon which instrument she became a great proficient. However, with all her own diligence and talents, afflicted by the science and experience of
Queen Mary II. joint sovereign with William III., seems to have done little more for music, than patronise Mrs. Arabella Hunt, and the old Scots tune of "Cold and raw the wind doth blow." See Mary.

Queen Anne, in Geography, a poll-town of America, in Prince George county, Maryland, situated on the W. side of Potomac river, across which is a wooden bridge. This small town is laid out on a regular plan, at the foot of a hill. It contains a few stores, and warehouses for the inspection of tobacco; 25 miles E.N.E. of Washington.

Queen Anne's, a county of Maryland, bounded W. by Chesapeake bay, and N. by Kent county; containing 16,648 inhabitants. Its chief town is Centerville. Belonging to this county is Kent island, 14 miles long from N. to S. and 6½ broad from E. to W. It is low, but the land is fertile, and its eastern side is bordered with salt marshes.

Queen Catherine's Foreland, the northernmost point of Terra del Fuego, at the east entrance into the Straits of Magellan, discovered by Frobisher in 1576.

Queen Charlotte's Foreland, the S.E. extremity of New Caledonia. N. lat. 22° 15'. E. long. 167° 14'.—Also, the S.W. point of New Hanover, in the East Indian sea, so called in 1767 by Capt. Carteret. The land about it is remarkable for a number of little hummocks, or hogs. S. lat. 2° 29'. E. long. 145° 27'.

Queen Charlotte's island, an island in the Pacific ocean, about six miles long, and one broad, discovered in the year 1767, by Captain Wallis. It is described as sandy and level, full of trees, without underwood, and abounding with scurvy-gras. The cases of this island appeared to be about 30 feet long, 4 feet broad, and 3½ deep. The inhabitants were of a middle stature, and dark complexion, with long black hair, hanging loose over their shoulders. The men were well made, and the women handsome. Their garments were a kind of coarse matting, fastened about their middle, and capable of being brought round their shoulders. The men who landed saw no appearance of any kind of metal, but observed several tools made of shells and stones, sharpened and fitted into handles, like adzes, chisels, and awls. They faw several repositories of the dead, in which bodies were left to putrefy, under canopics, and not deposited in the ground. The island was taken possession of by Captain Wallis and his crew, in the name of his Britannic majesty. They also left some hatchets, nails, glass bottles, beads, shells, flintknives, flint-swords, and halfpence, as presents to the natives. S. lat. 16° 18'. W. long. 138° 4'.

Queen Charlotte's Islands, a group of islands, discovered in 1767 by Capt. Carteret, consisting of Egmont's island or New Guernsey, Lord Howe's island or New Jersey, and several others. A quarrel having occurred in consequence of the impudent conduct of the master of Capt. Carteret's ship, between the crew and the natives, several of the latter were killed, and four of the former died in consequence of their wounds. This unfortunate event prevented any intercourse with the inhabitants of these islands. Egmont island, says Capt. Carteret, who called it by this name in honour of the earl, is the same with the Santa Cruz of the Spaniards; and the place in which the ship had lain he called Swelllow bay; about ten miles W. from this bay is a small island, near the coast, called Portland's island; and to the bay farther west, where the ship's cutter had been attacked by the Indians, he gave the name of Bloody Bay. In this bay is a small rivulet of fresh water, and here were seen many houfes, and near the water-side, one much longer than any of the rest, which seemed to be a kind of common hall, or council-house, and was neatly built and thatched. The sides and floor of this edifice were covered with a kind of fine matting, and bundles of arrows were hung up in it ready for use. At this place there were also many fine gardens and plantations, inclosed by a fence of stone, and planted with coconuts, bananas, plantains, yams, and other vegetables. About three miles W. of this town was another of considerable extent, in the front of which, near the water, was a broad-work of stone, about four feet six inches high, angularly formed like a fortification; from which, and from other circumstances, there is reason to believe that the natives have frequent wars among themselves. At the distance of two or three miles farther westward, was found a small bight, receiving a river, which was called Granville's river, and wayward of it is a point, to which was given the name of Ferrar's point. From this point the land forms a large bay, near which is a town of great extent, and apparently very populous. About seven miles W. of Ferrar's point is another, that was called Carteret's point, from which a reef of rocks, that appears above water, runs out to the distance of about a cable's length. To the W. of this was another large town, fronted like the last, and the people who thronged to the beach while the ship was paling, performed the same kind of circular dance with those of the former place. They were furnished with a number of canoes of different sizes. The inhabitants of Egmont island are extremely nimble, vigorous, and active, and seem as well qualified to live on the water as on the land, for they were in and out of their canoes almost every minute. With their bows and arrows they do execution at an incredible distance. Their arrows were pointed with flint, nor was there seen among them any appearance of metal. The country, in general, is woody and mountainous, intermixed with many vallies; several small rivers flow from the interior part of the country into the sea, and upon the coast there are many harbours. S. lat. 9° 50' to 11° 25'. E. long. 163° 30' to 165° 10'. Hawkeworth's Voyages, vol. i. p. 349, &c.

Queen Charlotte's islands, called by Capt. Gray, of the United States, who visited them in 1789, and by American navigators, "Washington islands," a group of islands on the N.W. coast of America. See Queen Charlotte's Island.

Queen Charlotte's Sound. See Queen Charlotte's Sound. Mr. Anderson, who visited this found four times, has made the following remarks on the country near it. The land is every where uncommonly mountainous, rising immediately from the sea into large hills, with blunted tops. At considerable distances are vallies, or rather impreffions on the sides of the hills, which are not deep, each terminating towards the sea in a small cove, with a pebbly or sandy beach, behind which are small flats, where the natives generally build their huts, at the same time landing their canoes upon the beaches. The bafes of these mountains, at least towards the shore, are constituted of a brittle, yellowish sand-flone, which acquires a blueish cast, where the sea washes it. It runs, in some places, in horizontal, and, at other places, in oblique strata; being frequently divided, at small distances, by thin veins of coarse quartz. The mould, or foil, which covers this, is of a yellowish cast, not unlike marle, and is com-
The quality of this soil is best indicated by the luxuriant growth of its productions; the hills being one continued forest of trees, owing the strength of their vegetation partly to the soil, and partly also to the agreeable temperature of the climate. In February, corresponding to our August, the thermometer was not higher than 66°; and in June, corresponding to our December, the mercury never fell lower than 48°. The weather is, in general, good; but sometimes rainy, with heavy rain, which, however, never lasts above a day; nor is it ever excessive. Among the trees, which covered the hills, and which are of two sorts, one supplied the place of sarsaparilla in making beer, for which purpose a strong decoction of its leaves was fermented with treacle or sugar. The other fort of tree resembled a maple, and its wood served for fuel. On the small flat spots behind there is a great variety of trees. Among other plants that were useful, may be reckoned the wild celery, which grows plentifully almost in every cove, and one that was called scurvy-grass, though very different from the plant to which we give that name. Both were boiled every morning, with wheat ground in a mill, and with portable soup for the people's breakfast, and amongst their pea-fowl for dinner. Sometimes they were used as fallow, or dressed as greens. There is another plant, which produces a fine silky flax, of which the natives make their garments. A species of long pepper is also found in great plenty. The birds are almost entirely peculiar to the place. The principal fish caught with the lines are mullets and elephant-fish, with a few eels and flounders; but those which the natives mostly supplied were a sort of sea-bream, of a silver colour, with a black spot on the neck, large congers, and a fish in shape like the bream, but so large as to weigh five, six, or seven pounds, and called "moggie" by the natives. Of all the sorts of fish, which are here numerous, the moggie, small salmon, and colour fish, as the seamens called it, though different from ours, are superior to the rest. The rocks furnish a great variety of shell-fish. Infest are very rare. In this extensive land there are not even traces of any quadruped, excepting only a few rats, and a fort of fox-dog, which is a domestic animal with the natives. Neither is there any mineral worth notice, but a green Jasper or serpent-stone, of which the New Zealanders make their tools and ornaments.

The natives do not exceed the common stature of Europeans, and, in general, are not so well made. Their colour is of different casts, from a deep black to a yellowish or olive tinge; and their features are also various, some resembling Europeans. But in general their faces are round, with their lips full, and also their noses towards the point; though the first are not uncommonly thick, nor the last flat. Their teeth are generally broad, white, and well set; and their eyes large, with a very free motion, which seems the effect of habit; their hair is black, straight, and strong; commonly cut short on the hind part, with the rest tied on the crown of the head; but some have it curling, and of a brown colour. In the young, the countenance is generally free or open; but in many of the men it has a serious cast, and sometimes a fullness or reserve, especially if they are strangers. The women are in general smaller than the men; but have few peculiar graces. The drefs of both sexes is alike; and consists of an oblong garment, about five feet long and four broad, and made of the flaky flax before mentioned. This seems to be their most material and complex manufacture, and is executed with knots; and their work is often ornamented with pieces of dog-skin, or chequered at the corners. They bring two corners of this garment over their shoulders, and fall it on the breast, with the other part which covers the body; and about the belly it is again tied with a girdle made of mat. Sometimes they cover it with large feathers of birds, (which seem to be wrought into the piece of cloth when it is made,) or with dog-skin; and that alone sometimes worn as a covering. Over this garment many of them wear mats, which reach from their shoulders to their heels. But the most common outer covering is a quantity of fudge-plant, badly dressed, which they fall on a string to a confiderable length, and throwing it about the shoulders, let it fall down on all sides, as far as the middle of the thighs. By way of ornament, they fix in their heads feathers, or combs of bone or wood, adorned with pearl-shells, or the thin inner skin of some leaf; and in the ears both of men and women, which are pierced, or rather slit, are hung small pieces of Jasper, bits of cloth, or beads, when they can get them. A few also have the leptom of the nose bored in the lower part. They wear long beards, but are fond of having them flaved. Some are punctured or flained in the face, with curious spiral and other figures, of a black or deep blue colour; but it is doubtful whether this be ornamental, or intended as a mark of peculiar distinction; and the women who are marked so, have the puncture only on their lips, or a small point on their chins. Both sexes often bemear their faces and heads with a red paint, which seems to be a martial octrine, mixed with grease; and the women sometimes wear necklaces of shark's teeth, or bunches of long beads, which seem to be made of the leg-bones of small birds, or a particular shell. They live in small coves, in companies of forty or fifty, or more; and sometimes in single families, building their huts contiguous to each other; which are in general miserable lodging places. The huts was about thirty feet long, sixteen broad, and six high, built exactly in the manner of an English barn. They seem to have no other furniture than a few small baskets or bars, in which they put their fishing-books and other trifle. They live chiefly by fishing, making use either of nets of different kinds, or of wooden fish-hooks, pointed with bone; but if oddly made, that a stranger would be at a loss to know how they can answer such a purpose. Their boats are well built of planks, raised upon each other, and fastened with strong withes, which also bind a long narrow piece on the outside of the seams, to prevent their leaking. Some are fifty feet long, and so broad as to be able to fail without an outrigger; but the smaller sort commonly have one; and they often fasten two together by rafters, forming a double canoe. They carry from five to thirty men, or more; and often have a large head, ingeniously carved, and painted with a figure at the point, which seems intended to represent a man with his features distorted by rage. Their paddles are about four or five feet long, narrow, and pointed; with which, when they keep time, the boat is pulled alone pretty swiftly. Their sail, which is seldom used, is made of a mat of a triangular shape, having the broadest part above. Their method of feeding corresponds with the naiilines of their persons, which often smell disagreeably, from the quantity of grease about them, and their clothes never being washed. We have seen them eat the vermin with which their heads are plentifully stacked. They also used to devour with the greatest cager-nefs large quantities of flinking train oil, and blubber of seals, which we we melting at the tent, and had kept near two months: and on board the ships they were not satisfied with emptying the lamps, but actually swallowed the cotton and fragrant wick with equal voracity. These people manifest as much ingenuity, both in invention and execution, as any un civilized nations under similar circumstances. For, without the use of any metal tools, they make every thing by which they procure their subsistence, clothing, and warlike weapons.
I, for various purposes, even the most trivial. Their substitute for a knife is a shell, a bit of flint or Jasper: and as an anger, they fix a shark's tooth in the end of a small piece of wood. They have also a small saw made of some jagged fishes' teeth, fixed on the convex edge of a piece of wood, nicely carved; but this, they say, is only used to cut up the bodies of their enemies whom they kill in battle. No people have a quicker sense of injury done to them, and none are more ready to resent it. Their temper is furious and misanthropic; and they are so dishonest, that they steal every thing upon which they can lay their hands. Such conduct may be expected, where little subordination exists, and where no man's authority seems to extend further than his own family. Their public sentiments are frequent, or rather perpetual, and it appears, from their number of weapons, and dexterity in using them, that war is their principal profession. These weapons are spears, patoos, and halberts, or sometimes hoes. The first are made of hard wood, pointed, from five to twenty, or even thirty feet in length. The short ones are uf'd for throwing as darts. The "patoos" or "emetics," is of an elliptical shape, about eighteen inches long, with a handle made of wood, hone, the bones of some sea animal, or green Jasper, and seems to be their principal dependence in battle. The halbert, or long club, is about five or six feet long, tapering at one end with a carved head, and at the other broad or flat, with sharp edges. Before they begin the onset, they join in a war-song, to which they all keep the exact time, and some raise their passion to a degree of frantic fury, attended with the most horrid distortion of their eyes, mouths, and tongues, to strike terror into their enemies: which, to those who have not been accustomed to such a practice, makes them appear more like demons than men, and would almost chill the boldest with fear. To this succeeds a circumstance, almost foretold in their fierce demeanour, horrid, cruel, and disgraceful to human nature; which, in cutting in pieces, even before they are perfectly dead, the bodies of their enemies, and, after dressing them on a fire, devouring the flesh, not only without reluctance, but with peculiar satisfaction. And yet these savages lament the loss of their friends, with a violence of expression, which indicates the most tender remembrance of them. The children are initiated, at a very early age, into all the practices, good and bad, of their fathers. They not only join in the war-song, but they likewise sing, with some degree of melody, the traditions of their forefathers, their actions in war, and other indifferent subjects; of all which they are immoderately fond, and spend much of their time in these amusements, and in playing on a fort of flute. Their language is far from being harsh or disagreeable, though the pronunciation is frequently guttural, and whatever qualities are requisite in any other language to make it musical, certainly obtain to a considerable degree here, if we may judge from the melody of some of their songs. It is also sufficiently comprehensive, though, in many respects, deficient, if compared with our European languages, which owe their perfection to long improvement.

Mr. Anderdon has given a specimen of it. (Cook's Third Voyage, vol. 1.) In the year 1770 Capt. Cook left among the inhabitants a boar and two fows, with some vegetables for cultivation. In 1773 he saw one of the fows, and understood that the other and the boar were both living. The sheep and goats did not succeed; the latter having been killed by one of the natives, and the ram having run into the sea.

Queen's, the middle county of Long island, New York, about 30 miles long, and 12 broad, containing six townships, and 109,330 inhabitants. Jamaica, Newtown, Hampden, in which is a handsome court-house, and Oyster bay, are the principal towns in this county.

Queen's, a county of Nova Scotia, comprehending a part of the lands on the cape, on the S. side of the bay of Fundy. The settlements are as follow; viz. Argyle, on the S. side of the bay of Fundy, where a few Scots and Arcadians reside; next to this is Yarmouth, settled chiefly by emigrants from New England; Barrington, within the island, called Cape Sable, settled originally by Quakers from Nantucket. Besides these are Port Royal, to called by the French, and originally settled by the North Irish; Liverpool and Rofeway, settled and inhabited by emigrants from New England.

Queen's County, a county of Ireland, established in the reign of the first Mary, which comprehended the old district of Leix. Both the county and chief town, Maryborough, received their names in compliment to the sovereign. It is situated on the S.W. of Kildare, from which it is partly divided by the river Barrow, and is of a very compact form, being 25 Irish (nearly 32 English) miles in length, and as many in breadth. The superficial contents are about 235,300 acres, or 367 square miles, equal to 378,023 acres, or about 590 square miles English. There are 50 parishes, 26 only of which have churches, and a population of 82,000 according to Dr. Beaufort, and about 90,000 as the medium of various calculations. The high and steep mountains of Sibb-bloom (called also Ard-na-Erin, which in the Irish language signifies the height of Ireland) form 10 impracticable a barrier between the King's and Queen's counties, that in a range of fourteen miles they afford but one, and that a very difficult and narrow path into the King's country, called the "Gap of Glandine." In this great ridge are the sources of the Barrow and the Nore; the Barrow running N.E. to Monalerevan, where it changes its direction to the S., and the Nore crossing the Queen's county by a southerly course into Kilkenny. The Dyfiart hills in the eastern division are conspicuous and picturesque, standing rather thinly than connected. From these eminences, through the villas formed by their particular situation, is commanded the view of a fine and beautiful country, highly adorned with rich plantations and magnificent demesnes. The rest of the county is rather flat, but lies high. The whole is watered with rivers and numerous mountain streams, and according to Sir Charles Coote, its superficial appropriations may be thus estimated.

The map belonging to the grand jury, reckons 244,935 acres, and of these 66,000 bog and mountain. A small every description of soil is found in this county, and it varies from a very stiff clay to a sandy loam, which, though light, is yet fertile; a strong gravelly soil, very favourable to corn, is also prevalent. Lime-flour is so common, that there are rich quarries of it in almost every townland. The soil
The foil of the Sliegh-bloom mountains is variable, the surface inclining to a black and alternately yellow flint clay, of unequal depths, covering a loam, rotten rock, or a gritty gravel, with occasionally a little appearance of lime-flint. The western side, more generally, inclines to a flinty red clay, not unlike the nature of the foil in some of the northern counties in Ireland, where oats and potatoes only are found; but it generally is, throughout, liogny, wet, and boggy to the summits, and very rocky. Through the whole of the county, except in the south-eastern corner, near Carlow, where the colliers are extensive, bog is well intermixed, and is the general fuel. The depth of these bogs is various, and in some parts undiscerned, the hell fuel lying in some a few fipades depth below the surface, in others very deep. The moors are a shallow bog, with a thin crust of gravel or clay, under one or two fipades depth; this particular kind is easily reclaimed, and becomes the best and surest land in the county, and the cost is here but trifling, indeed often repaid in one year, having all the materials within themselves.

Amongst the mineral productions of this county, Sir Charles Coote, the author of the Statistical Survey, enumerates "coal, iron, copper, manganese, mica, lime-flint, marble, free-flint, ochre, marple, fuller's-earth, and a great variety of clays valuable in every branch of pottery." Such an enumeration is of little use; being recommended neither by detail of facts and places, nor by accuracy of information. The coal district is in another part of the fame work more fully noticed; but the reader who wishes for information, is more likely to find it in the report of Mr. Griffith, mining engineer of the Dublin Society, which is shortly to be published. The coal is of that description called "flint coal," the "flance-coal" of Jamaica, and "bog" known by the name of Kilkenny coal. The Queen's county colliers seem to have laboured under many disadvantages, from want of capital or of proper exertion; but a prospect is opening upon us of more attention to this source of wealth. There is a very small quantity of old timber in the Queen's county. There are, indeed, leaves still in existence, by which the tenant was obliged to cut, burn, or destroy to many acres of wood, to clear the land for the plough; auitable which, if neceffary to the establishment of order in the county, was the cause of reducing it to the bare flate with respect to timber, with which the English traveller is so often struck. The Barrow and the Nore are the principal rivers which water this county. The latter is not navigable, though, being a fine deep and spacious river, it might be easily rendered so, by leveling the numerous weirs, that are of great detriment to the adjoining lands, and throw up a considerable quantity of water back.

The Barrow is navigable throughout from Portarlington, near which it beautifully expands and winds through extensive and fertile banks. There are no lakes which deferve notice. Maryborough is the county town, near which, as well as Mountmelich and Mountath, there was a considerable woollen manufacture of stuffs, &c. which has declined. For any particulars respecting the towns, the reader is referred to the respective articles. Besides those mentioned, Portarlington is a place of some importance, and Stradbally a neat town. The county is represeted in parliament by two knights of the shire, and by one member for the borough of Portarlington. Maryborough and Ballynacull were disfranchised at the union. Sir C. Coote's Statistical Survey. Beaumont's Memoir.

Queen's Creek, a river of America, in North Carolina, which runs into the Atlantic, N. lat. 34° 37', W. long. 77° 28',

Queen's River, a river of the island of Dominica, which runs into the sea near Roseau.

Queen-Bee, a term given by late writers to what used to be called the "king-bee," or king of the bees; a large and long-bodied bee, of which kind there is only one found in every swarm, and which is always treated with the greatest respect by the rell.

It is well known that the generation and whole economy of bees principally depend upon this female sovereign, and that her preference is absolutely necessary to the prosperity and safety of the whole community; infor that the loss of the queen proves the certain and total destruction of the swarm or hive, unless the owner supplies them in time with another ruler. Without her presence and direction, the other bees will do no manner of work; they will gather neither wax, nor honey, nor any other materials; nor can they breed and propagate their kind without her. A flock deprived of its queen, would yield to robbers, or else languish and pine away, so that the whole society would perish. But as soon as a languishing flock is supplied with a queen, pleasure and activity are apparent through the whole hive; the presence of the sovereign restores vigour and exertion, and her voice commands universal respect and obedience: of such importance is the queen to the existence and prosperity of the other members of this community. As the parent and sovereign of every swarm is a female, the whole government is vested in one; so that where there happen to be more, as there sometimes are, and especially in swarms that are united, confusion and discord prevail, until all, except one, are expelled and slain.

As in forming artificial swarms, and for other purposes, it will be necessary to distinguish the queen from the other bees, we shall observe, that she may be known by her size, which is much larger than that of the common working-bees, and longer than that of the drones; by the form and shape of her body, especially of the hinder part of it, which is more taper, and terminates in a much sharper point than the bodies of the other bees, in order the more readily to reach the bottom of the cells, where the eggs are deposited for the propagation of the species (see Generation of Bees); and also by her colour; her upper parts being finely at all different in this respect from the honey-bees, but her belly and legs are of a very deep yellow, resembling the parril and the richest gold. It is said that she may also be distinguished by the note of her voice, which is an octave; and by her being one of the last which falls with her belly upwards, when the bees of a single flock are dropped into an empty hive, in order to be united with those of another flock.

Naturalists have observed, that the queen-bees are produced in a manner peculiar to themselves, and different from the drones and working-bees. Some have supposed that the eggs laid by the queen in a hive, and defined for the production of queen-bees, are of a peculiar kind; but though this is not the case, as M. Schirach has lately discovered, yet there are particular cells appropriated for this purpose. These cells are generally near the edges, and at the bottom of the combs, and sometimes on the sides of a honey-comb; they are of an oblong orbicular form, and very strong; and are more or less numerous in different hives, as occasion seems to require. It has been also supposed, that the matter with which they are nourished is of a different kind and quality from that employed for the nourishment of the other bees; that which has been collected out of the royal cells being of a gummy glutinous nature, of a deep transparent red, and dissolving in the fire rather than crumbling to powder.
It has been generally supposed, that the queen-bee is the only female contained in the hive; that the drones are the males by which she is fecundated; and that the working-bees are neutral, or of neither sex. But M. Schirach has lately established a different doctrine, which has been also confirmed by the later observations of Mr. Debray. According to this writer, all the working or common bees are females in disguise; and the queen-bee lays only two kinds of eggs, viz. those which are to produce the drones, and those from which the working-bees are to proceed; and from any one or more of these, one or more queens may be produced; so that every worm of the latter or common kind, which has been hatched about three days, is capable, under certain circumstances, of becoming the queen, or mother of a hive. In proof of this doctrine, new and singular as it may seem, he alleges a number of satisfactory and decisive experiments, which have been since verified by those of Mr. Debray. For the proof of this doctrine by Schirach and Debray, and the objections of Mr. Hunter, we refer to the article Generation of Bees.

From this doctrine we may justly infer, that the kingdom of the bees is not, if the expression may be used, a jure divino, or hereditary monarchy, but an elective kingdom; in which the choice of their future ruler is made by the body of the people, whether he is yet in the cradle, or in embryo; and who are determined by motives of preference which will perhaps for ever chide the penetration of the most sagacious naturalists.

The conclusions drawn by M. Schirach, from experiments of the preceding kind, very often repeated by himself and others with the same success, are, that all the common or working bees were originally of the female sex; but that when they have undergone their final metamorphosis, they are condemned to a state of perpetual virginity, and the organs of generation are obliterated; merely because they have not been lodged, fed, and brought up in a particular manner, while they were in the worm state. He supposes, that the worm designd by the community to be a queen, or mother, owes its metamorphosis into a queen, partly to the extraordinary size of its cell, and its peculiar position in it; but principally to a certain appropriate nourishment found there and carefully administered to it by the working bees, while it was in the worm state; by which, and possibly other means unknown, the development and extension of the germ of the female organs, previously existing in the embryo, is effected; and those differences in its form and size are produced, which afterwards so remarkably distinguish it from the common working bees. Schirach's Histoire Nat. de la Reine des Abeilles, &c. Svo. 1772. Or, for an abstract, Monthly Review, vol. xlviii. p. 354. &c. Phil. Trans. vol. lviii. part i. p. 29. &c. See Generation and Sex of Bees.

This discovery is capable of being applied towards forming artificial swarms, or new colonies of bees, by which means the number of the useful effects might be increased, and their produce in honey and wax proportionably augmented. M. Schirach, as well as M. Hafforff, feems, however, to have been mistaken, when they affert, that the artificial queens, formed and reared in a community consisting only of working bees, proceed almost immediately to lay eggs, and to people the hive, without having had any communications with the drones, and at a time when, as they suppose, there were no drones in being. It is not necessary to admit the idea of the prolific quality of a virgin queen-bee; as nature has provided drones of different sizes, for the purpose of impregnating the eggs laid by the female, and continuing the species, adapted to different occasions and circumstances. See Drone.
longing to the Saxon kings, who had a castle here, near the western entrance of the Swale, which, after the conquest, was denominated the castle of Shepey. This fortress being totally demolished in the reign of Edward III., that monarch commenced, in 1360, a more extensive and magnificent one, which was finished in the period of six years, under the superintendence of the celebrated William of Wykeham, afterwards bishop of Winchester. When the castle was completed, Edward came and resided in it several days, during which time he constituted the then village a free borough, and ordered it to be called Queenborough, in honour of his consort Philippa of Hainault. By the charter of incorporation, which bears date in 1366, he conferred fundry privileges upon the burgesses, and empowered them to elect a mayor, two bailiffs, four jurats, a town ferjeant, and a water bailiff, who were to take their oath of allegiance before the constable of the castle, and to act as justices of the peace within the liberty of the corporation. This charter was confirmed, with additional privileges, by king Charles I.

Queenborough consists chiefly of one street, which is very wide, and is formed mostly of modern buildings. According to the parliamentary returns of 1811, the borough, which coincides in extent with the parish, contains 163 houses and 805 inhabitants, who are principally fishermen and oyster dredgers. The market days are Monday and Thursday weekly, and there is a well-attended fair on the 5th of August. This town sends two members to parliament, who are elected by the mayor, jurats, bailiffs, and burgesses, about 150 in number, though by the last decision of the house of commons in 1729, the elective franchise was declared to reside only in the mayor, jurats, and common council. The mayor is the returning officer, and the patronage is in the admiralty and board of ordnance.

Of the castle built by king Edward, no traces remain except the moat by which it was surrounded, and a well, by which it was supplied with water, as the town still is. Though a large and massive structure, and erected, as the letters patent express it, “for the strength of the realm, and for the refuge of the inhabitants of this isle,” it does not appear to have ever been of any particular use, at least it is never mentioned in history as having been besieged, or occupied as an important military post. It was nevertheless several times repaired; first by Richard II., and again in the time of Henry VIII. Queen Elizabeth also seems to have contributed to its preservation and embellishment, as her arms were displayed on the crenel of the great hall, surrounded by those of the nobility, and principal gentry of the county, with the date 1593, affixed to some panegyrical verses in honour of that prince. The church here was originally built as a chapel to Minster, a village situated about two miles from the town, and deriving its name from the minster, or nunnery founded there by Sexburga, widow of Ercobert, king of Kent, about the year 673. That prince placed seventy-seven nuns in her new institution, and took upon herself the office of abbess; which the afterwards resigned to her daughter Ermenilda, and retired to Ely, where her sister Ethelbedred predeceased. During the incursions of the Danes, this nunnery was deserted and nearly destroyed; but when their invasions ceased, it was again tenanted by a few nuns, and continued to exist, though in a very mean state, till the year 1130, when the buildings were re-edified by Corbel, archbishop of Canterbury, and filled with nuns of the order of St. Benedict. At the dissolution their number was limited to a prioress and ten nuns, whose estates were estimated at 129l. 7s. 10d. annual rent. Thence, with the feite of the suppressed monastery, were then granted to sir Thomas Cheyne, lord warden and treasurer of the household to king Henry VIII. Of the buildings, a gate-house, and part of the church, are the only remains. The latter consists of two ailes, a chancel, and a neat chapel, with the lower division of a square tower at the west end. In conformity with the date of its erection, some of the arches are semicircular in form, but most of them are in the early pointed style. In the south wall of the chancel, under a range of five-foil arches, is the effigy of a knight templar, said to represent and commemorate Sir Robert de Shurland, lord of Shurland, who was created a knight banneret by Edward I., for his gallant conduct at the siege of Carlaverock, in Scotland. Behind the figure, towards the back of the recess, is the representation of a horse’s head in the act of swimming, which has given rise to much enquiry among antiquaries, and to many fabulous and superstitious stories among the vulgar. On the pavement are several braies of knights and their ladies; and under the arch separating the chancel from the chapel, is a gorgeous altar-tomb in honour of sir Thomas Cheyne, above-mentioned. Another altar-tomb, near it, bears the recumbent figure of a Spanish general, or admiral taken prisoner by sir Francis Drake, on the defeat of the “Invincible Armada.” From an entry in the parish register, he appears to have died on board a ship at the Nore in 1591. Beauties of England and Wales, vol. vii. by E. W. Brayley.

QUEENSBOURGH, a township of America, in Washington county, New York, bounded easterly by Westfield and Kingbury; 35 miles N.E. of Albany.

QUEENSFERRY, South, a royal burgh and sea-port town in the county of Linlithgow, Scotland, is situated on the southern shore of the Firth of Forth, at the distance of nine miles W.N.W. from Edinburgh, on the great road to the north. It is first mentioned in the charters of king Malcolm IV. by the designation of “Paffagium Regium,” as is generally supposed from the frequent use of the ferry here by his great grandmother Margaret, queen to Malcolm Canmore, a prince highly celebrated in Scotti sh history for her charitable and beneficent qualities. At that period, however, it was only a village and port, endowed with some trifling privileges; indeed, its constitution as a royal burgh did not take place till about the year 1556, when its elevation to that rank was strenuously opposed by the corporation of Linlithgow. It is now governed by a provost, one land bailie, two sea bailies, a dean of guild, and a town council, who, like most other counsellors in royal boroughs, are self-elected. Formerly this port enjoyed a considerable trade, and even late as the year 1640, it was frequented by above twenty ships belonging to refident owners; but its traffic is at present confined to the importation of coal, for the consumption of the inhabitants, and of the materials used in the manufacture of brown soap, which, with the fishery and the builncss of the ferry, constitute the chief support of the town. The harbour is in good repair, and is frequently reforted to as a place of retreat in hard gales, by the smaller vessels navigating the Forth. The passage here does not exceed two miles in breadth, and, except in very boisterous weather, may be crossed at all times with safety and expedition. Much obscurity prevails relative to the founding of this ferry. The right of it is private property, and feemes originally to have been attached to the lands of Murie Hall, which lie in the vicinity of the town, and are traditionally said to have been appropriated for “upholding the passage.” The present proprietors are several gentlemen possessing land on either side of the Forth, who let the passage yearly by public auction. As all the northern mails, and most carriage travellers, pass at this ferry, the intercourse between its shores is constant and regular. Cattle also are transported
ported over in great numbers, as well as carts and waggons; but the difficulty and danger of effecting these objects, have induced cattle-drivers and carriers to go round by the bridge at Stirling.

The parish of Queensferry is of small extent, being confined entirely to the royalty. In ecclesiastical matters it forms part of the prebendry of Linlithgow, and fissued of Lothian and Tweedale; and, according to the population returns of 1811, contains 77 houses and 558 inhabitants.

On the summit of the ridge rising from the shore here, stands Hopetoun-houfe, the seat of the earl of Hopetoun, which is perhaps equal in magnificence of aspect to any palace or residence in Great Britain. The mansion is seated on a noble lawn, forming a kind of terrace along the Firth for more than a mile in front, and only terminated by the Frith, which winds round it, and appears like a wide and extensive lake, intermixed with islands and enlivened with a variety of shipping. Behind the house the ground is more various, breaking into hills, valleys, and promontories, which shoot into the Firth. All the grounds, to a considerable distance, are planted and adorned; and the house is deftantly flanked with a thick wood, to protect it against the violence of the northern winds. On this side the Firth affumtes, at different points, different appearances, sometimes putting on the semblance of a lake, and sometimes that of a river. The house is a very noble display of architectural magnificence. It was begun by the celebrated architect Sir William Bruce, and finished by Mr. Adam, who is believed to have added the wings. It is much to be regretted, that the interior of this princely mansion does not correspond with the grand scale of the exterior, in the size and decorations of the apartments. Beauties of Scotland by Robert Forfvy, vol. iii. Carlile's Topographical Dictionary of Scotland, 4to. 1814.

QUEENSFERRY, North, a small sea-port town in the dis- trict and parish of Dunfermline, Scotland, is situated on the northern shore of the Frith of Forth, opposite to the royal burgh of South Queensferry, described in the preceding article. The principal export is whin-flour for paving, which is found in vast abundance in the extensive "whin-flour quarries" adjoining. Of that material a large proportion is conveyed to London, and many towns on the eastern coast of England. A hamlet, called St. Margaret, between this village and the head-land, which forms the western boundary of Inverleithing bay, is noted as the landing place of prince Edgar Atheling, and his sister Margaret, afterwards queen of Scotland, when they fled from England to avoid the effects of the conqueror's jealousy of Edgar's claim to the English crown. By an act of parliament, lately passed, the ferry has been placed under excellent regulations; and the harbour on each side, but particularly on the north side, has been much enlarged and improved. A signal house here contains apartments for the accommodation of the trustees, the superintendant, and boatmen. Carlile's Topographical Dictionary of Scotland, 4to. 1813.

QUEEN'S-HOPE, or EAST-HOPE, a town in the parish of Elty, or Hope, cantred of Uwech, Kaint, (now called the hundred of Mold,) and county of Flint, North Wales, is situated near the river Alun, at the distance of six miles N.W. from Wrexham. Together with the adjoining castle and hamlet of Cae-Gwrle, it constitutes a borough, both by prescription, and in virtue of a charter granted by Edward the Black Prince in 1351. That deed orders that the constable of the castle shall be mayor, ex officio, and shall nominate two bailiffs, to govern under him, from among the burgesses. This place obtained the appellation of Queen's-Hope, after the year 1282, from the circumstance of its having been then beloved by Edward I; so his beloved and heroic confron Eleanor; or, as some affirm, from her majesty having lodged here, when on her way to Caernarvon to give the Welsh a ruler born within their own territories. The etymology of its ancient name, "Caer- gawr-le," (the camp of the gigantic legion,) seems to indicate that it was once occupied by the Romans; and in confirmation of this conjecture we may observe, that a Roman hypocaust has lately been discovered here, some of the tiles used in the construction of which were inscribed "Legio XX." Pennant supposes that it was an outpost to the grand station Deva, and notices the remains of two roads. The ruins of the camp of Caer-Gwre are seated on a lofty rock isolated from the surrounding land, and, on one side, extremely precipitous. At what time, or by whom it was originally built, is unknown; but in the reign of Owen Gwynedd, it formed part of the pollcitions of a chieftain named Gryffydd Macel. Edward I. made a grant of it to David, and afterwards, as above-mentioned, to queen Eleanor, at whose death both castle and manor were given to John de Cromwell, on condition that he repaired the fortifications, which had been set for to adjust considerably damaged, as was supposd to design, while the king and queen were resident in it. All that remains of this once magnificent forress, are a circular tower, and a few fragments of walls, together with the deep fosse, by which it was defended. This fosse is excavated from the solid rock, which is com- posed of breccia, or an exceedingly coarse grit.

The conjoint borough of Queen's-Hope and Caergwre, is contributory with the town of Flint in the election of a representative to the British parliament. It formerly had the privileges of a market and fairs, but there are now dis- continued. The parish is divided into two districts, called Hope and Kinnerton, and contains, according to the parliamentary returns of 1811, 547 houses and 2617 inhabitants. Of these a large proportion reside in the town, which consists of three broad parallel streets, intersected at right angles by three others of less breadth, the whole placed on the side of a rising ground, gently sloping to the river. The principal building is the church, which contains two mural monuments, one decorated with kneeling figures, but without any inscription; and the other commemorating one John Trevor, knt. secretary to the earl of Nottingham, the con- querer of the boated invincible armada.

Some objects in the vicinity of the place claim notice. On a hill, opposite to that of Caergwre, is the British en- campment of Caer-Ellyn, which is formed by a single ditch and rampart. The adjacent summits conflict chiefly of lime-flour, and display on their surface numerous organic examples of the fossil remains called entrochi and alfitroes. The uncommon species of the latter, usually denominated the aboreousentrochi, has been found here. At Rhuddyn are two springs strongly impregnated with muriate of soda, the waters of which are found highly serviceable in such chronic disorders as elephantiasis and cerephula. At this place is a fine old bridge over the river Alun. On the road to Mold, about two miles from Queen's-Hope, is Plas-Teg, the seat of the Trevor family. The house is a very noble building, and is generally believed to have been the work of Lingo Jones. Beyond this is Harts-Heath Hall, the property of Guillon Lloyd Wardle, efg. It is a large modern mansion, forming a square, with three fronts, and is surrounded by fine plantations. Carlile's Topographical Dictionary of Wales, 4to. 1812.
QUEENSTADT, a town of Westphalia, in the principality of Halberstadt; three miles N.E. of Halberstadt.

QUEENSTOWN, a port-town of America, in Queen Anne's county, Maryland, on the E. side of Chelfter river; six miles S.W. of Centerville, and 65 from Washington.

QUEENSTOWN, a town or village of Upper Canada, which lies on the W. side of the straits of Niagara, near fort Niagara, and seven miles below the Falls. It is at the head of navigation for ships; and the portage occasioned by the Falls of Niagara commences here. From the sudden change in the face of the country in the neighbourhood of Queenstown, and the equally sudden change in the river with respect to its breadth, depth, and current, it has been conjectured, that the great falls of the river must originally have been situated at the spot where the waves are so abruptly contracted between the hills; and moreover it is a fact well ascertained, that the falls have receded very considerably since they were first visited by Europeans, and that they are still receding every year. See Weld's Travels, vol. ii. P. 131.

QUEESAN ISLANDS. See Chusan.

QUE ESTATE, in Law, a plea whereby a man entitling himself to land, &c. faith, that the same estate which another had, he now has from him.

Thus, e. g., the plaintiff alleges that such four persons were fealled of lands whereinunto the advowson in quetion belonged in fee, and who did present it; and that afterwards the church was vacant; que eftate, i.e. which estate he now has; and, by virtue thereof, he presents, &c. See Prescription.

QUE EST MEME, a term used in actions of trespass, &c. for a direct justification of the very act complained of by the plaintiff as a wrong.

