QUONDANGA, in Geography, a town of the Birman empire; 32 miles N. of Prone.

QUORUM, a term frequently mentioned in our statutes, and often used in commissions, both of peace, and others. A justice of the quorum is thus called from the words in the commission, Quorum C. D. or A. B. aliquem veltrum unam effe volumens.

For an example: where a commission is directed to seven persons, or to any three of them, of which A. B. and C. D. are to be two; there A. B. and C. D. are said to be of the quorum, because the rest cannot proceed without them.

So a justice of the peace and quorum is one without whom the rest of the justices, in some cases, cannot proceed. See JUSTICES of the Peace.

QUORUM Nomina. In the reign of king Henry VI. the king's collectors, and other accontants, were much perplexed in passing their accounts, by new extracted fees, and forced to procure a then late-invented writ of quorum nomina, for the allowance and fusing out their quietus, without the allowance of the king.

QUOTA, in Law, a tax to be levied in an equal manner.

Vol. XXIX.
the points placed under them, but according to others sub-
fluted in their head; as is done by St. Peter, Acts, iii. 23.
by Stephen, Acts, vii. 43. and by Paul, 1 Cor. xv. 54.
2 Cor. viii. 15. &c. The second is by changing the letters;
as is done by Paul, Rom. ix. 33. 1 Cor. xi. 9. Heb. viii. 9.
and x. 5. and by Stephen, Acts, vii. 43. The third is by
changing both letters and points; as is done by Paul, Acts,
xiii. 41. and 2 Cor. viii. 15. The fourth is by adding some
letters and taking away others. The fifth is by transposing
words and letters. The sixth is by dividing one word into
two. The seventh, adding other words to make the sense
more clear: The eighth, changing the order of the words.
The ninth, changing the order of the words and adding
other words. Both of which are done by the apostles.
And lastly, changing the order of words, adding words,
and retrenching words; which is a method often used by St.
Paul.

Other authors, as bishop Kidd, M. le Clerc. Mr. Sykes,
&e. solve the difficulty another way. That usual
form of quotation among the evangelists, "That it might
be fulfilled which was spoken by the prophets," according
to these authors, means no more than an accommodation
of the prophet's words to the sense in hand.

The word ἐπαληθευμένος, fulfilled, does not necessarily determine
us to such a sense, as if the evangelists, designed to speak of
a prediction of future events accomplished; but may barely
express an accommodation of borrowed words. In effect,
fays bishop Kidd, a scripture may be said to be fulfilled
two ways; properly, as when that which was foretold comes
to pass; and improperly, by way of accommodation, as
when an event happens to any place or people like to what
fell out some time before. And thus it is that St. Matthew
says, on occasion of the murder of the innocents, that "then
was fulfilled what was spoken by the prophet Jeremy, In
Rama was a voice heard," &c.

This interpretation is confirmed by M. le Clerc, who observes
that the Jews, in their language, used to say, that
a paffage of scripture was fulfilled, as often as any thing
happened to which it might be applied; so that the evangel-
list Matthew, who was a Hebrew, and wrote, as is
commonly supposed, in that language, intended no more in the
paffage jult cited, but that a thing happened, to which
one might apply what Jeremy had formerly said on another
occasion.

Accordingly, fays Mr. Sykes, the evangelists, in citing
that paffage of Isaiah, Beheld, a virgin shall be with child,
&e. only use it as words of that prophet remarkably agreeing
to the miraculous birth of Jesus, and not as a prophecy
of his birth.

It may be added that this way of speaking was not un-
known among the heathen writers. Thus in Aelian, Dio-
genies Sinopenis used continually to say of himself, that he
fulfilled and underwent all the curses of tragedy.

The difficulty flated in this article has been already the
subject of discussion under the terms Accommodation and
Prophecy. Whilft it is allowed, that many paffages in the New Testament, and also in the writings of the Christian fathers,
are very different from the correspondent paffages as
they now stand in the Hebrew text; and that some words are
introduced as quotations which are no where to be found:
those who urge the objection should be dispofed to pay due
attention to the various modes of replying to it, which bibil-
cal critics have propofed. Some have puffed, with William,
that those early Christian writers quoted from the LXX:
where others have alleged that they sometimes quoted from their
memory; and this, it is said, is the more probable, because
the same paffage is quoted in some fakes by different authors
in very different words, even where the fense agrees. It is
moreover alleged, that the fense of the paffages supposed to
be lost is still to be found in the Old Testament, though
the words be not; such especially are Matt. ii. ult. and
John, vii. 38. But if it were granted, that some of the vers
originally belonging to the Old Testament are lost,
or materially corrupted, no objection could be justly alleged
against the authenticity and divine authority of the sacred
writings in general. As for the quotations that occur in
the New Testament, the most probable opinion is, that
some of them are made from the Greek version and some
from the Hebrew text. To those who affirm, that though
such quotations are made from the Greek version, where
that differs from the Hebrew, yet both the text and the
version are in such places always the same in fense, we reply
with Dr. Kennicott, that this is not the cafe: and he thinks,
that the only way of doing justice to our Saviour and his
apostles in their references to the Old Testament, is to say,
that for whatever purpose such quotations were made (whether
by way of express prophecy, or only of allusion and ac-
commodation) they were always conformant to the true fense
of the Hebrew text. For he fays, it is scarcely poible to
conceive, how any speaker or writer can quote jufly such
and fuch words, as (c. g.) from Mofes or from Isaiah,
when the words quoted are not the words of Moses or Isaiah,
and do not express even the fense of Moses or Isaiah; but
are only taken from fome version, which (upon the present
fuppofition) was no verfion at all in all these inflances, because
it did not agree here in fense with its original. The
foundation of this mistake, as this learned writer adds, is the
notion that has prevailed of the integrity of the modern
Hebrew text; for the writers who have held this to be perfec-
tive, have never been able and never will be able to vindicate
the prophetical quotations. Paffages quoted from the several
Jewish writers by inspired men must (he thinks) have been
quoted agreeably to the fense of the Hebrew text; but fuch
quotations do not agree in fense with the printed Hebrew
text. Therefore some alterations have happened, either in
the Greek text of the New Testament, or the Hebrew text
of the Old. Collins fays that the Hebrew text has been
delivered down perfect, and therefore that the quotations
are either forged or falsified in the New Testament. To this
it is replied, that as it appears from a collation of the Greek MSS. of the New Testament, that the words of
the quotations are not corrupted in the Greek text, so it ap-
pars from a collation of the Hebrew MSS. that the
words have been corrupted in the Hebrew. And this is
an answer which should approve itself to all Christians. See