Thus, in an action upon the case, the plaintiff faying the lord threaten his tenants at will in such fort, as he forced them to give up their lands; the lord in his defence pleads, that he paid to them if they would not depart; he would fume them at law. Que eft meme, i.e. this being the fame threatening that he used, the defence is good.

QUEGASCAR HARBOUR, in Geography, a bay on the S. coast of Labrador. N. lat. 56° 7'. W. long. 61° 23'.

QUEL, in Natural History, a name given by the Chinese to a peculiar earth found in many parts of the East.

It is of the nature of an indurated clay, and in some degree approaches to the tale, or our flatites and the galéctides do. It is very white and abditive, used by the women of China, to take off spots from the skin, and render it soft and smooth, as the Italian ladies use tale of Venice. They sometimes use the fine powder of this stone dry, rubbing it on the hands and face after washing; sometimes they mix it with pomatum.

QUEICH, in Geography, a river of France, which passes by Landau, and runs into the Rhine, near Germersheim.

QUEI-CHUN, a city of China, of the second rank, in the province of Quang-fi. N. lat. 23° 22'. E. long. 106° 44'.

QUEIGE, a town of France, in the department of Mont Blanc; four miles N.E. of Conflans.

QUEIGNE, a town of Africa, in the kingdom of Bambouk.

QUELING, a city of China, and capital of the province of Quang-fi, derives its name from a flower called "quei," which grows on a tree resembling a laurel; it exhales a sweet and agreeable odour, that the whole country around is perfumed with it. This city is situated on the banks of a river, which throws itself into the Ta-ho; but it flows with such rapidity, and amidst narrow vallies, that it is neither navigable nor of any utility to commerce. Quei-ling is a large city, and the whole of it is built almost after the model of our ancient fortresses; but it is much inferior to most of the capitals of the other provinces. Birds are found in great numbers in the territories belonging to it, the colours of which are so bright and variegated, that the artificers of this country, in order to give additional life to their flags, interweave with them none of their feathers, which have a splendour and beauty that cannot be imitated. Quei-ling has under its jurisdiction two cities of the second class, and seven of the third. N. lat. 25° 12'. E. long. 109° 51'.

QUEJOS, a river of Spain, in Navarre, which runs into the Ebro, near Tudella.

QUEIRA, a town of Africa, in Ladumar; eight miles S. of Benown.

QUEI-S, a river of Silefia, which rises in the principality of Jauer, passes by Friedberg, Griezenburg, &c. and joins the Bober, between Sprottau and Sagan.

QUEI-TE, a city of China, of the second rank, in Quang-fi. N. lat. 23° 18'. E. long. 109° 4'.

QUELAINES, a town of France, in the department of the Mayenne; eight miles S. of Laval.

QUELEA, in Ornithology, a species of Emberiza; which fee.

QUELINES, in Geography, mountains of Mexico, between the provinces of Guaxaca and Chiapa.

QUELLINUS, ERASMINUS, in Biography, called the Old, born at Antwerp in 1607, was a pupil of Rubens, and became a painter of history of very considerable reputation. He lived to the age of 71, and left a son John Erasmus Quellinus, who also became a painter, but who left the Flemish for the Venetian style of art, which he practised at Antwerp, his native city, till he arrived at the advanced age of 85, having been born in 1630.

QUELPAERT, in Geography, an island in the sea of Corea, on which a Dutch vessel, called the Sparrow-hawk, was wrecked in the year 1635, and is the subject of the king of Corea. No land presents a finer aspect; the middle of the island is occupied by a peak of about 800 toises, visible at the distance of about 18 or 20 leagues, and the land gradually slopes towards the sea, so that the habitations resemble an amphitheatre. The soil to a great height seems to be well cultivated. It belongs, however, to a people who are forbidden to hold any intercourse with strangers, and who dote in slavery unfortunate persons who are wrecked on the coasts. Some Dutchmen of the Sparrow-hawk, after a captivity of eighteen years, during which they received many balladines, found means to take away a bark, and to cross to Japan, from which they arrived at Batavia. N. lat. of the south point 33° 14'. E. long. 126° 35'.

QUELUSIA, in Botany, a name given by Vandelli to the beautiful Fuchia coccinea, now so common in gardens. The author suppose it a new genus, and meant thus to honour a royal villa near Lisbon, called Queles, where he first saw this plant in bloom.

QUEM REDDITUM REDDIT, in Law, an old writ which lay where a rent-charge, or other rent, which was not rent-service, was granted by fine holding of the grantor. If the tenant would not attorn, then the grantee might have had this writ.

QUEMARY, in Geography, a town of Bootan; 20 miles E. of Beyhar.

QUEMENNES, a small island in the English channel, near the coast of France. N. lat. 48° 22'. W. long. 4° 48'.

QUEM,
QUEMI, in Botany, a name used by some authors for the nigella, or gelt.

QUEMIGNY, in Geography, a town of France, in the department of the Côte d'Or; nine miles S.W. of Dijon.

QUENDAL BAY, a bay at the S. extremity of the island of Shetland. N. lat. 59° 49'. W. long. 1° 40'.

QUENDON Water-Barrow, in Rural Economy, a contrivance of the barrow kind, much employed in the neighbourhood of the little village of Quendon, in Essex, and from which it takes its name, for the purpose of conveying water, wash, and other liquid matters, to live flock of different kinds, as fattening cattle, hogs, horses, and other animals, as well as for some other uses. It is a simple and excellent invention for all such intentions, as very great facility is given to its motion by means of the wheels, and it is, on the whole, very compact in its general formation, which gives it a superiority over many other contrivances of a similar nature, as being capable of being put in motion, when full, without any great difficulty, or the application of any extraordinary power or force.

It is represented at figs. 6 and 7, in Plate Agriculture, showing the methods of clearing quarries, pits, &c. from water. Fig. 6. explains the plan, in which a, b, are the wheels, that fallen on to the side-beams cd, cd, which are about four feet in length, and have their ends e, e, fixed in such a manner as to serve for handles. E is an oval tub about thirty inches in depth, twenty-four in length, and eighteen in breadth, which is supported on the beams by two gudgeons, which play in semicircular boxes fixed near the ends of the beams: a crofs piece connects the two beams at ff, as does another at gg, to which two little curved pieces come, parallel to the form of the tub. The wheels are about four feet in height, and carry the tub suspended between them; for the gudgeons play almost over the two short axes, which square into the beams. Two flight legs are fixed underneath the barrow at i i, to keep it in an upright position, but they are not at all essential, for the tub would remain in a state of equipoise between the wheels even without such aid. It must be noticed, that the tub is funk rather more than one-half below the gudgeons.

Fig. 7. displays the profile of the vehicle; the dotted line shews the size and place of the tub, which is made oval, for the purpose of confining the breadth between the wheels, so as to pass in at narrow door-ways, &c.

It is probable that it might be somewhat improved by having the axes hooked within, so as to bear upon two loops in one of the iron hoops, and by this means render the use of gudgeons and boxes wholly unnecessary. The tub would lift off and on, as easily as at present, while it would hang in a more precise and perfectly centrical manner. And still further, it would be a great convenience, if the upper part of the tube were furnished with a proper spout in the front, in order to pour water or other liquid materials through between the pales, &c. for the supply of cattle, &c. This would be more easily accomplished, if the tube were allowed to swing in a free manner, as it might in that case be tilted up with great facility, so as to favour its being done, as shewn by the dotted line in fig. 2. About the little town noticed above, it is a great deal employed in carrying water for house use as well as that of farms. It is described in the Agricultural Magazine. Many other forms of water-barrows are made use of in different places. See Water-Barrow.

QUENEG, or QUENENA, in Geography, a district of Africa, in the country of Suguimella, near mount Atlas.

QUENOY, Le. a town of France, in the department of the North; five miles N.N.W. of Lille.

QUENTIN, in Commerce, a small weight used in Germany; the ounce contains two lochs, or eight quintins.

QUENTIN, St., in Geography. See St. Quentin.

QUEPO, a town of Mexico, in the province of Cola Rica, on the Eetrella; 70 miles S.S.W. of Carthage.

QUERA, a town of Italy, in the Trevilian; 15 miles W. of Ceneda.

QUERALOS, a town of Spain, in Catalonia; 24 miles E. of Urgel.

QUERCERA, in Medicine. See Epiolas.

QUERCETO, in Geography, a town of Etruria; nine miles S.S.W. of Volterra.

QUERCUS, in Botany, the Oak, an ancient Latin name, whose etymology has been considered as very uncertain, if not quite inexplicable. So it might well seem to those who looked no further than the Greek or Latin languages, for though some have deduced the word from xenos, a guest, because pigs feed on acorns; this explanation has not proved satisfactory. De Theis, on the authority of Lepelletier, has found a much better etymology for Quercus, in the Celtic quer, fine, and cue, a tree; and this appellation is supposed to have been appropriated to the oak, not only for the beauty of the tree, but because it bore the sacred plant, milfctoe. This tree was also called in the Celtic tongue derao, whence came the word druid, because it bore the sacred plant, milfctoe. This tree was also called in the Celtic tongue derao, whence came the word druid, because it bore the sacred plant, milfctoe. (See Druuids.)—Linn. Gen. 495. Schreb. 642. Willd. Sp. PI. v. 4. 423. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1025. Ait. Hort. Kew. v. 5. 287. Jull. 410. Tourn. t. 349. Lamarck Illutr. t. 779. Genit. t. 37. (lex; Tourn. t. 350. Suber; efuid.)—Claf. and forders, Monocia Polyandria. Nat. Ord. Amentacea, Linn. Jull.

Gen. Ch. Male. Cal. Perianth of one leaf, bell shaped, membranous, with about five small, sharp, often closed segments. Cor. none. Stam. Filaments from four to ten, papillary, fHORT; anthers large, of two round lobes.

Female, from a bud usually on the same tree. Cal. Perianth of one leaf, inferior, coriaceous, hemispherical, rough, entire, very small in the flower, permanent. Cor. none. P. P. Germ. Superior, ovate, very small; style simple, divided above into two to five segments, longer than the calyx: filigmas simple, permanent. Peric. none. Seed an oval or roundish coriaceous nut, of one valve, smooth, attached by its scarred base to the bottom of the short, hardened, permanent, cup-like calyx.

Female, Calyx bell-shaped, coriaceous, entire, rough. Corolla none. Style one. Stigmas from two to five. Nut coriaceous, embraced at the base by the hardened calyx.

This genus, so distinct in its botanical characters, and so valuable for its economical uses, consists, in the Species Plantarum of Linneus, of no more than thirteen species. The discoveries of Thunberg, but especially those of American travellers, aided by the more accurate enquiries of botanists, have so greatly enriched the subject, that Willdenow, who has studied it well, enumerates seventy-fix kinds of Quercus, and even these are not all that we have to describe. The importance of many species requires that they should all be particularized. Two or three of the East Indian ones, now for the first time described, offer some exceptions to the generic character of the calyx.

Section 1.—Adult leaves undivided and entire.

QUERCUS.

in Abbot's Infests of Georgia, v. 2. 181. t. 91. Michaux Querc. n. 7. t. 12. (Q. virginiana, falsic longiore folio, fructu minimo; Plak. Amathl. 180. t. 441. f. 7.)—Leaves membranaceous, linear-lanceolate, tapering at each end, entire, smooth, with a small point. Nut roundish. —Native of North America; in low swampy forests, near the sea-coast, from New Jersey to Florida, flowering in May. It is said by Mr. Aiton, on the authority of Knowlton's MSS., to have been cultivated in England by Mr. Fauld, before the year 1723; and indeed, by the collection at Bulstrode, this tree appears to have been planted there much earlier, among those introduced by the first Earl of Portland. It riles in its native country, as well as in England, to the height of fifty or sixty feet. The bark is smooth, the wood is good, and much in use, but of slow growth. Leaves scattered, on short flanks, four or five inches long, and not an inch wide, smooth, thin and pliant, of a fine green, with a willow-like aspect, deciduous, their edges lightly wavy. Acorus in pairs, roundish, scarcely above half an inch long, with a thin, taberculated, or telfillated cup. The leaves of the young plant are somewhat angular, or toothed at each side. There is said to be a dwarf straggling variety, with shorter leaves, which Catley has figured in his vol. 1. t. 22. Michaux has two supposed varieties, which other botanists include distinct species; see the following. The specific name, chosen by Linnaeus, is not a good one, being a corruption of the cork-tree.

2. Q. maritima. Ever-green Willow-leaved Oak. Willd. n. 2. Pursh n. 2. (Q. Phellos maritima; Michaux Querc. n. 7. var. 2. t. 13. f. 3.)—Leaves coriaceous, elliptic-lanceolate, entire, smooth, with a small point. Nut roundish. —Found on the sea-coast of Virginia and Carolina, flowering in May and June. This differs from the foregoing in its low shrubby habit, and firm evergreen leaves, which are more elliptical in shape, and not above two inches long. The whole plant is from three to eight feet only in height. It appears by the accounts of authors to be distinct from the above-mentioned variety of Phellos.

3. Q. frico. Silky Willow-leaved Oak. Willd. n. 3. Pursh n. 3. (Q. Phellos; Sm. in Abb. Inf. v. 2. 161. t. 31. Q. Phellos silicula; Michaux Querc. n. 7. var. 3. t. 1. f. 3.)—Leaves lanceolate-oblong, somewhat wavy, obtuse at the base; rather dilated upwards; silky beneath. Nut almost globular. —Native of the sea-coast, from Carolina to Florida, flowering in May. It is perhaps the most humble of the whole genus, scarcely ever exceeding two feet in height, and throwing out creeping foyons, whence it has obtained the name of the Running Oak. The foyons of the lower beneath gives them a glabrous appearance.

4. Q. myrtifolia. Myrtle-leaved Oak. Willd. n. 4. Pursh n. 4. "Leaves coriaceous, oblong, entire, smooth, acute at each end."—Native of Carolina, according to Wilson, who alone has noticed this species, and from whom Pursh has admitted it into his work. The branches are round, brown. Leaves an inch, or rather more, in length, coriaceous, evergreen, oblong, somewhat acute at the base; entire and slightly revolute at the margin; shining above, opaque, but smooth, beneath; on short footflakes. The form of the leaves is much like the common broad-leaved myrtle. The flowers and fruit are unknown. Willd.

5. Q. virginiana. Lithocarpus. Willd. n. 5. Pursh n. 5. (Q. Phellos; Linn. Sp. 1412. Q. tempervirides; Walt. Card. 234.)—Leaves coriaceous, elliptic-oblong, revolute, entire, pointless; obtuse at the base; clothed with hirsut down beneath. Fruit flaked. Nut oblong. —Found near the sea-coast of North America, in a foil of sand upon clay, from Virginia to Florida and Mississippi, flowering in May. Miller cultivated it at Chelsea in 1739, but we know not that this species is still preformed, or, at least, distinguished from Q. Ilex, in our gardens or plantations. It is one of the most valuable American trees, growing to the height of forty or fifty feet, and extending its branches, in open situations, to a great extent; whence it serves, by its dense evergreen leaves, to shelter cattle from the summer's heat and winter's cold. The wood is the finest and most durable ship timber. It is sold towards the end of autumn, and kept three months before it is used. Michaux recommends this tree to the notice of the French and Spaniards, as likely to thrive well on the sandy coasts of the Mediterranean, and of the western ocean. By his account it succeeds best where there is a basis of clay under the sand, to fix the larger roots. The aspect of the leaves is not unlike our European Q. Ilex, but they are, except when very young, more uniformly entire, and more shining; their under side being denser pubescent; and their short footflakes, as well as the mid-rib, reddish. The foliage of feeding plants, and of vigorous young shoots, is, indeed, strongly toothed. The adult leaves are scarcely more than two inches long, somewhat oval, or obovate and blunthilted, without any terminal bristle; silky in the spring; subfrequently of a dark blue shining green, and downy, with hairy pubescence, beneath. The flowers are but four or five. Stalks of the fruit an inch long. Acorus cylindrical, an inch long, with a felted, but not rugged or taberculated, cup. The acorns are said to be greedily devoured by hogs, and several wild animals; and to afford an oil, which the foyons of Florida mix with their food.

6. Q. cincinnati. Ash-coloured Silky-leaved Oak. Willd. n. 6. Pursh n. 6. Michaux Querc. n. 8. t. 14. (Q. humilis; Walt. Carol. 234. Q. Phellos ( ?) ferricia; Ait. Hort. Kew. ed. 1. t. 354. Q. Phellos 7; Linn. Sp. Pl. 1412.)—Leaves coriaceous, elliptic-lanceolate, revolute, entire, blunthilted with a small point; clothed with hairy down beneath. Fruit felle. Nut nearly globose. —Native of dry barren situations, and pine forests, from Virginia to Georgia, flowering in May. Michaux says it springs up chiefly on land that, after having been cultivated, becomes abandoned on account of the bad quality of the soil. The form of the tree is unfightly, and its fize very variable, from four to twenty feet in height. The wood is of no use but for firing. Leaves longer than in the preceding; the young ones placed at the top, with three points. Fruit nearly or quite felle, almost globular, and not much above half an inch long.

7. Q. microphylla. Small-leaved Dwarf Oak. Willd. n. 7. Nee in Annal. Scient. Nat. v. 3. 264. Fitch. Mico. Hisp. v. 1. 99. Willd. —Leaves lanceolate, pointed, entire, villous; downy beneath. Calyx of the fruit villous. Nut roundish. —Found by Louis Nee, on the hills of Aramboro, in New Spain. A shrub, from three to five feet high, with a rough ash-coloured bark. Leaves on short flanks, scattered, numerous, from four to six lines long, scarcely two lines broad, veiny, revolute, wavy, pointed, reddish-grey; villous above; densely downy beneath; thode about the extremities of the branches opposite. Stipulas awl-shaped, falling off at the close of summer. Acorus in axillary pairs, about the ends of the branches, ovate, the fize of a large pea, half covered by the villous cup, which is inviolated with unequal scales. Nee.

long."—Found by Lewis Nee, in the kingdom of Mexico, near Acapulco. A tree twenty-eight feet high, with alternate branches; the young ones somewhat furrowed, and clothed with brownish-red hairs. 

Q. glabra. Smooth-leaved Japan Oak. Thunb. Jap. 175. Wild. n. 9—"Leaves lanceolate-oblong, pointed, smooth, with parallel veins."—Gathered by Thunberg in Japan. A tree, whose branches grow two or three together, slightly spreading, rugged and knotty. Leaves alternate, flaked, lanceolate-oblong, entire, pointed, with parallel ribs (veins); tapering at the base; smooth on both sides; shining above, yellowish beneath. Spires of flowers either solitary, or two or three together, downy. Thunberg.

Q. concinna. Concentric-furrowed Oak. Loud. Cohr. 572. Wild. n. 20—"Leaves lanceolate-ovate, pointed, incurved at the ends. Calyx lax, very short, furrowed concentrically."—Native of the lofty forests of Cohrh. A large tree, whose wood is serviceable for various uses. Branches ascending. Leaves flaked, smooth on both sides. Acorns flaked, oblong-ovate, smooth, red, pointed, their cups short and lax, externally marked with five parallel circular furrows; see n. 27.

Q. molucca. Molucca Oak. Linn. Sp. Pl. 1412. Wild. n. 11. Rumphi Amboin. v. 3. 85. t. 56.—Leaves elliptic-lanceolate, entire, acute at each end, smooth. Nut roundish, furrowed.—Native of the Molucca isles. A large and lofty tree, whose wood is hard and heavy, lasting long under water. Leaves six or eight inches long and three broad, on short stalks, with eight or ten irregular lateral veins. Acorns short and roundish, furrowed in their upper part; the cup short, warty. By Rumphius's account, there seem to be more species than one comprehended under the chapter above cited, but he does not give us sufficient marks to define them specifically.

Q. picea. Clutter-fruited Oak.—Leaves elliptic-lanceolate, taper-pointed, entire, smooth. Spikes axillary, solitary, dioecious. Fruit spiked, aggregate, ovate.—Gathered by Dr. Francis Buchanan, in woods at Suemba, in Upper Nepal, flowering in May. 1802. This is a tree of vast dimensions, whose wood is useful, though inferior in quality to that of Quercus annulata, n. 22. The younger branches are angular, clothed with very minute green pubescence. Leaves alternate, flaked, of a broad lancolate, or elliptical figure, with a taper point, entire throughout, six or seven inches long, and two and a half wide; bright green, smooth and shining above; paler, opaque, but scarcely pubescent, beneath; furnished with numerous, parallel, transverse veins. Fruits not an inch long, deprelled. Stipulas deciduous. Flowers in long, linear, downy, pale, straight, solitary, axillary spikes; the males with about eight flowers, much longer than the calyx, and a roundish rudiment of a germin in the centre; females on a separate tree, crowded three together in fertile groups in each spike. Acorns edible, but not very good, the size and shape of a large filberd, even, pointed, dark brown; their cups short, scaly. The original natives of Nepal, or Nawaars, know this tree by the name of Ghy Saffi, or Pachpingals; their Hindo conqueres, the Parbutties, call it Aeraula.

Q. irihboides. Caltrap-fruited Oak.—Leaves ovo-lancolate, taper-pointed, entire, smooth. Spikes aggregate. Calyx of the fruit spiny, covering the nut.—Discovered by the same able botanist as the preceding, in the forests of Upper Nepal, flowering and fruiting at various seasons. A tree with smooth branches. Leaves on short stalks, lanceolate, more or less ovate, somewhat unequal at the base, about four inches long, and one and a half broad, rigid and rather coriaceous, with irregular, dilated, slightly curved veins; the upper surface polished; the under paler and opaque. Flowers monocious, in slender, downy, clustered, axillary or terminal, pendulous spikes, the male spikes more numerous. Stamens about eight, with a dotted central disk. Acorns spiked, flaked, rounded, smooth, obliquely pointed, about half an inch long, entirely concealed in the greatly enlarged calyx, which is downy, globose, and armed with very numerous, rigid, prominent, sharp thorns, a quarter of an inch, or more, in length, spreading in every direction. This species is called Cottom, or Cattuns, in the Parbunt language; Shingali, or Cuti Shingali, by the Nawaars. Its great peculiarity consists in the acorns, which are edible, being entirely enclosed in a strongly muciricated calyx, or globose cup, which approaches the nature of the chefetun, Ficus Cattunse, and in some of our specimens seems even to split into two or three valves. The flowers, however, agree with Quercus, to which genus Dr. Buchanan referred this remarkable plant. On one tree he observed the flowers to be all female.

Q. turfifolia. Laurel-leaved Oak. Wild. n. 12. Ait. n. 4. Purif. n. 8. Michaux Querc. n. 10. t. 17. 18.—Leaves ovate, entire, smooth, nearly sessile; tapering at the base. Nut roundish, even.—Native of shady forests, and the sea-coast, in Georgia and South Carolina, flowering in May. This is sometimes called the Swamp Willow, and was first brought alive to England, by the late Mr. Frazer, in 1786. It rises to the height of fifty or sixty feet. Michaux speaks of the wood as of a good quality, but inferior on the whole to that of our first species, Q. crenata. The leaves are crowded about the ends of the branches, deciduous, about four inches long, usually acute, but sometimes, as in Michaux's t. 18, remarkably obtuse. Acorns solitary, nearly sessile, almost globose, with a scaly cup.

Q. imbricaria. Shingle Oak. Wild. n. 13. Ait. n. 5. Purif. n. 7. Michaux Querc. n. 9. t. 15. 16.—Leaves elliptic-oblong, acute at each end, entire, almost sessile; downy beneath. Nut nearly globose.—Native of the banks of rivers among the Alleghany mountains, and in the countries to the west, rarely to the east of those mountains, flowering in May and June. Brought to England in 1786, by Mr. Frazer. The leaves are twice the size of the leaf, acute, but not contracted, at their base, and downy on the under side. Acorns much like the leaf-decibed. This tree is forty or fifty feet high. Its wood is chiefly used, by the French settlers in the Illinois country, for making boards to cover houses, whence the appellation of Q. imbricaria in Michaux, and of Shingle Oak among the English Americans. For although the scales of the cup are rather larger than those of Q. turifolia, the specific name does not allude to that circumstance.

Q. elliptica. Oval-leaved Mexican Oak. Wild. n. 14. Nee in Annal. Scient. Nat. v. 3. 275. Fitz. Mii. Hijf. v. 1. 177.—Leaves elliptical, entire, coriaceous, nearly sessile; rounded at each end; roughish beneath. Gathered by Louis Nee, but without flowers or fruit, in the kingdom of Mexico, by the road from Ixmiquilpan to Cimapan, as well as between Tixtla and the river Azul. The trunk is thick, twelve feet high, with a grey bark. Branches horizontal; the smaller shoots erect; all
all very leafy. Leaves three inches long, and one and a half broad, slightly revolute; smooth above; roughish and velvety beneath, the veins forked. Footstalk thick and very short.

17. Q. acuta. Pointed-leaved Japan Oak. Thunb. Jap. 175. Wild. n. 15—*Leaves oblong, pointed, entire, with parallel veins; rounded at the base; downy when young. —Oberved by Thunberg in Japan. The branches are knotty, oft-coloured, dotted with white, smooth downy at the summit. Leaves alternate, alternate, thick, smooth, when fully-grown; covered at the back, young, with rusty down. Spikes axillary, clothed with similar pubescence.

18. Q. magnoliaefolia. Magnolia-leaved Oak. Wildl. n. 16. Nee in Annul. Scient. Nat. v. 3. 268. Fitch. Mela. Hilp. v. 1. 103. —*Leaves ovate-oblong, coriaceous, entire, shining; downy beneath; somewhat emarginate at the base. Fruit racemose.* —Found by Louis Nee, in the kingdom of Mexico, between Chilpancingo and Tixtals, and about the river Azul. This is an elegant tree, twenty feet, or more, in height. Trunk thick, with a dark-coloured bark full of furrows. Branches horizontal; younger ones furrowed, and dotted with white. Leaves six or eight inches long, and three broad, ovate, rigid; sometimes emarginate at the base; green and shining above; downy beneath, with the larger veins prominent, and the smaller reticulated. Footstalk thick, a line in length. Stipulas crispated, downy, deciduous. Female flowerlets solitary, axillary, two inches long; the lower ones alternate, upper opposite. Acorns ovate, half covered by their hemispherical cup, which is the size of the feed of Otter arctium, its scales scarcely at any imbricated. Nee.

19. Q. lutea. Yellow-leaved Mexican Oak. Wildl. n. 17. Nee in Annul. Scient. Nat. v. 3. 269. Fitch. Mela. Hilp. v. 1. 105. —*Leaves oblong, entire, shining; somewhat heart-shaped at the base; downy and yellow beneath.* —Found in Mexico by the same celebrated traveller and botanist. This agrees with the preceding in its mode of growth, and fructification, infomuch that it may be thought a variety; yet the leaves are very different. They are of a larger size, broader towards the end, and contracted towards the footstalk, as well as more deeply emarginate at the base; and their under side is clothed with ochre yellow pubescence.

20. Q. femearipilosa. Marking-nut-leaved Oak. Leaves obovate, obtuse, coriaceous, entire; heart-shaped at the base; downy beneath; the young ones with spinous teeth.

—Gathered by Dr. F. Buchanan, on the banks of torrents in Upper N epal, where its Parbutie appellation is Gaffir, and its Nawar name Chir. This is a middle-sized tree, with angular branches, clothed when young with fealcy down. Leaves evergreen, alternate, on short thick stalks, obovate, oblong, four to five inches in length, and two in breadth; more or less heart-shaped at the base; their upper surface smooth and shining; the under envelope, clothed with white down, and furnished with numerous, irregular, rather diffuse, transverse, prominent veins; the margin in entire, slightly wavy. The exterior is usually rounded and obtuse, sometimes abrupt, sometimes tipped with a little spine. On young branches the leaves are serrated with strong spines, or even cutinuted, and clothed on both sides with rusty down. Stipulas in pairs, oval-shaped, erect, permanent, as long as the footstalk. Dr. Buchanan did not observe the flowers or fruit.

The aspect of the adult leaves is much like those of SeneCGFus Anacardium, or some of the entire-leaved species of Ficus.

Section 2. Leaves more or less toothed or serrated.

175. Banks Ic. Kämpf. t. 17. Wildl. n. 11. (Kas no ki: Kämpf. Amoen. 816.)—Leaves obovate, pointed; ferrated towards the extremes; glaucous beneath. Nut roundish.

—Gathered near Nagasaki, in Japan, by professor Thunberg, to whom we are obliged for a specimen. He describes it as a very large tree, whose branches are somewhat umbellate, erect, round, purple, smooth, except some prominent white points. The leaves are alternate, about three inches long, and near two broad, with a blunt projecting point; their upper surface smooth and polished; the under covered with a fine glaucous meaflness, and marked with prominent, straight, parallel, but rather dilate, obliquely transverse veins; the margin distantly ferrated upwards. Footstalks about half an inch long, purple. Flowers axillary. Acorns, by Kämpfer's figure, axillary, often in pairs, of a roundish timid shape, pointed, not an inch long, their cups short, seemingly marked with concentric lines; their flanks simple, short and thick.

22. Q. annulata. Ring-cupped Oak.—Leaves obovate, pointed; ferrated in their upper half; somewhat glaucous and downy beneath. Fruit spiky. Calyx furrowed concentrically. —Gathered by Dr. Buchanan, at various places in Upper Nepal, bearing fruit, in December 1802. A very large tree, whose wood is excellent; the branches two or three together, smooth. Leaves evergreen, rigid, exactly like those of the last species, but somewhat flaky beneath, and less glaucous; the young ones very flaky. Stipulas linear, hairy, longer than the footstalks, deciduous. Male flowers in pendulous, hairy, yellowish, short-stipes, springing from buds below the leaves, whose scales are imbricated in five rows: female from three to five, in foliary, axillary, upright, flaked, smooth spikes, about the length of the footstalks. Gafirs of the female flowers globose, smaller than hemispherical, composed of several concentric imbricated layers, of which the outermost is smooth and notched, the fmitu downy and entire. German globose. Style very short and thick. Stigmas three, obtuse. Acorns quite fillife on the common flower-klalk. Cup rather smaller than that of our British oaks, entire and even at the edge, composed of seven or eight concentric, annular, imbricated, creame scales, externally flaky. Nave, acute, smooth and pointed, twice as long as the cup. The Parbutie, call this tree Pulpaut, the Nawar Gaffur, or Puckufrings.

We find great reason to think that it is the same, as Dr. Buchanan suspected, the same species with Thunberg's glauca last described. The leaves of his species show a slight degree of pubescence about the veins, but have not the minute filmknes of our s. The greatest and most essential difference, if Kämpfer be as correct as usual, consists in the female inflorescence. He delineates the acorns of glauca on short, simple, axillary flanks, either foliarly or in pairs, and Thunberg describes the flowers as axillary. In our plant the female flowers are indeed axillary, but they compose a flaked spike, and neither they nor the acorns have any partial flanks. Such differences are found between other species of Oaks, and prove essential and invariable. We therefore cannot but, for the present at least, rely on Kämpfer's known fidelity, and propose our Q. annulata as a distinct species.

23. Q. lamellosa. Many-cupped Oak.—Leaves elliptic-oblong, pointed, ferrated, many-veined; glaucous and somewhat downy beneath. Calyx of many concentric entire layers, as long as the nut. —Discovered by Dr. Buchanan, in the more remote woods of Nepal, bearing fruit in December 1802. In the Nawar language it is called Tuppafusiphi. The tree is lofty, with smooth bluntly-angutar branches. Leaves alternate, six inches in length and two in breadth, elliptic-
elliptic-oblong, rigid, taper-pointed, sharply serrated; smooth and green above; glaucous and often finely downy beneath, with innumerable, prominent, crowded, flattish, parallel, mostly opposite, obliquely transverse veins; the apex and size of the leaves much resembling Dillenia indica. 

Footstalks an inch and half long, tumid at the base. 

Sipulas deciduous. Female flowers in short axillary spikes. 

Acorns ovate, pointed, the size of chestnuts, each completely enclosed and concealed by the large, globular, downy cup, which is as big as a small apple, and consists of eight or nine distinct, concentric, entire, unimbriated layers, much more deeply separated than the rings of Q. annulata. An approach towards the genus Fagus, or Cupanea of some authors, may be observed, as Dr. Buchanan fuggles, in this species, which is nevertheless a genuine Quercus, and far less doubtful than our tribobides, n. 13. It proves however that the mere elongation of the acorn, beyond the cup, is not an indistinguishable character of the present genus. See also tenant's, n. 42.

Female flowers scattered over the young branches, solitary, nearly sessile. Cup of the acorn prickly, the size of a hazel-nut. 

Synopsis. This species, like n. 13, appears, by its prickly cup, allied to Fagus; especially as Kempfer, who calls it Fagus folio fraxini, describes the dry cup as splitting into three, four, or five parts. The nut is eaten by the Japaneffe, either raw or cooked.

Leaves alternate, pointed, all acutely and equally serrated, furnished with straight parallel veins; green above and very silky when young; paler beneath, with a broad and downy at first, but subsequently more slightly villous; their length from one to three inches. Male flowers in hairy, drooping, long-tailed spikes, each an inch long. Our specimens are in an early state of foliage, nor have we any account of the fruit, or female flowers.

Leaves crowded about the extremities, on very short shoots, oblong-oblong, obtuse, with deep teeth delilicate of spines; villous above; downy beneath; plant, two inches long; their veins parallel. 

Synopsis. Kempfer says the wood is white.

Buchanan. The Parbutties call it Bawser, or Banu; the Nawars Sofli Shingali. This is a tree of vast dimensions, with a ficy bark, and rigid, brown, warty branches, clothed when young, with dense white down. 

Leaves alternate, somewhat two-ranked, flaked, elliptic-oblong, sometimes rather obovate, pointed, from three to five inches in length, and two or more in breadth strongly and sharply serrated, except at the very base, which is more or less rounded, and occasionally unequal; the upper surface green, shining, and naked, (except when young), but not quite smooth to the touch; the under clothed with fine, dense, uniform, white, woolly pubescence, and marked with prominent, parallel, but not very crowded, obliquelytransverse veins. 

Footstalks short, downy, scarcely an inch long. 

Sipulas ovate, membraneous, deciduous. Male flowers in short, dense, hairy spikes, at the base of the young shoots, as they prostrate from the bud. Calyx with five or six teeth. 

Authors about fix, fpherical. Female flowers, as far as Dr. Buchanan could observe, on a separate tree, in very short, solitary, axillary spikes. 

Acorns either solitary, or several crowded together, small, ovate, hairy, half covered by their fcal unarmcd cups.

Synopsis. This species, like n. 13, appears, by its prickly cup, allied to Fagus; especially as Kempfer, who calls it Fagus folio fraxini, describes the dry cup as splitting into three, four, or five parts. The nut is eaten by the Japaneffe, either raw or cooked.

Synopsis. This species, like n. 13, appears, by its prickly cup, allied to Fagus; especially as Kempfer, who calls it Fagus folio fraxini, describes the dry cup as splitting into three, four, or five parts. The nut is eaten by the Japaneffe, either raw or cooked.

long, rigid, broadly elliptical, often nearly orbicular, very much undulated at the margin, their deep broad spiny teeth pointing every way; the upper surface dark green, rather glaucous, be sprinkled with minute flaky hairs; the under densely clothed with white entangled down. We have seen neither flowers nor fruit. Willdenow appears mistaken in differing the synonym of Magnol, which anwers extremely well to the Linnæan specimens, though indeed the author speaks of his plant as a variety of Q. Ilex. It is, nevertheless, true that Linnæus confounded herewith a plant from Magnol’s herbarium, which is not distinct from Q. Ilex.

31. Q. Ballota. Sweet-acorn Oak. Desfont. Atlant. v. 2. 350. Wild. n. 24. (Hex major; Cluf. Hitt. 1. 23.)—Leaves elliptical, coriaceous; entire or serrated; very downy beneath. Bark even. Nut cylindrical, elongated. Native of several places in the neighbourhood of mount Athos, according to professor Desfontaines, from whom we have a wild specimen. It flowers in May. This is a large and handsome evergreen tree, whose trunk is from twenty to thirty feet high; the wood hard, compact, and very useful; the bark even, not torky, though full of fissures, branches downy. Footstalks a quarter of an inch long, downy. Leaves various in shape, but more or less elliptical, an inch and half or long; either quite entire, or serrated with small spiny teeth; their upper surface, at least when young, be sprinkled with minute flaky hairs; the under always very white and densely downy. Male flowers in copious, long, lax, pendulous spikes, with usually seven filaments; female on the same tree, axillary, solitary or aggregate. Acorns cylindrical, an inch and half or two inches long, half an inch in diameter, etable and very palatable, either raw or roasted. Cup hemispherical, covered with numerous, obtuse, downy, closely imbricated scales.

32. Q. Ilex. Common Evergreen Oak, or Holm Oak. Linn. Sp. Pl. 1412. Wild. n. 25. Ait. n. 7.—Leaves ovate-oblong, acute, coriaceous; entire or serrated; hoary beneath. Bark even. Nut ovate. The varieties are; 1, with lanceolate entire leaves; Smilax Dalech. Bauh. Hitt. v. 1. part 2. 101. Suber ficundus; Matth. Valgr. v. 1. 188, as to the figure: 2, with lanceolate serrated leaves; Hex; Matth. Valgr. v. 1. 186. Duham. Arb. v. 1. t. 123: 3, with rounder, less rigid, and more or less serrated leaves; Phellodrys; Matth. Valgr. v. 1. 189, as to the figure. Hex n. 3; Duham. Arb. v. 1. t. 124. This species occurs in various parts of the south of Europe, and of Africa. It is, as well as evergreen, with us, thriving particularly near the sea, though of slow growth, flowering in May and June. It usually forms a large bushy tree, but occasionally rises with a straight naked trunk, and round head, to a great height. The wood is hard and heavy, valuable for many purposes. The French use it for pulleys in the navy. The bark is hard and even, not torky. Leaves various in shape and size; dark green, convex, and quite smooth, above; hoary or downy beneath; their edges either revolute and entire, or irregularly notched and serrated. Footstalks half an inch long, downy. Acorns usually two, on an axillary downy stalk which is longer than the footstalk, ovate, hardly an inch long, with a scaly downy cup. They are eaten by hogs, but are very different in shape and quality from those of the lath-decoryed species. So many varieties, or species, nearly corresponding with these two, are mentioned by authors, that it is difficult to understand them. The subject requires, and will defers, a practical investigation. Lanarck, under the article Céme, in his dictionary, mentions several kinds, which he knew but imperfectly, and which we have no means of elucidating further, so that we dare not adopt, or attempt to reduce them to order.

33. Q. Suber. Cork Tree. Linn. Sp. Pl. 1413. Wild. n. 26. Ait. n. 8. Hunter’s Evel. Sylv. 362, with a plate. (Suber; Camer. Epit. 115. S. primus; Matth. Valgr. v. 1. 187. S. latifolium, perpetuo viris; Duham. Arb. v. 2. 291. t. 50. S. latifolium; Ger. Em. 1457, the middle figure only.)—Leaves ovate-oblong, hirtfith, coriaceous; entire or sharply serrated; downy beneath. Bark cracked, fuscous; Native of the south of Europe, and north of Africa. Duhamel says it can hardly bear the climate of the north of France. It lives however in our English gardens, where it has been kept more than a century. The bark is remarkable for a thick fpyony coat, yielding the well-known substance called cork. The leaves much resemble the broad variety of Q. Ilex, nor do the acorns greatly differ from those of that tree. We have not been able to ascertain what authors mean by their Suber angustifolium non ferratum, the figure of which, Matth. Valgr. v. 1. 188. Duham. Arb. v. 2. t. 81, we have cited as our first variety of Hex. We should suspect the Suber itself to be altogether a variety of Hex, differing only in the bark; and that there might be a broad and a narrow-leaved variety of each; were not the dwarf tufted clumsy habit of the Cork Tree, on the sandy plains of Italy, Spain, &c. so peculiar. Yet this possibly may, as well as the nature of the bark, be owing to the soil, for in strong ground the cork, according to Duhamel, degenerates. Willdenow says “the leaves of Suber are a little elongated at the base, running down into the footstalk, which is not the case with Hex,” but this character seems scarcely permanent.

34. Q. coccifera. Kermes Oak. Linn. Sp. Pl. 1413. Wild. n. 27. Ait. n. 9. (Hex coccifera; Camer. Epit. 774. I. aculeata cocciglandisera; Ger. Aix. 245. t. 53; Nillole in Mem. de l’Acad. des Sciences for 1714. 435. t. 17. 18. I. cocci from Ger. Em. 1452.)—Leaves elliptic-oblong, rigid, smooth on both sides, with spreading, finely, spinous teeth. Nut ovate. Calyx with spreading pointed scales.—Native of the south of Europe, and the Levant, flowering in the spring. This is a bulky evergreen shrub, celebrated for producing the kermes, a valuable article of dyeing, before the introduction of cochineal, and which afforded the color kermesinos, or crimson. The kermes is an insect, of the genus Coccus, which sticks to the branches, in the form of a red ball, the size of a pea. It is now out of use among dyers, and is only used by French apothecaries. The leaves of this shrub are, at most, but half the size of the leaf, though they vary much in magnitude as well as figure. They are distinguished by their rigidity, smooth thickness on both sides, and their prominent needle-like marginal prickles. The scales of the mature calyx are also much more elongated and prominent than in Hex or Suber, and of an angular awl-shaped figure.

35. Q. Pseudo-coccifera. Baillard Kermes Oak. Desfont. Atlant. v. 2. 349. Wild. n. 28.—Leaves elliptic-oblong, rigid, smooth on both sides, with spinous ferratures. Nut ovate. Calyx with flat, slightly spreading scales. Observed by Desfontaines at Algiers and about mount Athos. At Tunis it is called the meal-bearing oak,” probably from the use of the acorns as food. This is a tree, from fifteen to twenty feet high, with round branches, clothed with ruly down when young. The leaves are twice or thrice as large as those of Q. coccifera, thicker and less wavy, with much smaller and shorter spinous ferratures, rather than teeth. Calyx clothed with numerous, flat, short, slightly spreading scales. Nut ovate, pointed. Willdenow, not having seen a specimen, has misunderstood the
I. The heart-shaped leaves of *Quercus robur* are nearly always pubescent on the lower surface, and the young shoots are tomentose. The flowers are produced in catkins, the male catkins being borne in long, hanging clusters, and the female catkins in short, erect clusters. The staminate flowers are greenish-yellow, and the pistillate flowers are greenish-white. The fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

II. The description of *Quercus pedunculata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

III. The description of *Quercus acutissima* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

IV. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

V. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

VI. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

VII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

VIII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

IX. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

X. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XI. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XIII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XIV. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XV. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XVI. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XVII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XVIII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XIX. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XX. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXI. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXIII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXIV. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXV. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXVI. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXVII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXVIII. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXIX. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.

XXX. The description of *Quercus turbinata* is given in the text. The leaves are oblong-oblongate, with a sharp tip and a rounded base. The flowers are produced in fall, and the fruits are acorns, which are covered with a thick, tough skin, and are furnished with a hard, woody base.
rowed, villous. Leaves alternate, from five to seven inches long, and three broad; green and shining above; more or less downy, and flesh-coloured, or reddish-brown, beneath; the margin undulated and crenate, the notches rounded, their edges turned towards the point of the leaf. Fruit supported by a very short common stalk. Calyx hemispherical, the fide of Chick peas, Cicer arrietum; its facles acute at the point. Nut but little larger than the calyx. Plukkenet's t. 154, f. 3, in some measure resembles the species before us, but is said to have a large fruit, and is cited by authors as Q. Primus. Nec.

44. Q. Splendens. Silky-leaved Mexican Oak. Willd. n. 37. Nec in Annal. Scient. Nat. v. 3. 275. Fitch. Misc. Hilp. v. 1. 113. Willd.—"Leaves oblong-ovate, bluntly toothed; slightly downy above; densely silky beneath."—Native of New Spain, near Taxact. Trunk erect, much branched, fifteen feet high. Branches partly horizontal, partly erect, clothed with red shining down. Leaves scattered, crowded, three inches long, and an inch and half broad; green, with a thin downy coat, above; thickly clothed beneath with shining pubescence, the midrib only being prominent; their edges bluntly and unequally toothed. Footstalks very short, with an awl-villous filipula at each side. Flowers and fruit not observed. Nec.

45. Q. rugosa. Rugged Mexican Oak. Willd. n. 38. Nec in Annal. Scient. Nat. v. 3. 275. Fitch. Misc. Hilp. v. 1. 112. Willd.—"Leaves ovate-oblong, coriaceus, rugose; toothed towards the end; Heart-shaped at the base; downy and rufous beneath."—Native of the woods of Huiaquiluca and Ocaula, in the way from Mexico to Santo Christo de Chalma. A middle-sized tree, having numerous, alternate, round, gray branches, rough with minute prominent points. Leaves three inches in length, hardly two in breadth, thick and coriaceus; rugged, green and shining on the upper side; brown and downy at the back; heart-shaped at the base; the margin toothed from the middle to the extremity. Footstalks two lines long, thickened at their base. Female flowers in scaly axillary clusters. Nec.

46. Q. Macrophylla. Large-leaved Mexican Oak. Willd. n. 39. Nec in Annal. Scient. Nat. v. 3. 274. Fitch. Misc. Hilp. v. 1. 111. Willd.—"Leaves obovate, crenate; tapering and heart-shaped at the base; downy beneath. Fruit spiky."—Found by Louis Lee, the discoverer likewise of the five preceding species, in the districts of Chilpancingo and La Curva, and on the mountains of Quirapu, in New Spain. This is a tree, thirty feet high, with a stout upright trunk, and dense head. The principal branches are horizontal; the rest upright, furrowed when young. Leaves a foot long, and seven or eight inches broad; rounded at the end; gradually tapering down to the maragnate, or heart-shaped, base, where they measure only four lines across; their upper surface green and shining; the under yellowish, clothed with very minute down; the margin crenate and wary. Footstalks very short and thick. Female flowers fesile on a common stalk, and encompassed with downy bracteas. Nec.

47. Q. Primus. Chefufat-leaved White Oak. Linn. Sp. Pl. 1413. Willd. n. 40. Ait. n. 10. Pursh n. 30. (Q. Primus, var. i, palustris; Michaux Querc. n. 5. t. 6. Q. cedanea folia, procera arbor virginiana; Pluk. Alm. 309. Phytr. t. 54. f. 3. Catcbe. Carol. v. 1. t. 18.)—Leaves on longish stalks, obovate, acute; somewhat downy beneath; with nearly equal, dilated, callous-tipped, tooth-like ferratures. Calyx of the fruit contracted at the base. Nut ovate.—Found in low shady moist woods, and on the banks of rivers, from Pennsylvania to Florida, flowering in May. It appears to have been known in England in 1730. This is one of the tallest trees produced in the southern parts of the United States, and remarkable for the beauty of its form, as well as the large size of its acorns, which are plentiful and sweet, a delicious and beneficial food for hogs and other wild animals. The wood is excellent, much used for making wheel-carriages, and yet so readily split as to serve for Balket-work and brooms. The leaves are six inches, or more, in length, and three broad; silky in the spring; smooth and glaucous in summer; sometimes very downy on old trees. Footstalks an inch long. Stamens five to ten. Acorns an inch and half long, ovate; their cups shallow, covered with numerous closely-imbriicated scales. Michaux says the bark is thick, peeling off in long strips.

48. Q. Chinquaquin. Chineaquin, or Dwarf Cheufat Oak. Pursh n. 34. (Q. prunoides; Willd. n. 41. Q. Primus, var. i, pumila; Michaux Querc. n. 5. t. 9. f. 1. Q. Primus Chinquaquin; Michaux Arb. v. 2. 65. t. 10. good. Pursh.)—Leaves on short stalks, obovate, smooth; glaucous beneath; tapering at the base; with nearly equal, dilated, acute, callous-tipped, tooth-like ferratures. Calyx of the fruit hemispherical. Nut ovate.—Found on dry mountainous lands, from Pennsylvania to Carolina, flowering in May, when, according to Mr. Pursh, it is highly ornamental. This is a humble shrub, not above three or four feet high. The young leaves are whitish and downy beneath; the adult ones smooth and glaucous, scarcely above one-third the fize of the preceding. Female flowers, according to Michaux, small, two or three together, on a short, foliary, axillary stalk. Acorns of a middling fize, with a thin, nearly hemispherical, cup.

49. Q. Montana. Rock Cheufat Oak. Willd. n. 42. Pursh n. 32. (Q. Primus; Sm. in Abbot's Inf. v. 2. 163. t. 82. Q. Primus, var. 2, monicoca; Michaux Querc. n. 5. t. 7.)—Leaves on shortish stalks, obovate, acute; downy and white beneath: with nearly equal, dilated, short, blunt, callous-tipped tooth-like ferratures. Fruit in pairs, on short stalks. Calyx hemispherical, with rugged scales. Nut oblong-ovate.—Found abundantly, in rocky situations, on the mountains of North America, from New England to Carolina, flowering in May. Michaux faggrets that this species would be well worth cultivating in Europe. The tree rises to the height of sixty feet; the wood is tough and very useful, the bark excellent for tanning. It differs from Q. Primus, n. 47, with which it has been confounded, in the constant white downiness of the under side of the leaves, which are much smaller and less dilated upward. The acorns moreover are but half the fize of that species, and more oblong, two together on a very short stalk.

50. Q. Bicolor. Swamp White Oak. Willd. n. 43. Pursh n. 31. (Q. Primus, var. 5, tomentula; Michaux Querc. n. 5. t. 9. f. 2. Q. Primus difcolor; Michaux Arb. v. 2. 46. t. 6. Pursh.)—Leaves nearly sessile, obovate; downy and white beneath; with very broad, unequal, obtuse, callous-tipped, lobe-like teeth. Fruit in pairs, on long bristle-pointed stalks. Calyx hemispherical. Nut oblong-ovate.—Native of low wet woods, from Pennsylvania to Carolina, flowering in May. Pursh. It grows to a very large tree. The leaves have extremely broad shallow teeth, or, as they might be called, lobes, approaching to the figure of our common English Oak leaves; their under side white and very downy. The acorns are sweet and edible, like most of the Primus tribe. Willdenow says the teeth are occasionally variable in fize, one or two of them being sometimes remarkably elongated; and that the base of the leaf is more entire than in the foregoing.

51. Q. Cajanca. Yellow Oak. Willd. n. 44. Pursh n. 33. (Q. Primus, var. 3, acuminata; Michaux Querc. n. 5. t. 8.)
QUERCUS.

52. Q. aquatica. Water Oak. Soland, in At. Hort. Kew. ed. 1. v. 3; 357. ed. 2. n. 11. Pursh n. 11. Michaux Querc. n. 11 t. 19. t. 20. f. 1, 3, 4, 9, 10, and t. 21. (Q. folis cuneiformibus, foliobtus lobatis, intermedio producundis; Cron. Vrg. 149. Q. folio non fertato, in humitate quasi triangulato; Catell. Carol. v. 1 t. 20. Herb. Linn.)—Leaves wedge-shaped, smooth; tapering at the base; dilated and obscurely three-lobed at the end, the middle lobe largest. Calyx nearly hemispherical. Nut roundish.—Native of swamps in North America, from Maryland to Florida, blooming in May. Miller is said to have cultivated this species in 1748, but it is little known in England. The tree is forty feet high; its wood, according to Pursh and Michaux, is little esteemed; but the latter is of opinion that it might prove more valuable if felled in winter; he mentions also that the tree is not peculiar to swamps, or inundated meadows, but occurs sometimes in dry sandy ground, as on plains near the sea-coast of Florida. Few trees vary so much in the shape of their leaves, according to age or situation, as this. The proper form of its foliage is wedge-shaped, much elongated and tapering at the base; dilated, rhomboid, or very lightly and bluntly three-lobed at the extremity; the edges entire; both sides usually smooth. 

53. Q. nigra. Barren Oak, or Black Jack. Linn. Sp. Pl. 147. Wildn. n. 46. Ait. n. 12, Pursh n. 15. Sm. in Abbot's Inf. v. 2 t. 115. t. 59. Michaux Querc. n. 12 t. 22, 23. (Q. marylandica, folio triplo, ad piaftaras accedente; Catell. Carol. v. 1 t. 19.)—Leaves wedge-shaped; somewhat heart-shaped at the base; dilated, abrupt, and very slightly three-lobed at the end; the middle lobe short; smooth above; rusty beneath. Calyx hemispherical, with membranous scales. Nut roundish-ovate.—In barren sandy or gravelly woods, from New Jersey to Florida, flowering in May. This tree is of low growth, especially in the more northern states. It bears abundance of acorns, very good food for hogs. The wood is small, but excellent for fuel.

54. Q. tribula. Downy Black Oak. Wildn. n. 47. Ait. n. 13. Pursh n. 14. Michaux Querc. n. 14 t. 26. (Q. rubra; Abbot's Inf. v. 1 t. 99. t. 50.)—Leaves wedge-shaped, with three terminal, bluntly-pointed lobes, the middle one longest; downy beneath. Calyx of the fruit flattish. Nut nearly round.—Native of barren tracts, near the sea-coast, from New Jersey to Georgia, flowering in May. It was brought to England in 1800, by Meills. Frazer. The tree is fifty or sixty feet high, of rapid growth, even in a poor soil. Michaux describes it as very fit for making live fences; though the wood is most generally used in America for paling. The leaves are much smaller than those of Q. nigra, rounded, not heart-shaped, at the base, and with longer footstalks. Their lobes are direct, not laterally dilated, each tipped with one or more small bristles, and the under side is covered with dense white down. The foliage of young shoots, that spring up while forefells of this tree have been burnt, are often near a foot long, deeply pinnatifid, and sharply lobed; as represented in Michaux, t. 26, f. 2.

55. Q. minima. Dwarf Jagged Oak. Wildn. n. 48. Pursh n. 13. (Q. aquatica; Sm. in Abbot's Inf. v. 2 t. 117. t. 59. Q. aquatica elongata; Ait. n. 11 t.)—Leaves oblong-wedge-shaped, smooth, somewhat fuscous; three-lobed at the extremity; lobes dilated, pointed, the middle one largest;forks of the vein downy beneath.—In barren lands, called pine-barrens, of South Carolina, flowering in May. Pursh describes it as a "low-growing species, always growing distinctly from Q. aquatica." The leaves are almost fuscous, two or three inches long, much more diffusely lobed than in Q. aquatica or nigra, and more fuscous or angular bident, than in any of the last described. The acorns are almost globular, with a very shallow cup.

Section 4.—Leaves fuscous, with pointed lobes.

56. Q. hemisphérica. Hemisphéric Oak. "Bartram's Travels 320." Wildn. n. 49. Pursh n. 12. (Q. aquatica maritima; Michaux Querc. n. 1 t. 20. f. 2.)—"Leaves evergreen, oblong-lanceolate; undivided, three-lobed, or fuscous; smooth on both sides; lobes pointed." Wildn.—Native of Georgia and Florida. Some of these leaves are very deeply three-lobed, or pinnatifid; others linear-oblong and undivided. Willdenow says they are evergreen, and that the foliage of the young plant is so like Q. Phellos, our first species, as to be hardly distinguishable. Michaux, however, asserts this supposéd species to be but a maritime variety of aquatica, and Pursh thinks it a young plant of that kind.

57. Q. elongata. Downy-leaved Oak. Wildn. n. 50. Ait. n. 14. (Q. falcata; Michaux Querc. n. 16 t. 28. Pursh n. 22. Q. difcolor; Ait. ed. 1. v. 3 t. 35.)—Leaves downy beneath, fuscous, with three or more somewhat falcate, bristle-pointed lobes; the terminal one elongated, jagged. Calyx hemispherical. In sandy soil, near the sea-coast; from New Jersey to Georgia, flowering in May. A very large tree, commonly called Spanish Oak; in the southern states, Red Oak. Pursh. The height of the tree is fifty or sixty feet. Leaves on long stalks, obtuse or rounded at the base; deeply lobed, or in some measure palmate; the lobes often recurved, or fiddle-shaped; taper-pointed, and more or less notched at the end, each segment tipped with a long bristle. Acorns small, roundish; its cup hemispherical, with lax
lax scales. The leaves of young trees are said to be very like those of *trihoba*, n. 54.

58. *Q. tinctoria*. Dyers' Oak, Black Oak, or Quercitron. Wild. n. 51. Ait. n. 15. Pursh n. 16. (Q. tinctoria angustula; Michaux Querc. n. 13. t. 24. Q. diffusa; Wildl. Arb. 274.)—Leaves downy beneath, obovate-oblong, dilated, widely finnated; lobes short, obtuse, slightly toothed, bristle-pointed. Calyx of the fruit flat underneath. Nut globose.—In all large woods, particularly in the mountainous parts, from New England to Georgia, flowering in May. It is one of the largest trees of the American forest, highly valuable for its timber, as well as bark, which is so very superior in tanning to any other species of Oak. *Pursh.* Michaux says, this Oak is found only in a good soil, always at a distance from the sea; containing its greatest size, which is eighty feet in height, and eight in diameter, in the valleys between the high mountains of North Carolina. The bark is used by tanners, throughout the north and west parts of the United States. It gives a yellowish colour, whence the name of Quercitron, and which enhances the value of the leather. The bark, bruised and powdered, was in great request among dyers in France, before the war interrupted this branch of commerce. The leaves are conspicuous for their broad, angular, abrupt figure, a span long, and nearly as wide, with shallow sinuities, and bristle-tipped angles. *Acorns* almost sessile, globular, with a scaly, shallow, flat-tipped cup.

59. *Q. diffusa*. Simms Dyers' Oak. Wildl. n. 52. Pursh n. 17. Sm. in Abbot's Inf. v. 2. 1111. t. 56. (Q. tinctoria finuosa; Michaux Querc. n. 13. t. 25. Q. virginiana, venus rubris mucicata; Pluk. Phyt. t. 54. f. 5.)—Leaves downy beneath, oblong, pinnatifid; leaves oblong, toothed, bristle-pointed. Calyx turbinate. Nut ovate.—In large forests, from Pennsylvania to Carolina, flowering in May. This resembles the preceding and *Q. coccinea*. n. 61. The young expanding leaves are covered with white down on both sides, which is not the case with either *rubra* or *coccinea*. *Pursh.* This differs from the last in having much more finnated, or pinnatifid leaves, and larger, more ovate, *acorns*, whose cups are turbinate, or tapering at the base. The qualities of the wood and bark probably agree with the *tinctoria*, or Michaux, who considers the present plant as but a variety, would have mentioned the contrary.

60. *Q. rubra*. Mountain Red Oak. Linn. Sp. Pl. 1413. Wildl. n. 53. Ait. n. 16. Pursh n. 20. Michaux Querc. n. 20. t. 35. 36. Abbot's Inf. v. 2. 205. t. 120. (Q. eufilia divifura, folioz ampliobus aculeatis; Cateb. Carol. v. 1. t. 23.)—Leaves smooth, oblong, wedge-shaped at the base; deeply and widely finnated, on short stalks; lobes three or five, divided, acute, two or three-eleven, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of dry barren ground in Maryland, Virginia, Carolina, and Georgia, abundantly flowering in May. This species is shrubby, not above fifteen feet high; its wood of a bad quality, used only for fencing. The shortness of the footstalks, and the fewness of the lobes of the leaves, added to their acute base, are sufficient botanical distinctions between the present and the two last, especially as the size and quality of the tree are so unlike those species.

61. *Q. coccinea*. Scarlet Oak. Wildl. n. 54. Ait. n. 17. Pursh n. 18. Michaux Querc. n. 18. t. 31. 32. (Q. rubra S; Sm. in Abbot's Inf. v. 1. 27. t. 14. Q. eufilia divifura, folioz ampliobus aculeatis; Cateb. Carol. v. 1. t. 23.)—Leaves smooth, oblong; wedge-shaped at the base; deeply and widely finnated, on short stalks; lobes three or five, divided, acute, two or three-eleven, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of dry barren ground in Maryland, Virginia, Carolina, and Georgia, abundantly flowering in May. This species is shrubby, not above fifteen feet high; its wood of a bad quality, used only for fencing. The shortness of the footstalks, and the fewness of the lobes of the leaves, added to their acute base, are sufficient botanical distinctions between the present and the two last, especially as the size and quality of the tree are so unlike those species.

62. *Q. Catebzei*. Barren Scrub Oak. Wildl. n. 55. Pursh n. 21. Michaux Querc. n. 17. t. 29. 30. (Q. rubra S; Sm. in Abbot's Inf. v. 1. 27. t. 14. Q. eufilia divifura, folioz ampliobus aculeatis; Cateb. Carol. v. 1. t. 23.)—Leaves smooth, oblong; wedge-shaped at the base; deeply and widely finnated, on short stalks; lobes three or five, divided, acute, two or three-eleven, bristle-pointed. Calyx of the fruit turbinate, half as long as the nut.—Native of dry barren ground in Maryland, Virginia, Carolina, and Georgia, abundantly flowering in May. This species is shrubby, not above fifteen feet high; its wood of a bad quality, used only for fencing. The shortness of the footstalks, and the fewness of the lobes of the leaves, added to their acute base, are sufficient botanical distinctions between the present and the two last, especially as the size and quality of the tree are so unlike those species.

63. *Q. palustris*. Marsh, or Pin Oak. Wildl. n. 56. Ait. n. 18. Pursh n. 23. Michaux Querc. n. 19. t. 33. 34.—Leaves smooth, oblong, deeply and widely finnated, on long stalks; lobes distinct, parallel, acute, sharply toothed, bristle-pointed; forks of the veins densely woolly beneath. Calyx of the fruit flattened. Nut nearly globose.—Native of low swampy woods, from New England to Pennsylvania, and in the Illinois country, flowering in May. Mesf. Frae are recorded as having brought this species to England in 1800, but it was previously cultivated in Holland and France. This is a large tree, whose wood is tough, used for making spokes of wheels. The leaves are smaller than those of *rubra* or *coccinea*, and with more numerous lobes than *Catebzei*; their sinuities round and very wide, and the forks at the origin of their veins marked by a tuft of glandular hairs. The *acorns* are small, globose, with shallow cups, and generally very abundant.

64. *Q. acutifolia*. Pointed-leaved Mexican Oak. Wildl. n. 57. Nee in Annal. Scient. Nat. v. 3. 267. Fitch. Mic. H/if. v. 1. 102. Wildl.—Leaves ovato-lanceolate, finnated, taper-pointed; unequal at the base; leaves toothed, bristle-pointed; forks of the veins villous beneath. Fruit racemose.—Native of New Spain, in the road from Acapulco to Mexico. This is the largest of all the Oaks in New Spain. *Trunk* thick, twenty-five feet high, ornamented with a dense head of innumerable branches. *Leaves* from five to seven inches long, an inch and a half or two inches degree. Pursh says, this is exclusively known by the name of Red Oak, though various others are so denominated in several parts of America.
inches broad, their footstalks an inch in length; ovate and unequal at the base, gradually contracting upwards to a sharp point, finnated, befit with awl-shaped teeth; green and shining above; reddish and veiny beneath, the forks of the veins villous. Female flowers in axillary four-flowered clusters, (or rather, we presume, fillets). German ovate. Acorn small, scarcely big as a pea, nearly covered by the cup, which is clothed with blackish scales. Nee.

65. Q. candicans. Hoary Mexican Oak. Willd. n. 58. Nee in Annals Scient. Nat. v. 3. 1775. Fisch. Mfsc. Hihp. v. 1. 115. Willd. — "Leaves ovate, finnated; white and downy beneath; lobes toothed, bristle-pointed."—Native of New Spain; in sandy ground near Tixtala. A tree of a middling size, with a dense head of upright branches. Leaves nine inches long, four wide, tapering at each end, finnated, with bristle-pointed teeth; green and smooth above; white and downy underneath. Footstalks four lines in length. Flowers and fruit not observed. Nee.

66. Q. biebiana. Holly-leaved, or Bear Oak. "Wangenb. Amer. 79. t. 6. f. 17," Willd. n. 59. Ait. n. 19. (Q. Biebii; Michaux Querc. n. 15. t. 27. Pursh n. 24. Q. aquatica? Sm. in Abbott's Inf. v. 2. 157. n. 79?) — Leaves obovate-ovate-shaped, with three or five deep bristle-pointed lobes, entire; downy beneath. Fruit filleted, in pairs.—Found in dry barren fields, and on mountains, from New Jersey to Virginia, flowering in May; covering, wherever it occurs, large tracts of ground, thence termed Oak-barrens. It is known by the name of Bear Oak, Black Scrub Oak, and Dwarf Red Oak. Pursh. A shrub four to six feet, occasionally more, in height, with downy branches. Footstalks downy, near an inch long. Leaves two inches, or two inches and a half long, and near two wide, tolerably uniform, acute at the base, cut into five, rarely but three, deep divided, broad, acute lobes, entire at the margin, and scarcely toothed at the summit, though tipped with one or two bristles; the upper side green, veiny, and smooth; the under pale, and finely downy. Female flowers in pairs, on thick, solitary, axillary, downy fillets, much shorter than the footstalks. Acorns about half an inch long, nearly globular, half covered by their fey hemispherical cups. Michaux thinks this species would serve well for making quick hedges. A specimen from Kalm, unnamed, is in the Linnaean herbarium.

67. Q. pseudosideris. Baftad Cork Oak. "Santi Viagg. 156. t. 4." Spreng. Antig. Bot. 16. t. 1. Willd. n. 60. Desfont. Atlant. v. 2. 348. — Leaves ovate-oblung, finnated, hoary beneath; lobes numerous, pointed, entire. Bark fungous, cracked. Nut ovate. Calyx muricated, with lax, recurved, linear scales. — Native of the mountains of Tuscany, Spain, and Barbary. Desfontaines gathered it on mount Atlas, and the abbe Durand near Tangier. A tree fifty or sixty feet high, whose bark is corky, though less so than in Q. Saber, n. 33. Young branchets downy or hoary, sometimes smooth, frizzled. Leaves deciduous, an inch and a half to three inches long, an inch or an inch and a half wide, acute; entire and slightly heart-shaped at the base; somewhat dilated upwards, and bordered with numerous, uniform, small, broad, acute, lobes or serratures, separated by roundish sinuses; upper surface green and smooth; under glaucous, hoary, or somewhat downy. Acorns on short stalks, ovate, above an inch long, half covered by the cup, which is downy, and clothed with lax glabrous scales, recurved at their tips. Desfontaines says the leaves of young trees are deeply finnated and frizzled; those of old ones more slightly so. In our specimens from Durand and Broussonet, the under side is feebly downy, except a dense fringe at the mid-rib. The transverse veins are more numerous, straight, and parallel, than in Sprengel's plate. Footstalks rather above half an inch long, smooth or downy. Acorns nearly felid, crowded about the ends of the branchets. Yet we think it must be, at least, the plant of Desfontaines.

68. Q. Argilopta. Great-prickly-cupped Oak, or Velanda. Linn. Sp. Pl. 1414. Willd. n. 61. Ait. n. 20. Mill. t. 1. 215. Oliver's Travels, English edition, v. 2. 44. t. 13. (Q. orientalis, cajanus folio, gladee recitata in cupula crassa et quamom; Tourn. Cor. 40. Velani; Tourn. Vov. t. 1. 128. Glans Cor; Delach. Hilt. v. 1. 7.) — Leaves ovate-oblung, with bristle-pointed tooth-like lobes; hoary beneath. Calyx of the fruit very large, hemispherical, with lanceolate, elongated, spreading scales. — Native of the Levant. Miller cultivated this Oak in 1731. The tree is so lofty as some other species, nor is the wood much esteemed, or used, but in cabinet work. Leaves filleted, about three inches long, bright green; a little downy at the back; their edges, as in the last, very coarsely and acutely serrated, rather than lobed, each tooth tipped with a bristly point. Acorn large, short, a little hollow at the top. Cup filleted, woody, two or three inches in diameter, from the projection of its numerous, oblong, thick scales. These cups are used, as well as the gall-nut, (see n. 40.) by the Orientals, Italians, and English, in dyeing, and are a considerable article of commerce. Tournefort says the modern Greeks call these acorns Velani, a corruption of Bebān, and the tree Velanda. The young acorns and cups, gathered from the tree, are much more esteemed than such as fall of themselves, when fully grown, and fell for twice the price of the latter. Dalechamp, Lobel, and Bauhin, mistake the unique cup and acorn of this species, as belonging to Q. Coris, n. 83.

 Sect. 5. — Leaves finnated, with blunt or pointed lobes.

69. Q. alba. White Oak. Linn. Sp. Pl. 1414. Willd. n. 62. Ait. n. 21. Pursh n. 29. Michaux Querc. n. 4. t. 5. (Q. alba virginiana; Cateeb. Carol. v. 1. t. 21. f. 2.) — Leaves oblong, deeply pinnatid; glaucous beneath; lobes oblong-linear, obtuse, entire, dilated upwards. Fruit filleted. Calyx deprested, warty. — Native of woods, on a fertile soil, from New England to Carolina, flowering in May; cultivated here in 1724, by Mr. Furber. Pursh says it is one of the most abundant and useful of its genus, in America, and grows in the middle States to an immense size. The adult leaves are nearly a span long, deeply and elegantly pinnatid; tapering and acute at the base; gradually dilated upward; somewhat abrupt, though threelobed, at the end; their lobes all entire, blunt, pointless, veiny; the upper surface green and shining; the under opake and glaucous; not downy, as Linnaeus and Willdenow define them, except perhaps when young. Footstalks stout, angular, half an inch, or more, in length. Frugiflalks twice as long, each bearing one or two, laterally fesfle, ovate acorns, full an inch in length, with a short tubercu- culated cup. Michaux observes, that this Oak is preferred to all others in America, for building houses and ships; as well as for cafs. The wood is so tough and pliable, as to serve for making balsks and brooms. The acorns are sweet, and Parkinon records that, in his time, the Indians were paid to obtain from them, by boiling, an oil which they used in cookery. A supposed variety, called repanda, is figured by Michaux, in which the leaves are merely waved, not lobed; and green on both sides, though downy beneath. With this we are unacquainted, as also with Wildenow's intermediate variety, called pulchercn.
Linn. Sp. Pl. 1414. Willd. n. 63. Ait. n. 22. (Pha- 
gus eculius, mas et foemina; Dalech. Hift. 5.)—Leaves 
ovate-oblong, finuate, smooth; paler beneath; segments 
bluntish; somewhat angular at the base. Fruit nearly 
sef- 
file. Calyx fcyly, hemispherical.—Native of theouth of 
Europe. Cultivated by Miller in 1739; hardy in our 
gardens, flowering in May. Aiton. So little attention has 
been paid to this species by botanies, writers, that we can 
find no certain description nor figure of it, except in Dale-
champ. We even doubt whether the plant intended in 
the firft edition of the Hortus Kewenfis is the same one; yet 
this seems what Willdenow meant in his Arbore; or Bann-
zucht, though he does not cite either that work or Hort. 
Kew. in his Sp. Pl. What Linnæus briefly describes in his 
Manifefis, 496, under the name of Eculius, seems to be 
Cercis, with which latter the description, copied by Will-
denow, and the specific character extracted therefrom, well 
agree; but not at all with the original and authentic speci-
men of Eculius in the Linnaean herbarium. By this last 
alone can any one determine what Linnæus had in con-
temination, when he wrote both editions of Species Plantae-
rum, and we shall here describe the fpecies. The brach 
is angular, furrowed, and smooth. Leaves latticed, ag-
gregate at the top, from two to three inches long, and one 
and a half, at molt, in breadth; smooth and fining above; 
paler, rather glaucous, and about equally finm, beneath, 
with finely reticulated veins; tapering at the very base, but 
just above it dilated, angular, and in some measure cordate, 
as Dalechamp’s figures more distinctly fhew. The summit 
is obtufe, and the margin cut unequally, on each fide, into 
bout five broad, blunt, entire, tooth-like furranies, or 
small lobes. Footstalks near an inch long, delirited of the 
long, linear, tufted, fipulaceous fcales, or ramofa, found in 
Angiois, Cercis, and Aubriaca hereafter mentioned. 
Young acorns axillary, nearly fefile, solitary or in pairs; 
the cups fcyly, the fize of small peas. Dalechamp repre-
sents the full-grown acorns about an inch long, embraced 
by an hemifpherical fcyly cup, about one-third that length. 
He fays they are sweet and catable, brought to table roafed 
by the Spaniards, as well as the fuccif Italianfs, but sometime 
found to affect the head, like danfe. The name 
Eculius is derived by etymologists from ecula, food, and is 
commonly taken for the Beech-tree, ordinary readers of 
Virgil’s Georgics not diftinguifhing one from the other; 
just as the Cieada of that poet has been vularly fuppofed 
the grafpoffr. The Delphin edition of the Georgics has 
the above word Eculius, as Linnaeus has adopted it, un-
warrantably, for the generic appellation of the Horfe Chef-
nut; and the editors rightly observe, that fome perifons 
confound it with Fagus, the Beech. Our Q. Eculius 
is most probably the 2459 of Diofocries, which he exprefly 
says is a kind of Oak. See Fagus.

Robur; Willd. n. 64. Ait. n. 23. Lamarck Dict. v. 1. 
717. Mart. Ruff. t. 11. var, fefilels. Q. fefilia; Ehrh. 
Arb. 87. Q. platyphyllos mas et foemina; Dalech Hift. 
2. 3. Q. latifolia mas, que brevi pediculo etl; Bauh. Fiw. 
419. Raff Syn. 440.)—Leaves on longifh footstalks, de-
ciduous, oblong, smooth; ffinues opofite, rather acute; 
lobes obtufe. Fruit fefile. Nut oblong.—Native of 
woods and hedges, in the temperate parts of Europe; 
rather lefs common in England than the preceding, flower-
ing in April or May. Professor Martyn has rightly cor-
rected Miller, who mentions the prefent as the common 
Oak of this country, and the former as rare. Why the 
German botanifts, like Lamarck, take this for Robur, is 
difficult to understand, unless the meafure origimate in in-
attention to the qualities, as well as history, of the trees. 
The word of our fefiliaflora, in which name we gladly follow 
Mr. Salisbury, is of far lefs value than the true British Oak, 
and the importance of diftinguifhing the two fpecies be-
comes, therefore, the more obvious. The leaves grow on 
longer footstalks, and are generally more equably and 
regularly pinatifid. The femar flowers, and the acorns, are 
ahnof perfectly fefile. In English Botany four fignias 
are delineated; but we know not how far that character, which 
would be an excellent one, is conftant.

n. 66, excluding the reference to Fl. Brit. (Q. Robur 
lanuginofa; Lamarck Dict. v. 1. 717. Robur prima; 
Cluf. Hift. v. 1. 183.)—Leaves oblong-obovato, foldked, 
finuated; downy beneath; lobes obtufe, angular, wavy; 
somewhat heart-shaped and unequal at the base. Fruit 
early fefile.—Native of France, Autfria, Hungwy, Tar-
tary, and of the Val d’Aofl, Piedmont, in which laft place 
it was gathered by Mr. Davall. We have seen a tree of 
this
this species, growing on the north lawn at Holkham, Norfolk, the seat of Mr. Coke, where it was planted by his ancestors, the earl of Leicester; but no British writer seems acquainted with the species in question, though unquestionably distinct. Willdenow justly says it is like his Robur, our _Fagus_, but abundantly different, being of more humble stature, with smaller leaves, downy beneath, very hoary and white in the spring, somewhat heart-shaped at the base, and with smaller fruits. To this we would add, the leaves are remarkably undulated, especially in drying, and their upper surface is more or less besprinkled with very minute, scattered, hairy hairs. The fruit in Mr. D'Avall's specimens is quite small, either solitary, or in one instance accompanied by two abortive ones; in those from Holkham the female flowers are more or less elevated, three together, on a thick downy stalk. Hence perhaps, Willdenow terms the fruit _fruticosus_. The scales of the cup in both are downy, thin, flat, and closely imbricated.

A variety of this, with deeper segments, and of more humble growth, is Robur tertiis, Clus. Hist. v. 1. 18. f. 1. Of this a specimen, erroneously named _Cerris_, and pinned to _Eucalyptus_, n. 70, above described, is preferred in the Linnean herbarium.

74. _Q. obtusifolia_. Durmarl Oak. Mart. Ruff. t. 12. (Q. obtusifolia β; Sm. Fl. Brit. 1027. Q. pubescens; Ait. n. 25, but not of Willdenon. Q. Robur nigra. Lam. Dict. v. 1. 717. Châne noir; Secondat du chêne, 3. t. 52.)—Leaves elliptic-oblong, stalked, finely downy; and hoary beneath; leaves numerous, obtuse, even, and entire; base equal. Fruit _fruticosus_.—Native of France and the south of England, flowering in April and May. Professor Martyn had his specimens from the New Forest, Hampshire, where it is known by the name of the Durmarl Oak. The whole tree is well described by him as having much the air of a chestnut, and being of finer growth than the true _Robur_; the bark lighter coloured and smoother; the wood not so strong, nor so firm in texture. The leaves are less deeply, but more copiously, finuated, with five, six, or seven short lobes at each side; the under surface downy, and of a hoary grey, with purplish ribs. The foliage appears later than in either of our common Oaks; and lasts longer, sometimes the whole winter. _Acorns_ small, rather large. Lamark's description, indicated above, accords exactly with our English plant, to which also, we presume, the synonym of _Secondat_ must belong, though we have not been able to consult his book. A more accurate study of this genus has led us to agree with our departed friend Willdenow, in distinguishing the Durmarl Oak from our _Fagus_, but he errs in regarding it as _pubescens_, and his Mr. Aiton into the same mistake. Its _leaves_ are more oblong, less deeply finuated, flat, not undulated; the under side whiter, with more veined leaves. _Fruticosus_ larger, and more decidedly _fruticosus_.

75. _Q. pyrenaica_. Pyrenean Oak. Willd. n. 67.—
Leaves oblong, pinnatifid, stalked; downy beneath; somewhat heart-shaped and unequal at the base; lobes obtuse, slightly toothed. Fruit _fruticosus_.—Native of the Pyrenees. _The leaves are larger than in_ fagus, _pinnatifid, stalked, deeply finuated; denely downy underneath. Footstalks downy._ _Acorns_ four, sessile on one common elongated stalk. _It differs abundantly from_ pubescens, _having much larger leaves, finuated in a pinnatifid manner, very downy beneath; and stalked fruit._ Such is Willdenow's account. We have seen no specimen. Can this be the above-mentioned variety of _pubescens_?