Upon the whole we observe, that the writers of the New
Testament did not make it a confant rule to quote from the
Greek version, because there are many places where their
quotations differ from that verfion and agree with the Hebrew.
And as the quotations now agree with the Hebrew, fre-
quently in the express words, generally in the fense; so it
it is much probable, that they always agreed at first, and
that where the Hebrew was expressed properly in the Greek
version, they used the words of that verfion; and where the
verfion was not proper, they translated for themselves.

With regard to Matt. ii. ult. the firth of the paffages
above cited, Dr. Doddridge (Fam. Expof. loc.) observes,
that Nazareth was a little city on the confines of Zabulon
and Ilaifer; so contemptible among the Jews, that it
was a proverb among them. No good thing can be expected
from thence. Thus was fulfilled what was spoken in effect by
many of the prophets, "he shall be called a Nazarene!" i. e. he
shall
shall appear in mean and despiseful circumstances, and be treated as the mark of public contempt and reproach. If this suffice be not approved, Dr. Doddridge professes to acquiesce in Chrysostom's opinion, that the passage referred to is lost, avouching his dissatisfaction with other interpretations of this passage. The second passage, viz. John, vii. 38, our learned expositor thus explains. "He that believeth in me, as the scripture hath said, out of his belly shall flow rivers of living water, i.e., as the scripture has in many places said and pronounced, he shall receive those supplies in so great an abundance, that he shall not only be refreshed himself, but out of his belly, or within him shall flow vital streams, and as it were rivers of living water for the refreshment and comfort of others." Chrysostom, and after him many other eminent writers, Calvino, Zegerus, and I. Capelli, refer the words "as the scripture hath said," to the former clause, and understand them, as if our Lord had said, "He that believeth in me," which the scripture requires, and thus avoid the difficulty, which arises from our not finding the following words in scripture. But Gratious, with whom Dr. Doddridge agrees, supposes, that here is a general reference to the several prophecies which refer to the effusion of the spirit by the Messiah, under the

R.

A liquid consonant, and the seventeenth letter of the alphabet.

The grammarians hold it a semi-vowel, especially in the Greek, where, in common with the other vowels, it admits an aspirate, &c. though whether the aspirate should be sounded or not, is some doubt. We find instances of each.

Thus, in the Latins wrote reds; and ή pa the Eotolians wrote βσδηθ; and in English words derived from the Greek it is followed by an h, as rhaphody. The ancient Goths, and Teutones, Littleton observes, always prefixed b to r. See H.

The found is formed by a guttural extrusion of the breath, vibrated through the mouth, with a sort of quivering motion of the tongue drawn from the teeth, with the tip a little elevated towards the palate.

In some words, as Rate, rape, and river, it has a rough sound; in others, as bard, card, regard, its sound is smooth. Re at the end of many words is pronounced like a mute r, as in theatre, sepulchre, and manitaire. Rh is used in words derived from the Greek, as mythb, rhymt, and rhyme.

The Hebrews allow the r, or r, the privilege of a guttural; that is, they never double it, which yet is done by the Arabs, Greeks, and Latin, &c.

Perius calls the r, litera canina, because the dogs seem to pronounce it in snarling; yet it should seem to have had a quality proper to the Romans than among us, by its being frequently interposed to prevent the clashing of vowels; as in rurus, quaeo, nurus from voxo, mures from μυώ, nus muros from μυως μυς; and this softness was such as frequently occasioned its being droped as useless in writing. Thus for Heruifti they frequently wrote Thufi, and even Tufi; and for siriam, sirfis, sirfis, sius, sirfis, sirfis.

In effect, there was that agreement between the sound of the r and r, that as the Romans avoided the doubling of their consonants, it was no wonder they here dropped the r in such words; the s supplying the place of both. Hence too it came to pass, that what they att first pronounced at, of, of, of, of, of, was afterwards ara, arena, carmen; and those name named Fufi and Valesi, were afterwards called Furri and Valesi. Cicero tells us, the Papiri were first called Papisi; and even fixes the time when the change was made, viz. in the year of Rome 415. Felix adds, that olfr, pignor, plurima, were anciently written olsfr, pingifes, plufrs.

From the same softness of the found of the r, it came to be used indifferentlly with the l, in many words; c.g. Latin, and Latin, Palst, and Parilia, &c.