76. _Q. figinea_. Beech Oak. Lamark Dict. v. 1. 725. Willd. n. 68. (Phellodrya alba angustifolia, folio ferrata; Dalech. Hist. 25.)—Leaves oblong stalked, ovate, with numerous, uniform, shallow lobes; downy beneath; somewhat heart-shaped and unequal at the base. Fruit _fruticosus_.—Native of Spain and the south of France. Leaves small, an inch and half long, deciduous, ovate, very slightly finuated; or, more properly speaking, coarsely toothed. the lobes being very short, equal, and obtuse; the upper side polished and smooth; the under white and downy. _Footstalks_ downy. _Fruit fruticosus_. Willdenow. In the Linnean herbarium are specimens, gathered by Baron Allochomar in Spain, which answer extremely well to the above description, and not amiss to the figure of Dalechamps, which Lamark cites with hesitation. In these however, the lobes, or teeth, are acute, and the upper surface covered with minute hairy hairs. There are also long, linear, recurved, rametaceous _fallops_, that are so few and deciduous. We do not scruple to consider this as Lamark's plant at all, and probably Willdenow's.

78. _Q. obtusifolia_. Blunt-lobed Iron Oak. Michaux Querc. n. 1. 1. Pursh n. 25. (Q. Rellata; Willd. n. 71. Ait. n. 26. Wangenheim. Amer. 76. t. 6. f. 15.)—Leaves oblong, finuated, roughish on both sides; _lobes obtuse_; the upper ones dilated, abrupt, slightly divided. Calyx of the fruit hemispherical.—Found in most of the upland forests, from Canada to Florida, blooming in May. The tree is fifty or sixty feet high, spreading, its timber of great value for ship-building. The whitens of the bark, as in _Q. alba_, cauies both these species to be called White Oak by the Americans, who nevertheless know how to distinguish their timber. The _leaves_ of the present are roughish beneath, with minute tufts of hairs, not hoary; and their upper surface appears to partake occasionally, if not always, of the same fort of pubescence. Their length is from three to five inches; the base wedge-shaped, spreading upwards into two smaller, opposite, rounded lobes, beyond which the leaf dilates, suddenly and widely, into a pair of broad, slightly cloven, or emarginate, lobes, and, after another sudden contraction, ends in a terminal three- or five-toothed leaf. The margin is entire throughout. _Footstalks_ short, downy. _Acorns_ three or four on a short stalk, of a middling size, scarcely exceeding our British Oaks, elliptical, about half enclosed in the fealy cup.

79. _Q. lyrata_. Over-cuped Lyrace Oak, Swamp-pollt, or Water White Oak. Walt. Carol. 235. Willd. n. 72. Ait. n. 27. Pursh n. 28. Michaux Querc. n. 3. t. 4.—Leaves oblong, deeply finuated, smooth; much contracted in the middle; _lobes_ acute; the upper ones dilated, angular, and abrupt. Calyx of the fruit globose, mottled, nearly covering the nut.—Native of swamps, from Carolina to Florida, and on the Mississippi; flowering in May. Pursh. Michaux says, that though he always found this species in watery places, its growth, in a dry and sandy-ground, exceeded that of many other species planted with it. He gives fifty or sixty feet as the height of the tree; Pursh from eight to fifteen only. The smooth fine-green _leaves_ have more acutely-angular lobes than the foregoing, and are remarkably contracted about the middle. _Acorn_ globose, nearly covered by the globular prickly cup.

Wild. n. 75. Ait. n. 28, 3. Q. Cerris. 

L. & Dec. v. 1, 719. Q. coccifera; Jull. in Hort. Paris. Q. burgundica, calyce basialis; Baud. Pin. 420. Cerris Plini, maior glande; Lüb. c. v. 2, 156. Dod. Pempt. 831. Ger. Em. 1345. Cerris; Dalle. Hift. v. 1, 6, (good.)—Leaves on very short stalks, oblong, deeply and unequally pinnatifid; hairy beneath; lobes lanceolate, acute, somewhat angular. Stipulas longer than the footstalks. Calyx of the fruit hemispherical, bristly.—Native of France, Italy, and the Levant. Sometimes cultivated in England, but not commonly. This is a tall handsome tree, whose synonyms are much confused by old writers with Q. Argéipha, n. 68, and by more recent botanists with the following. Its leaves are deeply pinnatifid in the manner of the foregoing; more or less unequally; but the lobes are more acute, pointed, and more generally angular, sometimes remarkably lobed or compound. The under side differs essentially, in being neither downy nor hoary, but rough with minute, scattered, tawny, bristly hairs; the upper, which is of a darker green, and rather shining, is also occasionally roughish near the touch. Footstalks thick, hardy a quarter of an inch, sometimes not a line, in length. Stipulas linear, acute, downy, from half an inch to an inch long, permanent, accompanied by an axillary tuft of finer, but smaller, scales. The cernua have not been observed. They are represented, two or three together, large, oblong, with an hemispherical cup, which is fringed with long bristles, projecting in every direction. They are said to be peculiarly bitter and astringent.

Lamarck adds, from his own observation, that the Q. orientalis latifolia, glande maxima, cupula crisiform, Tourn. Cor. 40, scarcely differs in any respect from this. If so, the term latifolia is not happily applied, unless Tournefort had also noticed, as in our last, the deep divisions of the leaves, which are full as remarkable in the present species.

84. Q. auffricana. Aulnian Oak. Wild. n. 76. (Q. Cerris; Hoff. Syn. 520, &c. Ait. n. 28. Q. crista, cinnam. Linn.; Lamarck. Dicr. v. 1, 718. Q. calyce hispidus, glande minor; Bau. Pin. 420. Cerris; Clh. Hift. v. 1, 20, excellent. Cerris minoris ramulus cum flore; Ger. Em. 1346, with Clusius's figure. Cerris Plinius minor gale; Lüb. c. v. 2, 156. Ger. Em. 1345. Aegilops minor gale; Dö. Pempt. 831. Halichloës, Cerris foemina; Dalle. Hift. v. 1, 7. —Leaves on long stalks, ovate-oblong, slightly, but copiously, downy, and hoary beneath; lobes short, ovate, acute, entire. Stipulas shorter than the footstalks. Calyx of the fruit hemispherical, bristly.—Native of Austria, Hungary, Carniola, Italy, and other parts of the south of Europe, in Rocky mountainous places. It occurs not unfrequently in plantations of exotic trees, both in France and England, being generally mistaken for Q. Cerris, from which nothing can be more certainly distinguished. This tree is taller than the Common Oak, Q. Robur, and in favourable situations rises perpendicularly to a considerable height, as Clusius described it. Though Lamarck says it is smaller, less handsome, more twisted and knotty, than the last, as well as often hollow. The wood is whiter, softer, and less valuable, than Q. Robur; the bark grey, tolerably even. Branches forming a round...
QUERCUS.

A round and compact head. Leaves two or three inches long, acute, generally rounded and a little unequal at the base; their upper surface of a fine shining green, and nearly smooth; the under whitish, clothed with fine dense down on the margin cut, at each side, into four, five, or six, tolerably regular, rounded or ovate, acute, pointed, entire lobes, or some deep, separated by round fumule; the disk of the leaf being left entire, of a considerable width. Footstalks near an inch long, downy. Stipulas as in the foregoing, but smaller and shorter, usually about half the length of the footstalks. Acorns like those of the tall, but smaller. The figures of Lobel, Dodoens, and Ger. Lin. 1345, do not well represent the leaves of this species, or indeed of the former: that of Clusius, adopted by the editor of Gerarde, in p. 1346, is perfectly correct. The cuts of Dalechamp, both of one and the other, are sufficiently expressive, and very correct as to the footstalks. The lobes of neither of these species are quite pointed, but rather more pointed, as well as acute, than those of F. sylvestris, n. 70.

We have thus added eight species of Quercus to Wildenow’s list. Thence botanists who may take the trouble of following us with attention, will perceive that this valuable genus still requires elucidation, particularly with respect to the European, and, above all, the oriental kinds; some of which first, barely indicated by authors, we have now been obliged to leave unexplained. Of the most common and important species, Q. Robur, we have been in Mr. Coke’s woods at Holkham, some thriving varieties, at least, though distinctions and qualities are well worthy of examination. Two of these have shorter footstalks than the common Robur, and one of them is three weeks earlier in coming into leaf than the other. The footstalks of both are longer than is usual in Robur. How far a difference of quality in the wood may accompany these botanical distinctions, we must refer to the inquiries of those who are interested in, and have the means of investigating, so important a subject, which is indeed the first economical, and even national, consequence. It is much to be wished that the species of the Norway Oak, so valuable for floors, on account of its straightness, and freedom from knots, could be determined. Perhaps these circumstances are owing to its being drawn up straight, with few branches, in its close native forests, and therefore it may not be specifically different from one or other of our own species. Michaux, and other writers on the American Oaks, have taught us, that the subfequence of the leaves in this genus is of more specific importance than had previously been supposed, and we therefore have paid the more regard to it in discriminating some of the European kinds. The flowers, male and female, appear still to demand more precise investigation and comparison, than they have any where received.

Quercus, in Gardening, furnishes plants of the forest, deciduous, evergreen, ornamental tree-kinds, of which the species cultivated are, the common oak-tree (Q. robur); the willow-leaved oak-tree (Q. phellos); the holly-leaved oak-tree (Q. prinus); the black oak-tree (Q. nigra); the red oak-tree (Q. rubra); the white oak-tree (Q. alba); the Italian or small prickly-cupped oak-tree (Q. fuscus); the great prickly-cupped oak-tree (Q. celticus); the Turkey oak-tree (Q. cerisa); the evergreen or holm oak-tree (Q. ilex); the holly-leaved evergreen oak-tree (Q. granatina); the cork-barbed oak, or cork tree (Q. fubur); and the kermes oak-tree (Q. cocycera).

Of the first there are several varieties; as with the acorns on long peduncles. This is found in the wilds of Kent and Suffolk, where there are many large trees. The leaves are not so deeply sinuated, nor are they so irregular as in the common oak, but the indents are opposite; they have scarcely any footstalks, but fit close to the branches; the acorns stand upon very long footstalks. The timber of this sort is accounted better than that of the common oak, and the trees have a better appearance.

The broad-leaved evergreen oak, which grows upon the Apennines, and also in Suabia and Portugal. The leaves are broader, and not so deeply sinuated as those of the common oak; they are of a lighter green on their upper side, and pale on their under; have very short footstalks, and their points are obtuse; the acorns have very long footstalks, which frequently sustain three or four in a cluster.

The dwarf oak, which grows in the south of France and Italy, and is a low bushy oak, rides but six or seven feet high, standing many slender branches the whole length. The leaves are oblong, and obtuse indent, about three inches long, and an inch and a half broad, standing upon slender footstalks; the acorns small, growing in clusters.

There are also many other varieties of common oak, which dealers in timber and woodmen distinacly by their use, qualities, and accidents, and to which they give different names; but these being merely local, and not founded on permanent characters, it is difficult to ascertain them.

In the second species they distinguish two sorts; one of which is called the Highland willow oak, and grows upon poor dry land; the leaves are of a pale green, and entire, shaped like those of the willow tree; the acorns are very small, but have pretty large cups. The other grows in low moist land, and rides to a much greater height; the leaves are larger and narrower, but the acorns are of the same size and shape. It is suggested, as probable, that their difference may be owing to the soil in which they grow. Martyn observes, that the latter becomes a large timber tree, and that there are said to be several varieties of it.

The third species has seemingly two varieties, one of which grows to a much larger tree than the other; but this may be occasioned by the soil, for the largest trees grow in rich low lands, where they become bigger than any of the North American oaks. The wood is not of a very fine grain, but is very firm and heavy; the bark is grey and heavy; the leaves are five or six inches long, and two inches and a half broad in the middle, indented on the edges with many transverse veins running from the middle to the borders; they are of a bright green, and more nearly reemibly those of the chinnut tree as freely to be distinguished from it. The acorns are very large, and their cups are short. The leaves of the other variety are not so large, and are freely veined; and the acorns are smaller, and a little longer. The different varieties are distinguished by the form of their leaves, which in the one is ovate, and in the other oblong.

The fifth sort has several varieties. And in the ninth sort there are several varieties.

The tenth species has likewise several varieties, differing greatly in the size and shape of their leaves; but these will all arise from acorns of the same tree; even the lower and upper branches have very frequently leaves very different in size and shape; those on the lower branches being much broader, rounder, and their edges indented and set with prickles; but those on the upper long, narrow, and entire. The leaves are from three to four inches long, and an inch broad near the base, gradually tending to a point; they are of a lucid green on their upper side, but whitish and downy on their under, and do not fall till they are thrust off
off by young leaves in the spring. The acorns are smaller than those of the common oak, but of the same shape.

The twelfth species has also two or three varieties; one with a broad leaf, a second with a narrow leaf, both evergreen; and one or two which cast their leaves in autumn; but the broad-leaved evergreen is the most common. The leaves of this are entire, about two inches long, and an inch and quarter broad, with a little down on their under sides, on very short footstalks; these leaves continue green through the winter till the middle of May, when they generally fall off just before the new leaves come out, so that the trees are often almost bare for a short time. The acorns are very like those of the common oak.

The exterior bark forms the cork, which is taken from the tree every eight or ten years; but there is an interior bark which nourishes them, so that flaking off of the outer bark is far from injuring the trees, that it is necessary to continue it; for, when the bark is not taken off, they seldom last longer than 50 or 60 years in health; whereas trees which are barked every eight or ten years will live 150 years, or more. The bark of a young tree is porous, and good for little; however, it is necessary to take it off, when the trees are twelve or fifteen years old, for without this the bark will never be good. After eight or ten years, the bark will be fit to take off again; but this second peeling is of little use. At the third peeling, the bark will be in perfection, and will continue so for 150 years; as the beff cork is taken from old trees. The time for flaking off is in July, when the second sap flows plentifully: the operation is performed with an instrument like that which is used for disbarking the oak.

It is from the last species they collect the kermes, or scarlet grain, a little red gall, occasioned by the puncture of an insect called coccus flicies. With this the ancients used to dye cloth of a beautiful colour.

Method of Culture.—These trees are all capable of being raised from the seed or acorns, which, in the common oak, should be gathered in autumn when quite ripe, just as they drop from the trees; but those of most of the foreign oaks are generally procured from abroad, and sold by the feedmen.

All the sorts should be sown as soon after they are obtained as possible, as they are apt to sprout if they remain long out of the ground; and for their reception, a spot of light ground in the nursery should be prepared by digging or ploughing, dividing it into four feet wide beds, in which the acorns should be sown, either in drills, two inches deep, in five or six rows lengthwise of the bed; or make the mould off the bed, the depth of two inches, into the alleys; then fowing the acorns all over the surface, about two or three inches apart, press them down with the spade, and spread the earth evenly over them two inches thick. When they come up in the spring, they should have occasional waterings and weeding; and when the plants are one or two years old, it is proper to plant them out in nursery-rows; this may be done in autumn, winter, or early in the spring, taking them carefully up out of the feed-bed, shortening their perpendicular tap-roots, and trimming off any lateral shoots from the stumps, leaving their top perfectly entire; then planting them in lines two feet and a half asunder, and fifteen or eighteen inches in the rows, where they should stand, with the usual nursery care, till of a proper size for final planting out either as forest trees, or for ornament, training them up as full standards, with clean straight stems, and with their tops all entire.

But in raising the striped-leaved varieties of the common oak, and any particular variety of the other species, it should be by grafting, (as they will not continue the same from seed,) which should be performed upon any kind of oakling flocks raised from the acorns, and trained for standards, as in other kinds.

With respect to the final planting out, it may be performed in all sorts of deciduous oaks any time in open settled weather, from November till February or March; and in the evergreen kinds in October, November, or the spring; and in a mild open season in any of the winter months.

When the trees of all the sorts are from about three or four to six feet stature, they are proper for being planted out for good; though, as forest or timber trees, it is better to plant them out finally while they are quite young, as from two to three or four feet in height; or when planted immediately from the feed-bed, where they are to remain, it may be advantageous, as the very young oaks root more freely than older trees, and take a freer growth. Those designed as forest or timber trees should be planted in large open tracts of ground, to form woods, placing them in rows only from four or five to ten feet asunder, and from two or three to five or six feet in the rows, to allow for a gradual thinning. But perhaps the best method of all for raising them, as timber trees, is from the feed, by fowing or setting the acorns. See Plantation and Planting.

Sometimes, indeed, large plantations of these trees, for woods, are raised by fowing the acorns at once in the places where they are to remain; it being generally found that the trees raised at once from the acorn, from their not being checked, much outstrip the transplanted trees in their growth. The method of performing it is this: the ground being prepared by good ploughing and harrowing in the autumn, having procured a proper quantity of acorns, draw drills across the ground four feet asunder, and two inches deep, dropping the acorns into them fix or eight inches asunder, allowing for failing and thinning, covering them in even with the earth the depth of the drills; or, instead of drilling them in, they may be planted with a dibble the same depth and distance.

The general management of these trees in woods, or timber plantations, is the same as directed for forest trees in general. See Plantation.

All the above sorts of trees may be employed to diversify large ornamental plantations in out-grounds, and in forming clumps in spacious lawns, parks, and other extensive open spaces: the evergreen kinds, in particular, have great merit for all ornamental purposes in pleasure-grounds and plantations. And all the larger growing kinds, both deciduous and evergreens, are highly valuable as forest trees for timber; but the firft sort claims precedence as a timber tree, for its prodigious height and bulk, and superior worth of the wood.

In planting any of the species for ornament or variety in large pleasure-grounds, some may be disposed in ensembles in any continued plantation, some in clumps, and others singly.

All the different sorts of the oak will succeed in any soil of a middling quality, where the exposure is not unfavourable; but to the most advantage, where the land is of a loamy nature; they, however, thrive tolerably in those soils which are of a gravelly, sandy, or clayey description.

Beside the great value of these sorts of trees for the utility and durability of their wood, as timber, for the purposes of ship-building, house-building in some parts, park-paving, posts, railings, and a variety of other strong uses; they, in many of the kinds, afford considerable additional advantage.
advantage by their produce in bark, for the use of the tanners and cork-cutters, in tanning leather, and being made into corks; after the former of which, it is also much employed in gardening, for the forming of bark-hot-beds, in raising tender hot-house exotic plants: as well as in their annual crops of acorns, as an excellent food for the keeping and fattening of swine, deer, and some other animals.

Quercus, in Planting, a classical term sometimes applied to the oak-tree in nursery collections, intended for this sort of application. See Oak-Tree.

Quercus Marina, the Sea-Oak, in Botany, the name of one of the broad-leaved dichotomous fescue-cutis.

It is not agreed, among the late botanists, what was the sea-oak of Theophrastus; and the most ancient botanists, Clusius and Celspinumin, suppose it to have been a species of the shrubby coralline; but that forms by no means to have been the case, since Theophrastus says his sea-oak had a long, thick, and fleshy leaf, where we may much more naturally conclude it to have been of the fucus clafs.

Quer, in Geography, a province of France before the revolution, in the government of Guienne; bordered on the E. by Rouergue and Auvergne, on the S. by Upper Languedoc, on the W. by Perigord and Agenois, and on the N. by Limousin: it contained two bihlopic, viz. Cahors and Montauban. The air is good, and the land is fertile: its capital was Cahors. It now constitutes the department of the Lot.

Querele, in Ornithology, the purple-throated chatterer of Latham, a species of Ampelis.

Querela, Querrel, in Law, denotes an action, or declaration, preferred in any court of justice. See Quarrel.

In an action where the plaintiff is called quereu, i. e. complainant, his brief, complaint, or declaration, is called quarrela.

Querela Audita. See Audita.

Querela coram rege et consilio, a writ by which one is called to judge a complaint of a trespass made to the king himself, before the king and his council.

Querela Duplex. See Double Quarrel.

Querela, ex gratia. See Ex Gravi, &c.

Querenghi, Antonio, in Biography, a man of letters, was born at Padua in 1456. He displayed, at an early period of his life, a decided attachment to literature; he wrote verses before he was twelve years of age, and soon became distinguished by his deep knowledge of the languages, civil laws, and the philosophy that was taught at that period. For some time he applied himself to theology, and made considerable proficiency in it. He next went to Rome, where he entered into the service of several cardinals, and at length became secretary of the faced college, in which capacity he was present at the election of five popes. Clement VIII. conferred upon him the canonry of Padua, which occasioned him to reside in that city, but he returned to Rome in the pontificate of Paul V., by whom he was promoted to some offices of trust. He died at Rome in 1633, at the age of 87. He was a man of various and extensive literature, and was much regarded by the learned of the time in which he flourished. His writings were numerous, and comprehended the sciences and polite literature. He is chiefly known to posterity by his poems, which are correct and elegant, but by no means animated. Moreni.

Queretano, in Geography, a town of Mexico; 80 miles N.N.W. of Mexico. N. lat. 20° 25'. W. long. 101° 36'.

Querfaa, in the Materia Medica of the Arabians, a

name given by Avicenna and others to cinnamon, when gathered with the wood of the young branches.

It was a common practice in the early times not to strip the small bark from medicinal trees, but to cut off the little boughs, and use the bark and wood together. This is the Greek called syly cinaminum, or woody cinnamon; and the Arabians, qurfaa, qurwar, or kaffa.

Querfurth, in Geography, a town of Saxony, situated on the little river Weis, inconsiderable in itself, but having large fuburbs; the number of houses is estimated at upwards of 500. The old cafile belonging to it stands on a hill, and it has likewise a superintendency; 16 miles S.W. of Halke. N. lat. 51° 23'. E. long. 11° 45'.

Queria, in Britany, received that name from Loelinge and Lineus, in compliment to Don Joseph Query Martinez, a Spanish physician, who thought he wrote against the Linnean system, and even the fpecies of plants, contending that palm-trees ripen fruit without impregnation, was an affidious practical botanist. He published a Spanish Flora, in his native tongue, consisting of four volumes quarto, of which the first three appeared in 1762, and the fourth in 1764. A fifth and sixth were added by Ortega in 1784. Quer was professor of botany in the royal garden at Madrid, and died in 1764, aged 69. He wrote also on the Uni Urfps, (which he removes from the genus Arbatata,) as a specific in calculous complaints; and on the medical use of Glicata.—See Haller's Bibl. Bot. v. 2. 516. and Dryandr. Bibl. Banka.—Linn. Gen. 43. Schreb. 58. Willd. Sp. Pl. v. 1. 493. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 185. Juss. 350. Lamarek Illir. t. 52. Gertr. t. 128.—Clafs and order, Triandria Trigonia. Nat. Ord. Caryophyleae, Linn. Juff. Gen. Ch. Cal. Perichnitt inferior, of five erect, oblong, acute, permanent leaves; the outermost revirted. Cor. none. Stam. Filaments three, capillary, short; anthers roundish. Pill. Germin superior, ovate; fylces three, the length of the flamens, fyllis simplex. Peric. Capsule roundish, of one cell, with three valves. Seed foliary, roundish, compressed.

Eff. Ch. Calyx of five leaves. Corolla none. Capsule of one cell, with one seed.

Obi. Lineus remarks, that this genus differs evidently from Minuartia, see that article, in having a foliary seed. Q. canadensis, figured by Gartner, is removed hence by Michaux to his genus Amychis, which belongs to a different natural order, the Heloreica of Lineus, and has a capsule delimit of valves. Gartner indicates its close affinity, except in number of flamens, to his Paronychia, see that article. Michaux and Pursh afford that its flamens vary from two to five.

1. Q.hispanicus. Spanish Queria. Linn. Sp. Pl. 132. Willd. n. 1. Ait. n. 1. Loell. It. 48. 83. Quer. Fl. Eifpan v. 4. 667. t. 15. f. 2.—Flowers crowded into a tuft. Native of sandy grounds in Spain. Seeds were sent to Kew, in 1890, by the late Marchioness of Bute. The plant is a diminutive hardy annual, flowering most part of the summer. Root fibrous. Whole herb whitish, brittle, one or two inches high, with several leafy, round, rather downy, slightly reddish fylces. Leaves opposite, fiddle, awl-shaped, three-ribbed, curved to one side, rather longer than the joints of the flaments. Head of flowers obscurely quadrangular, densely dichotomous, easily breaking off from the flament. Basitales opposite, awl-shaped, recurved, and hooked, easily catching hold of the coats of animals. Flowers very minute.

3. Q. icichatoma. Three-forked Queria. Thunb. in Trans. of the Linn. Soc. v. 2. 329—Wild. n. 3. (Rubia fpcicis ternas; Thunb. Jap. 357.)—Flowers racemose. Stem triplic forked.—Native of Japan.—Herb with widely spreading, thread-shaped, smooth branches. Leaves opposite, on very short flanks, ovate, acute, nearly entire, smooth, widely spreading, as long as the finger nail. Clusters axillary, three; two opposite, one terminal, composed of three or four pair of opposite, minute, deciduous flowers. To this description Thunberg adds—"Corolla cylindrical. Fruit inferior, oblong, smooth."—This must be altogether a mistake, if the plant has any pretensions to be reckoned a Queria. Having seen no specimen, we leave the matter as we find it. The genus before us must probably depend on the first species only; and whether the character of the foliary leaf, by which alone it stands distinguished from Mimaria, be sufficient, there being the strictest conformity in habit and every other particular, we feel much inclined to doubt.

QUERIGUT, in Geography, a town of France, in the department of the Arriére, and chief place of a canton, in the district of Poix; 27 miles S.E. of Tarascon. The place contains 809, and the canton 24,883 inhabitants, on a territory of 1,243 square kilometres, in seven communes.

QUERIMBA, a cluster of islands, deriving its name from the principal, in the Indian sea, near the coast of Africa; fertile in dates, oranges, grapes, and other fruits and legumes. The pastures feed great numbers of large and small cattle, and the coasts abound with fish. These islands, when first discovered by the Portuguese, were inhabited by Arabsians; but at present they are chiefly occupied by the descendents of Portuguese. S. lat. 12° 20'.—Allo, a country of Africa, bordering on the coast. S. lat. 9° to 13°.—Allo, a river of Africa, which runs into the Indian sea, S. lat. 12° 20'.

QUERKINESS, or Kerkeines, two islands in the Mediterranean, near the coast of Tripoli; one of them about ten miles long and five wide, anciently called "Cer-

quina;" the other, which is smaller, is united to the larger by a bridge; 15 miles S.S.E. of Cape Oudia. N. lat. 34° 59'. E. long. 11° 12'.

QUERO, a town of South America, in the jurisdiction of Riohamba.

QUERPO. See Cuerpo.

QUERQUEDULA, in Ornithology, a species of Anas. See Duck and Teal.

QUERRE, in Geography, a town of France, in the department of the Mayenne and Loire; 12 miles N. of Angers.

QUERRIEN, a town of France, in the department of the Finistere; six miles N. of Quimper.

QUERRIES, or EQUERRIES. See Equirry.

QUERREUX, in Geography, a town of France, in the department of the Somme; five miles N.E. of Amiens.

QUERRY, Gentleman of the, is an officer appointed to hold the king's furrip, when he mounts on horseback.

QUERS, in Geography, a town of France, in the department of the Upper Saone; three miles S.E. of Luxeuil.

QUESADA, a town of Spain, in the province of Jaen; 12 miles S.E. of Ubeda.

QUESENDORF, a town of Prussia, in the palatinate of Culm; four miles S.E. of Bretchn.

QUESNAY, Francis, in Biography, a celebrated French physician, was born at Mercy, a little town not very distant from Paris, in 1694. His family were employed in rufic occupations, and gave him no other education than what was deemed necessary for their mode of life; so that at the age of sixteen he was scarcely able to read. About this time, however, a thirst for information seized him, and partly by the aid of a country surgeon, and the few books that he possessed, but principally by his own labour, he acquired a knowledge of Latin and Greek, and entered with ardour into the study of the ancient and modern writings on philosophy. In opposition to the grovelling notions of his relations, he resolved to turn his pursuits to medicine, having perceived its connection with the various branches of physical science; and his master, the surgeon of Equeville, was soon convinced of the superior acquirements of his pupil, some of whose essays he presented as his own, on applying for admission into the college of St. Côme, and they were received with great applause. This still farther roused the zeal of Quesnay, and he repaired to Paris, where he entered with great alacrity into the studies connected with the profession. After some time he settled at Mantes, a considerable town in his native province. Here he was discovered by Garengeot, an eminent surgeon, who was engaged with Peyronie in an attempt to establish an academy of surgery, for the collection of surgical knowledge. Having written a refutation of the doctrines of Silva, respecting blood-letting, which led him to a public controversy, in which he was deemed victorious by Peyronie, he displayed such profound views, indefatigable zeal, and great general knowledge, as determined Peyronie to appoint him the secretary of his new academy. This distinguished post raised him still higher in the public estimation; but the labours connected with it at length injured his health, which had been for some time delicate, and he determined to turn his attention to medicine more particularly, and took the degree of doctor of physic. He had been employed during the campaigns of the king, and on the death of M. Terray was appointed consulting physician to his majesty; and was much esteemed and favoured by madame de Pompadour; he seems, indeed, to have been much employed, and to have been held in high consideration by the dauphin.
the father of Louis XVI., and by the whole court. After the dauphin had undergone the small-pox, the king presented him with letters of nobility, unfeigned, as a mark of his esteem. He was appointed alio erit physician in ordinary to his majesty. He was a member of the Academy of Sciences, of the Royal Society of London, &c. Notwithstanding his long life, and his courtly favour, as well as extensive employment, he died possessed of little fortune, his liberality to his friends having prevented him from accumulating money. His death took place at Verfailes, in December, 1774, at the age of eighty.

This able and indefatigable man left several works, which bear the stamp of considerable research, clear and methodical views, and acute observation, mixed, however, with some disposition to hypothesis. His first essay on blood-letting, already mentioned, was published in 1730, under the title of "Observations sur les Effets de la Saignée, avec des Remarques critiques sur la Traité de Silva;" and a second edition, considerably enlarged, was printed in 1750. But in the mean time he published another work, entitled "L'Art de Guerir par la Saignée," Paris, 1736, in which he recommends blood-letting in many diseases. In the same year appeared his "Effet Physique sur l'Économie Animale," in two volumes, 12mo., which was reprinted in 1747, in three volumes. This work, however, was deemed very imperfect by Haller, and is in fact characterized by a love of hypothesis, rather than by the details of experience and observation. In 1745, his "Preface des Mémoires de l'Académie de Chirurgie," gained him considerable applause, as a work of literary research. In 1744 he published his "Recherches critiques et historiques sur l'Origine, sur les divers États, et sur les Progrès de la Chirurgie en France," which called forth some replies on the alleged inaccuracy of some of the historical statements. His other publications were entitled, "Traité de M. de la Peyronie du 18 Avril, 1747;" "Examen impartial des Contestations des Médecins et des Chirurgiens de Paris," 1748, 12mo.; "Mémoire présenté au Roi par son premier Chirurgien, où l'on examine le Sage de l'Antiquité Législation sur l'État de la Chirurgie en France," 1749, 12mo.; "Traité de la Suppuration," 12mo.; and "Traité de la Gangrène," 12mo.; all in the year 1749. And lastly, his "Traité des Fièvres continues," 1753, in two volumes, 12mo. Eloy Dieët. Hift. de la Médecine.

Quesne, Henry Du, was born in 1652, and at the age of fourteen entered the French navy, and served with great distinction under his father. He was present at the bombardment of Algiers in 1683, and negotiated the peace of Tunis. At the period when the highest prospects in his profession lay before him, his attachment to the Protestant religion caused him, at the repeal of the edict of Nantes, to quit his country and the service, but he refused with indignation the offers that were made him to take a command in the armies of its enemies, and retired to Switzerland. His high reputation raised him to great credit with the Protestant powers, which he employed in engaging them to undertake the protection of his persecuted brethren; and through his means a great number of victims of the most cruel intolerance procured their liberation from the galleys. In 1701 he held his estate in Switzerland, and retired to Geneva, of which he was admitted to the citizenship. Here he died in 1723, respected alike for his learning and piety. As an author he had taken a considerable share in the version of the New Testament published by the pastors of Geneva, and he was author of a work entitled "Refections Anciennes et Modernes fur l'Eucharistie."
that reflect great honour on the learning of the editor. Its value was enhanced, in the judgment of his countrymen, by his introducing into it an able defence of the sentiments of the Gallican church, in opposition to the pretensions of the church of Rome. This circumstance gave great offence to the papal government, and the edition was condemned in the following year at Rome. On account of his attachment to father de Saint-Merthe, general of the oratory in France, he was obliged to quit his diocese, and from other unpleasant circumstances he thought it right to withdraw privately from France into foreign countries. He took refuge at Bruffels, where he continued his "Moral Reflections" on the acts of the apostles, and the epistles. Thus, with his former work, he published in 1687. He afterwards revised and made additions to the former work on the Evangelists, and printed an uniform edition of the whole in 1693 or 1694, in four vols. 8vo.

In the year 1703 the Jesuits, always insinuical to the rights and liberties of mankind, and who, to the utter disgrace of the present period, have been just re-established in their powers, availed themselves of their influence with an ignorant and bigoted king of Spain, to obtain an order for the arrest of father Quefnel, who was now thrust into a dungeon belonging to the archiepiscopal palace at Bruffels.

From this situation he was unexpectedly delivered in less than four months by the ingenuity of a Spaniard, who contrived to open a passage through the walls of the prison sufficiently large for his escape. Having thus obtained his liberty, he made the best of his way to Holland, where he published several pieces in vindication of himself and writings from charges preferred against both before the ecclesiastical court of Mechlin, and the sentence of condemnation pronounced by the archbishop. In the year 1705 the enemies of Quefnel applied to the pope Clement XI. for the condemnation of the "Moral Reflections," to which he acceded, although he had some years before expressed his decided approbation of them, and even wished to engage the author to come to reside at Rome. Such, however, was the pontiff's infidelity, that he issued a decree which condemned the "Moral Reflections" in general, but without specifying any particular doctrines which merited such a sentence. At length, at the instigations of the Jesuits, eager in the cause of persecution, Lewis XIV. joined himself against Quefnel, and applied to the pope for a more definite decree; his holiness, for so the mott wicked as well as most virtuous of the popes have ever been denominated, in consequence of this application, established a congregation of cardinals, prelates, and divines, to enter into a particular examination of the doctrines and maxims which Quefnel had advanced. That his work might not be condemned without any efforts on his part to vindicate it from the accusations of his enemies, our author wrote, on this occasion, two letters to the pope, which were safely conveyed to Rome, but Clement did not deign to give a reply. State policy had already determined what measures he should adopt, and, after the feilions of the congregation were ended, he issued the celebrated bull Unigenitus, in September 1713, which pronounced a sentence of condemnation upon 101 propositions extracted from the "Moral Reflections."

Father Quefnel spent the last years of his life at Amsterdam, where he formed some Janesdelf churches, and published his apologetic and controversial pieces against the bull Unigenitus, and its abettors. He died in 1719, in the 86th year of his age. Independently of his "Moral Reflections," he was author of several other works of high reputation, of which we may mention, a tracts on "Predilection and Grace," in four vols. 12mo, under the fictitious name of feu Germain; and "The Discipline of the Church deduced from the New Testament," in two vols. 4to. A list of this author's works may be seen in Moreri.

**QUEST**

**QUE**

Francis Quefnel, called the Fleming, an excellent sculptor, was born at Bruffels in 1594. He learned his art under his father, who was a sculptor, and at an early age displayed so much ability, that the archduke Albert gave him a pension and sent him into Italy. After the death of that prince, he was patronized by the confable Colonna; and the celebrated Poufin residing with the confable at the same time, the two artists contracted an intimate friendship, and studied together. Quefnel formed himself upon the tale of the ancients, and chiefly excelled in making bas-reliefs and models in a small size, representing cupids and children, to which he gave inguilar grace and delicacy. He employed himself several years on a marble font, for the chapel of Loretto, in which he imitated the genuine beauties of the antique. When the canopy of St. Peter's was finished, pope Urban VIII. ordered four colossal statues to be placed in the niches. That of St. Andrew was given to Quefnel, and although one of his competitors ventured to affirm that he could only cause to achieve a great child, yet when the figure was completed, it entirely effaced his own performance. Notwithstanding the talents of this artist, which were united to much perseverance and industry, he could barely earn a subsistence, and was in a very low state of health and spirits, when, in 1642, Lewis XIII. engaged him as his sculptor, and as the head of an intended school for that branch of art, at a very liberal salary. This change of fortune he was unable to bear, and as he was the point of setting out, he sunk into a melancholy derangement, from which he never recovered. His death, which happened at Lorphon in 1646, has been imputed, but probably on insufficient evidence, to poison, administered by the hand of a brother with whom he lived on very bad terms. He was mild in his manners, but of a refined disposition. His reputation is chiefly founded upon the exquisite statues which he gave to marble, and the peculiar grace and beauty of his infantile groups, finished with perfect anatomical exactness.

**QUEST**

Quefnel, Ls, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Arques. The place contains 3666, and the canton, to which belong the cant well divisions, 9909, each on a territory of 235,000 square miles, in 29 communes. N. lat. 50° 15'. E. long. 3° 43'.

Quefnel, a town of France, in the department of the North, and chief place of a canton, in the district of Lille. The place contains 4022, and the canton 15,047 inhabitants, on a territory of 325,000 square miles, in nine communes.

**QUEST**

Quest, or Inquest, an inquiry, or inquiry, made upon oath of an impanelled jury. See Inquest, and Jury.

The word is formed from the French queste, search; of the Latin questum, a thing sought.

**QUEST**

In Quest, the seeking out of hounds, or the venting and winding of hounds. See Hound.

**QUESTEMBERT**

in Geography, a town of France, in the department of Morbihan; five miles W.S.W. of Rochfort. The place contains 3568, and the canton 13,118 inhabitants, on a territory of 257,000 square miles, in nine communes.

**QUEST**

Question, Questio, in Logic, &c. a proposition, which truth or a per son being inquisitive about, proposes by way of interrogation to another. Logical questions are variously distributed; the ordinary M in 2 division
division is into first or primary questions; as, Quid est? What is such a thing? And secondary, which arise out of the former; as, How is it?

Question, Quiddibilical. See Quiddibilical.

Question, in Law. The quæstio de jure is generally to be distinguished from the quæstio de facto.

Question is also sometimes used for torture; which see.

QUEST-MEN, persons chosen yearly in each ward, to inquire into abuses and misdemeanors, especially such as relate to weights and measures.

QUEST-MEN, in Ecclesiastical Law. See SIDESMEN.

QUESTOR, QUESTOR, formed a quadrum, seeking, searching, or collecting the revenues of the state, an officer in ancient Rome, who had the care of the public treasuries.

The quætorship, quæsture, is very ancient, as having been established under the kings, probably in the time of Romulus or Numa, or at least under Tullus Hostilus. Tacitus (Annal. xii. 22.) says, that the first quætor were elected by the people, 64 years after the foundation of the republic; but he is of opinion that they had, long before that period, been annually appointed by the consuls, and even by the kings. But this obscure point of antiquity is contested by other writers. Dionysius and Livy date the original of quætor about A. D. 269. Plutarch refers the institution to the time of Valerius Poplicola, when he allotted the temple of Saturn for the treasuries, and granted the people the liberty of choosing two young men for the treasurers. Afterwards, sive. A. D. 332, two others were created to take care of the payment of the armies abroad, of selling the plunder and booty, &c. for which purpose they generally accompanied the consuls in their expeditions; and they were distinguished by the name of pergrini from the other quætor, who assumed the title of urbani. This number continued till the entire conquest of Italy; and then, A. D. 439, it was again doubled. The four that were added reigned with the proconsuls and procurators, in the provinces, where they were employed in regulating the taxes and customs due to the state.