Though the r more frequently degenerated into l, thus remars became changed into remars; interlg, interlg, into intellige and peluugo; strater into fratules, &c.; and the same is sometimes done between r and r, as arcus, and anus, &c. In the notes of the ancient, R. or R. signified Roma; R. Roma civitas; R. G. Roma civitas; R. F. Roma civitas; R. E. D. rete factum et dictum; R. G. F. regis filius; R. P. res publica, or Romani principes; and R. R. K. F. F. R. Romana rur ferro, famc, flamma.

R was anciently a numeral letter, signifying 80; according to the verfe,

"Qoctoginta dabit tibi R, fiquis numerabit."
When a dash was added at top, as $\overline{R}$, it signified eighty thousand.
The Greek $\overline{R}$, with a small mark over it, signified a hundred;
with the same mark under it, it denoted $1000 \times 100$; thus $\overline{R} = 100,000$.

In the Hebrew numeration, $\overline{1}$ denoted 200; and with
two horizontal points over it, $1000 \times 200$; thus $\overline{1} = 200,000$.

$R$ on the French coins, denotes their being flurck at
Orleans.
$R$, or $\overline{R}$, in Medicinal Prescription, stands for recipe, take.
RAA, in Geography, a town of Norway; 10 miles N.E.
of Frederickestad.

RAAB, Gyra, or Jarasun, a town and fortress
of Hungary, situated in a pleasant level country, at the conflux
of the Danube, the Raab, and Rabitz, which surround its
hills, are constricted of stone, and its streets are
large and straight. It is the seat of a bishop. Its fortifications
consist of seven bastions, and it always has a strong
garrison, provided with military fortes. The fortifications
of the city and castle are chiefly the works of the emperors
Ferdinand I. and Maximilian II. In this place are seen
some Roman antiquities; 56 miles S.E. of Vienna. N. lat.
$47^\circ 42'$. E. long. $18^\circ 43'$. 

RAAB, a river of Stiria, which rises near mount Rettltstein,
and runs into the Danube, near Raab in Hungary.

RAAF, or RAFF, ANTHONY, in Biography, the most
exquisite and celebrated tenor singer of the last age,
was born at Bonn in 1710. He was a scholar of Bonnclaci,
and equally admired for his taste, expression, and style of
singing, by the Italians and Germans. In 1729 his voice
was filled from a high treble to a firm and tenor
sufficiently for him to perform a capital part in an opera at
Naples. After singing in all the great cities of Italy, he
returned to Germany, where he was courted and cared for
by all the princes of the empire. He was knighted by the
elector of Bavaria, and appointed his chamber musician.

In 1771 he performed again at Naples in Metastasio's "Attilio Regolo," with the Mingotti, and in the letters of
Metastasio of that period, we have the poet's opinion of his
performance. (Mem. of the Life and Writings of Metastasio,
vol. i. p. 403.) He performed in an opera composed by
Christian Bach at Manheim in 1770, when the celebrated
air "Non fo done vie" was in his part, and which was
afterwards sung on our opera stage with such effect by Ci-
prandi. Rafl was at Paris more than once; for in 1780,
his 70th year, Laborde speaks of him with great respect.
"This celebrated tenor has acquired great reputation, and
though at present d'un certain age, he obliges us still to
admire his talent, and regret that he has left." According
to Gerber, Musical Lexicon, vol. ii. he sung at Manheim in
1783, and was living in 1792.

RAAGOE, in Geography, a small island of Denmark,
neat the N. coast of the island of Lolland. N. lat. $54^\circ 58'$.
E. long. $11^\circ 19'$.

RAAJAGUR, a town of Hindooftan, in the country
of Malwa, near the river Niumondge; 74 miles N.E. of
Ougrein. N. lat. $24^\circ 2'$. E. long. $76^\circ 56'$. 

RAALBRANN, a town of Austria; seven miles S.E.
of Meifau.

RAAN, a town of Austria; four miles E.S.E. of
Iooren.

RAASAY, an island of the Hebrides, or Western
Islands, Scotland, is situated between the main land and the
Isle of Skye, and is included within the parish of Portree and
shire of Inverness. It is about fifteen miles in length, and
from two to five in breadth. On all sides the coast rises
to a great height above the level of the sea; and on the east
side its aspect is peculiarly bold, and almost perpendicular.
The interior is throughout its whole extent mountainous
and hence is better adapted for pasturage than for village,
but there are nevertheless several spots of very fertile and
well cultivated land. The supply of free-stone is almost
exhaustible, and there is likewise plenty of lime-stone.
Formerly there were in Raasay several ancient chapels, but
there are now ruined and only used as places of burial.
Here are likewise remains of two forts, the highest of which
was situated at the southern extremity of the island, and is
called Dunn-Cann, as tradition records, from Cann, cousin
of one of the ancient kings of Denmark. The other fort,
called Castle-Broichin, is a well-known land-mark among
failing. The rock on which it is situated is nearly round,
covering an area of little more than seventy feet square;
and 60 feet high, except at the spot where the cliff leads up
to it; and is fifty feet above the level of the sea at its base.
The castle is built of stone and lime, and seems to have
been left strongly fortified by art than by nature. It was
anciently the chief seat of the lairds of Raasay. Now,
however, the family residence is at Clachan, or Kirk-town,
near the opposite extremity of the island. One of the old High-
land alliances has continued for more than two hundred
years, and is still subsisting between Macleod of Raasay,
and Macdonald of Skye, in consequence of which the survivor
always inherits the arms of the deceased; a natural model
of military friendship. At the death of the late Sir James
Macdonald, his sword was delivered to James Macleod, eqq.
the present laird of Raasay. Dr. Johnson, in his Tour to
the Hebrides, speaks in warm terms of the elegance and
hospitality with which he was entertained by this truly
respectable family. Carllive's Topographical Dictionary of
Scotland, 2 vols. 1813. Pennant's Tour through Scotland,
vol. ii.

RAASS, a town of the duchy of Stiria; five miles W.
of Marburg.

RAASTORF, a town of Austria; four miles N.
of Entzermorff.

RAAT, a town of Hindooftan, in the country of Agra;
128 miles S.S.E. of Agra. N. lat. $25^\circ 37'$; E. long.
$70^\circ 58'$. 

RABA'CAL, a town of Portugal, in the province of
Beira; 12 miles S. of Coimbra.

RABANUS, MAURUS MAGNENTIUS, in Biography,
a celebrated German prelate in the ninth century, was born
at Fulda in the year 785. He was educated partly at Fulda,
and partly at Tours, under the famous Alcuin. In the
latter situation he distinguished himself by an unwearied
application to his studies, and his almost unequalled proficiency
in all the learning of the times, both profane and sacred.
Not long before the death of Alcuin he returned to Fulda,
and embraced the religious profession in its abbey. In the
year 810 he was placed at the head of a school belonging
to the abbot Ratgarus, and the fame of his superior learning
soon raised the seminary into great reputation, and
filled it with pupils, many of whom were afterwards prom-
oted to the highest ecclesiastical dignities, and proved the
brightest ornaments of the age. In 815 he was ordained
priest, and in 822 he was elected abbot of Fulda. About
830 he was, by his prudence and good conduct, the means
of effecting a reconciliation between the emperor Louis le
Debonnaire and his sons. Shortly after this, Ebbo, arch-
bishop of Rheims, who had been condemned for high trea-
son, was committed to his custody. In 838, at the request
of
Rabans in 856, at the age of 71. He is described by Dupin as "having excelled all his contemporaries in the learning of those times, in explaining the principles of the liberal arts and sciences, and the rules of grammar and rhetoric; in a readiness in collecting from the fathers of the church common places upon the sacred scriptures; in allegorizing the historical parts of the Bible; in an exposition of the mystical meanings of the ceremonies; in a facility at turning prose into verse, and in the manner of reducing all common places in precepts and instructions." And Motheim says "he is deservedly placed at the head of the Latin writers of this age; the force of his genius, the extent of his knowledge, and the multitude of productions that flowed from his pen, elevated him to this distinguished rank, and render improper all comparison between him and his contemporaries." He was denominated the great light of Germany and France, because from his fund of knowledge those nations derived principally their religious instructions. His writings were everywhere in the hands of the learned, and were held in so much veneration, that during four centuries, the most eminent Latin divines appealed to them as authority in religious matters. His writings consist of Commentaries on the Scriptures; Homilies on the Epistles and Gospels; Scripture Allegories, and a great many theological and literary pieces. Of which the most considerable number were collected and published at Cologne in 1627, in six vols. folio. Some other pieces of this author, not to be found in that collection, may be found in Baluze's "Miscellanea," among Father Sirmond's publications, and in the eighth vol. of the Collect. Council. Motheim. Dupin.

Rabastens, in Geography, a town of France, in the department of the Upper Pyrenees, and chief place of a canton, in the district of Tarbes; 10 miles N.E. of Tarbes. The place contains 750, and the canton 7422 inhabitants, on a territory of 150 kilometres, in 25 communes.

Rabastens, or Rabasteins, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Gaillac; 21 miles S.W. of Alby. The place contains 6076, and the canton 8124 inhabitants, on a territory of 1524½ kilometres, in five communes. The principal article of its trade is wine.

Rabat, a town of Africa, in the empire of Morocco, situated on the S. side of the river Salle. Rabat had formerly, at intervals, a number of European factories; but the difficulty of navigating the river, the obstructions arising from the arbitrary power of the sovereign, and the disposition and prejudices of the Moors, have disfigured the European trade. Nevertheless, Rabat is the most proper place for trade of any upon this coast, both for its vicinity to Europe, and the quantity of wool, leather, and wax, which it is capable of furnishing. From its central situation in the empire, it is also better adapted for the conveying of the commodities imported to every part of the country; but a despotic government acknowledges no principle but the convenience of the moment; it commands, judges, and executes, without considering either cause or confluence. At Rabat, near the mouth of the river, are the ruins of a castle, built in the twelfth century by Jacob Almanzor, but entirely destroyed by the late emperor. The walls, which still remain, are near two miles round, and fortified by square towers. They enclose the castle, the town of Rabat, and a large space of ground where J. Almanzor built beautiful palaces, and laid out delightful gardens, watered by plentiful streams, which he brought from the neighbouring spring. These walls, as well as the palace and the town, were built by Spanish slaves, whom he took prisoners in his first campaign. Within the same inclosure he also built a very large mosque, of which the ruins still remain. The roof was supported by 360 columns of rough marble. Near it was a handsome square tower, strongly built with cut stone, near 200 feet high, and called the tower of Hafan. From this tower may be had an extensive view over the sea, and ships may be discovered at a prodigious distance. This monument is in almost perfect preservation. There are some docks for building ships both at Salles and Rabat; but the difficulty of navigating the channel, and the probability that the sand will continue to accumulate, give ground for apprehending, that very soon, only vessels with oars will be able to enter the river. Chenuer's Morocco, vol. i.