In the time of the republic, the senate appointed quætor in each province, to aish the proconsuls, as lieutenants or treasurers, in the administration of the revenues; but, under the emperors, there was properly but one quætor, or treasurer-general of the empire; those other inferior or subordinate quætor were then called affiliates of the quætor, adjudicatores quætorum.

The quætor's office was originally confined to the army. They paid the soldiers, and took charge of monies coming by spoil and plunder, &c.

At length there were new ones erected to reside in the city, and to receive the public money, taxes, tribute, &c. Their number was increased as the empire increased. Sylla augmented it to twenty; Julius Caesar to forty; some being nominated by the emperor, and others by the people. Tacitus (Annal. xi. 22.) seems to consider twenty as the highest number of quætor; and Dion (lib. xiiii. p. 374.) intimates, that if the dictator Caesar once created forty, it was only to facilitate the payment of an immense debt of gratitude. Under succeeding emperors their number was not fixed. Of these, two were appointed for the city, to take care of the public treasuries, and to keep the laws and decrees of the senate; the others pertained to the provinces and the armies.

The quætorship was the first office which any person could bear in the commonwealth, and might be undertaken at the age of twenty-four or twenty-five years. Accordingly, the quætorship was called the first step of honour, and the quætor, who were generally employed in the provinces abroad, affiliated to them severally by lot, no sooner returned from their provincial administration than they took their places in the senate; and from that time forward, from the rank of equestrians, or what we commonly call knights, became senators for life.

The youth and inexperience of the quætor, who entered on that important office in the 25th year, engaged Augustus to remove them from the management of the treasuries; and though they were restored by Claudius, they seem to have been finally disfranchised by Nero. In the provinces of the imperial division, the place of the quætor was more ably supplied by the procurators, or, as they were afterwards called, "rationalis." But in the provinces of the senate we may still discover a series of quætor till the reign of Marcus Antoninus. From Ulpius we may learn, that under the government of the house of Severus, their provincial administration was abolished; and in the subsequent troubles, the annual, or triennial elections of quætor, must have naturally ceased.

There was also another kind of quætor, called quætori parcticidio, whose office was to enquire into, and take cognizance of capital crimes, after the consuls were denied this privilege.

QUESTOR facri palatii, or of the sacred palace, was one of the first dignities under the emperors of Constantinople.

It was this quætor that subscribed the receipts of the emperor, and the answers to the petitions and supplications presented to him. He also drew up and signed the laws and constitutions which the emperor thought fit to publish; and took care of the administration of justice.

Some compare his function to that of our lord high chancellor. It was usually one of the jurisconsults that was charged with this office; it being required, that he should know the laws of the empire, to be able to prescribe and fee them executed, and judge of causes brought by way of appeal before the emperor.

Constantine was the first who created quætor of the sacred palace.

QUESTUS, or QUESTUS. See QUESTUS.

QUESTUS est nullis, a writ of naushe, which, by statute, 15 Edw. 1. 1. it against him to whom a house, or other thing, that breeds a nuisance is defended, or alienated; whereas before that statute, the action lay only against him who first levied, or caused the nuisance, to the damage of his neighbour.

QUETIF, JAMES, in Biography, a learned French Dominican monk, was born at Paris in the year 1618. He embraced the monastic profession among the preaching friars when he was not more than 17 years of age, and having completed his philosophical course at Paris, he was sent by his superiors to Bordeaux, where he studied divinity, and received the orders of a monk. He died in 1658.

He died in 1658.
work entitled "Scriptores Ordinariae Preieatorum, cum 
notis Historici," which was completed by father Echard.

QUETREVILLE, in Geography, a town of France, in 
the department of the Channel; six miles S. of 
Constances.

QUETTEHOU, a town of France, in the department 
of the Channel, and chief place of a canton, in the 
district of Valognes; nine miles N.E. of Valognes. 
The place contains 1291, and the canton 14,956 
inhabitants, on a territory of 150 square miles, in 
18 communes.

QUETTENBRUN, a town of Austria; eight miles E. of 
Laab.

QUETZ, a town of Saxony, in the circle of Leipcifc; 
two miles S.S.E. of Zorbig.

QUEVACAMPS, a town of France, in the department 
of Jemappe, and chief place of a canton, in the 
district of Tournaï. The place contains 955, and the 
canton 10,264 inhabitants, on a territory of 107 
quarters, in 15 communes.

QUEVAUILLERS, a town of France, in the departmen 
t of the Somme; eight miles S.W. of Amiens.

QUEVE, in Commerce, a wine measure used in some 
parts of France. A queue of Champagne contain 384 
pintes of Paris, or about 95 English gallons; a queue 
of Burgundy contains 432 pintes of Paris, or 107 English 
gallons.

Queue, Fr. tail, as applied to the heads of musical notes; 
the minim is the only white note with a tail to it, and 
the crotchet the first black note with a tail to it.

Queue, in Heraldry, the tail of a beall.

If a lion has a forked tail, he is blazoned by double-
queue.

Queue d’Aronde, q. d. swallow’s tail, in Fortification, 
a term applied to outworks, when narrower at the gorge 
than at the face or front; i.e. where the sides open towards 
the champain, and contract towards the gorge. The name is 
occasionally by its resemblance, in figure, to a swallow’s tail; 
which the French call queue d’aronde.

Of this kind are some fingle as well as double tennials; 
and some horn-work whose fides are not parallel.

On the contrary, when the fides are less than the gorge, 
the work is called contre queue d’aronde.

Queue d’Arondo, in Carpentry, a method of joining, 
called also dove-tail.

QUEVEDO DE VILLEGAS, Francisco, in Biography, 
a celebrated Spanish writer, was born at Madrid in 1570.

He became distinguished at an early period for his literary 
attainments, and obtained the honour of knighthood, but 
dinding his satirical vein too freely against the administra-
tion of count d'Olivarés, he was thrown into prison, from 
whence he did not make his escape till the disgrace of that 
minister. He died in the year 1645, at the age of 75. 
He is regarded by his countrymen as having attained to a con-
iderable degree of excellence in most of the different kinds of 
composition. His herautical poems are faid to be charaterized 
by energy and spirit; his lyricl by sweetness and beauty; 
and his humorous poems by cafe, pleasantry, and ingenious 
invention. His printed works fill three vols. 4to. of which 
two are occupied by poetry and one by prose. The former 
were collected by Joseph Gonzales de Salas, who illustrated 
them with notes and dissertations. They were published in 
1650, at Madrid, under the title of "Il Parnasso Espanol."
The humorous pieces of Quevedo have rendered his name 
well known in foreign countries, and have been translated 
into the English and other languages.

QUEVILLE, in Geography, a town of France, in 
the department of the Lower Seine; three miles W. of 
Rouen.

QUEULEN, a river of Chili, which runs into the Pacific 
ocean, S. lat. 39° 16'.

QUEYPO, a town of Mexico, in the province of Coila 
Rica, near the Pacific ocean.

QUEYRAS, a town of France, in the department of the 
Higher Alps; 12 miles S.E. of Briançon.

QUEYTOR, a name sometimes given to the river Are, 
at Deal to that part which runs between Are and Prom.

QUI, in Rural Economy, a common term frequently 
applied to the female of the cow kind of animals while in 
the young state. It is the most generally employed in the northern 
parts of the country. See Why.

Qui-Calf, a name usually made use of in the northern 
parts of the island, to signify a female or heifer calf. See Why-Calf.

Qui Tam, in Law, is used where an information is exhib-
ted against any person on a penal statute at the suit of the 
king and the party who is informer, when one part of the 
penalty for breach of the statute is to be given to the king, 
the poor, or to some public use, and the other part to the 
informor or prosecutor; and the party informing prosecuted 
for the king and himself. The suit is called a qui tam action, 
because it is brought by a person, "qui tam pro domino rege, 
&c. quam pro se ipso in hac parte sequitur." If the king, 
therefore, himself commences this suit, he shall have the 
whole forfeiture. (2 Hawk. P.C. 268.) But if any one 
hath begun a "qui tam" or "popular" action, no other 
person can prosecute it; and the verdict passed upon the defendant 
in the first suit is a bar to all others, and conclusive even to 
the king himself. This has frequently occasioned offenders 
to procure their own friends to begin a suit, in order to 
forestill and prevent other actions; which practice is in 
some measure prevented by a statute made in the reign of a 
prince very sharp-minded with regard to penal laws, viz. 
4 Hen. VII. c. 20.; which enacts, that no recovery, otherwise 
than by verdict, obtained by collusion in an action popular, 
shall be a bar to any other action prosecuted bona fide. A 
provision, says judge Blacklone, that fees borrowed from 
the rule of the Roman law, that if a person was acquitted of 
yany accusation, merely by the preservation of the acquittal, 
a new prosecution might be commenced again him. Ff. 47.
15. 3. See Information.

QUIA, in Logic. See Reason.

Quia dominus remittit curiam, in Law. See Recto.

Quia captoris, a denomination given to the statute of 
Wilm. 3. 18 Edw. I, which directs, that upon all fales or 
collations of land, the feoffor shall hold the fame, not of 
his immediate feoffor, but of the chief lord of the fee, of 
whom such feoffor himself held it; and hence it is held that 
all manors existing at this day must have existed by immemo-
ral prescription, or at least ever since this statute was made; 
for no new manor can have been created since that statute; 
because it is essential to a manor, that there be tenants who 
hold of the lord, and that statute enacts, that for the 
future no subject shall create any new tenants to hold of 
himself.

Qui impoveriti, a superfeoda granted in many cufes where 
a writ is erroneously fixed ou, or misjudged.

Such is that granted in behalf of a clerk of the chancery 
fixed against the privilege of the court, in the common pleas, 
and pursed to the exigent.

QUIADKOUA, in Geography, a town of Prussia, in 
the province of Bartenland; nine miles S.E. of Allersburg.

QUIBBLETON, a town, or rather a village of Ameri-

THE UNITED STATES OF AMERICA.
QUIBERON, a fortified town of France, in the department of Morbihan, and chief place of a canton, in the district of L'Orient, situated at the extremity of a peninsula, to which it gives name, opposite to the island of Belle Île; remarkable for an unfortunate expedition of English troops and emigrants against France, in the year 1705; 17 miles S.E. of Port Louis. The place contains 1916, and the canton 5618 inhabitants, on a territory of 95 kilometers, in three communes. N. lat. 47° 90'. W. long. 3° 2'.

QUIBO, a small island on the outer part of the bay of Panama; it is uninhabited, but affords wood and water for shipping.

QUIBONDO, a small island in the Indian sea, near the coast of Africa. S. lat. 8° 8'.

QUIBOR, a town of South America, in the government of Caracas; 15 miles S.W. of Segovia Nuova.

QUIBURI, a town of New Navarre; 20 miles S.S.E. of Cafa Grande.

QUICAPOUX, a river of America, which runs into the Missipi, N. lat. 43° 4'. W. long. 92° 5'.

QUICARO, a town of New Navarre; 150 miles S.S.E. of Cafa Grande.—Allo, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 54'. W. long. 82° 42'.

QUICI, in Entomology, a species of the cerambyx, mentioned by Maregrave.

QUICK, in Gardening, a term applied to signify any sort of young plant, but especially those of the white-thorn kind. By it is also often understood a live hedge, but more properly the shrubs of which such live hedge is formed. In a strict sense it is, however, applied to the crataegus oxyacantha, or hawthorn, the young plants or fets of which are commonly sold by the nursery gardeners under the name of quicks.

In the choice of these fets, those which are raised in the nursery are in general to be preferred to such as are drawn out of the woods, as the latter have seldom good roots; many persons, however, prefer them, as they are larger plants than are commonly to be had in the nursery. See CRATEAGUS.

QUICK. See MEDLAR and PYRUS.

QUICK-BOOM. See PYRUS, and SERVICE-TREE.

QUICK-BOOM, in Planting, a name given in some places to the tree usually known by the title of mountain-ash. It has been recommended as useful for forming fences, in some cafes, by Dr. Anderson, and others. Where it is employed in this way, the plants must be kept down to the proper height, by being cut over as often as there may be occasion; and thus encouraging them to throw out lateral branches in a greater abundance, and, of course, induce the fence to become more close and thick in its lower parts. By these means a tolerably perfect hedge may be raised, from plants of this fort, in situations where the white-thorn will not succeed in any proper manner.

QUICK-HATCH, in Zoology. See Ursus Lusus.

QUICK-HEGGS, in Agriculture, a name given to all such as are raised from quicks, or any other sort of living plants. The proper forming and planting of quick-hedges have hitherto been much too little attended to by the farmer, as it is a matter of great importance, and which interests him in a very high degree. Whatever fort of plants may be employed for this purpose, the work should constantly be well performed in the first infancy, and the hedges and plants afterwards kept in order and regularity by suitable pruning, cutting in, and other proper management. There is a great number of different methods of raising and making hedges of this kind, as by planting the fets on the plain surface, or the mould a little raised above it, or on mounds, formed by the fods and mould dug up in the line of the hedge, elevated to different considerable heights; by setting the plants out in one row only, in double ones, or sometimes in a still greater number; by putting them in, in straight lines, in irregular manners, in the triangular form, or in the quincunx method. They are sometimes cut over at certain heights, at others not cut down at all; the fides are also in some cafes clipped or cut in, but in others this is avoided altogether. When planted on banks, they are mostly cleaned and moulded up annually.

A great variety of different sorts of plants is employed in forming and constructing these hedges, as those of the hawthorn, the black-thorn, the crab-tree, the hazel, the willow, the beech, the elder, the poplar, the alder, and several other kinds, according to particular circumstances and situations. And on the exposed coasts, or shores of the southern parts of the kingdom, a new fort of shrub or plant has lately been recommended for this use, which is that of the tamarisk, or tamarix gallica, as it thrives rapidly, it is said, when planted in situations most exposed to the blast or stroke of the sea; forms an admirable shelter, and being of quick growth, soon comes to answer the end designed. The writer of the agricultural report of the county of Cornwall has known a hedge of it, which he has been told was planted about seven years ago, and the bushes, apparently cannot be less now than from ten to twelve feet in height, and are feathered to the very bottom. It thrives well about the Lizard, bears cutting perfectly well, and in exposed situations, where it might be injured if left to grow high, may be kept close and low to much advantage. It unfortunately, however, will not stand the frost, and should never be attempted, of course, in situations exposed to the severe effects of it. The propagation of it is by cuttings, which take root without any difficulty. It is supposed that this shrub was brought by the monks from Normandy to Mont St. Michael in the above county, and thence spread to other parts. See HEDGE, and QUICKSET HEDGE.

The quick-hedges of this country are in a very great degree raised from the white-thorn, which unquestionably forms the cheapest and most durable kind, where the nature of the soil, situation, and other circumstances are favourable for the purpose. It will not, however, flourish in bad land, in exposed situations, where the bottom is wet and springy, or where the growth of weeds is very abundant. In all such cafes other kinds of plants are therefore had recourse to in the formation of them.

In many upland districts beech-hedges have been planted to considerable extents, and found, when kept under proper management, to be very handiome, and of great service in such exposures. Birch-hedges have likewise been tried in different cafes, and found to grow remarkably fast, even in cold bare tilly foils, but they require to be cut over at the time they are about four feet in height and carefully plated. Both these sorts of hedges have this in their favour, that they will grow in very poor soil as well as in very exposed situations; and both will flourish and grow strongly where the white thorn cannot live. Their want of prickles, however, is a great objection to them in this view: but they afford good shelter.

Quick-hedges constitute the ordinary fort of fences in this country, and unles in particular situations, and for particular purposes, are the most proper and eligible. It has been
been observed by the writer of a late work, that in parts which have been long inclosed without arable cultivation, hedges, of seemingly great age, are met with, which are many times crooked, ragged, and irregular, as though they had been, in the first instance, formed and laid out from the wild underwood of such places. While in other cafes, low plants of the various coppice kinds rise and grow on dikes or mounds but little raised above the surface of the land, seemingly as though they had formerly been collected from brush-woods and replanted on such banks, in somewhat the same manner as is full practiced on higher banks in particular districts towards the well, and in South Wales. But taking the country at large, the method of raising quick-hedges by setting grown plants taken from such situations, has long ceased to exist and prevail as a general practice; young plants of white-thorn, or other forts, set out in the bank and ditch mode with a low protecting dead fence on the side contrary to the ditch at first, is the plan commonly had recourse to, such plants being first raised in small grounds for the purposes in regular rows, and not taken, as formerly, from brush-woods and waste commons.

Quick-Lime, in Rural Economy, such lime as is in the caulicle or moist active state, and which possesses the greatest power of operating upon different sublimes with which it may come in contact. It is quite the opposite in its qualities and properties, to that which has fallen down into a powdery state, in consequence of being saturated with water and carbonic acid gas, or fixed air, or which is flaked and become effete. Its powers, when applied upon land in this condition, have already been noticed in speaking of lime. See Lime.

But it possesses qualities and properties in the way of a cement, the utility of which for building, for various domestic purposes, properly belong to this place. According to Dr. Anderfon, lime is in the belt and moist fit state for this use when the most perfectly caulicle, or in the most crystallizing condition. It is remarked, that the powder of lime, when reduced by means of water into a thin or fluid fort of paste-like form, and then suffered to become dry, fortes into a coherent mass, which fixes to ftones and other rough bodies in a very firm manner, and in this way becomes a proper cement for building any fort of walls. And that, after this paste material has once become firmly dry, it is quite indifoluble in water, and incapable of ever being softened again by the moifure of the atmosphere or other similar caufes. Hence it excels many other forts of cements.

When compofed for the purpose of building walls, &c., it is usually denominated mortar; but when formed as an application in the way of a smooth coating upon any plain surface without intermixture with flony matters, it is commonly here termed plaster.

When made from the lime of the purer fort of lime-flone, it is found to be more soft and crumbling, and to acquire a lefs degree of hardnefs, and to be broken with much lefs force, than where the lime-flone from which it is made contains a large proportion of fand, in which cafe it becomes much more hard, firm, and durable.

It has, however, been difcovered that the pureft lime may be rendered a firm cement by adding a proper proportion of clean hard fand to it; hence the practice of blending fand with lime, when intended for mortar, has become fo universal. This is fully fhewn to have been very early the cafe, by the olden lime-built walls which are now to be met with.

It nevertheless still remains a defideratum to afcertain the due proportion of fand which is neceflary, as both writers and practical masons greatly difagree in opinion on this matter, as well in their directions about the mode of mixing the materials, as of applying the cement; some of the more-modem, especielly, afcribing extraordinary effects to a fmal variation in these particulars, while others deny that these circumstances have any fensible effect on the durability and firmnefs of the cement.

It is conceived that these different and contradictory opinions arise from an imperfect knowledge of the nature of quick-lime, and the variations it may admit of; for these variations are fo very great, as to render it impoffible to afford any general rules that can possibly apply in all cafes. It is, therefore, conceived to heve those who are defirous of acquiring any confident and fatisfactory knowledge on this head, to endeavour to afcertain, in the first place, the circumstances which render calcareous sublimes of all capable of becoming a cement, and then to trace the feveral changes that may be produced upon it by other extraneous caufes.

Having explained the circumstances which caufe the differences in lime-flone, and pointed out the different confituent principles of it, as well as various other peculiarities; it is fated that lime, which has in any way abfolved its full qunntity of air from the atmosphere and become mild, is altogether unfit for becoming a cement, and that, of course, it is evident, that a great change may be produced upon the quality of any lime, by having allowed lefs or more of it to be in this flate before it is worked up into mortar. And further, that if a large quantity of water be put to fresh falted quick-lime, and beat up with it into a thin fort of paste, the water dilolves a fmall proportion of the lime, which as it gradually absorbs its air, is converted into cryftals; between the particles of which cryftals, that part of the lime which was not dilolved, and the other extraneous matters which may have been mixed with it, are entangled, fo as to form a firm coherent mafs of the whole. And that the paffy sublimes formed in this manner, is the well-known article mortar; and this heterogeneous, imperfectly femi-cryftallized mafs, constitutes the common cement employed in building ordinary walls or other ereftions. These circumstances, therefore, being known, it is thought that it will not be difficult to comprehend what are the particulars that are neceffary to form the molt perfect cement of this nature. That fince lime becomes a cement only in confequence of a certain degree of cryftallization taking place in the whole mafs, it is sufficiently obvious that the firmefts and perfeftion of that cement must depend upon the perfection of the cryftals; and the hardnefs of the matters that are entangled among them; for if the cryftals are ever fo perfect and hard of themselves, if they be separated from one another by any brittle incoherent medium, it is evident that the whole mafs must remain in fome degree brittle and incoherent. That as water can only dilolve a very small proportion of lime, even when in its molt perfect caulicle or caulicle state, or while it remains deprived of its carbonic acid gas, and as happens in other fimilar cafes, no more of the lime can be reduced to a cryftalline mafs than has been actually dilolved in the water; it happens of course, that if mortar be made of pure lime and water alone, a very fmall proportion only can be dilolved by that fmall quantity of water that is added to it; and as this fmall proportion alone can afterwards be cryftallized, all the remaining undifolved particles of the lime will be entangled among the few cryftals that are formed. And as the undifolved lime in this mafs will in time absorb its air, and be converted into mild calcareous earth without having had a fufficiency of water to allow it to cryftallize, it muft concrete into a firable mafs exactly refembling chalk; it follows, that this kind of mortar,
tar, when as dry as it can be made, and in its highest degree of perfection, will always be soft, and easily crumbled into powder.

But that, if, instead of forming the mortar of pure lime alone, a large proportion of sand be added to it, the water will in this case dissolve as much of the lime as in the former; and the particles of hard sand, like flitches or threads, when making sugar-candy, or other crysals, while surrounded by the watery solution, will help to forward the crysallization, and render it more perfect than it otherwise would have been, so as firmly to cement the particles of sand to one another. And as the granules of sand are perfectly hard of themselves, so as not to admit of being broken down like the particles of chalk, it necessarily follows, that the cement made of these materials must be much more perfect in every respect than the former.

After considering a variety of circumstances in regard to the solubility of lime in water, and its crysallization, it is remarked, that when a large quantity of sand is mixed in the mortar, that sand will of course bear a great proportion to the whole mafs; so that the water that may be mixed with the mortar will be much greater in proportion to the quantity of lime contained in this mortar, than if the whole had consisted of pure calcareous matter. And that, as the sand absorbs none of that water,—that water, now pure, is at liberty to act once more upon those few particles of calvick lime that may still remain in the mortar, which will be dissolved and converted into crysals in their turn. In this way it may happen, in some circumstances, that a very large proportion of the lime may become crysallized; so that the mortar will consist almost entirely of sand enveloped in crysalline matter, and become in due time as hard as stone itself; whereas mortar, consisting of pure lime, without sand, can hardly ever be much harder than chalk. It is not, however, to be supposed, that in any case this dried mortar will assume that transparent crysalline form, or the compact firmness of some sorts of calcareous matters, such as marble and limestone. In mortar, in spite of the utmost care that can ever be taken, a very considerable quantity of the lime must remain undisolved; which undisolved lime, although it may be so much separated by the sand and crysalline lime-stone as not much to affect the hardness of the mortar, yet it must still retain its white chalk-like appearance. As marble and lime-stone are, however, always formed by those particles of lime that have been wholly dissolved in water, and from which they have been gradually separated by a more slow and more perfect mode of crysallization, they have nothing of that opaque calx-like appearance, but diffuse other colours, and appear more firm, uniform, and compact; the sand and other matters that may be enveloped in them being entirely surrounded with a pure crysalline matter.

But to obtain the most perfect kind of mortar, it is not, however, enough that a large proportion of sand should be employed, and that the sand should be intimately mixed with the lime; it is also of the utmost importance that a large proportion of water be added; for without this it is impossible that a large proportion of the lime can be crysallized; and the mortar, in that case, would consist only of a mixture of chalky matter and sand, which could hardly be made to unite at all, and would be little more coherent than sand by itself, and less so than pure chalk. In that case, pure lime alone must afford rather a firmer cement than lime with sand. It is also of very great importance that the water be retained as long in the mortar as possible: for if it be suddenly evaporated, it will not only be prevented from acting a second time upon the lime, after a part of what was first dissolved has been crysallized, but even the few crysals that would be formed when the water was suddenly evaporating, would be of themselves much more imperfect than they otherwise most certainly would have been. In proof of which, instances of the crysallization of common salt, lump sugar, and sugar-candy, are adduced; after which it is noticed, that every one knows what a difference there is between the firmness of the different substances; and that as great must be the difference between the firmness of that cement which has been slowly dried, and that which has been hastily hardened by the powerful action of a warm air.

It is contended, that it is owing to this circumstance that the lime, which remains all winter in a mortar tub filled with water, is always found to be much firmer and more coherent than the mortar that was taken from the same tub and used in any work of masonry, although in this case the materials were exactly the same. From the same cause, any work cemented with lime under water, if it has been allowed to remain undisturbed and uninjured until it has once become hard, is always much firmer than that which is above the surface of the water.

In order to render the force of the above reasoning more strong and convincing, lime cement or mortar is compared to a mafs of matter consisting of a congeries of floes closely compacted together, and united by a strong cementing matter that had, while in a fluid state, pervaded all the interfaces between the floes, and afterwards become a solid indifusible substance. If the cementing matter be exceedingly hard and coherent, and if the floes bedded among it be also very hard and firm, the whole mafs will become like a solid rock, without fissures, that can hardly be broken to pieces by the power of man. But, although the cement should be equally firm, if the floe, of which it consists, be of a soft and friable nature, suppose chalk or sandstone, the whole mafs will never be capable of attaining such a degree of firmness as in the former case; for when any force is applied to break it in pieces, although the cement should keep its hold, the solid matter cemented by it would give way, and the whole would be easily broken to pieces. Whereas in mortar, the sand that is added to it represents the floes of a solid matter in the composition, the particles of which are united together by the lime which had been formerly dissolved, and now crysallized, which becomes an exceedingly solid and indifusible concretion. And as the particles of sand are of themselves exceedingly hard, and the cement by which they are united equally so, it is plain that the whole concretion must be extremely firm, so as to require very great force to disunite any particle of it from the whole mafs. But if, instead of employing sand, the only solid body that is entangled among the cementing matter should be chalk, (as in all cases where the mortar consists of pure lime alone,) or any other slightly cohering substance, let the cementing particles of that composition be ever so perfect, it is impossible that the whole can ever attain a great degree of firmness, as these chalky matters will be easily broken afunder.

It is remarked, in addition, that a variety of conjectures have been made about the nature of the lime cement employed by the ancients. It has been thought that they polished an art of making mortar, which has been long since entirely lost; as the cement in the walls which have been built by them, appears to be, in many cases, much firmer than that which had been made in modern times. Yet, when the mortar of these old buildings is analyzed, it is found to consist of the same materials, and nearly in the same proportions, in which they are now made use of,
And it is thought probable, that their only secret consisted in mixing the materials more perfectly than the rapidity or avarice of modern builders will permit, in employing their mortar in a much more fluid state than is done now, and in allowing it to dry more slowly, which the inmoderate thicknes of many of their walls would naturally produce, without any preconcerted design on their part. Tradition has even handed down to the present times the memory of the most essential of these particulars; as the lower classes of people, in every part of the nation, at this moment invariably suppose and believe that these old walls were composed of a mortar so very thin, as to admit of its being poured, like a fluid, between the stones, after they were laid in the wall; and the appearance of these old walls, when taken down, seems to favour this popular tradition. Nor is it doubted but that this may have been the case. The stones in the outer part of the wall, it is thought, were probably bedded in mortar nearly as is practised at present; and the heart, after being packed well with irregular stones, might have the interstices between them entirely filled up with fluid mortar, which would inhere itself into every cranny, and in time adhere as firmly as the stones themselves, or even more so, if the stones were of a handy friable nature. And that, as these walls were usually of very great thickness, it might often happen, that the water in this mortar, by acting successively upon different particles of caustic lime, would at length be entirely absorbed by successive crystallizations, so as to become perfectly dry, without any evaporation at all; in which case, a very large proportion of the original lime must have been regularly crystallized in a slow and tolerably perfect manner, so as to attain a firmness little inferior to lime stone or marble itself.

It is supposed that, upon these principles it is easy to account for the superior hardness of some old cement, when compared with that of modern times, in which a practice very different is usually followed, without having recourse to any wonderful arecons whatever.

Monseur Loriot, a late French writer, imagined that he had made a perfect discovery of the way in which the ancients employed their quick-lime, so as to obtain such an extraordinary firm cement; from which discovery, he conceived, very important benefits might be derived to society. According to his opinion, the ancient cement consist of lime and sand nearly in the same proportions as are commonly employed for that purpose at present. But instead of making it of flaked lime entirely, as is done now, he contends that they employed a certain proportion of their lime unflaked, which they mixed with their mortar immediately before it was used. And it is further noticed, that this newly discovered cement dries and hardens almost under the hands of the operator, without cracks or flaws of any sort; that it neither expands nor contracts with the air; and that it is impervious to moisture, and may not only be employed for making roofs of houseth which are subjected to continual drooping of water, basins, aqueducts, canals, &c., which will instantly contain water in any quantities, but even finer works of the pottery kind; that it perfectly refrains fruits, and has a variety of other interesting qualities. The trials of Dr. Anderson with the same sort of materials do not, however, confirm the great certainty and utility of this discovery. “That such effects as the writer describes,” says the doctor, “will invariably be produced, merely by adding a certain proportion of unflaked lime in powder to mortar, or even by making the mortar entirely with powdered quick-lime, I may without hesitation venture to deny, not only from the reasoning that has been given, but from actual experiment, again and again repeated by myself; and which is likewise, in some measure, corroborated by the experience of Mr. Dolfie.’’

On these accounts, it is supposed, that if Monseur Loriot, has really experienced these uncommon effects from the mortar he has tried, it must have been occasioned by some other unobserved peculiarity, and not merely by the circumstance to which he seems to attribute it. Possibly the doctor supposes the lime he employed may have been impregnated with a gypsum, or the sulphate of lime, as is probable, for many reasons. The effects and qualities of which, as to becoming a fine powder, and of suddenly setting, are well known, but it never acquires the flaky hardness that lime cement is sometimes endowed with, although it takes the smoothest polish of any cement we know: on which account, it has long been employed as a plaster where fine ornaments are required.

There are unquestionably, however, many doubtful and mysterious circumstances connected with this matter, which require the aid of further trials and experience in their full explanation.

There are still further a few other circumstances that may influence the quality of common lime-mortar. If lime-stone be sufficiently calcined, it is deprived of all its moisture, and of all its carbonic acid gas, or fixed air. But experience shows, that lime-stone will fall to powder on the effusion of water upon it, when it is much less perfectly calcined, and while it still retains almost the whole of its fixed air. And that as masons have hardly any other rule for judging whether lime-stone be sufficiently calcined, except this single circumstance of its falling to a powder when water is poured upon it, it may thus easily be perceived, that the same lime may be more or less fitted for making good mortar, according to a circumstance that, in a great measure, eludes the observation ofoperative masons; for if it should happen that all the pieces of lime drawn from a kiln at one time, were sufficiently calcined to make it fall to a powder with water and no more, that powder would be altogether unfit for making mortar of any kind. This is a case that can seldom happen: but as there are a great many intermediate degrees between that state and perfect calculation, it must often happen that the stone will approach nearer to one of these extremes at some time than at another; so that the mortar may be much more perfect at one time than at another, owing to a variation in this particular.

All those who have written on the subject of lime as a cement, have endeavoured to ascertain what is the due proportion of sand for making the most perfect cement. But a little attention to the matter will shew, that all rules, which could be prescribed as to this particular, must be so vague and uncertain, as to be of little utility to the practical mason; as besides the variation which may arise from a more or less perfect degree of calculation above it, it is a certain fact, that some kinds of lime-stones are much more pure, and contain a much smaller proportion of sand than others do; some being found almost perfectly pure, while others contain eleven-twelfths of sand and all the intermediate proportions of it. Therefore it would be absurd to lay that pure lime would require as small a proportion of sand when made into mortar, as that which originally contained in itself a much larger proportion of sand than any writer has ever ventured to prescribe for being put into mortar.

Besides, there are differences caused by the different nature of the calculation in the different sorts of lime-stone, from which it may, upon the whole, be concluded, that...
about one-tenth of pure lime-flone is not enough calcined to admit of being made into mortar; and that of the most impure forts of lime-flone, not above one-fourth part of the lime contained in it is so much calcined as to be in a cauful state.

The variation that is produced by these means in regard to the proportion of sand that will be required to the lime in the one or the other case, is found to be extremely great as hardly to be conceived. It is, however, stated, that the belt mortar that has been seen made, was formed of lime which had been found to contain eleven parts of sand to one of lime; to this there was added between twelve and threc its whole bulk of sand by measure; which may be allowed to have been at least three times its quantity by weight. Therefore, supposing that every particle of that lime had been so perfectly calcined as to be in a caulcious state, there could not be less than forty-four parts of sand to one of lime. As much may, however, be allowed for the uncaulcious part of the lime as is pleased, and the calculation made accordingly. But it is hardly possible to suppose that above one-hundreth part of this mats, independent of the water, conflitl of pure cauful caulcious earth.

On these considerations it is conceived, that it is impossible to prescribe any determinate proportion of sand to lime, as that must vary according to the nature of the lime and other incidental circumstances, which would form an infinity of exceptions to any general rule. But it would seem that it might be safely inferred that the moderns in general rather err in giving too little sand, than in giving too much. It deferves, however, to be noticed, that the land, when naturally in the lime-flone, is more intimately blended with the lime than can possibly be ever effected by any mechanical operation; so that it would be in vain to hope to make good mortar artificially from pure lime, with such a small proportion of caulcious caulcious matter as may sometimes be effected when the lime naturally contains a very large proportion of sand. But there seems to be no doubt, that if a much greater proportion of sand were employed, and if that were more carefully blended and expeditiously worked than is common, the mortar would be much more perfect than is usual in modern times, as has been proved by actual trials.

Another circumstance that tends greatly to vary the quality of cement, and to make a greater or smaller proportion of sand necessary, is the mode of preparing lime before it is beaten up into mortar. When for plaster, it is of great importance to have every particle of the lime-flone flaked before it is worked up; for, as smoothness of the surface is the most material point, if any particles of lime should be beaten up in it, and employed in work before sufficiently fallen, the water, still continuing to act on them after it was worked up, would infallibly flake such particles, which forcibly expanding themselves, would produce those excrescences on the surface of the plaster commonly termed blisters. Consequently, in order to obtain a perfect kind of plaster that will remain smooth on the surface, and free of blisters, there is an absolute necessity to allow the lime to lie for a coniderable time macerating or soaking in water, before it is worked up. And the same sort of proceed is necessary for the lime when intended for use as mortar, though not to absolutely. Great care is, however, required in the management in this respect; the principal things being the getting of well-burnt lime, and then allowing it to macerate or soak with the water for only a very short time before it is used; but that which is the best burnt will require the maceration of some days in the water before it is sufficiently flaked in the whole mats for this purpose. See Souring Lime for Mortar and Plaster.

It has been almost universally admitted, that the hardest lime-flone affords a lime that will consolidate into the firmest cement; and hence generally concluded, that lime made of chalk, produces a much weaker cement than what is made of marble or lime-flone. It would seem, however, that if ever this be the case, it is only incidentally, and not necessarily so. As from the nature of caulcious matter, every kind of lime is equally fit for becoming a firm cement, if it be first reduced to a proper degree of caulcious, and has afterwards a due proportion of sand properly mixed with it, before it be employed in work. Different forts of lime, without doubt, differ much from each other in the proportion of sand they naturally contain, and, of course, require very different proportions of sand to be added to them before they can be made equally perfect as a cement; which is an economical consideration, of so small a matter in some cases, as it may make one fort of lime a great deal cheaper than another on some occasions, and, of course, deserves the attention of builders in general. See Lime.

The excellencies and defects of other substances that may be occasionally mixed with lime in making cement may be justly noticed. Those commonly used as an addition to mortar, besides sand of various denominations, are powdered sand-flone, brick-dust, and sea-shells. And for forming plaster, where clofeness rather than hardnes is required, they are lime that has been flaked and kept long in a dry place, till it has become nearly effete, powdered chalk or whiting, and gypsum in various proportions; besides hair and other materials of that nature. But some others have been more lately advised, such as earthy balls, lightly burnt and pounded, powdered and sifted old mortar rubbish, and others of a similar kind. All of which substances are found objectionable in some respect or other for this use, sand being the only perfectly suitable material that can be easily met with; on which account it has been always justly preferred. Pure firm crystallized sand is the best, but all pure sands are not equally proper in this intention. See these substances respectively. See also Cement and Sand.

It is stated by Sir Humphry Davy, in his work on "Agricultural Chemistry," that there are two modes in which lime acts as a cement; in its combination with water, and in its combination with carbonic acid. When quick-lime is rapidly made into a paste with water, it soon looses its softness, and the water and the lime form together a solid coherent mass, which consists of nineteen parts of water, to fifty-five parts of lime. When this hydrate of lime, while it is consolidating, is mixed with red oxide of iron, alumina, or silica, the mixture becomes harder and more coherent than when lime alone is used; and it appears that this is owing to a certain degree of chemical attraction between hydrate of lime and these bodies; and they render it less liable to decompose by the action of the carbonic acid in the air, and less soluble in water. It is thought that the basis of all cements that are used for works which are to be covered with water must be formed from hydrate of lime; and that the lime made from impure lime-flones answers this purpose very well. Pozzolana, it is said, is composed principally of silica, alumina, and oxide of iron; and it is used mixed with lime, to form cements intended to be employed under water. It is stated that Mr. Smeecon, in the construction of the Eddyton lighthouse, used a cement composed of equal parts, by weight, of flaked lime and puzzolana. Puzzolana, it is said, is a decomposed lava. Tarras, which was formerly imported in considerable quantities from Holland, is found
to be a mere decomposed basalt: two parts of flaked lime and one part of tarras form the principal part of the mortar used in the great dykes of Holland. It is supposed that sublimes which will answer all the ends of puzzolana and tarras, are abundant in the British isles. An excellent red tarras may be procured in any quantities from the Giant's Causeway, in the north of Ireland: and decomposing basalt is abundant in many parts of Scotland, and in the northern districts of England in which coal is found.

It is observed that Parker's cement, and cements of the same kind made at the alum-works of lords Dundas and Mulgrave, are mixtures of calcium, ferruginous, silicious and aluminous matter, with hydrate of lime.

It is noticed, that the cements which act by combining with carbonic acid, or the common mortars, are made by mixing together flaked lime and sand. These mortars at first solidity as hydrates, and are slowly converted into carbonate of lime by the action of the carbonic acid of the air. It was found by Mr. Tennant, that a mortar of this kind, in three years and a quarter, had regained sixty-three per cent. of the quantity of carbonic acid gas, which constitutes the definite proportion in carbonate of lime. The hardening of the mortar in very old buildings is also thought to depend upon the perfect conversion of all its parts into carbonate of lime. The purest lime-stones are the best adapted, it is said, for making this kind of mortar. The magnesian lime-stones make excellent water cements, but act with too little energy upon carbonic acid gas to make good common mortar. The Romans, on Pliny's authority, made their boil mortar a year before it was used; so that it was partially combined with carbonic acid gas before it was employed, it is supposed.