Rabat Affirmoune, a town of Persia, in Farillan; 120 miles E. of Schiras.

Rabat Aroob, a town of Persia, in the province of Kerman; 40 miles E. of Keshan.

Rabat el Cadi, a town of Persia, in the province of Kerman; 40 miles E. of Maltih.

Rabat Mahob, a town of Persia, in the province of Kerman; 60 miles N. of Kabis.

Rabat al Najaf, a town of Persia, in the province of Kerman; 60 miles N.E. of Maltih.

Rabat Shibarjilan, a town of Persia, in the province of Chorasan; 260 miles N.E. of Ipahan.

RABATE, in Falconry. A hawk is sometimes laid to rabate, when, by the motion of the hand of the bearer, the lure, call, &c. the leaves purifying her prey, or quarry, and recovers the lift.

RABATE, in Commerce. See Rebate.

RABBAB, in Ancient Geography, a town of Judea, which belonged to the tribe of Gad; situated upon the torrent of Jabba; it was besieged by Josab. after he had defeated the Ammonites. Here was the head of Og, king of Bashan, who alone remained of the race of giants. - Alto, a town of Palestine, in the tribe of Judah. See Rahab.

RABBATH-AMMON, or PHILADELPHIA, a town of Asia, situated in the mountains of the southern part of Palatine; S.E. of Tiberias, and S. of Bostra.

RABBATH-MOAB, or ARACOPOLIS, a town of Asia, situated at some distance to the east of the lake into which the river Jordan discharges itself.

RABBED, in Geography, a small island in the gulf of Bothnia. N. lat. 63°. 14'. E. long. 22°. 14'.

RABBEET, in Carpentry, is a deep groove or channel, cut in a piece of timber longitudinally, to receive the edge of a plank, or the ends of a number of planks, which are to be securely fastened in it. The depth of this channel is
is equal to the thickness of the plank, so that when the end of the latter is let into the rabbet, it will be level with the outside of the piece. Thus, in ship-carpentry, the ends of the lower planks of a ship's bottom terminate upon the stem areo, and the stem-port abait, with whose sides their surfaces are even. The surface of the garboard bead, whose edge is let into the keel, is, in the manner, level with the side of the keel at the extremities of the vessel.

**Rabbit-Plane.** See Plane.

**RABBETING,** the planing or cutting of channels, or grooves, in boards.

**RABBI,** or **Rabbin,** a doctor of the Jewish law.

The word in its original, ריבי, signifies master.

The words rabbi and rabbin have the same signification; yet is there some difference in their use. When we speak absolutely, and without applying the term to any proper name, we say rabbin, not rabi. Thus we say, it would be unjust to attribute to the ancient rabbis all the notions of the moderns.

On the other hand, when we prefix the term to the proper name of some Jewish doctor, we say rabbi, not rabbin; rabbi Solomon Jarchi is of this opinion.

Yet rabbi having no plural, we say, the rabbins Juda Chiug, and Juda ben Chabin, are the authors of two ancient Hebrew grammars.

The title rabi is said to have been first assumed, as a distinguishing title of honour, by men of learning, about the time of the birth of Christ; though it had been commonly given to several magistrates and officers of state, and to those who were of sufficient rank and condition in life. See Ether, i. 8. Jer. xii. 11. Job. xxxii. 9.

The first Jewish rabi said to have been distinguished with any title of honour, was Simeon, the son of Hiilel, who succeeded his father as president of the sanhedrim; and his title was that of rabbin. The later rabbis tell us, that this title was conferred with much ceremony. When a person had gone through the schools, and was thought worthy of this degree, he was placed in a chair raised above the company; and then were delivered to him a key and a table-book; the key as a symbol of the authority conferred on him to communicate the knowledge he had acquired, which key he wore as a badge of honour, and when he died, it was buried with him; and the table-book was a symbol of his diligence in his studies, and desire of farther improvement.

To these ceremonies were added the imposition of hands by the delegates of the sanhedrim, and the proclamation of his title. It has been disputed, chiefly between Vitringa and Selden, whether our Lord had taken the degree and title of rabi in the Jewish schools; Vitringa maintains the affirmative, and Selden the negative. See Jennings's Jewish Ant. vol. i. p. 400, &c.

The Jewish writers distinguish between the titles rabi, rabbi, and rabban.

In the Old Testament we find the term רבי, rabi, in composition with some other words, employed as a name of office and dignity, but not till the people became acquainted with the Chaldeans, concerning whom only it is used. The word, both in Hebrew and in Chaldee, signifies sometimes great, sometimes many, and when used substantively, denotes one who is at the head of any business, of whatever kind it be. Thus רבי, rabi hachebel, is, in the LXX, παλαιος, בֵּיתוֹן, rabi tebachim, παλαιος, τῆς, chief cook. (Jonas, i. 6. Jer. xxxix. 11, see also Dan. i. 3.) It is used in the plural also for chief men in general, superintendents, or those at the head of affairs. Thus רבי, rabbi hammelech, are the chief men employed by the king over the different departments of the state. (Jer. xxxix. 13.)

The term rabi is the import of the Latin word princeps, but not of the English word prince, at last in its most common acceptation; for they are not the king's sons, or nobles of any order, who are so denominated among the Chaldeans. The word evidently appears to have been equivalent to the term פרא, fraur, among the Hebrews. Accordingly, he who is styled by Daniel, in the above cited pallasage, רבי, rabi ferum, is four times, in the same chapter, called פרא, fraur bofarum. (Dan. i. 7, 8, 9, 18.) And this use of the name rabi seems to have continued long in Syria, as well as in Chaldea. Thus in the Syriac New Testament, it is found in the same manner, united with the common appellation of any sort of officer, in order to denote the principal person in that office: thus, rabi-cabana, (Matt. xxvi. 51.) is the high priest; rab-machias (Luke, xix. 2.) is chief of the publicans, and rabi-ragheba (1 Pet. v. 4.) is chief shepherd. Rab, construed in this manner, is equivalent to the Greek αὐτός, as used in composition. The preceding titles are accordingly thus expressed in Greek, ἀρχιερεῖος, αὐτοκράτορας, and αὐτοκράτορας.

Again, the word rabi is sometimes found in that version, combined not with the title of any sort of officer, but with a term denoting the office or charge itself; in which case it always means the person who is principally entrusted with the business. Thus, rabbeth (Matt. xx. 8.) is the steward, τετραγωνος, he who is over the household; and rabb-tonghetha (Mark, v. 35.) is the ruler of the synagogue, αὐτοκράτορας. It is not unlikely, though no example occurs in scripture, that the term has at first been similarly compounded with some word signifying a school, or, perhaps, with the name of the art or science taught, in order to denote the overseer of such a seminary, or the teacher of such an art. When the term rabi came to be peculiarly applied, as an honourable compellation of the learned, the word with which it was, at first, for distinction's sake, compounded, would be superfluous and unnecessary. It is, at least, certain, that the Jewish doctors, who resided at Babylon about the time of our Saviour, were called simply rab. But in the Old Testament there is no trace of such a title as rab, rabi, or rabban, given to a man of letters; nor is any one of the old prophets, or scribes, or indeed any other person, distinguished by this mark of respect prefixed to his name. Although the introduction of titles is always occasioned by the erection of useful important offices, it is commonly in the decline of merit that pompous titles are most affected. At first, without doubt, vain-glory has led many to assume them, to whom they did not belong, in right of office, and an interested adulation has induced others to give them. Some of them, however, came from among the Jews, to be converted into a kind of academical distinctions, which, in order to give them more weight, are said to have been conferred solemnly in their schools or colleges, accompanied with certain religious ceremonies. From this practice sprung literary degrees in Christian universities, to which there is nothing similar in all Pagan antiquity, either Greek or Roman, but to which the Jewish custom above-mentioned bears an evident and close analogy.

As for rabi and rabbi, the only difference, it hath been said, betwixt them is, that rabi was the title of such as had had their education, and taken their degree in some foreign school, e. g. at Babylon; whereas rabbi was the title of such as were educated in the land of Judea, and more honourable than the other. But the highest and most honourable title was rabban; which, they say, was never conferred on more than fifteen persons; viz. on R. Simeon, five of his
his descendants, and R. Jochanan, who was of a different family.

Those who belonged to the Jewish schools were divided into three claus or orders. The lowest was that of the disciples or learners; the second, that of the fellows, or companions, who, having made considerable progress in learning, were occasionally employed by the masters in teaching the young students: and the highest was that of the preceptors, or teachers, to whom they appropriated the respectful title of doctor, or rabbi, differing, as some have said, from rab by only the addition of the affix pronoun of the first person. This title rabbi was the highest academical honour. In the gospels, דבשא is given as the Greek translation of the Syriac rabbi. (John, i. 38.) Yet this word does not, as the Greek, literally signify teacher; but, having been conferred at first, as a mark of respect on actual teachers, and afterwards on other learned men, was justly accounted as apposite a version as the Greek language afforded.