It is likewise suggested, in regard to the cultivation and improvement of land by means of this material, that quick-lime in its pure state, whether in powder, or dissevered in quick-dolphins, is injurious to plants; grafs in several instances having been killed by watering it with lime-water; but that lime, in its state of combination with carbonic acid, is an useful ingredient in soils. Calcereous earth is found in the ashes of the greater number of plants; and exposed to the air, lime cannot long continue calciferous, but soon becomes united to carbonic acid. That lime, when combined with about one-third of its weight of water, constitutes hydrate of lime; and that it becomes carbonate of lime by long exposure to the atmosphere, the place of the water being supplied by carbonic acid gas. On mixing freshly burnt or flaked lime with any moist fibrous vegetable matter, a strong action occurs between them, and they form a sort of compost, part of which is commonly soluble in water. In this way, lime renders matter, before comparatively inert, nourishing; and from charcoal and oxygen, abounding in vegetable matter, it becomes converted into carbonate of lime at the same time. Lime, or powdered calcereous sublimes, have no action in this way on vegetable matter; by their operation they prevent the too quick decomposition of bodies previously dissevered; but do not tend to form soluble matters. Consequently it is clear that the operation of quick-lime and mild calcereous sublimes, depend upon wholly different principles. The former, on being applied to land, tends to bring the hard vegetable matter contained in it into more rapid decomposition and solution, as a proper food for plants. The latter only improve the texture of it, or its relation to absorption: it is merely an earthy ingredient. Quick-lime, in becoming mild, has a similar action, but while taking on that state, prepares soluble out of insoluble matter. On this depends the operation of lime in the preparation for wheat crops, its efficacy in fertilizing peas, and in bringing into cultivation all sorts abounding in hard roots, dry fibres, or inert vegetable matter. The question, of course, whether quick-lime should be applied to land or not, depends on the quantity of inert vegetable matter it contains; and that whether mild lime, marls, or powdered lime-stones, should be used or not, on the quantity of calcareous matter already in the land. All sorts of land are improved by mild lime, and ultimately by quick-lime, which do not suffer with acids; and the sandy sorts more than the clayey kinds.

In land deficient in calcareous matter, but containing much soluble vegetable manure, the use of quick-lime should constantly be avoided, as tending either to decompose the soluble matters, by uniting to their carbon and oxygen in becoming mild, or to combine with the soluble matters, and form compounds with less attraction for water than the pure vegetable sublimes. The same is the case in regard to most animal manures; but its operation is different in different cases, according to the nature of the animal matter. On the whole, it should however never be employed with animal manures, except when too rich, or for preventing noxious effluvia. It is hurtful in mixture with common dung, and tends to produce insolvency in the extractive matter. It is useful in mixture with simple vegetable barks, &c.

The solution of the question about the utility and disadvantage of magnesian lime, which has lately been found useful in small quantities on the poorer lands in Leicester-shire, as from twenty-five to thirty bushels the acre, and in larger ones, on the rich soils; it is supposed to depend upon that fort of lime having a less attraction for carbonic acid than the other, in consequence of the portion of that sublimes in it, and thereby remaining longer in the caustic state; and its becoming sooner a carbonate of lime in the rich than in the poor soils. Magnesia, while in the caustic state, is poisonous to certain kinds of plants, and acts so in the mixture as lime. It may be usefully applied in large quantities to peat-earths; and to lands injured by too much of this fort of lime, peat-earth will be a proper and effectual remedy, when used in a suitable proportion.

More full information may be met with on this curious and interesting subject in the first volume of Anderson's Essays on Agriculture and Rural Affairs, in Duffie's Memoirs of Agriculture, vol. ii. and in Sir Humphry Davy's "Agricultural Chemistry."
to the nutrition of the crops over which they are sown. The proportions in which they are used to the acre over the clover, and occasionally the wheat crops, are from fifty to one hundred bushels. They are suppoed to be very servicable to the two clover crops, and greatly beneficial to the succeeding wheat one, by some persons; but others are of quite the contrary opinion, thinking them of very little use to the wheat, except by increasing the quantity of the clover. They are also useful in defraying mofs in the surface of grass lands. They are to be kept dry, and commonly sown over the crops in November or January in mild moist weather.

In Oxfordshire, peat-ales are made use of from about twelve to forty bushels upon the acre; and those of coal from sixteen to upwards of fifty. They are sown over the wheat, clover, savin, and turnip crops, the coal being somewhat the bolt on the clovers, and the peat on the turnips.

In Berkshire, peat-ales are used very generally for most sorts of crops, except wheat, barley, and peas, either sown with the seeds and harrowed in together, or sown on the land as a top-dressing, only; but they are more preferred for all sorts of artificial grass crops, and natural meadow and pasture gracies, as well as turnips. The quantities employed are from fifteen to twenty bushels and upwards on the acre. They are applied in March or April, severer acres being capable of being sown in the course of the day. They only last about a couple of years in the land. The ashes of bean stubble are likewise found beneficial herabout, bringing up white clover when put upon the grass lands.

Different sorts of ashes have been found very useful on the grass lands in Sussex, at the rate of from twenty to thirty bushels on the acre, employed as a manure.

In Essex coal-ales are laid upon the clover, savin, and grass crops to the quantity of sixty bushels on the acre or more, with very great effects in promoting their increase.

In the county of Hertford they manure for turnips and some other crops with rabbit and poultry dung, at the rates of from fifty to sixty bushels or more on the acre, with good success. And in some part of the Oxford district, pigeons' dung is found an excellent manure when thrown over the young barley crops, mixed with that of poultry. In Essex, too, it is found beneficial for promoting seed when sown over the rape or cole crops in the proportion of eight bushels to the acre.

There are several other articles which are occasionally thrown over crops on the surface of the lands as a manure, in this intention, such as those of the dust of malt, rape-cake, bones, plaster of Paris, and some others. Malt-duff is made use of on wheat and barley in many parts of the county of Oxford, and one or two other sorts of crops, being sometimes a very forcing manure, and at the same time lifting. The plaster of Paris has been used on clover, savin, lucern, and other crops with immense effect, in some parts of Oxfordshire, town over them about March, to the quantity of six bushels per acre. But in Sussex, in the proportion of eight bushels to the acre, when town over natural grass, bean, potatoe, pea, and barley crops, it had not the least good effect. Nor even when tried on other sorts in the quantity of six bushels to the same extent of land.

Powdered oil-cake that has been spoiled by keeping, is an excellent application as manure in the above way. The same is also the cafe with chopped tanpers' hair, which has been found superior in this use to either malt-duff or any sort of calcareous matter. Horn-irnings are likewise very beneficial when laid on in this manner to grass lands, in the proportion of from fifty to one hundred bushels to the acre, lasting five or six years, and being of very easy carriage they should be employed in damp weather about February or March. See MANURE.

All these different sorts constitute excellent quick forcing manures, when applied in some of these ways for some of the above purposes, and should be much more generally employed in such methods than is at present the case.

QUICK Match, in Artillery, is formed of three cotton strands drawn into length, and dipped in a boiling composition of white wine vinegar, salt petter, and meal powder. After this immersion, it is taken out hot, and laid in a trough where some meal powder, moistened with spirits of wine, is thoroughly incorporated into the twills of the cotton, by rolling it therein: thus prepared, they are taken out separately and drawn through meal powder, and then hung upon a line to dry. There is also quick match made of wrought instead of cotton. For its use, see Fire-Ship. QUICK with Child, in Law. See Reprieve.

QUICK Pulse, in Medicine. See Pulse.

QUICK Sand, in Sea Language, denotes a loose quaking sand, into which a ship sinks by her own weight, as soon as the water retreats from her bottom. See QUICKSand.

QUICK Thorn, in Agriculture, a name frequently applied to young plants of the hawthorn or white-thorn kind, which are fit for being planted out for the purpose of forming a hedge-fence. See QUICKS, and QUICKSET.

It also signifies this fort of thorn generally. QUICKEN TREE, in Gardening, the common name of a tree of the ornamental fruit kind. See SOURS.

QUICKENING, in Midwifery, the first perception women have of the motion of the fetus. This usually happens in the third or fourth month of pregnancy. It has puzzled physiologists to explain why the motion of the fetus should not be perceived earlier, as it is endowed with life from the first moment of conception. But, besides that the parts of the fetus are too soft and tender to affect the uterus by its motion, the membranes enveloping it are too thick, and there is then a proportionally smaller quantity of fluid in the ovum than afterwards, which keeps the embryo from touching the sides of it. The uterus also during this period is confined in the cavity of the pelvis, which being of small capacity, and every way surrounded with bones, leaves little room for the motion of the fetus. But as soon as the uterus emerges into the cavity of the abdomen, it readily yields to the motion of the included fetus, and the parts by which it is now surrounded being extremely delicate and senile, they are affected by the slightest stirring of it. In some women of delicate habits, the moment of quickening is marked by a slight hysteric paroxysm. In these cases it seems probable, that the uterus has flapped suddenly into the abdomen, but ordinarily it rises slowly and gradually, whence the shock on the bowels is so inconsiderable, as scarcely to make any sensible impression. See CONCEPTION.

QUICKING-DRAG, in Agriculture, a name sometimes given in different districts to the couch and quick drag. See DRAG.

QUICKLOCK, in Geography, a town of Sweden, in the Lapmark of Lutea; 15 miles N.W. of Lutea. N. lat. 67° 20'. E. long. 15°. QUICKS,

QUICKS,
QUICKS, in Agriculture, a name commonly given to the young fets of the white-thorn, which are wied in planting hedges of that fort. See Quickset-Hedge.

It is thought to be indispensably necessary to the success of this fort of fets, as hedge plants, in every situation, that they be well provided with roots and root fibrils of the healthy kind, by Mr. Nichol, who has had much experience upon the subject. And that this is well secured by taking them from a eminuity of rich mould at the end of the first or second year, according to their strength; and nursing them, after that, likewise in rich earth, for one or two fasons longer at the farther, but, in the latter case, removing them into fresh rows at the end of the firm year. It is contended, that plants of this age, and thus treated, will outgrow those of greater size in any fort of foil or situation. This has been repeatedly proved by impartial trials; and the caufe, it is supposed, is obviously this, that small plants, even by the same treatment, are raised with better roots, in proportion to their fizes, than large ones. Therefore in the choice of quicks, regard should be had to the roots, not the tops of the plants. Their being buried the fteafon previous to their being removed for hedging pur-poses, in rich meadow earth, and being allowed a sufficiency of room, kept clear of weeds and other matters, is the best mode of preparation, it is imagined, that can possibly be adopted.

There is, however, it is maintained, a double advantage in making use of young plants of this nature. They are cheaper and fitter for exposed situations than those of older growths; not becaufe their tops are less bulky, which, fince they are to be cut over about half their lengths before being planted, is immaterial, but becaufe they have better proportioned roots to the fize and strength of the ftems, and of course are better fitted to fck palurage for their common fulence and support.

The ftems of the plants, as has been fuggéted above, should be cut over about half their lengths; or, in general, about fix inches above the ground mark: an operation which may be performed by the common hedge fhears, a large fharp knife; or by gathering a handful of them evenly, and laying them upon a block or other fimilar body, and chopping them off by means of a hatchet. They should always be carefully raifed, and even the fmalleft fibre be retained. And at all times, until replanted, the roots should be exposed as little as possible to the air or atmofphere.

See Quickset.

Quicks is alfo a term sometimes applied to the weed called couch-gras, in different places, and which is of a very troublesome nature, not being extirpated out of the land without much difficulty. See Couch.

QUICKSAND, any fort of spot or bed of running land, either near to the surface of the foil, or at any depth below it, which has a finking quaggy feel under the foot at certain times or fenas, in conquenice of containing certain proportions of water. The writer of the work on "Landed Property" has remarked, that they are for the moft part topical, and in general only temporary, commonly appearing in and after wet fenas only; clothing and becoming firm when their fupplies of moisture are ex- hasted by long drought. In these fenas the surfaces are free from the depofition of the moory earth of bog plants, which demand a conflant coohiefs, if not a perpetual fupply of moisture, being caufed by heads or small beds of fand or gravel rifing through thinner strata to the surface. They are of course apt to be fearchd in dry hot fenas. In order to remove them, the fame writer advises, that the centre of the part which is affected should be marked out when the fcafon is wet, in order that a drain may be cut, when it is dry, of a fufficient depth quite up to the mark, letting it have the neceafary defcent, and then filling it with suitable materials to admit of the water being conveyed off as it is collected in the sub-foil. When the defect has been thus removed, where it is situated in the area of a feld, it is a good practice to cover the part by foil of the fame nature as that of the feld where it is situated, by bringing it from thofe parts which are the moft elevated, as by this means it may be rendered of an uniform quality with the reft, and of course have a better appearance, as well as be more ad- vantageous in the growth of crops.

Dangerous tracts and spots of this nature are frequently found in marhy and fandy lands, which are occasionally covered by the tides. And large deep beds or layers of quick or running land are often met with in digging pits, quarries, mines, and other forts of shafts, to great depths under the ground, and caufe much trouble and difficulty in getting on with fuch kinds of work, on account of the quantities of water which they contain and let pass off into them: thus occasioning the neceafity of much difficult drainage, and other inconveniences. See Quarrries, Fists, &c. Draining of.

QUICKSAND Bay, in Geography, a bay on the weft coaft of North America. N. lat. 45° 50'. W. long. 124°.

QUICKSET, in Agriculture, a term generally applied to the white, or hawthorn plant, the fets or young plants of which are raifed by nurferymen for fale, for the purpofe of planting and forming hedge-fences. The roots of the thorn will, however, anfwer equally well, and in fome cafs much better, as there is a certainty of their being of the right fort, or fuch as have prickers upon them, which does not always happen in using the quickfets, as they are liable to difappear when raifed in this method, but which is never the cafe in the root-mode. See Fence-Thorn, and White- Thorn.

Young plants of the quickfet kind are built raifed in small portions of ground fent apart for them; in which, after they are come up from the bed to fome height, they fhould be transplanted in lines at narrow diftanies, in a ftraight man- ner, with small intervals between the rows; where they are to remain from three to five years or more, being annually well cleaned and moulded up. Some, however, transplant them more than once, and think it an advantageous way, but they do well in either method. Well grown plants, with flout clean ftems, are the moft proper for planting out as hedge plants.

Quickset Hedge, a name given to all forts of hedge-fences which are conqituted of any fort of living plants; but more especially of thofe of the white-thorn kind. Hedges of this nature compofe the principal fences of this country. In the drier and better forts of foil, thofe of the thorn kind generally prevail; but in moft other situations, thofe of fome other forts of plants, according to the particular nature of the foils and expofures. The quicks or quickfets of the thorn forts are commonly fuppofed to form the beft hedges, when planted in the railed bank or dike method. The manner of placing them out in thefe, is different in different cafs, both in refpect to the form and number of the rows, as well as the diftanies of the plants from each other. Some think one regular or irregular row the moft proper, others prefer two ftraight ones; and fome fuppo- fe a few inches diftance from plant to plant the moft benefi- cial; while others think eight or nine inches to be much better. Strong well-grown quickfets are commonly pref- ferred in all cafs. It is remarked in the Elfix Report, by one of the perfons engaged in drawing it up, that in the
parish of Birdbrook, in the north-east part of it, "some excellent hawthorn hedges have been lately raised, by planting one row only at six inches asunder, rather than two rows nine inches or a foot apart. The hedges have not been cut down, nor do they require it, to thicken their bottoms, as they are, at this time, a complete protection against hogs, and in other respects form a beautiful and effectual fence. Nothing can be more evident, it is thought, than that a row of plants set thus, . . . six inches distant from each other, will form a more complete and effectual fence at the bottom, than an equal number planted thus, . . . at a double distance, and occupying the fame length, but a greater depth of ground upon the hedge row." This reasoning of Mr. Vancouver's, Mr. Young observes, may, for aught he certainly knows, be conclusive, but it strikes him in a different light. It is true, that the plants in each row are, in the latter mode, at double the distance from each other than they are in the former; but it is to be observed, that in the double row, the plants are diagonally as near each other as in the single row, and, consequently, there is the same vacant space for any animal to pass through in the single row as in the double; and what must be a great advantage to the latter, the plants will shoot out their branches laterally on the outside at least, just as far as those in the single row, and twice as far lengthwise, meeting with no obstruction in their progress. Of course, it is naturally to be concluded, that the double-rowed plantation must form a fence, if not altogether twice as strong and secure, yet vastly stronger and securer than the single one. He does not, however, prejudice to fet speculation against fact, as he has not seen the hedge noticed above, while Mr. Vancouver has. He has, however, himself planted one in a single row, as above described and recommended; the plants have grown well; the hedge is a good one, but would, he thinks, have been still better, if there had been two rows instead of one, as some others are that he has of that description.

In Suffolk, the quickset hedges at Goodwood are capital, and deferving of every attention, being railed and trained in a most mellerly manner. The duke of Richmond planted them about eighteen or twenty years ago. They surround a very commodious farm, and are in a wonderful state of preservation. They form an excellent fence, without the affilence of any ditch, bank, rail, or pale; composed of three rows of white-thorn plants, which spread three or four feet at bottom, but are clipped regularly and gradually to a thin edge at top; their shoots are four inches, and trained with such care, that even in winter, without a leaf, the thicknes is uncommon. By the young hedges now in training, it appears that one method pursued has been to plant the centre row first, and when that is well established, to add another on each side of it; at least this is done in these new hedges. They are kept in a state of garden cleanliness; the branches are drawn into the line defined, by being tied with mat, or other lines, and the clipping done with the exactest attention; the union of the hedges with the gate-polls is close and perfect, and as to gap, &c. there is no such thing. How they have been preferred from cattle, but especially from sheep, is marvellous, if either are ever allowed to enter these clofs; — an attention never ceasing, and a boundless expense, so far as necessary, must have been exerted. They cannot be recommended to the imitation of farmers on account of this expense and expence of them, but they are beautiful as an object to the farming eye, and for their perfection, they merit all that can be said of them.

On the Walburton farm in the same district, there are some very good quickset hedges, which were planted about twenty-three years ago; the quick was set about two inches asunder, and single; they are cut twice in a year; are four and a half feet high, and two feet thick. There is very little ground roll by the hedge, as it occupies only four feet. The same excellent fort of quickset hedges has also been made in some other places.

Here two rows of white-thorn plants are common, which are put on the bank of the ditch, care being taken not to have them too near it, for fear of its draining them too much and preventing their growth.

In some districts, where the cultivation is principally of the arable or tillage kind, and in exposed upland situations, there is frequently a great prejudice and objection to the introduction and formation of any fort of hedges, whether of the quickset or any other description, as they take up much space, harbour birds and insects, greatly shade the grain, and tend to promote blight, rust, and mild-w, by preventing the free circulation of air. Alfo in bleak exposures they are not railed without great difficulty. Such objections, however, speedily vanish where they are kept sufficiently low and well cut in and trained on the sides. See Hedge and Fence.

QUICKSILVER, a very ponderous fluid mineral, by the chemists called mercury. For the method of gaining, preparing it, &c. with its properties, uses, &c. see Mercury.

Quicksilver, when rubbed down and blended with unctionous matters, forms a fort of ointment, which is useful in healing of different diseases of the cuticular kind, as well as in delrying lice and other vermin that infect animals of different kinds, which form the live-fock of the farmer.

It has also been stated on the authority of Mr. Bradford, as communicated to the Society for the Encouragement of Arts, &c. to have been found useful in its crude flate in destroying insects on fruit trees. On a plum-tree he made the following trials: he took a small awl, and pierced, floping, through the round, and into part of the wood of the branch, but not to the heart or pith of it; and poured in a small drop or two of the quicksilver, and flopped it up with a small wooden plug, made to fit the orifice; and the result was, he says, that the insects all drop off from that very branch the next day; and in a day or two more, from off the other branches of the tree, without any other puncture: and the tree continued in full vigour, and threw all the summer after. Encouraged by this success, he next tried it upon a honey-fuckle, the leaves of which were quite covered with them; and here he scraped away the top of the ground with a trowel, and run his awl, in the same flaping manner, into the main joint, just above the roots; but with the fame caution as above, not quite to the inner pith; and the fucces was the fame as before. The insects all drop off dead the next day after the experiment was made.

These trials are said to have been confirmed by other experiments; but they are still in want of full and satisfactory confirmation.

QUICKSILVER, Virginia. See Virgin.

QUICKSILVER Water. See Water.

QUICKSTADT, in Geography, a town of Norway, in the province of Aggerhus; 42 miles N. of Christiania.

QUICK-WORK, in a Pipe, is a general name given to all that part of a fhum which is under the surface of the water; when she is laden fit for a sea-voyage. The term is also applied, occasionally, to that part of the side which is above the lower rail, and which is usually painted with trophies, &c. on the outside. Falconer.

QUICK-WORK is likewise applied to the strakes that fhit in the inside, between the spiritting and clamps.
QUID, What, in the Schools, is used to denote the definition of a thing.
It is thus called, because the definition answers to the question, quid est? what is it?
Hence we have two kinds of quids; nominal, quid nominis; and real, quid rei.
Quid juris clamat, in Lat. a writ that lies where I grant the revocation of my tenant for life by fine in the king's court, and the tenant will not attain; then the grantee shall have this writ to compel him.
This writ seems to be obsolete, since the fourth and fifth of Anne. See ATTORNEMENT.
Quid pro quo, q. d. what for what, denotes the giving one thing of value for another; or the mutual consideration and performance of both parties to a contract.
Quid pro quo, or Qui pro quo, is also used, in Physic, to express a mistake or cheat of an apothecary, in administering one medicine for another; or in using an ingredient in a composition different from that prescribed.
A northern physician, in a printed thesis on quid pro quo's, owns ingenuously, that they are very frequent. He distinguishes very accurately a great variety of kinds of quid pro quo's; some with regard to the operation, others with regard to the subject; and others with regard to their form, or effects. The first comprehends the quid pro quo's of the physician; the second, those of the patient; the third, those of the apothecary.
Quid Loff, a term which signifies the loss of the ruminant power in animals of the live-bone kind. It is mostly produced by local weaknesses of the stomach, caused by eating improper coarse kinds of food in too large quantities, or other similar means. It may be belled relieved by the use of strong acids of the vegetable and other kinds, and its return prevented by strong bitter infusions, as those of gentian, bark, &c. See CUD.
QUIDDEINEN, in Geography, a town of Prussia, in Oberland; 6 miles S. E. of Holland.
QUIDDENY, Quiddany, (of the Latin cydonium, or cydoniata,) a confluence of quinces, called also marmalade.
QUIDDITY, Quidditas, in the Schools, a word of the fame signification with essence.
The name is derived hence, that it is by the essence of a thing that it is tale quid, such a quid, or very thing, and not another. Whan upon seeing, or hearing, the name of a thing, with whose nature, &c. we are unacquainted, we ask, Quid est? What is it? We mean no more by the interrogation, but that we desire to have its nature and essence explained by a definition. Whence quiddity is usually defined the essence known or expressed in a definition.
And hence what is essential to a thing is fals to be quidditive; as quidditive knowledge, &c.
QUIEBOU, in Geography, a town of France, in the department of the Channel; 6 miles S. W. of St. Lo.
QUICH, Michael Le, in Biography, a learned Dominican monk, who flourished in the latter part of the 17th and in the 18th century, was born in the year 1661. He received a liberal education, having been instructed in classical learning at his native place, and he was then sent to study philosophy at the college du Plessis, at Paris. At twenty years of age he determined to renounce the world, and took the habit in a Dominican convent. Here he studied with uncommon industry and proportionate success, the Greek, Hebrew, and Arabic languages, criticism, divinity, the sacred scriptures, and ecclesiastical antiquities. In the year 1690 he first appeared as an author, by publishing "A Defence of the Hebrew Text and the Vulgate Version," against a work, entitled "The Antiquity of Time restored," written by father Pezron. The latter having published a reply, Quen answered in a work entitled "The Antiquity of Time exploded." He next attacked him in "Remarks," on his "Attempt at a literal and historical Commentary on the Prophets," printed in the Memoires de Trevoux, for March 1711. During the following year he published "S. Ioannis Damasceni Opera quae exstant Gr. et Lat." in 2 vols. fol. accompanied with dissertations aboundance. He intended to have given a third volume, containing such pieces as had been falsely attributed to that father, but it was never sent to the press. The same fortune has attended his labours on "The Works of Leo of Byzantium," to which he had paid a considerable share of attention. Towards the close of his life he entered into a controversy with father Courayer, concerning the validity of the ordination of the church of England, in which the palm of victory was given to his opponent. Le Quen died in 1733, at the age of 72 years, respected for his piety, and uniform correctness of conduct. He was author of various "Dissertations" to be found in Defmolets "Memoires de Literature et d'Histoire," and the "Mercure de France." At the time of his death he was engaged in printing the most considerable of his works, relating to the ancient and present state of the eastern churches. "His plan includes the whole of his churches, under the four grand patriarchates of Constantinople, Alexandria, Antioch, and Jerusalem; presents a geographical description of each diocese, and of the episcopal cities, and then gives a particular account of the origin and establishment of the churches, their extent, their jurisdiction, their rights, their prerogatives, the succession and order of their bishops, their political government, the changes which they have undergone," &c. As the author did not live to finish his work, it was published with additions, in the year 1749, under the title of "Michaelis le Quen Orients Christiani, in quatuor Patriarchatus digelatus, qua exhibitur Ecclesiæ Patriarchæ, ceterique Prefules Orientis," &c. in 3 vols. fol. Morey.
QUIENFIORD, in Geography, a bay on the coast of Norway; 72 miles N. of Christianland.
QUIENS, a river of Norway, which runs into the sea, 18 miles N. of Cape Lindesfæns.
QUIESCENT, something at rest.
QUIETISM, in Ecclesiastical History, the sentiments of the Quietists, a religious sect, which made a great noise towards the close of the 17th century.
Melinos, a Spanish priest, who died at Rome in the prison of the inquisition, praised for the author of Quietism; and yet the Illuminato Spain had taught something like it before.
A sect similar to this had appeared at Mount Athos, in Thessaly, towards the close of the fourteenth century, under the appellation of Hesychasts, which denotes the name with Quietists. These were a branch of the Mytics, which see, or those more perfect monks, who, by a long course of intense contemplation, endeavoured to arrive at a tranquility of mind entirely free from every degree of tumult and perturbation. These Quietists, in conformity to an ancient opinion of their principal doctors, who imagined that there was a celestial light concealed in the deepest retirements of the mind,) used to fit every day, during a certain space of time, in a solitary corner, with their eyes eagerly and immovably fixed upon the middle region of the belly, or navel; and basked, that, while they remained in this posture, they found, in effect, a divine light beams forth from the soul, which diffused through their hearts inexpressible sensations of pleasure and delight. To such as inquired what kind of light this was, they replied, by way of illustration, that it was the glory of God, the fame celestial radiance that surrounded Christ. 

QUI
Chrift during his tranfiguration on the mount. Barlaam, a
monk of Calabria, from whom the Barlaamites derived their
denomination, ftyled the monks, who adhered to this insti-
tution, Mallalians and Euchites: and he gave them also the
new name of Umbilicani. Gregory Palamas, archbishop of
Thebalfonia, defended their cafe againft Barlaam, who
was condemned in a council held at Constantinople in the
year 1341.

The name is taken from a fort of absolute refi, and inac-
tion, which the foul is supposed to be in, when arrived at
the flate of perfection, which in their language is called the
univefle life. To arrive at this, a man is fielt to pas through
the purgative way: that is, through a course of obedience, 
infpired by the fear of hell: hence he is to proceed into
the illuminative way, before he arrives at perfection.

The fentiments of the Quietifts, with regard to God, are
wonderfully pure and difinterested. They love him for him-
self, on account of his own perfedions, independently of any
rewards or punishments: the foul acquifes in the will of
God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-
fomuch that instead of diftinguifhing between the fentiments
of God, even at the time when he precipitates it into hell; in-

At length the foul, after long trial, enters into refi, into
a perfect quietude. Here it is wholly employed in contempl-
ating its God; it acts no more, thinks no more, desires no
more; but lies perfectly open, and at large, to receive the
grace of God, who by means thereof drives it where it will,
and as it will.

In this flate it no longer needs prayers, or hymns, or
vows; prayers where the spirit labours, and the mouth
opens, are the lot of the weak, and the imperfect; the foul
of the fain t is, as it were, laid in the cofin, and between the
arms of its God, where, without making any motion, or
exerting any action, it waits, and receives the divine graces.
It then becomes happy: quitting the eflence it before had,
it is now changed; it is transformed, and, as it were, funk
and swallowed up in the Divine Being, infomuch as not to
know or perceive it being diftinguifhing from God himfelf.
Fenel. Max. des Saints. QUIETISTS, the disciples of Mich. de Molinos; or
the adherents to the opinions delivered in the article
QUIETISM. The fentiments of Molinos were contained in a
book, which he published at Rome in the year 1681, under
the title of the "Spiritual Guide:" in confequence of which he
was cafely imprisoned in 1685, where he was fon obliged
to renounce, in a public manner, the errors of which he was
accused: and this folemn recantation was nevertheless fol-
lowed by a fentence of perpetual imprifonment, from which
he was in an advanced age delivered by death, in the year
1696. Molinos had a defirable number of disciples in
Italy, Spain, France, and the Netherlands. One of the
principal patrons and propagators of Quietifm in France,
was Marie Bouvieres de la Mothe Guyon, a woman of
fashion, remarkable for the goodnefs of her heart, and the
regularity of her manners; but of an unferetted temper,
and fubject to be drawn away by the feduftion of a warm and
unbridled fancy. This female apoifie of myfticism defirec
d all her ideas of religion from the feelings of her own heart,
and defcribed its nature to others as she felt it herfelf. Ac-
cordingly, her religious fentiments made a great noise in the
year 1687; and they were pronounced unfound, after ac-
curate examination by cveral men of eminent piety and learn-
ing, and proficiently confuted, in the year 1697, by the cele-
brated Boffuet. Hence arose a controversy of great mo-
mence, between the prelate laft mentioned, and Fenel, arch-
bishop of Cambray, who seemed difposed to favour the reli-
gious fylenm of Madame Guyon, and who, in 1667, publifhed
a book, cited in the lafl article, containing feger of her
tenets. Fenel's book, by the intereft of Boffuet, was
condemned in the year 1699, by Innocent XII. and the fen-
tence of condemnation was read by Fenel himfelf at
Cambray, who exhorted the people to reftpect and obey the
papal decree. Notwithstanding this fecting acquiffion, the
archbifhop perfifled, to the end of his days, in the fentimn-
ents which, in obedience to the order of the pope, he
retracted and condemned in a public manner. See the article
FENELON.

QUIETO, in Geography, a river of Iftria, which runs
into the Adriatic, two miles W. of Baffin.

QUIETUS, freed or acquitted, a term used by the clerk of
the pipe, and the auditors in the exchequer, in their
acquittances or discharges given to accompats, which
usually conclude with the words unabide receffis quietus; which
is called a quietus eff.

A quietes eff granted to a scholar, discharges him of all ac-
counts due to the king.

QUIIFORO, in Geography, a district of Africa, on the
Gold Coast.

QUIGNONES, FRANCES DE, in Biography, an eminent
Spanifh cardinal in the 16th centny, who embraced the reli-
gious life at an early age, in a monastery of Francisicans, and
fubfequently afforded fuch evidence of superior talents, that
he was elected general of his order in the year 1522. He ob-
tained the office of confessor to Charles V. and upon the cap-
ture of Rome by the imperial army in 1527, and the im-
perifnon of pope Clement VII. in the call of St. Angelo,
his fervices were solicited by that pontif, in negociating for
his liberty, and were afterwards rewarded with a cardinal's
hat. After this, he was by the fame intereft nominated
bifhop of Cauria, and fent in the capacity of apolloftical leg-
ate into Spain, and the kingdom of Naples. He died in the
year 1540. He was author of a reformed breviary
printed at Rome in 1536, which met with the approbation of
popes Clement VII. and Paul III. but it was afterwards
fuppressed by Pius V.; hence it has become fcarce, and is
fought after by collectors. Several fpurious editions have been
printed at different times. It is inserted in the "An-
nales Minores" of Wadingus, and in the second edition of
Joly's treatife "De Reformandis Horis Canonices."

QUIJJUBATUL, in Ornithology, the name of an Amer-
ic species of paroquette.

It is of the fize of a lark, and in general of a yellow co-
our. Its eyes are black, and its beak grey. The edges of
its wings are of a dusky green, and its tail long and yel-
low. It is a very beautiful bird, and very carly timid.
See Psittacus Guarinda.

QUIKNE, in Geography, a town of Norway, in the
province of Bergen; 105 miles N. of Christiana.

QUII, in Zoology. See Quirpele, and Viverra
Mungo.

QUILACUI, in Ornithology, the name given by the people of the Philiphine iflands to a very beautiful fpe-
cies of parrots, which is commonly found wild in the woods
there. It is all over of a fine green colour, and is smaller
than the common parrots, and has a broad black bill, and
black legs. It is a very wild bird, and will not learn any
thing.

QUILATE, in Spanish and Portuguese Coinage, a term
used for coro : which fee.

QUILEA, in Geography, a fea-port town of Peru, near
the Pacific ocean, which gives name to a fertile valley, in the
jurisdiction of Arequipa. S. lat. 16° 45'.

QUILICI,
QUILICY, Gaetano, in Biography, an Italian opera-singer, with a bale voice: a good musician, who arrived here in 1759, during the performance and opera regency of the Mattei. He continued to perform on our lyric stage near thirty years, and is, we believe, still living in London, we fear, in penury and obscurity. Since quitting the stage, he has supported himself, a bed-ridden wife, and an idiot son, by teaching to sing, and has made some admirable scholars.

QUILLIMAN, in Geography, a river of Africa, which runs into the Indian sea, 20 miles S. of Melinda. S. lat. 3° 16'. E. long. 46° 10'.—Alfo, a tea-port town of Africa, in the kingdom of Melinda, at the mouth of the before-mentioned river, belonging to the Portuguese. S. lat. 3° 10'.

QUILLAMANE, a town of Africa, in Mozambique. S. lat. 18° 15'. E. long. 37° 30'.

Female, Calyx five-cleft. Corolla none. Germens five, superior, opposite to the segments of the calyx. Styles five. Capsules five, coriaceous, of two valves, and one cell. Seeds numerous, oblong, inserted into the bottom of the capsule, dilated and winged at the summit.

Such is the character made out by Jullieu, from the publications of Molina and Frezier, and from specimens of the fruit, brought to Europe by Dombey. They belong to a tree, whose bark has a lofty quality. The leaves are alternate, simple, evergreen. Flower axillary.—The genus appears akin to the Magnolias of Jullieu, but whatever it may be, the name is barbarous and quite inadmissible; only tolerable for a time, till some botanist, furnished with better materials to define the genus, shall be entitled to give it a more classical appellation. Jullieu remarks, that another plant of Dombey's appears to belong to the above genus. This is a tree referred by him to Discica Geoffroidi, whose fruit is called Gaya colorado, and which is the name of the "Logus, or Peruvian tree with five capsules," of Joseph de Jullieu, whose branches, according to his manuscript account, are long and plant, as to be twinned into cords, serving, in the province of Cuzco, for the support of hanging bridges.

QUILLÌA, in Geography, a town of Chili, on the Aconcagua, 30 miles E.N.E. of Valparayo.

QUIRAN, a town of France, in the department of the Aude, and chief place of a canton, in the district of Limoux, 10 miles S. of Limoux. The place contains 1500, and the canton 9195 inhabitants, on a territory of 2743/4, square kilometres, in 22 communes. N. lat. 42° 52'. E. long. 2° 16'.

QUILLA-YACU, a town of Peru, in the diocese of Lima; 60 miles E.N.E. of Guanuco.

QUILLE, a town of Sweden, in West Gothland; 23 miles N. of Uddevalla.

QUILEGUÉ, a town of France, in the department of the Eure, and chief place of a canton, in the district of Pontaudemer, seated on the Seine; eight miles N. of Pontaudemer. The place contains 1200, and the canton 2722 inhabitants, on a territory of 1073/4 square kilometres, in 16 communes. N. lat. 49° 29'. E. long. 0° 38'.

QUILLET, Claude, in Biography, born at Chineu, in Touraine, about the year 1602, was brought up to medicine, which he practiced some years, till he was obliged to quit the country on account of his opposition to a measure of Richelieu, which is thus narrated. Quillet was at London at the time that Loubadement, a creature of the cardinal, was sent thither to take informations respecting the pretended perfidiousness of some muses by the forecuses of Urban Granier (see his article), an imposture which Richelieu thought fit to favour. The counterfeit Satan one day threatened, that on the morrow he would lift up to the roof of the church any one who should presume to call his power in question. A large company appeared on the next day with M. Loubadement, when Quillet, who also was present, challenged the devil to keep his word. To the surprise of the superstitious who had met on the occasion, nothing followed, but the challenger found to his cost that he had given offence to a mightier power than Satan, and felt it necessary to quit London in haste, and retire to Italy. He went to Rome, and was engaged as secretary to the French ambaffador at that court. He probably returned to France with that minister, after the death of Richelieu, and in 1655 he published at Leyden, under the name of Calvisius Lactus, the poem by which he is chiefly known, entitled "Callipedia, or pulchræ Proles habendi ratione." In the first edition were some farfical lines against Mazarin. The cardinal sent for him, and having gently remonstrated with him for treating his friends with levity, promised to give him the first vacant abbey. Quillet threw himself at the cardinal's feet, alked pardon, and assured him he would instantly obliterate the offensive lines, and begged, as a sign of his penitence, to be allowed to dedicate the poem to him. This was done in the Paris edition of 1656, and Quillet became the flatterer of him who had been the object of his satire. He died at Paris in 1661, repeating not of his adulation, but of the licentious call of some of his verses. The Callipedia has gone through many editions, and has been translated into various languages. "It is," says an able critic, "an ingenious performance, agreeably varied by fable and episode, but frivolous in its main topic, and in its reproofs. Its details are frequently loose and inflammatory, and that cardinal should have allowed it to have been dedicated to him, is a proof how little regard was paid, at that period, to the rules of decorum. The verification, though generally free and flowing, is by no means correct, and the fiction is frequently impure." Quillet composed a version of Juvenal in French verse, and a Latin poem in twelve books, entitled "Henriados," or the actions of Henry IV. This, with other papers, he left to Menage, with 500 crowns to defray the charge of printing them, but the abbe took the money, and neglected the conditions.

QUILLIGA, in Geography, a country of Africa, in Upper Guinea, near the river Majoalbarbary.

QUILLOBO, in Botany, a name given by fome to a species of ketmia, called allu quaquaboo.

QUILLOT, Killo, or Kilbo, in Commerce, a Turkish corn measure, weighing, in wheat, about 23 okes, or 60 lbs. airdroopus; 4 killos make 1 fortin; 82 killos answer nearly to 1 English quarter. A killo of rice contains 10 okes, and the oke is 400 drachmas.

QUILLOTA, in Geography, a town and jurisdiction of Chili. The town does not contain above 100 families, but those scattered over the country exceed 1000.

QUILLY, a town of France, in the department of the Lower Loire; 7 miles N. of Savenay.