In process of time, the term rabbi was used with great latitude; being belted on those who were not actual teachers; and yet it always remained, ever since it had been appropriated to the learned, a relation to learning, and denoted that the person who enjoyed it, though not actually employed in teaching, was well qualified for the office. Rabban, as some have alleged, is not the name of a degree superior to rabbi, though it seems intended for heightening the dignification, and may be understood to denote eminent or learned rabbi, but it was very seldom used. The title rabboni, which we find to have been twice given to our Lord, (Mark, x. 51. John, xx. 16.) is rabban, with the addition of the affix of the first person, and accommodated to the pronunciation of Judaea. The use of the term rabban does not seem to have extended far beyond Palestine, as we may conclude from the following circumstances. Although the word rabbi is very common in the Syriac translation, the Greek דבשאιא being generally so rendered; yet in the only place where that translator introduces the word rabboni, which is that quoted from John, he prefixes in Hebrew, that is, in the dialect of Palestine, which was then so called, adding the explanation given by the evangelist, that is, teacher; which plainly shews that the word rabboni was not Syriac. This is the more remarkable, as in the other passage, where the historian interprets, in the same manner, the word rabbi, adding (John, i. 38.) דבשא דבשאאיא דבשאאיא," that interpreter omits this explanatory clause as intended only for the Greek reader, and speaks of whom he understood Syriac. In the passage in Mark, where rabboni occurs, as the evangelist had added no explanation, his interpreter has not thought it necessary to change their own word rabbi; thus regarding the difference in signification between the two words as inconsiderable, to which we may add, that the apostle John explains both by the same Greek word. It may be here observed that it was customary to enhance the import of a title by doubling it. Thus our Lord, speaking of the Pharisees, says, (Matt. xxii. 7.) "they love to be called of men, rabbi, rabbi." In this manner he was himself addressed by Judas, at the time when that disciple chose to assume the appearance of more than ordinary regard. (Mark, xiv. 45.) The title "rabbi" seems to have been used in the same manner. (Matt. vii. 21.) The words Jewish rabbi and Jewish doctor were commonly used synonymously. In Justin Martyr's dialogue with Trypho the Jew, the rabbis are always called דבשאאיא. But some may object that this does not account for the application of the title to our Lord. As he did not derive his doctrine from any of these learned seminaries, frequented by such of the youth as were reckoned the flower of the nation, the name doctor could not, with propriety, be applied to him. To this objection it may be replied, that as in Judea at the time they spoke not Greek, but a dialect of Chaldee, not differing considerably from what is called Syriac, it is evident that the actual compellation by which our Saviour was addressed, was rabbi, equivalent to the Greek דבשאאיא. Besides, though the title rabbi could regularly be conferred only by those who had the superintendency of their schools, yet the people would be disposed to give the compellation through courtesy, and on the presumption that it had been conferred, wherever they law or supposition distinguished abilities in teaching; and this probably was the reason why it was given to John the Baptist. (John, iii. 26.) Moreover, in the Jewish state, a divine commission was conceived to confer all sorts of dignities and honours, in an eminent manner, and thus superfluous all ordinary rules and human definitions. Accordingly, some of those who gave the title of rabbi to our Saviour, were willing, either sincerely or pretentiously, thus to account for their doing so. Thus Nicodemus assigns the reason why he fulfilled him rabbi (John, iii. 1. c.), although he knew that he had not been educated in human literature, and had not received from man any literary honours. Upon the whole we may remark, that the term דבשאאיא may be fitly express, either by the English term doctor, or by the Syriac rabbi, which is now so much naturalized among us, that its meaning, as a Jewish title of literary honour, can hardly be mistaken. It must also be allowed, that the rabbi among the Jews of our Saviour's age, was a title in the highest degree respectable; and on that account it was interdicted by their master, even to the apostles themselves. Campbell's Seventh Preliminary Dissertation.

The modern rabbins are entitled to a considerable respect among the Jews: they have the first places in the synagogues; they determine all matters and controversies of religion, and very frequently pronounce upon civil affairs. They have even a power to excommunicate the disobedient.

They retain a vast number of superstitious traditions, from the writings of their predecessors; which they observe as scrupulously as they do the law of Moses.

The ancient rabbins were infinite dealers in allegories. Their writings are almost wholly allegorical, particularly their comments and interpretations of the scripture.

They had a great number of rules, and forms of interpreting and quoting, which some modern writers suppose to have been followed by the apostles, in their interpretation and quotation of the prophecies of the Old Testament, in the New. See Quotation.

RABBINICAL Character. See Hebrew.
RABBINICAL Hebrew. See Hebrew.
RABBINIST; a follower of the doctrine of the rabbins; a term used in contradistinction to Caraita.
Father Simon contends for Rabbani, or Rabbannite, instead of Rabbai: in effect, the former readings are apparently preferable to the latter; the word being derived from the Hebrew רבאינא, which is the name of the sect, and which the Jews use to distinguish their doctors from those of the Caraita Jews.
Rabbani, then, signifies a Jewish doctor who adheres to the traditions of his fathers; not simply a rabbin or doctor; for the Caraites, who oppose those traditions, have their rabbins as well as the other Jews.
RABBIT, Cuniculus, in Zoology, a well-known animal of the hare kind, or the lepus cuniculus of Linnaeus, with a short tail and naked ears. In the wild state the colour of the fur is brown; but in a tame state it varies to a black, white.
RABBIT.

pied, and quite white; the eyes are of a fine red. In their
wild state they inhabit the temperate and hot parts of
Europe, and the hottest parts of Asia and Africa. See
Lepus Cuniculus.

The female, or doe rabbit, goes with young thirty days,
and then she kindles; and if she take not buck presently
she loses her month, or at least a fortnight, and often kills
her young and eats them.

In England they begin to breed at a year old, but in
some places much sooner; and they continue breeding very
fast from the time they begin, four, five, six, or seven
times a year being common with them. They have usually
from four to eight in a litter, and hence it is that a small
number at first will soon flock a whole warren, if left to breed
a little while undisturbed. The does cannot fumble their
young till they have been at buck again; this therefore is to
be done presently, else there is a fortnight lost of the time for
the next brood, and the present brood also probably lost.
When the buck goes to the doe, he always first beats and
stamps very hard with his feet, and when he has copulated
with her, he falls backwards, and lies, as it were, in a
trance; in this state it is easy to take him, but he soon recov-
ers from it.

The buck-rabbits, like our boar-cats, will kill the young
ones, if they can get at them, and the does in the warrens
prevent this, by covering their flocks, or nests, with gravel
or earth, which they cloke fo artificially up with the hinder
part of their bodies, that it is hard to find them out. They
never fumble the young ones at any other time than early in
the morning, and late at night; and always, for eight or
ten days, close up the hole at the mouth of the nest, in this
careful manner, when they go out. After this they begin
to leave a small opening, which they incafe by degrees,
till at length, when they are about three weeks old, the
mouth of the hole is left wholly open, that they may go
out; for they are at that time grown big enough to take
care of themselves, and to feed on grasses.