QUILOA, a country and kingdom of Africa, situated near the salt coast, near the mouth of the Convo, about 180 miles from north to south; but the extent inland towards the west is unknown. This country was first discovered by the Portuguese, in the year 1498. The king and his ful-
jests are Mahometans; the latter partly black and partly tawny. They all speak the Arabic and several other languages, which they learn from the nations they traffic with. Their dresses is that of the Arabian Turks: the women especially affect finery, with variety of ornaments about their necks, arms, wrists, and ankles; particularly bracelets made of ivory, curiously wrought, which upon the death of a parent, husband, or near relation, they break in pieces, in token of sorrow, whilst the men express theirs by shaving their hair, and abstaining from food. The capital of the kingdom is situated on an island near the mouth of the Coavo, and is said to be large, rich, and well built. The houses are of stone and mortar, handsemde, and after the Spanish manner. They are several stories high, and have each a pleasant garden behind, well watered and cultivated, here being plenty of springs of fresh water. The houses are finely furnished within, and terraces on the top, with a kind of hard clay, and the streets so narrow, that one may easily step from one side to the other. On one side of the town is the citadel, where resides the Mahometan prince. It is adorned with flately towers, and surrounded with a ditch and other fortifications. It hath two gates, one towards the port, whence one may see the ships falling in and out; the other looking towards the land. The country about Quiloa, though low, is yet very pleasant and fertile in rice and millet, fruits and good pasture; so that they breed abundance of cattle, besides plenty of all sorts, both wild and tame. They have fhe like wife in great plenty, and very good. The climate is likewise affirmed by most travellers to be very temperate and healthy; Sanut being the only author of the climate who hath ventured to assert the contrary in all these respects. S. lat. 8° 35'.

QUILONE, a province of Africa, in the kingdom of Saba.

QUILOVIA, a small island in the Indian sea, near the coast of Africa. S. lat. 15°.

QUILTAINEN, a town of Prufia, in the province of Oberland; 8 miles S.E. of Holland.

QUITAO, one of the Laccadive islands, in the Indian sea. N. lat. 13°; W. long. 72° 45'.

QUIETING denotes the operation of weaving a sort of coat or texture, formed of the strands of rope, about the outside of any vessel, to contain water, \\

QUIMICHPATLAN, in Zoology. See Scirurus Vo-

QUIMINATIN, in Geography, a small island in the sea of Mindoro. N. lat. 10° 55'; E. long. 120° 46'.

QUIMIRI, a town of Peru, in the diocese of Lima; 40 miles N.E. of Nacfa.

QUIMO, a small island on the east side of the gulf of Bothnia. N. lat. 63° 17'; E. long. 21° 52'.

QUIMPER, a city of France, capital of the department of Finisterre, and chief place of a district, leated on the Oder; before the revolution the see of a bishop, the seat of a governor, an admiralty, \\

QUIMPERLE, a town of France, and chief place of a district, in the department of Finisterre. The place contains 4162, and the canton 9128 inhabitants, on a territory of 125 kilometres, in 15 communes.

QUIN, Dr., of Dublin, in Biography, an eminent physician, and one of the most enlightened dilettante musicians with whom we have ever been acquainted. This gentleman, who, during his travels, resided in Italy some years, had heard and studied music with such taste and intelligence, that his opinions and conversation on the subject were equally entertaining and instructive. He resided in Dublin at the time of Handel's arrival in that city, 1742, and perfectly remembering his performance, perfan, and manners, in 1745 wrote us this, that "Handel was received in Ireland by persons of the first distinction with all possible marks of esteem, as a man, and admiration as a performer and composer of the highest order." And adds, "the Messiah, I am thoroughly convinced, was performed in Dublin for the first time, and with the greatest applause. Mrs. Cibber and Signora Avolio were the principal performers. Thee, with the assistance of the choirmasters of St. Patrick's cathedral and Churh-church, formed the vocal band; and Dublin, with several good instrumental performers, composed a very respectable orchestra. There were many noble families here, with whom Mr. Handel lived in the utmost degree of friendship and familiarity. Mrs. Vernon, a German lady, who came over with King George I., was particularly intimate with him, and at her house I had the pleasure of seeing and conversing with Mr. Handel; who, with his other excellencies, was possessed of a great stock of humour, no man ever told a story with more. But it was requisite for the hearer to have a competent knowledge of at least four languages: English, French, Italian and German; for in his narrations he made use of them all."
frequently put up with for the sake of his companionable qualities. Quin died at Bath in 1766, at the age of seventy-three. Garrick, whose superior talents are supposed to have driven him from the stage, but afterwards his ready friends, wrote a poetical epitaph for his monument. While Quin continued on the stage, he constantly kept company with the most celebrated geniuses of the age. He was on intimate terms with Pope and Swift; and was frequently invited by the earl of Chesterfield to his table. His peculiar judgment in the English language recommended him to his royal highness, Frederic prince of Wales, who appointed him to instruct his children in speaking and reading with graceful propriety. When Quin was informed of the elegant manner in which his present majesty had delivered his first gracious speech from the throne, he was in raptures, and the king soon after gave orders, without any application on the part of Quin or his friends, that a genteel pension should be paid him during his life.

Quin, in Geography, a village of the county of Clare, Ireland, where are the remains of a monastery, which was founded for Franciscan friars in 1422, and repaired by the Roman Catholics in 1624. Bishop Pococke speaks of it as one of the finest and most entire monasteries he saw in Ireland. It is situated on a fine stream, with an ascent of several steps to the church; at the entrance one is surprised with the view of the high altar, entire, and of an altar on each side of the arch of the chancel. The building is quadrangular, with piazzas supported by a number of pillars; there are apartments on three sides of the cloisters, with a vaulted room under them all. A round tower and some other ruins are adjoining. Quin is 15 miles from Limerick, on the road to Galway, and about 100 miles W.S.W. from Dublin. Archdall's Monasticon. Carlisle.

Quina-Folia, in Botany. See Leaf.

Quinaburg, in Geography, a river of America, formerly called "Mobegon," which rises in Brimfield, Massachusetts, and is joined at Oxford by French river, which has its source in Sutton, Worcestershire. It runs a southerly course, and discharges itself into Shetucket, about three miles above Norwich Landing, in Connecticut. In the first part of its course it furnishes many good mills; as it advances, the intervals in many places are wide, and afford a most excellent foil.

Quina-Quina, in Botany, a Peruvian name, generally applied to the Peruvian bark. (See Cinchona.) Jullien, however, in his Gen. Pl. 366, informs us, that it properly belongs to a tree, nearly if not entirely agreeing in genus with Myroxylon of Jacquin, or Myroxylon of Linnaeus. (See the last-named article.) An account of the Quina-quina may be found in the Memoires de l'Academie des Sciences for 1738, p. 237.

Quinaria, so called by Loureiro, Fl. Cochinch. v. I. 272, from the prevalence of the number five in the parts of fructification, is the Wampi or Wampi of the Chinese, now established as a genus by the name of Cookia. (See that article.) This plant puffed long in the gardens of England, for Guarea trichillata, according to the observation of the late Mr. Dryander.

Quinarius, Quinary, in Antiquity, a little Roman coin, equal to half the denarius. See Coin. The quinarius was properly the Roman halfpenny. Medals indeed use the term quinarius in the general for a medal of any matter, not exceeding the size of our farthing; but F. Chamillart, in an express dissertation, shows this to be an abuse. The silver coins, current under the republic, he fluxes, were two: the one weighing a drachm, and called denarius, as containing ten ales; the other weighing half a drachm, and called quinarius, as containing five ales: which coins continued on the same footing under the emperors.

Hence the origin of the word quinarius: and hence, in propriety, it is only the silver medal of the weight of half a drachm that the same belongs to; the Romans having never given it to any other species of the same size with it. It is only by way of analogy, therefore, that the moderns apply it to the medals of gold, or copper, of the same size with the silver quinarius; those of gold being fixed at a value much above, and those of brass much below five ales.

The only relation between these quinaries is, that the gold quinarius is the half of a gold medal, as to weight and value; and the brass quinarius a half a brass medal, as the silver quinarius is half a silver one.

Hence a series of quinaries should seem at least a necessary in the cabinets of the curious, as the series of great medals; they being all equally different species of money, which teach us how many kinds of pieces there were of any metal current in commerce.

Add to this, says our author, that the quinaries were of a finer and more finished coin than the other medals, being wrought by the hands of the masters; which seems owing to the nicety required in engraving whole figures in so small a compass. He adds, that though quinaries are very scarce, yet M. the duke of Maine had almost a complete set of them.

Quinault, Philip, in Biography, a French poet, was born in 1636, probably in a low condition; though while some say he was the son of a baker, others maintain that he was descended from a family of consequence at Paris. He had, however, very few advantages of education, but was soon found to possess a talent for poetry and the belles lettres. Before the age of twenty he brought out some pieces on the stage; and for a number of years, he continued to produce dramatic works of different kinds, which were much applauded by the public voice; but some of which drew upon the author the fates of Boileau, who carried the matter so far as to injure his own reputation. Quinault now associated himself with Lulli in the composition of operas, and displayed an excellence in lyric poetry, or that adapted to music, which placed him beyond competition in that branch, and has ranked him among the distinguished characters of the age of Lewis XIV. Nothing, it is allowed, can be more tender, delicate, and ingenious, than the turn of his fongs and love-dialogues; and no one has more happily accommodated the melody of French verse to musical expression. His "Armida" and its "Atys" are spoken of as master-pieces of their kind. Notwithstanding the high reputation which he enjoyed as a poet, he applied himself to the study of the law, and eventually made his fortune by marrying the rich widow of a merchant, to whom he had been useful in his profession. After this, he purchased the place of an auditor in the chamber of accounts. He was received into the French academy, and, in the name of that society, harangued the king on his return from the campaigns of 1675 and 1677. He died in 1688, having enjoyed a pension from Lewis XIV, several years previously to his decease. In his last illness he was extremely penitent, on account of his having devoted his talents too frequently to the excitement of the licentious passions. He left a family of five daughters, and was esteemed in society attentive, polite, and mild. Besides his numerous pieces for the stage, he wrote occasional poems. His works were printed at Paris in 5 vols. 12mo., 1739, and again in 1778.
It has been said that Quinault's apprenticeship to poetry was served under Triilan F'Hermile, by being his domestic. The lefions of Triilan were probably of some use to him, as that author had had long experience in theatrical matters; but Quinault owed still more to nature: as before he was twenty years old, he had distinguished himself by several pieces for the stage, which had considerable success: and before he was thirty, he produced sixteen dramas, some of which were well received by the pit; but not all equally. It is supposed that some of these early pieces prejudiced Boileau against Quinault early in his career. There was neither regularity in the plan, nor force in the style; romantic lovers and common-place gallantry, in scenes which required a nervous pencil and vigorous colouring. These were defects not likely to escape the lafh of the French Juvenal. He covered the young poet with ridicule; reproached him with the affectedly soft and languishing dialogue of his lovers, by whom even I hate you was said tenderly.

Quinault, born with great sensibility, was so wounded by his severity, that he applied to the magistrates, not only to silence Boileau, but oblige him to remove his name from his fates; but the attempt was vain. His enemy insulted him still more cruelly by an epigram on the subject:

"Peace! peace! my friend—

If from the public thou'dst avoid disgrace,

From thy own works, not mine, thy name efface."*

It was not till after Quinault was inflamed by Lulli to write for the opera, that he silenced all his enemies, except Boileau and his party, who envied him his success. The French nation knew no better music that that of Lulli, and thought it divine. Quinault's was thought of secondary merit, till after his decease; and then, in proportion as the glory of Lulli faded, that of Quinault increased. Voltaire, in the first edition of his "Sicile de Louis Quotzorke," in 1749. seems to have been the first who spoke out on the subject; not forry, perhaps, to lower Boileau a little in the eyes of the public. He there says, that "Quinault was celebrated for his beautiful lyric poetry, and for the gentleness with which he opposed the unjust failures of Boileau. His poetry was greatly superior to the music of Lulli. It will always be read; and Lulli, except in a few of his recitatives, can no longer be supported. However, it was long believed that Quinault entirely owed his favour to Lulli. Time appreciates all things."

After this, his writings began to be examined and felt; and of late years, his name is never mentioned by his countrymen without elege. His operas, though admirable to read, are ill calculated for modern music; and are obliged to be new written, ere they can be new set, even in France. Marmontel, who had modernized several of them for Piccini to set in 1788, gave M. Laborde a dissertation on the dramatic writings of Quinault for music; which is published in the fourth volume of his "Essai fur la Musique."

He begins by ascertaining that Quinault was the creator of the French opera upon the most beautiful idea that could be conceived; an idea which he had realized with a superiority of talent, which no writer has since approached.

His design was to form an exhibition, composed of the prodigies of all the arts; to unite on the same stage all that can interest the mind, the imagination, and the senses. And this illusive theatre Voltaire has admirably described:

"Il faut fe rendre à palais magique," &c.

"Halte to the magic palace, where abound

The joys sublime of verfe, of dance, and found:

Where bright illusion fascinates the sight,

And firen-notes the enchanted ear delight;

Where all the plastic powers of art are shew'd,

And joys unnumber'd are combin'd in one."

For this purpose a species of tragedy is necessary, that shall be sufficiently touching to move, but not to suff er as to refuse the enchantments of the arts that are necessary to embellish it. Historical tragedy, in its majestic and gloomy simplicity, cannot be sung with any degree of probability, nor mixed with festivities and dances, or be rendered susceptible of that variety, magnificence, show, and decoration, where the painter and the machine ought to exhibit their enchantments.

In Italy, where genuine tragedy has no theatre appropriated to its use, a people passionate for music have permitted Regulus, Themistocles, Alexander, and even Cato himself, to utter their speeches in song; but a people, whose taste ought to be more severe, and more delicate, as to probability, having for comparison the school of Corneille and Racine, would have been very unwilling to sublimate the recitative of Lulli to the declamation of Baron. Melody itself is a fabulous and magical language; and in a theatre "where all is prodigy, it seems confident that the manner of speaking should be that of enchantment as well as the text. We are then in a new world: it is nature enchanted, and visibly animated by a crowd of intelligences, whose wills are laws. Music there plays a marvellous part; music there constitutes the probability of the marvellous; but in a representation where all pales for natural, according to truth and history, by what means can we be prepared to hear Augufus, Cornelia, Agrippina, or Brutus sing?" Might it not be replied, "By the same means as the French are reconciled to these fabulous characters conversing in rhyme."

When once it is settled that all the characters converse in a musical language, no other is expected, and the audience is soon reconciled to it. But all this is to prove that the French alone are right, and Italy and all the rest of the world wrong as to the musical drama. The rest of Europe is tired and ashamed of flying gods and goddesses, and have long since surrendered mythological wonders both in poetry and music to their children. But all people are thought barbarians, who do not implicitly adopt the taste and fashions of France.

But to return to Quinault, whom all the wits of the time tried to write down. Ignorant of music and its powers, they thought Lulli always right, and the poor, modest, unpertaining Quinault always wrong. Poettery has long discovered the converse of this supposition to be the truth. Quinault's great mistake and misfortune, says La Harpe, was the calling his pieces tragedies, and not operas. He would not then have been regarded as a rival of Racine, or have offended classical hearers or readers with the little semblance these compositions had to Greek and Roman dramas, or to the genuine tragedies of the moderns.

QUINCE Tree, in Gardening, the common name of a tree of the apple kind. See Pyrus Cydonia.

Quince, in the Materia Medica. The fruit of the quince is astringent and tonic; and its expressed juice, in small quantities, as a spoonful or two, is of considerable service in nafcet, vomiting, nervous eruptions, and some kinds of alvine fluxes. This juice was formerly ordered in the Lond. Pharm. to be made into a syrup, called "syrupus cydoniarum," or syrup of quinces, prepared by digesting three pints of the depurated juice with a drachm of cinnamon, half a drachm of ginger, and half a drachm of cloves, on warm

ashes.
...
who had fourteen colleagues joined with him in the same function.

Under Tarquin the Proud, there were first two magistrates erected to take care of the sacrifices to be performed; those were called *duumviri*. Their number, at length, grew to ten, and then they were called *decemviri*. In the time of Cicero it had reached to fifteen, when they assumed the name of *quindecimviri*; and though their number grew to forty afterward, yet Servius oberves, on the sixth of the *Juno*, that their name never after changed, but they still continued to be called *quindecimviri*.

They were the perfons who examined the Sibyls' books, and were the interpreters of them; yet they never did this but by express order of the senate, declared by a senatus consultum. They also prefixed at the sacrifices, and all other extraordinary ceremonies of religion.

On medals, a dolphin joined with a tripod marks the priesthood of the *quindecimviri*; who, to publish their solemn sacrifices, used on the eve of them to carry a dolphin at the end of a pole throughout the city; that fish being esteemed sacred to Apollo, as the crow was among birds.

**QUINPAUGE**, or *East River*, in Geography, a river of America, in Connecticut, which runs a southerly course into the N.E. corner of New Haven harbour.

**QUINGEY**, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Besançon; nine miles S.W. of Besançon. The place contains 10,799, and the canton 11,734 inhabitants, on a territory of 272½ square miles, in 36 communes. N. lat. 46° 6', E. long. 5° 57'.

**QUINGOMBO**, in Botany, the name given by the people of Congo to a species of ketmia, distinguished by M. Tournefort by the name of the ketmia Brafihens folio ficos, fructu pyramiduto fulcato, the fig-leaved Brafihen ketmia, with a pyramidal fulcated fruit.

**QUINISDAL**, in Geography, a town of Norway, in the province of Christianfand; 35 miles W.N.W. of Christianfand.

**QUINIVEXTUM**, in Ecclesiastical History, denotes a council held at Constan[tinople in the year 602; called also the council in Trullo, and by the Greeks *Penileite*, q.d. *five-fifth*; as intimating that it was only a supplement of the two preceding councils. Though, in propriety, Fleury observes, it was a council itself.

Marshall oberves, that the fifth and sixth general councils having made no canons relating to the external celebration of divine worship, the government of the church, and the lives and manners of Christians, the Orientals judged it necessary to supply that defect by this; so that the 102 canons falsely attributed to those, were in reality made here. See *Trullum*.

**QUINNET**, in Mining, the name of a tool used in the cleaving rocks by means of gunpowder. This is a sort of wedge fitted to the flat side of what is called the gun; that is, a cylindric piece of iron, only flattened in one part to receive this, and drilled through. When a proper hole has been made in the rock by the borier, the powder is put in, and then the orifice being stopped by the gun, and that wedged in by this quinnet, the powder being fired by a train communicating with the hole drilled through the guns, exerts all its force on the rock, and splits it in several directions at one explosion. Phil. Trans. N° 167.

**QUINOLA**, in Geography, a town of Mexico, in the province of Culiacan; 50 miles S.E. of Culiacan.

**QUINQUAGENARIUS**, among the Romans, was an officer in the army, who had the command of a company of fifty men.

**QUINQUAGENARIUS** was also an officer of policy, who had the inspection of fifty houses, or families.

And in the ancient monasteries, quinquagenarius was a superior who had fifty monks under his guidance.

**QUINQUAGESIMA-SUNDAY, SIMBOI-SUNDAY**, it is thus called, as being about the fiftieth day before Easter. Anxiously they used Quinquagesima for Whitunday, and for the fifty days between Easter and Whitunday; but to distinguish this Quinquagesima from that before Easter, it was called the Fastial Quinquagesima.

**QUINQUANGULAR LEAF. See LEAF.**

**QUINQUANNION, QUINQUENIUM**, in the French Calfcounf, a repite of five years, which inofent debtors formerly obtained by virtue of the king's letters, to have time for the payment of their debts.

When the thing intended was only to prevent the sale of their effects at an under-value, the term of one year was ordinarily granted, and this was called the benefit of *annuion*.

But when the debtor would avoid the surrendering of his effects, upon proving that he was reduced by poverty, lofes, &c. to make use of this expedient, the term of five years was granted, and called the benefit of *quinquannion*.

**QUINQUATRIA**, in Antiquity, a name given to the fells of Minerva, otherwise called Panathenaia.

Some think they were termed quinquatria, because they lasted five days; but others, with more reason, think it was because they fell out five days after the ides of the month.

**QUINQUE PORTUS, the five cinque ports.**

"Servitvum quod barones quinque portus praescripto runn recognoucerunt facere ad summonitionem regis per annum, fi contigerit per 15 dies ad cultum corum proprium; ita quod primus dies computatur a die quo vel navim crux erexit, usque partes ad quas tendere debeant, vel ulterior, quamdiu rex volunt ad cultum ejus." Thorn.

**QUINQUEFOLIUM**, in Botany, Cinquefoil, the old name of the Lininian genus *Potentilla*, many, but by no means a majority, of whose species have five leaflets on a stalk. Gartner, who, like many others, was discontented with *Potentilla*, substituted the word *Pentaphyllum*. See *Potentilla*.

**QUINQUEMPOIX**, in Geography, a town of France, in the department of the Lower Seine; seven miles N. of Rouen.

**QUINQUENNALIA, in Antiquity, games, or feasts founded at Tyre, celebrated every five years, in honour of the deified emperors.**

The quinquennalia began to be expreferred on medals about the middle of the third century. F. Pagi produces a medal wherein are engraven thofe of the emperor Pollium; they are not found on any medals of his predecessors.

**QUINQUENNALS, a magiflate in the colonies, and municipal cities of the Roman commonwealth; much the same with edile at Rome.**

They were not thus called from their continuing in their office five years; but because they were elected every fifth year, to preside at the census, and to receive the declaration each citizen made of his effects.

**QUINQUENNES, in some old Hiflrians, a name given to a certain people of India, among whom the women began to bear children at five years old, and seldom lived to more than eight years.** Piny gives us this account; and Solinus, who repeats it from him, increases the miracle by telling us, that
that they were a nation of women who had no men among them.

QUINQUEPARTITE LEAF, among Botanists. See LEAF.

QUINQUEPRIMI, among the Romans, the five principal men in the female of every municipal town.

QUINQUEREMIS, in the Naval Architecture of the Ancients, a name given to a galley which had five rows of oars. They divided their oars in general into monocrora and polycrota; the former had only one tier of rowers; the latter had several tiers of them, from two or three, up to twenty, thirty, or even forty; for such a vessel we have an account of in the time of Philopater, which required no less than four thousand men to row it. See POLYCROTA.

QUINQUERITIONES, among the Romans, an appellative given to those who had gained the victory in the quintucretum, or pentathlon.

QUINQUERTIUM was the same with the Grecian pentathlon, comprehending the five exercises of running, leaping, throwing, darts, and wrestling. See PENTATHLON.

QUINQUE VIR, frequently wrote V. VIR, a Roman magistrate, who had four colleagues joined with him in the same function.

There were various kinds of officers thus denominated. Pomponius the lawyer mentions quinqueviri on this and on that side of the Tiber, established for the administration of justice in the night-time, in lieu of the ordinary magistrates, who were not judged proper to run up and down the streets in the dark.

Robins tells us, that they were sometimes the quinqueviri who conducted the colonnes, and divided the lands assigned to them among the several families.

Sometimes the epulones were five in number; in which case they were called quinqueviri. See EPELO.

QUINQUEVIRI MONETARI, were officers first erected under the constitution of Valerius Poplicola, to moderate the excessive usury, or interest, which creditors or bankers used to extract from the people.

QUINQUINA. See Cortex Peruvianus.

QUINSEY, sometimes written Quinsey, and Quincy, in Medicine, a corruption of the French word jacinthe, which again is derived from the Greek, jas, which signifies the pomegranate flower, or the heart of the internal pomegranate. The term is applied generally to inflammations of the throat, but more particularly to the acute inflammation of the tonsils.

A tonsil, enlarged from inflammation, is also emphatically called a quinsy. See JANISINE.

Quinsy, among domestic animals, is the live-flack sort, is an affection about the throat and breast, which often attacks them, and which is very obblimate and troublesome. In horses it is usually called anticor.

QUINSIEME, or QUINZIEME, in our old Law Books. See FIFTEENTH.

QUINSIGAMOND, or Long Pond, in Geography, a lake of Massachusets, between Worcester and Shrewbury. This is a beautiful lake, in form of a crescent, about five miles long, and from 60 to 100 rods broad. It is intersected with a number of iflets, one of which is upwards of 200 acres in extent.

QUINSON, a town of France, in the department of the Lower Alps; 25 miles S.S.W. of Digne.

QUINT, a sequence of five cards of the same colour. See SEQUENCE.

QUINTA, Ital. QUINTE, Fr. (See Fifth and DIA-PENTE.) The chord of the 5 in thorough-bass is resolved two ways: first, by the base rising one note, and the lowest treble note descending; secondly, by the highest note of the chord rising, and the lowest remaining stationary, when the discord is resolved upwards. This is what Rameau calls le double emploi de la dissonance.

QUINTA PALA, in old madrigals, a 5th vocal part, composed of the relufs of the other four.

QUINTA SENTENS. See QUINTESSENCE.

QUINTAIN, QUINTAIN, in Ancient Customs, a poft, or pillar, driven into the ground, with a buckler fixed to it, for the performance of military exercises on horseback, the throwing of darts, breaking of lances, &c.

Matth. Paris describes the quintain as a kind of mark, formed like a man from the nave upwards, holding a shield in his left hand, and in his right a sword or fist; the whole so fitted as to turn round on its foot, and so as that a cavalier running a-tilt against it with a lance, if he hit it in the breast, it willed round, and, unless he were very dextrous, struck him with the sword held in the other hand.

In other places, at the top of a post, was erected a slender beam fitted to turn round a quintain; at one of whose ends was a hoop or flat board, and at the other a bag of sand or dirt. The sport was, with a long staff, or wooden lance, to ride a-tilt at the board, and to be either so skilful or lucky to escape the blow of the sand-bag.

This form take to be the same with the arietum levantinum, frequently prohibited in our old lyords and episcopal constitutions.

The custom is still retained in Shropshire, and some other counties, among the nuptial solemnities. He that breaks the most poles against the quintain, has the prize; which was anciently a peacock, but is now a garland.

Some derive the word from an ancient game called quintus; others from a man of the name of Quintus.

The vallus and palus, mentioned in Caesar, are taken, by Vigenere, for a kind of quintain, or wooden man, fixed up as an adversary, or man of flaw, to prove one's dexterity against.

Mention is made of this exercise in the Code, De Aleatoribus, and in the Parallele of Cujas on the same. Javanal speaks of women engaging in it:

"Aut quis non videt vulnera pari? &c."

QUINTEN was also a right which the lord had to oblige all the millers, watermen, and other young people unmarried, to come before his castle every three years, and break several lances or poles against a post, or wooden man, for his diversion.

QUINTAL, in Commerce, the weight of a hundred pounds.

The quintal admits of some difference in different places, according as the pound consists of more or fewer ounces, and as the ounce is lighter or heavier. But, r. gr. the Paris quintal, or hundred, in the old french, yields 12 lbs. at Montpelier; and the Montpelier hundred only 8 lbs. 9 oz. 18 gr. French poids de marce, or 88 lbs. avoidus nearly. The quintal of Conflantinople is esteemed the heaviest of all those used in the Levant: it contains 44 oks, or 100 rottoles; the oke being 4 yd., droumes or chequers, or 40 drachms, and the rottole 176 drachms.

The quintal, or kinst, of cotton yarn is 45 oks.

The quintal, or cantaro, weighs about 123 lbs. avoidus, and the oke 21 lbs. 13 oz.; the rottole, 190 oz., and the chequers, 114 oz. avoidus. The quintal is equal to 112 lbs. of Amsterdam; 124 lbs. of Venice; and 100 of Leith. The quintal of Lisbon contains 4 arvos, the arvo 32 pounds, the pound, libra, or arvo, 2 marks, or 16 ounces; the ounce, 8 outvix; 3½ quintals make a ton. The pound
pound of Lisbon weight 9552 Dutch 26s, 768 2/3 grains English Troy weight; and therefore 83lbs. of Lisbon = 84lbs. avoirdupois weight.

The English quintal usually consists of 112lbs. avoirdupois, and is divided into four quarters.

Quintal was also formerly used for a weight of lead, iron, or other common metal, usually equal to a hundred pounds, at six score to the hundred.

QUINTESSE, ifle de, in Geography, an isle in lake Ontario, Upper Canada, which lies close off the shore of Ameliasburg, and opposite the W. point that forms Sandy bay.

Quinte, in French Music, is the name of the instrumental tenor part in full pieces, usually written in the mezzo-façanno clef on the second line. All the instrumental tenor or alto viola parts, in Purcell's time, were written in this clef, as may be seen in his overtures and anthems. This was an imitation of France, where all the tenor parts in Lulli and Rameau's operas are in the mezzo-façanno clef.

QUINTELLO, Ital. QueNUE, Fr. a vocal or instrumental composition in five parts, dialogued, and generally a partis equale. The instrumental quintets of Boccherini and Mozart are sublime productions: there is, perhaps, no instrumental music in which more genius and abilities are manifested, than in the quintets of these great masters.

QUINETANAR, Et. in Geography, a town of Spain, in New Castile: 37 miles S. of Hueta.

QUINTER, Quintero, Fr. in the first attempts at harmony, was counterpoint in a series of 5ths, any two of which, in aftertimes, would ruin for ever the reputation of a composer.

QUIN'TESSENCE, quinta essentia, in the old Chemistry, properly denoted the fifth essence, or the result of five successive distillations. The term, now obsolete, was used to express the highest degree of rectification to which any substance can be brought. It also signified a preparation consisting of the effential oil of some vegetable substance, mixed and incorporated with spirit of wine.

Thus, on a proper quantity, e. gr. of effential oil of fennel, pouring twelve times the quantity of pure alcohol prepared per fe, they infantly unite into one familiar liquor, which is the quintessence of that plant.

The ancients were perfectly unacquainted with the method of dissolving oil in spirit of wine; and even some of the moderns have questioned its reality; but the certainty of the thing is easily proved, from the instance above, and from a thousand others.

If such quintessence be several times digested, cohabated, &c. the oil will at length be broken to pieces, as, like the spirit itself, perfectly to mix with water; which is one of the most extraordinary effects in all chemistry.

After the like manner is made a quintessence of camphor, by only pouring on it spirit of wine.

Quintessences, thus prepared, were suppos'd to have great medicinal virtues; on account of the pure and potent ingredients used in their composition; which retain, in a great degree, all the virtues of the plants they are procured from; and hence their denomination.

Boerhaave thinks, they might properly be called vegetable sulphars made potable, and raised to their utmost degree of power and efficacy.

Dry quintessences may be made from the liquid ones, by adding to them some more effential oil of the same vegetable from whence the liquid quintessence was procured, with a little sugar, all mixed together, and distilled, by a very gentle heat, till all the moisture is come over; the matter remaining is then a dry quintessence.

This form was deemed principally useful for travellers, sailors, &c. inasmuch as it renders the quintessence portable; so that the quantity, e. gr. of a pin's point, shall be an efficacious medicine.

Quintessence, in Alchemy, is a mysterious term, signifying the fifth, or last and highest essence, or power, of a natural body.

This is suppos'd to be, as it were, the soul drawn from the gross body and its four elements, by a most perfect distillation; and, by means of which, the thing is said to be spiritualized, i. e. rend-red exceedingly pure, spiritual and, as it were, incorruptible.

The ancients, who allowed nothing to be real but what has a body, would have the soul of man to be a fifth element, a kind of quintessence without a name, unknown here below, indivisible, immovable, all celestial, and divine. Felenon.

Quintessence of the Elements, is the hermetic mercury. Quintessence of Wine, a term used by Glauber to express an effential oil of wine, which he directs to be made by a careful distillation; and which he is very fond of, as having a power to moderate, improve, and even to specificate the poorer wines into the nature of those from which it was obtained.

This is one of the schemes of Glauber, generally esteemed an impracticable one, though very plausible in theory; but though in general there is a disagreeable flavour in the quintessence drawn after his method, which is different from the true flavour of the wine, and spoils the liquor it is added to; yet, by proper care, there is a possibility of succeeding so far as to render this extraneous flavour almost imperceptible, and produce an oil that will mend poor wines extremely, and give a truly vinous flavour to such as are in themselves tasteless. But whatever may be done by this method, may also be done with much more certainty, and much less trouble, by the concentration of wines by freezing. This may be easily practised in the wine countries; and by this means Burgundy, Champagne, and other the most valuable wines, may be reduced into thick extracts and robs, by the means of which wines may be made in England; a very small quantity of these concentrated wines being sufficient to convert the whole of any of the poor tasteless and in epitaph wines, which are of themselves little or no value, into the very wine from which the rob was made; and that in such perfection, that the nicest judge cannot find out the difference.

These robs of wine, made and preferred upon the spot, would also be of infinite use in the wine countries, as they might be kept to improve the wines of bad years. Stahl, De Concentr. Vin. Shaw's Chem. Eff.

QUINT-EXACT, in old Law Books, the last call of the defendant fined to an outlawry. If he appear not to it, he is, by the judgment of the coroners, returned outlawed, if a feene, waived.

QUINTI, Bay of, in Geography, a bay and harbour in the N.E. part of lake Ontario, at the mouth of the Trent; formed by a large peninsula, consisting of the townships of Ameliasburg, Sophiasburg, and Marysburgh, extending eas'ly from an isle, where is a portage at the head, or W. end of the bay, to Point Pleasant, the eastermost extremity of the peninsula, opposite to Amherst island. The river Trent discharges itself into the head of the bay, westward of the portage, and supplies it with the waters of the Rice lake. Westward of the portage in lake Ontario, is the harbour of Presque Ile de Quinté, now called Newcastle. The fertility of the soil about the bay of Quinté is generally allowed. The land is rich and easily wrought, and produces several crops without manure; 25 bushels of wheat being often
often produced from an acre. The timber, like that of the other parts of the province, consists of oak, elm, hickory, maple, &c. The bay is narrow throughout, and about 50 miles long, through which distance it is navigable for the small vessels that are used on the lakes. It abounds with wild fowl, and various kinds of fish. The river Trent affords a salmon fishery. In falling from the head of the bay of Quinte into lake Ontario, you crost a short portage, in front of the township of Murray, being the isthmus between it and the peninsula of Prince Edward. At the end of the portage, and before you enter lake Ontario, is a small but very beautiful lake, having very good land on its banks. To the northward of this portage it has been proposed to make a canal for connecting the waters of the bay with those of the lake. A little to the westward of the portage and proposed canal, is the harbour of Newcastle, a situation well suited for commerce and protection, and sheltered from all winds. A knoll on the peninsula affords a healthy site for the town.

QUINTILE, QUINTILIS, in Astronomy, an aspect of the planets, when they are seventy-two degrees distant from one another, or a fifth part of the zodiac.

QUINTILIAN, Marcus Fabius, in Biography, a celebrated teacher of eloquence, was born about the year 42 of the Christian era, during the reign of the emperor Claudius. He is supposed to have descended from a family originally Spanish, but that his father, or grandfather, had settled in Rome. The place of his birth is not known, but it seems certain that he was educated in that capital, where he studied rhetoric under Domitius Afer, a celebrated orator. He opened a school at Rome, and was the first who obtained a salary from the state as a public teacher. After he had remained twenty years in this laborious employment, and obtained the applause of the most illustrious Romans, not merely as a preceptor, but as a pleader at the bar, Quintilian retired to enjoy the fruits of his labours and industry. In his retirement he affidiously devoted his time to the study of literature, and wrote a treatise on the "Causes of the Corruption of Eloquence." Some time after, he wrote his "Institutions Oratoriae," the most perfect and complete system of oratory extant. It is, in truth, one of the most valuable remains of antiquity. It was composed for the use of his son, whose early death he had occasion to deplore, and is an institute for the education of an orator, whom he takes up from the cradle, and conducts through all the periods of instruction to the exercise of his proper art. It accordingly contains many excellent precepts with respect to education in general, especially the early parts of it, which are applicable in all times and countries, as being founded on the nature of the mind. The style of Quintilian is laid, by critics, to exhibit tokens of the deterioration of the Latin tongue; but, on the other hand, it must be observed, that every deviation from the usage of the Augustan age has been too readily regarded as a deprivation. Quintilian was appointed preceptor to the two young princes whom Dotmanus defined for his successor on the throne; but the celebrity which the rhetorician received from the favours and attention of the emperor, and from the succours which his writings met with in the world, were embittered by the loss of his wife, and of his two sons, one of whom he describes as a prodigy of early excellence. It is said that Quintilian was poor in his retirement, and that his indigence was relieved by the liberality of his pupil, Pliny the younger. He is supposed to have died about the year 95. His "Institutiones" were discovered in the year 1415, in an old tower of a monastery at St. Gall, by Poggio Bracciolini. The treatise on the "Causes and Corruption of Eloquence" has not come down to us. The name of Quintilian is affixed to certain "Declarations," of which there are 19 of moderate length; but as the style, method, and manner, are totally different from the rules laid down in the "Institutiones," no good judges attribute them to the name of Quintilian. Of the editions of Quintilian some of the most valuable are those of Gcifier, 140. Gotting. 1738; of Lug. Batavorum, 8vo. cum notis variorum, 1665; of Gibbon, 4to. Oxon. 1693; and that of Rollin, re-published in London in 1792. There is an English translation by Mr. Guthrie.

QUINTILIANUS, QUINTILIANUS, in Ecclesiastical History, a sect of ancient heretics, the same with the Pepuzians; thus called from their prophetes Quintilia.

In this sect, the women were admitted to perform the sacredtial and episcopal functions; grounding their practice on that passage of St. Paul to the Galatians, where he says, "That in Christ there is no distinction of males and females." In their assemblies, it was usual to fee the virgins enter in white robes, perforating the prophetelles. The Quintiliani bore some resemblance to the modern Quakers.

QUINTILIS, in Chronology. See JULY.

QUINTIN, or QUINT, in Commerce. See QUINTIN.

Quintin, in Geography, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of St. Brieux; nine miles S.W. of St. Brieux. The place contains 3976, and the canton 12,510 inhabitants, on a territory of 147½ kilometres, in eight communes.

QUINTINE, John de la, in Biography, famous for his skill in horticulture, was born at Poitiers in 1626. He received a learned education, and was brought up to the profession of the law, in which he gained reputation as a pleader at the bar. A passion for agricultural knowledge led him to study, with great attention, all the authors, ancient and modern, upon that topic; and on a visit to Italy as tutor to a youth, he made great additions to his knowledge from actual observation. On his return he devoted himself almost entirely to experiments on the culture of trees and plants, and made many discoveries which greatly improved the art of gardening. He was the first perfon who laid down just principles of the art of pruning fruit-trees. He also remarked that a transplanted tree grew only by the new roots which it threw out, and that the old fibres were useless, and ought to be cut off. It does not appear at what time he began to follow gardening as a profession, but he had certainly acquired a high degree of reputation in it when he was invited to England by Charles II, who offered him a considerable pension to engage him in his service. He twice visited London, and a paper of his was published in the Philosophical Transactions, on the culture of melons. He was made, by Lewis XIV., director-general of the gardens in all the royal palaces. In 1695 he published "Infructions pour les Jardins Fruitiers et Potagers," which obtained a high degree of popularity, was frequently reprinted, and was translated into several modern languages. The last edition was entitled "Parfait Jardimier," in two vols. 4to. The author died at Paris in the year 1700.

QUINTO, in Geography, a town of Spain, in Aragon; 20 miles S.E. of Saragossa.

QUINTUS CALABER, in Biography, a Greek poet, who wrote a supplement to Homer's Iliad, in 14 books, in which a relation is given of the Trojan war from the death of Hector to the destruction of Troy. He is supposed, from the style of his work, to have lived in the fifth century, but nothing certain can be collected concerning his person and country. His poem was first made known by
cardinal Bessarion, who discovered it in St. Nicholas' church, near Orianto in Calabria; hence the author was named Quintus Calaber. It was published at Venice by Aldus, but there is no date attached to the title page.

**Quintus Curtius.** See Curtius.

**Quintus Ferrieris, in Anatomy,** a name given by Fallopius and many others to one of the muscles of the thigh, now called the psoas magnus.

**Quintus Oculorum,** a name given by Vesalius and some others to one of the muscles of the eyes, more expressively called by others obliquus superior oculi, and opex circum-gyratio oculi.

**QUINVA,** in Botany, a name by which some authors have called the amaranth, or cockcomb.

**QUIZANO,** in Geography, a town of Italy; 18 miles S.W. of Brescia.

**QUIZIEME,** Fr. in Myrt, the double octave, above or below any found (see Fifteenth); which is the name of a stop in our organs, equidistant from the diapason.

**QUIOPELA,** in Zoology. See Viverra Mungo.

**QUIPOS,** in Literary History, a name given to knots on cords of different colors, in Peru, which imperfectly supplied the place of writing. This device was adopted, as it has been said, for rendering calculation more expeditious and accurate. The various colors denoted different objects, and each knot expressed a distinct number. Thus an account was taken, and a kind of register kept of the inhabitants in each province, or of the several productions collected there for public use. But as these knots, however varied or combined, no moral or abstract idea, no operation or quality of the mind could be represented, they contributed little towards preserving the memory of ancient events and institutions. The Mexican paintings and symbols, rude as they were, conveyed more knowledge of remote transactions than the Peruvians could derive from their balloted quipos. If, indeed, the latter had been of more extensive use, and better adapted to supply the place of written records, they perished generally, together with other monuments of Peruvian ingenuity, in the wreck occasioned by the Spanish conquest, and the civil wars subseuent to it, that no accession of light or knowledge is derived from them. Robertson's Hist. Amer., vol. iii.

**QUIQUIL,** in Zoology, a species of Mylctela; which see.

**QUIRAZAI,** or Churapo, in Ornithology. See Crax Alector.

**Quire of Paper,** the French cabier, the quantity of twenty-four or twenty-five sheets.

**Quiricia,** a name given by some to the flem called quiris by the generality of writers.

**Quirico,** in Geography, a town of France, in the department of the Ifer; 12 miles E. of Bailly.

**Quirinacium Opium,** in the Materia Medica, a name given by some to the gum we know by the name of afia factida.

**Quirinalia,** in Antiquity, fairs celebrated, among the Romans, in honor of Romulus, who was called Quirinus. See Quirites.

The Quirinalia, called also flitorum seris, were held on the 13th of the calends of March, i.e. on our 17th of February.

**Quirini, Angilo-Maria,** in Biography, a learned cardinal, by descent a Venetian, was born in the year 1682. While young he entered into the order of the Benedictines of Monte Cassino. At Florence he pursued a very extensive course of study under several of the most eminent men in science and literature of that age. Upon his entering a professorship in his convent, he delivered an oration "D. Mollica Historia Praetentia," which was printed. His studies were interrupted some time, by an imagination that he was afflicted with a stone in his bladder; but the death of his physician, who fell a victim to a false impression respecting his own case, freed him from his fancied complaint. and in the year 1710 he set out upon his literary travels. He visited Germany, Holland, England, and France, making in the latter country an abode of more than two years, during the greatest part of which time he resided in the Benedictine abbey of St. Gemain des Prez. In the course of his travels he formed an acquaintance with almost all the literary characters in those countries, and visited every object of learned curiosity, at the same time every where exciting a general esteem of his talents, his industry, and his conduct. Upon his return to Italy he published a Difertation containing a Plan for a History of Italy;—an Essay on the History of Farfa, in the Duchy of Spoleto;—and an edition of the Office for Divine Service according to the Ufage of the ancient Greek Church. He was soon after created bishop of Corfu, by pope Innocent XIII., a dignity which he filled in such a manner as to inspire the Greek separatists with admiration for his perfon. His residence in Corfu was the cause of his composing a learned work, entitled "Primordia Corcyra ex antiquissimis Monumentis Illustrata," 4to. 1725. In the year 1727, Benedict XIII. raised Quirini to the cardinalate, after having nominated him to the bishopric of Brescia. His promotion to that fee was followed by some publications relative to the literature of Brescia. His attachment to the see of Rome was displayed by a life of pope Paul II. printed in 1742, the object of which was to defend the memory of that pontiff against the attacks of Platina. Soon after this he was appointed librarian to the Vatican; and in this and other poetis he continued to serve the cause of literature. It was through his means that a new edition of the works of St. Ephrem was given in 6 vols. fol. in the Greek, Syrian, and Latin languages. He likewise edited the letters of cardinal Pole, written against the principles of the reformers. This prelate died, greatly regretted, at his episcopal residence, in 1755, at the age of 75. Though a vigorous champion of the papacy, he wrote with a spirit of candour and moderation, which obtained the applause of the Protetants themselves. He was associated to several literary societies, among which were the academies of Peterburg, Berlin, and Vienna, and the Institute of Bologna. He enjoyed a large revenue, which he expended with munificence, on objects of charity and public splendour. At Rome he beautified the church of St. Mark, whence he derived his cardinal's title; and he contributed liberally to the fine Catholic church at Berlin. He laid the foundation, by a valuable gift of books, of a public library at Brescia. His own seat and valuable library he presented to the Vatican. His charities were numerous and extensive, and he was indefatigable in performing his pastoral duties, visiting the alpine parts of his diocese in the most inclement seasons. Besides the works already mentioned, he published an account of his own life, and a narrative of his travels.

**Quiriaping,** in Geography, an island on the coast of Chili, near the entrance into the bay of Concepcion. S. lat. 36° 35'.

**Quiris, Quirinus lupus,** a name given, by the writers of the middle ages, to a flem famous among them for its imaginary virtues, but of which they have left us no description.

**Quirister, Chorister,** or Chorista, a person appointed
pointed to sing in the quire, or choir, of a cathedral. See Anthem, Chantor, and Choir.

Quirites, in Antiquity, an appellation given to the people of Rome, chiefly the common citizens, as distinguished from the folkery.

It took its rise from the Curetes, the inhabitants of the Sabine town Cures. On this occasion Romulus, and Tatius, king of the Sabines, having united their two people, and their two flutes, into one, upon Romulus' death and dedication, the Sabines, disdaining the Romans in number, became masters of the councils; and accordingly appointed, that Romulus should be denominated Quirinus, from Cures, a city of the Sabines; or rather from Quirinus, the name of a god worshipped in that city.

From the new Quirinus, all the people came afterwards to be called Quirites; unless we will suppose, that the same authority which denominated Romulus Quirinus, from Cures, did not also denominate the people Quirites, immediately from the Curetes.

Some authors derive the word Quirinus from Curis; which, in the Sabine tongue, signified a pike, or halbert. Struvius adds, that Romulus was always painted with a pike in his hand.

Julius Caesar, as Tacitus informs us, (Annal. i. 43.) appealed a sedition by the office of this word Quirites, which opposed to folderis, expressed contempt, and reduced the offenders to the less honourable condition of mere citizens. The emperor Alexander also applied it to the same purpose. See his biographical article.

Quirik, in Building, a piece of ground taken out of any regular ground-plan, or floor.

Thus, if the ground-plan were square, or oblong, and a piece be taken out of a corner, to make a court, or yard, &c. the piece is called a quirk.

Quiroga, in Geography, a town of Spain, in Galicia; 24 miles N.E. of Orense.

Quiros, Cazes, lies on the E. coast of the island of Espirit Santo, in the South Pacific ocean. S. lat. 14° 56' 8". E. long. 167° 20'.

Quirifele, in Zoology, the name of a small animal, called by some authors the Indian ferret, or viverra Indica, and by others quit. See Viverra Mange.

Garcias and some authors give very remarkable accounts of the cunning this creature has to terrify all kinds. They tell us, that when this little creature intends an attack upon one of these animals, it first prepares against danger, by gnawing a quantity of the root of the lignum colubrinum, or snake wood; and when it has thoroughly impregnated its saliva, it wets with it its fore-feet, and with them daubs over its head and its whole body; and that thus prepared, it boldly attacks the snake, and never leaves off till it has killed it. Garcias affirms us, that many of the Portuguese have been eye-witnesses of these combats.

It is probable enough, that this creature may attack a snake when thoroughly hungry, knowing its flesh to be good food; but the story of the antidote is to be suspected. See Ichneumon.

Quirpen, in Geography, an island in the North Atlantic ocean, near the N. coast of Newfoundland. N. lat. 51° 40', E. long. 52° 22'.

Quirswyck, a town of Norway; 60 miles N.E. of Romidal.

Quis, in Natural History, a kind of marcescent of iron or copper, from which vitriol is drawn. It is more frequently called pyrites.

Quisbro, in Geography, a town of Sweden, in Nericia; 12 miles S.W. of Orebro.

Quiscalus, in Ornithology, a species of Gracula; which fec.

Quisibi, in Geography, a town of Arabia, in the province of Oman; 180 miles W. of Julfar.

Quisil Aurem, a town of Asiatic Turkey, in Caramania; 15 miles W. of Cogni.

Quisongala Islands, a cluster of small islands in the Indian sea, near the coast of Africa. S. lat. 10° 40'.

Quispichanchi, a jurisdiction in the diocese of Cuzco in Peru, beginning at the south gate of Quito, and stretching from E. to W. about 20 leagues. The lands of this jurisdiction belong, in general, to the richer inhabitants of Cuzco, and produce plenty of wheat, maize, and fruits. Here are also manufactures of baize and coarse woollen stuffs. Part of the jurisdiction borders on the forests inhabited by wild Indians, and produces great quantities of coca, or cacao, an herb greatly used by the Indians working in the mines, and forming one of the principal branches of its commerce; the town lies 12 miles S. of Cuzco.

Quis. Cal. Perianth inferior, tubular, thread-shaped, very long, deciduous, its border in five or seven segments. Cor. Petals five, inserted into the mouth of the tube, siphon, oblong, obtuse, spreading, much larger than the segments of the calyx. Stam. Filaments ten, bristle-shaped, inserted into the tube of the calyx, five of them below the recept; another, in or above the mouth of the tube. Pyl. German superior, ovate; style thread-shaped, longer than the stamens; stigma orbicular, dilated. Peric. Drupa dry, with five unequal angles. Seed. Nut elliptical-oblong, pentagonal.

Quis. Cal. Calyx with a thread-shaped tube; five-cleft. Petals five. Drupa superior, with five angles. 1. Q. indica. Linn. Sp. Pl. 556. (Quisqualis; Rumphi. Amb. v. 5. 71. t. 38. Q. pubescens; Burm. Ind. 104. t. 35. f. 2, and Q. glabra; t. 28. f. 2.)—Native of Java, and the Molucca isles; naturalized by Rumphius in Amboyna. The stem is shrubby, at first low and stumpy, but subequently throwing out long trailing or twining shoots, which become as thick as a man's arm. To this diversity of habit, and the changeable hue of the flowers, the name alludes. The young branches are clothed with fine soft down. Leaves opposite, occasionally scattered, on short downy stalks, ovate, pointed, entire, two or three inches long; their ultimate veins finely reticulated; both surfaces more or less downy, rarely smooth. Flowers in axillary or terminal bracteate spikes. Bracteas ovate, downy. Corolla two inches long, downy, whitish in the morning, turning pale red in the afternoon, rosy-coloured in the evening, and the next morning of a blood red. Fruit as big as one joint of the finger. Nut eatable when quite ripe, having the flavour of a bilbert. When unripe, Rumphius compares its taste to that of a radish. These nuts are a popular remedy, among the Malays, for worms in children. Two or three of the pungent unripe ones, or five of those that are arrived at maturity, are a dose. Some persons are attacked with a dangerous hiccup from eating two or three of the nuts in question, whilst others find no such effect from a considerable number. The integuments are carefully removed. They probably partake of the poisonous
poisonous qualities of the Mezeron tribe; though in a mild degree, as Rumphius speaks of the flavour of several parts
of the plant, without mention of any very hurtful
properties. Even the kernels of our European Daphnes are highly
acrimonious.

QUISSISANA, in Geography, a town of Peru, in
the diocese of Cucio; 32 miles S.S.E. of Cucio.
QUISSAC, a town of France, in the department of
the Gard, and chief place of a canton, in the district of Le
Vigan, having a mineral spring; 20 miles N. of Montpelier. The place contains 1310, and the canton 3884
inhabitants, on a territory of 160 kilometres, in 12 con-
munies.

QUISTELLO, a town of Italy, in the department of
the Mincio; 15 miles S.S.E. of Mantua.

QUISTORP, Jonas, in Biography, a German Lutheran
divine and professor, was born at Rollock in the year 1584.
He pursued his academical studies at his native city, at
Berlin, and at Frankfort on the Oder; and afterwards
travelled through Holland, Brabant, and Flanders, in
the capacity of governor to the son of a patrician of Lubeck.
In 1614, his learning and abilities pointed him out as a fit
perfon to fill the divinity chair at Rollock; but before he
entered upon the duties of his office, he was created doctor
of divinity. He obtained other Preferments in the church,
particularly the archdeaconry of St. Mary's at Rollock.
In 1645, he was appointed pastor of the same church,
and superintendent of the churches in the district of that
city. He had the felicity of rendering important services to
the celebrated Hugo Grotius, during his last fatal illness at
Rollock. Upon the death of that great man, he wrote a
Latin letter to Calvius, containing an account of his sick-
ness and last sentiments, which is inserted in the "Biblo-
theque Choixlle" of Colonies; and in the "Vindiciae Gr
tianae," under the title of "Grotii Manes." Quistorp died
in 1648, at the age of 64. He was the author of "An-
notationes in omnes Libros Biblicos," "Commentarius in
Epistolam Sancti Pauli," and several other works. He left
a son of the same name, who was born at Rollock in 1624,
and died in 1669. He became pastor, professor of divinity,
and rector of the university in that city.

QUISTRUM, in Geography, a town of Sweden, in
the province of Wilt Gothland; 9 miles N.W. of Uddevalla.

QUITANGONE, a river of Africa, which runs into the
Indian sea, 15 miles N. of Mozambique, s. lat. 14° 40'.
QUITAPABILLA, a river of America, being a
branch of the Swetara, which falls into the Sulquannah
at Middleton.

QUITAPORA, a town of the state of Georgia. N.
lat. 33° 27'. W. long. 80° 58'.

QUITCH, in Agriculture, a name frequently applied, in
different districts, to a very troublesome set of plants of
the weed kind; for though it properly belongs to the couch-
grass plant only, it is much used to dignify others of the
trooping perennial rooted sort, as the bent, creeping, soft,
and tall oat-grass, as well as some others, which are only
capable of being destroyed by repeated summer ploughings,
or forcing them out and burning them on the ground. See COUCH.

QUITCH-GRAFS, the common name given in some places
to a very troublesome sort of weed, found in many districts,
and which requires great exertion to eradicate it out of the
land. See COUCH.

QUITCH-DRAG, that sort of useful tool of the drag-kind,
which is employed in the dragging out and removing this
sort of weed from ploughed lands. It is made in several
different methods, according to circumstances; but has
mottly something of the long triangular form in the beam
part, into which the teeth or tines are fixed. These are
f cartesian so large in this as in the heavy sorts of drags;
but they are mostly a little hooked, or bent forward, to-
towards the points or lower ends. The frame-part is some-
times fast with two rows of tines, or more.

It is a sort of tool which is frequently made use of for
rendering arable ground perfectly clear of root weeds, being
had recourse to before the last ploughings. Where the
land has been cross-ploughed, this kind of drag may be
employed with great advantage in bringing it into proper
order. It has some other names in different counties. See COUCH-DRAG, and DRAG.

QUITCHE-Rake, a name given in many districts to the rake
employed in collecting the weed called couch, from the sur-
fice of ploughed ground, as well as some other sorts in par-
ticular cases. The head of this tool, into which the teeth
or tines are fastened, is usually about five feet in length;
the tines are made in a round form, having a projection of
about eighteen inches below the head, each being gra-
dually turned or crooked forward about two inches; the
distance from each other also about two inches. There is
commonly a small beam made to rest in the middle with
two pieces of wood, which come from each corner of the
rake-head, into which the tines are fastened by means of a
pin that goes through the beam, and keeps the rake steady.
In working, this implement may be put on the carriage-part
of a two-wheeled plough, to be drawn by one horse; a man
going behind to occasionally lift up the rake when full, in
order to leave the couch and other weeds in rows, for
the purpose of burning them. In this manner, a great deal
of weeds and trumpery may be collected together in the course
of a day. See COUCH-GRASS Rake.

QUIT-CLAIM, a release, or quitting one's claim or
pretensions to a thing.

QUITERVIA, in Geography. See SOPALA.
QUITIVA, or KITA, a town of Africa, in the
country of Darach, defended by a caille; 75 miles S.E.
of Morocco. N. lat. 28° 6'. W. long. 5° 26'.
QUITO, an extensive province of South America,
which was subjected to the Peruvian empire, by Huana
Capac, about the year 1526, at the time when the Spaniards
first visited the coast of Peru. Huana prevailed on his legiti-
mate and eldest son Huscar to allow one of his natural chil-
dren, Atahualpa, by the daughter of the last king of Quito,
to hold this kingdom as a fief of the empire. Atahualpa,
however, rebelled, seized the empire, imprisoned his brother,
and soon after put him to a violent death. His prosperity was
of short duration; for in the year 1533 he suffered the fame
fate, by order of Don Francisco Pizarro, who had deputed
Sebastian de Benalcazar to conquer the kingdom of Quito.
Having by a series of victories made himself master of the
kingdom, he proceeded in the year 1534 to rebuild the
capital, which had suffered much from internal commotions,
and called it "San Francisco de Quito," a name which it
still retains, though it was not till seven years after this date
that it obtained the title of city. The province, which the
Spaniards found annexed to the kingdom of Peru, con-
cluded in that state till the year 1718, when it was dismem-
bered from Peru, and attached to the viceroyalty of New
Granada. At the same time the audience of Quito was
suppressed, together with that of Panama, in the kingdom of
Terra Firma; though the latter continued dependent on
the viceroys of Lima. See NEW GRANADA and PERU.

This province is bounded on the north by that of Santa
Fe de Bogota, and includes part of the government of Po-
payan; on the south it is limited by the governments of
towards the east it extends over the whole government of Maynas, and the river of the Amazon, to the meridian of demarcation, or that which divides the dominions of Spain and Portugal. Its boundary on the west is the sea, from the coast of Machala, in the gulf of Puna, to the coast of the government of Atacames, and the jurisdiction of Barbacoas, in the bay of Gorgona. Its greatest breadth from north to south is about 200 leagues; and its length from east to west, the whole extent from Cape de Santa Elena, in the South sea, to the above-mentioned meridian, which, by the most accurate computation, is 600 leagues. All the parts, however, that can properly be said to be peopled, and actually subject to the Spanish government, are those intercepted by the two Cordilleras of the Andes, which, compared with the whole extent of the country, may be termed a street or lane, extending from the jurisdiction of the town of St. Miguel de Ibarra to that of Loja; the country from hence to the government of Popayan, and also that comprehended between the western Cordillera and the sea. With this limitation, the extent of the jurisdiction from east to west will be 15 leagues, or somewhat more, being the distance intercepted between the two Cordilleras. But to this must be added the countries comprehended in the governments of Juan de Bracamoros, which borders on the jurisdiction of Loja, and the extremity of the whole province, and situated on the east side of the eastern Cordillera; and to the northward, the government of Quixos, and that of Maynas to the eastward of it, but separated by large tracts of land inhabited by wild Indians; and on the north side of the province from that of Popayan; though the latter is properly a distinct province from that of Quito. Thus on the west side of that interval between the two Cordilleras lies the government of Atacames, and the jurisdiction of Guayaquil; on the east side, the three governments above mentioned; and on the north, that of Popayan.

This province, exclusive of these five governments, consist of nine jurisdictions, called in that country provinces, that of Quito being subdivided into as many others as there are governments and jurisdictions. Thence in the province of Quito, beginning with the most northern, are the following, viz. the town of San Miguel de Ibarra, the village of Otabal, the city of Quito, the affluent of Latacunga, the town of Riobamba, the affluent of Chimbo, or Gaaranda, the city of Guayaquil, the city of Cuenca, and the city of Loja.

The jurisdiction of Quito, the third of those above enumerated, consists of 25 parishes, besides those in the city, and extends more than five leagues, comprehending lands covered with plantations, producing a variety of plants and fruits, according to the quality, situation, and exposure of the ground. Thence in the temperate parts yield plentiful harvests of maize; and thence at the bottoms of deep cavities, being in a hot temperature, are planted with fugar-canes, from which are extracted great quantities of sugar and rum. The plantations near the summits of the mountains, having a variety of temperatures, produce wheat, barley, potatoes, and of all kinds, and potatoes. Above these plantations are fed numerous flocks of sheep, producing that wool which affords employment to a great multitude of people. Some farmers breed cows, with the view to the advantage derived from their milk in making cheese and butter. In other farm-houses, various occupations are observed, such as breeding of cattle, agriculture, and manufactures, particularly of cloth, bays, and serges. The degree of cold and heat in this jurisdiction is subject to sudden variations, according to the situation of different places; but in the same place vicissitudes seldom occur. The villages in this jurisdiction are constructed with little regularity. They confit principally of a church and parsonage, called the convent, the priests being formerly all religious; the other parts present a number of huts with mud-walls, scattered all over the country, where every one has his appropriate piece of ground, which he tills for his subsistence. A great part, and in some places the whole, of the inhabitants are Indians, who live there when out of place; though in some parts the inhabitants are Melizos, and here and there a Spanish family; but these are extremely poor.

Quito, the capital of the above described province, rebuilt in the year 1534, (see the preceding article,) and situated in the inland parts of the continent of South America, on the eastern skirts of the West Cordillera of the Andes; distant from the coast of the South sea about thirty-five leagues to the west. On the N.W. is the mountain and defile of Pichincha (which see), on the activity of which the city is built, and also among the breaches that are formed by the eminences of this mountain; so that many of the buildings stand upon arches, and the streets are of course very irregular and uneven. With regard to magnitude, this city may be compared to one of the second order in Europe; but the unevenness of its situation is a great disadvantage to its appearance. Near the city are two spacious plains, one on the S., called Turu-bamba, three leagues in length; and the other on the N., termed Inca-Quito, about two leagues in extent; both of which are intersected with fields and cultivated lands, which much contribute to the variety and beauty of the scenery. These plains contract as they approach the city, and at their junction form a neck of land, covered with those eminences on which part of Quito stands. The principal square in Quito has four sides, in one of which stands the cathedral, and in the opposite the episcopal palace; the third side is taken up by the town-hall, and the fourth by the palace of the audience: this square is very spacious, and has in its centre an elegant fountain. The four streets terminating at the angles of the square are straight, broad, and handsome; but at the distance of three or four quadrass, (each quadra being about one hundred yards,) the troublesome declivities commence; and on this account the inhabitants cannot enjoy the benefit of coaches, or wheel carriages. The principal streets are paved; and those which are not paved are almost impassable after rain, which is here very common. Besides the principal square, there are two others, that are very spacious, and several that are smaller. In the most of the convents are situated, and there make a handsome appearance, and some of them, particularly that of the order of Franciscans, are elegant structures. The principal houses are large, and some of them have spacious and well-contrived apartments, though none are above one story in height, but their doors and windows are low and narrow. The materials made use of in building at Quito are "adobes," or unburnt bricks and clay, cemented by a substance called "fangagua," a species of mortar that is uncommonly hard, used by the ancient Indians for building all kinds of houses and walls. The city is divided into seven parishes; the cathedral is richly adorned with tapestry hangings and other costly decorations; but the parish churches are of mean appearance. The convents of monks are those of the Augustines, Dominicans, and Fathers of Mercy, &c. colleges, &c. Quito has also several nunneries. The college of Jesuits, as well as all the convents of monks, are large, well built, and very splendid. Here is also an hospital, with separate wards for men and women, under the name of the order of Our Lady of
of Bethlehem. Among the courts whole feisions are held at Quito, the principal is that of the Royal Audience, established there in 1568; the exchequer or chamber of finances, a treasury for the effects of persons deceased, &c. The corporation consists of a corregidor, two ordinary alcalde's chosen annually, and regidores. The cathedral chapter consists of the bishop, dean, archdeacon, chancellor, treasurer, a doctoral, a penitentiary, a magistral, three canons by presentation, four prebends, and two demi-prebends, with the following salaries; that of the bishop 24,000 dollars, the dean 2500, the four succeeding dignities 2000 each, the canons 1500 each, the prebends 600, and the demi-prebends 420. This church was created into a cathedral in 1545, and among other festivals celebrated in it, the most magnificent are those of Corpus Christi, and the Conception of our Lady, when all the courts, offices, and persons of eminence assist. In the former there is a singular pomp of the procession of the host, and here are also dances of a peculiar nature, which were performed before their conversion to Christianity. The corporation and cathedral chapter keep, by vow, two annual festivals in honour of two images of the Virgin, which are placed in the villages of Guapulo and Quinchua, belonging to this jurisdiction. These images or statues are brought with great solemnity to Quito, and each festival is succeeded by nine days' devotion, the audience and other courts assisting on the occasion. These festivals are held in commemoration of the affluence vouchsafed by the holy Virgin, at the time of an earthquake and terrible ejection from Pichincha, by which Latacunga, Hambato, and a great part of Riobamba, were utterly destroyed; whereas by the supposed interposition of the Virgin, the city escaped even the slightest damage.

The celebrated city of Quito is famed by Alcedo to contain 58,000 persons, some of whom are distinguished by their rank. These are the descendants either of the original conquerors, or of other persons who in succeeding times came over from Spain invested with some lucrative office, and who have preferred the lucre, both of their decent and wealth, by intermarriages, without mixing with meaner families though famous for their riches. The lower orders of people consist of four classes, Spaniards or whites, Mefítizos, Indians or natives, and Negros, with their progeny. The former, according to the statement of Ulloa, compose about a sixth part of the population; the Mefítizos, or descendants of Spaniards and Indians, amount to about a third part; the Indians form about another third; and the others, who are about one-sixth, are the Chaps. The Spaniards are prevented by their pride from applying to any kind of business, and therefore many of them are poor and wretched. The Mefítizos occupy themselves in arts and trades, but principally in those of the highest repute, such as painting and sculpture, in which they excel. These men of talents, however, are indolent and litleful, so that they loiter about the streets during the whole day. The Indians, who are generally shoemakers, bricklayers, weavers, or engaged in similar occupation, are not more industrious. Persons of fortune among the Spaniards affect great magnificence in their dress, wearing the finest gold and silver tifilaces; but that of the middling and lower class is a black cloak, and under it a long coat, reaching down to their knees, with a close sleeve, open at the sides, without folds, and ornamented with rows of buttons. The Mefítizos generally wear blue cloth, manufactured in this country. The dress of the Indians consists only of white cotton drawers, made either from the fluffs of the country, or from others brought from Europe, reaching down to the calf of the leg, and edged with lace suitable to the tuff. The use of a shawl is supplied by a black cotton frock, woven by the natives; and over this is a kind of serge cloak, through which the head passes, and a hat made by the natives. The men, both Crones and Spaniards, are well made, of a proper stature, and of a lively agreeable countenance. The Mefítizos in general are also well made, often taller than the ordinary size, very robust, and have an agreeable air. The Indians, both men and women, are generally low, but well proportioned and very strong. The Indians have no beard, nor have either males or females any indications of the age of puberty. The youths of family are instructed in philosophy and divinity, and some, with reluctance, proceed to the study of the civil law. The country is observed to abound more in women than men; and it is observed, that nature begins to decay at the age of thirty in the male sex, especially among those who have been tenderly brought up; whereas the females enjoy a more confirmed state of health and vigour. This difference is ascribed partly to the climate and partly to the food, but principally to early intemperance and voluptuouness, and also the want of proper employments. The liquors that are used here are rum and brandy, in which they freely indulge, and also the infusion of the Paraguay herb, which serves for tea. The vices prevalent here are idleness, drunkenness, and gaming. The common people and Indians are much addicted to theft, in which they are very artful and dextrous. In Quito, and in all the towns and villages of its province different dialects are spoken, Spanish being no less common than the Inga.

Quito is so happily situated, that neither the heat nor cold is troublesome; though the extremes of both may be felt in its neighbourhood. An equality of temperature takes place throughout the whole year, the difference between the seasons being scarcely perceptible. The winds are salubrious, and blow continually, but never with any violence. The rains occasionally descends in impetuous torrents. Earthquakes are not uncommon, and when they occur very violent; that of 1775 was very destructive. The great earthquake on the 3th of February 1797, which changed the face of the whole province, and in one instant destroyed thirty-five or forty thousand persons, has so altered the temperature of the air, that the thermometer is now commonly 41° to 54°, and seldom rises to 68° or 70°; whereas Bouguer observed it continually at 66° or 68°. Since this cataclysmic earthquake are continually recurring; and such shocks, it is probable, that all the higher ground is one vast volcano. Von Humboldt adds, that what are called the mountains of Cotopaxi and Pichincha are but little summits, the craters of which form different conduits terminating in the same cavity. The earthquake of 1797 afforded a melancholy proof of this; for the ground then opened every where, and vomited forth sulphur, water, &c. Notwithstanding the dangers and horrors that surrounded them, the people of Quito are gay, lively, and variable, and very much addicted to pleasure, luxury, and amusement. Humboldt informs us, that the volcanos of Quito eject pumice, bafalt, and porphryny scarified; with enormous quantities of water and liquid clay, which diffuse fertility eight or ten leagues round. The fertility of this country is such, that, as we are informed, a full description of it would appear incredible. The equalibity of the climate, as well as the fertility of the soil, occasion a regular succession of the productions of the earth; when the fruits have obtained their maturity, and the leaves begin to change their colour, fresh leaves, blossoms, and fruits, are seen in their proper gradations on the same tree. The same incessant fertility is conspicuous in the corn, reaping and fowing being both carried on at the same time. This remarkable fecundity of the soil is naturally productive of excellent
excellent fruits and corn of every kind, as is evident from the delicacy of the beef, veal, mutton, pork, and poultry of Quito. One of the principal foods used by the inhabitants is cheese, of which it is computed that the quantity annually consumed amounts to between seventy and eighty thousand dollars of the money of that country. The vicinity also affords excellent butter. The manufactures of this province are cottons, fome white, called tencuyes, and others striped bays and cloths, which meet with a good market at Lima, for supplying all the inward provinces of Peru; and the returns are made partly in filver, and partly in gold and silver fringes made in that city, wine, brandy, oil, copper, tin, lead, and quicksilver. The products of the earth are chiefly confirmed within the province; except the wheat, part of which is sent to Guayaquil. But this trade is carried on by Mellitzos and poor people. Goods, manufactured by the public, or woven by private Indians, are sent, together with some kinds of provisions, to the jurisdiction of Barbacana. These provisions are exchanged for gold, found in that country, and which is afterwards sent to Lima, and disposed of at a greater price. Their chiefs find a vent in the governments of Popayán and Santa Fé. The coast of New Spain supplies this province with indigo, of which a great quantity is consumed; blue being universally the colour which these people affect in their apparel. They also import, by way of Guayaquil, iron and steel, both from Europe and the coast of Guatemala. S. lat. 0° 13’ 27”. W. long. 88° 10’ 15”. Ulloa’s Voyage, vol. i.

QUITET-RENT, q. d. quiet rent, a certain small rent, payable yearly, by the tenants of mofl manors, in token of submission; upon the payment of which, they are quiet, and free. It includes both rents of affile and chief rents.

These rents differ very greatly in different manors, being in some a mere trifle, while in others they are very heavy and oppressive to the tenants. This part of the feudal system is now considerably on the decline.

In some ancient records it is written white rent, because paid in filver, to distinguish it from rent-corn, rent- pepper, &c.

QUITIA, in Geography, a town of Africa, on the Slave coft. N. lat. 6°. E. long. 0° 8’.

QUITTANCE. See Acquitenance.

QUITTER, or Quiyor, in horses, is an ulcer formed between the hair and hoof, usually on the inner quarter of a horse’s foot; it often arises from tears and bruises, sometimes from gravel, which, by working its way upwards, lodges about the coronet; if it is only superficial, it may be cured with cleansing dressings, bathing the coronet every day with spirits of wine, and dreeing the side with lime-water, or a detergent application, such as red precipitate. But where the matter forms itself a lodgment under the hoof, there is then no way to come at the ulcer but by taking off part of the hoof; and if this be done well, the cure may be effectually without danger.

When the matter happens to be lodged near the quarter, the farrier is sometimes obliged to take off the quarter of the hoof, and the cure is then for the most part but palliative; for when the quarter grows up, it leaves a pretty large seam, which weakens the foot; this is what is called a false quarter, and a horse with this defect seldom gets quite found.

If the matter, by its confinement, has injured or destroyed the coffin-bone, which is of so soft and spongy a nature that it soon becomes carious, it will be necessary to enlarge the opening, cut away the spongy flesh, and apply the actual cayntery, or hot iron, pointed pyramidically, driving the bone with doffles of lint dipped in tincture of myrrh, and the wound with the green or precipitate ointment. When the fore is not enlarged by the knife, which is the best and least painful method, sublimate is generally applied; or blue vitriol powdered, and embued with a few drops of oil, is also used for this purpose, and is said to act as effectually, and with less pain to the animal.

In the time of the action of these caustic remedies, the foot should be kept in a poultice. And where fumes form they should be laid open by a knife, and be afterwards fumulated by the application of some detergent remedy. The following has been advised by a late writer: Take of corrosive sublimate, red precipitate in fine power, of each equal parts; honey sufficient to form a pafle.

The wound is advised to be afterwards dressed with common digestive ointment, prejudice being given by means of a bandage. It is sometimes written quitter.

QUITTER-BONE, another term applied to the fame discafe by farriers and perflons engaged in husbandry.

QUITY, in Botany, a Brazilian name used by fome authors for the sapindus, or soap-berry tree of the West Indies.

QUIVER, seemingly corrupted from the Fr. couvrir, to cover, a cape or shield for arrows.

QUIVISA, in Geography, a town of Hindooflan, in Bahar; 25 miles S.W. of Bettyh.

QUIVISA, in Botany, from the vulgar name of this tree or shrub in the illes of Bourbon and the Mauritius, bois de quivi. Jaff. Gen. 264. Cavan. Dift. 357. (See Gu- lierbert.) One cannot but wonder how a writer of Juf- fien’s learning could, for a moment, tolerate fo faulty a name; efplicially as his authority leads beadles perfons into the adoption of fuch, for want of reading his preface; where, in a note to p. 249, he declares thefe rude and barbarous names to be merely borrowed for a time, till the genera to which they belong are better determined.

QUIXOS, in Geography, a jurisdiction of South America, attached to the province of Quito, on the eafter part of the Cordillera of the Andes. Quixos on the north eide borders on the jurisdiction of Popayán; reaching eafterward to the river Guaymico, and towards the west separated from the jurisdictions of Quito, Latacunga, and the town of San Miguel de Ibarra, by the Cordilleras of Cotopaxi and Cayambe. This country was first discovered, in 1535, by Gonzalo de Pineda, one of the officers sent from Popayán by Sebastián de Beleazar (or Benelazar), to trace the course of the river Magdalena; and in confequence of his report, Gonzalo Pizarro, in 1539, reconnoitred its whole extent, and effected settlements in it. But upon the failure of his expedition, the conquest of this country was finished till the year 1340, when the marquis de Canete, viceroy of Peru, gave a commiffion to Gil Remirez Davalos, a man of undaunted courage, for reducing the Indians, and making settlements in the country. This object he accomplished, and founded the town of Baza, the capital of the government, in the year 1559; and this was soon followed by other towns and villages, the principal of which are Archidona and Avila. The temperature of this country is hot and moit, the rains being almost continual. It is covered with thick woods, fome trees being of a prodigious magnitude. In the S.W. part of the jurisdiction of Quixos is the canela or cinnamon tree, which led Gonzalo de Pineda to call the country Canelos, a name which it still retains. The other products of Quixos are the fame with thofe in all the other lands under the fame climate as this government. Adjoining to this is the district of Macas and Maynas. See Macas and Maynas.

QUIZA, in Ancient Geography, a town of Africa, in Mauritania Cofariifina. This was a fortrefs, according to Pomponius Mela and Pliny. Antoine makes it a municipality, and places it between Portus Magnus and Africarum.
This page contains a legal document in Latin, discussing various judicial and legal terms and principles. The text includes references to various legal cases, statutes, and definitions, such as:

**Quo warranto** - A writ that lies against any person or corporation (which fees) who usurps any franchise, or liberty, against the king; as to have wafe, flray, fair, market, court baron, lea, or such like, without good title; to inquire by what authority he supports his claim, in order to determine the right.

**Quo modo** - A writ that lies for him who has a grant of housebote and haybote in another man's woods, against the grantor making such wafe, as that the grantee cannot enjoy his grant.

The page also contains references to specific cases and legal authorities, such as:

- **Lever** - A writ that exempts a clerk from the chancellor towards the procurers of the clergy in parliament. Rep. Orig. 261.
- **Quod clericorum beneficiorum** - A writ to exempt a tenant in tail, tenant in dower, by the curtesy, or for term of life, having lost their lands by default, against him that recovers, or his heir. Reg. Orig. 171.
- **Quod erit desperat** - A writ for tenant in tail, tenant in dower, by the curtesy, or for term of life, having lost their lands by default, against him that recovers, or his heir. Rep. Orig. 171.

The text discusses various legal concepts and principles, including jurisdiction, property rights, and the rights of parties in legal proceedings. It also refers to the nature of common recovery, its jurisdiction, and the role of the king's personal authority in such matters.
The term is formed from the Latin quodlibet, any thing, what you please; and so well satisfied were the public of the impertinences of these questions, that the term quodlibet has been since retained, to signify any little ridiculous quibble.

QUOIA, in Geography, a country of Africa, situated above 100 miles from the coast of the Atlantic, between the 8th and 10th degrees of W. longitude, and between the 7th and 9th degrees of N. latitude.

QUOIF, in Ship-Building, a piece of oak thickfluff on the deck, to which the deck water-way on each side is hatted, otherwise the butt would come in the middle, and could not be eaulked.

QUOIL, QUOIL, or Coils, in the Sea Language. A cable is said to be quiled, when it is laid round in a ring, one turn over another, on the deck of a ship.

The middle of such ring, or quoil, is a good place to lay shot in; they are more safe there, than in lockers along the side, where the enemy's fast may fall into them.

QUOIL, Weather. See Weather Quoil.

QUOIN, or Coin, formed from the French coin, of the Latin cuneus, wedge, aboard a ship, is a wedge fastened on the deck, close to the breach of the carriage of a gun, to keep it firm up to the ship's side, and prevent its rolling; and also to raise or depress it.

QUOINS, Canics, are short three-legged quoins, put between casks to keep them steady. See Coins.

QUOINS, in Architecture, denote the corners of brick or stone walls.

The word is particularly used for the flones in the corners of brick buildings. When these fland out beyond the brick-work (their edges being chamfered off) they are called ruffle quoins.

QUOINT, in Geography, a small island in the Indian Sea, near the W. coast of Madagascar. S. lat. 14°. E. long. 48° 14'.—Alfo, an island in the East Indian Sea, N. of the Nicobar islands. N. lat. 9° 56'. E. long. 93° 20'.

QUOITS, a kind of exercise or game, known among the ancients under the name of the disus. See Disc.

QUOILL, in Zoology, a name given by the natives of New Holland to an animal resembling a pole-cat, with a brown back, spotted with white, and the belly of a pure white, in which it differs from others of these feline animals.

Cook's Voy. 1770, vol. iii. p. 626.