People who keep rabbits tame for profit, breed them in
hutches; but these must be kept very neat and clean, else
they will be always subject to diseases. Care must be taken
also to keep the bucks and does apart till the latter have
just kindled; then they are to be turned to the bucks again,
and to remain with them till they flun and run from them.

The general direction for the choofing of tame rabbits is,
to choose the largest and fairest; but the breeder should re-
member, that the skins of the silver-haired ones fell better
than any other. The food of the tame rabbits may be cole-
wort and cabbage-leaves, carrots, parsnips, apple-ribs,
green corn, and vetches, in the time of the year; also vine-
leaves, graz, fruits, oats, and oatmeal, milk-thistles, fow-
thistles, and the like: but with these too foods they must
always have a proportionable quantity of the dry foods,
as hay, bread, oats, bran, and the like, otherwise they will
grow pot-bellied, and die. Bran and grains mixed to-
gether have been also found to be very good food.
In winter they will eat hay, oats, and chaff; and these may
be given three times a day: but when they eat green things,
it must be observed, that they are not to drink at all, for it
would throw them into a droppy. At all other times, a
very little drink serves their turn, but that must always be
fresh. When any green herbs or grazes are cut for their
food, care must be taken that there is no hemlock among it;
for though they will eat this greedily among other things,
when offered to them, yet it is sudden poison to them.

Rabbits are subject to two principal infirmities. First,
the rot, which is caused by the giving them too large a
quantity of greens, or from the giving them fresh gathered,
with the dew or rain hanging in drops upon them. It is
excess of moisture that always causes this disease; the
greens, therefore, are always to be given dry, and a suffi-
cient quantity of hay, or other dry food, intermixed with
them, to take up the abundant moisture of their juices.
On this account, the very dry food that can be given them
is the shortest and sweetest hay that can be got, of which
one load will serve two hundred couples a year; and out of
this flock of two hundred, two hundred may be eaten in the
family, two hundred fold to the markets, and a sufficient
number kept in case of accidents.

The other general disease of these creatures is a fort of
madness: this may be known by their wallowing and tum-
bling about with their heels upwards, and hopping in an odd
manner into their boxes. This distemper is supposed to be
owing to the rankness of their feeding; and the general cure
is the keeping them low, and giving them the prickly herb,
called tart-rhife, to eat.

The general computation of males and females is, that
one buck rabbit will serve for nine does; some allow ten to
one buck; but those who go beyond this always suffer for it
in their breed.

The wild rabbits are to be taken either by small cur dogs,
or by spaniels breed up to the sport; and the places of
hunting those who straggle from their burrows is under
cloze hedges or bushes, or among corn-fields and fresh
pastures. The owners use to confine them with small grey-
hounds; and though they are seldom killed this way, yet
they are driven back to their burrows, and are prevented
from being a prey to others. The common method of
taking them is by nets, called purfe-nets, and ferrets.
The ferret is sent into the hole to force them out, and the
purfe-net being spread over the hole, takes them as they
come out. The ferret’s mouth must be muffled, and then
the rabbit gets no harm. For the more certain taking of
them, it may not be improper to pitch up a hay-net or two,
at a small distance from the burrows that are intended to be
hunted: thus very few of the number that are attempted
will escape. The method by the dog, called the lurcher and
tumbler, is also a very good one.

Some, who have no ferrets, soak the rabbits out of
their holes with burning brimflour and orpinum. This
certainly brings them out into the nets, but then it is a very
troublesome and offensive method, and is very detrimental
to the place, as no rabbit will for a long time afterwards
come near the burrows, which have been fumed with these flink-
ing ingredients.

The tefticle of a rabbit is a very good object for ex-
amining the structure of this part of generation in animals.
The tefticles of various animals are very variously com-
posed, but all, in general, of vessels variously rolled and
folded together; and even the human tefticles are of the
came fort, being composed solely of rolls of vessels, without
any intermediate substance, only consisting of vessels and
their liquors. Phil. Trans. No 52.

The skins of rabbits are a great article of commerce,
numbers being exported to China: the fur is of great use
in the hat-manufactory.

Rabbit, in Agriculture, is sometimes employed as farming
flock. It is sufficiently evident, however, that this is a
depreration of farming flock that can only be attended to
with advantage under particular favourable circumstances
of soil and situation.

Rabbit warrens, can only be beneficently introduced
where the lands are not capable of affording crops of tolerable
grain or grases. The great uncertainty of this fort of
husbandry
husbandry renders it much more advantageous for the farmer to depend upon such crops, than on it. In hilly tracts of land, where the plough cannot be introduced, and where the soil is of such a light faney porous nature, as to afford little or no grass for the pasturage of sheep, or in rocky situations, this system of management may take place with profit to the farmer.

And it has been observed by the author of the Rural Economy of Norfolks, that this sort of animal is there confined to the heathlets, and the barren hills upon the coast. A level country is unfit for rabbit-warrens, but convenient for the plough; on the contrary, rabbits delight in the sides of sandy hills; which, where turn-writ ploughs are not in use, are extremely inconvenient for tillage; and, when cultivated, are generally unproductive. For the rabbit, on level ground, finds it difficult to make its burrow; the excavated mould is all to be dragged upward to the surface; hence a piece of ground altogether level, can seldom be stocked successfully with rabbits; unless it be first laid up by art, at a great expense, into inequalities. While, on the contrary, against the side of a steep hill, the rabbit has no difficulty to encounter; the declivity affords him a ready vent for his mould; his work is all down hill; and, unless the soil be too stony, or too rocky, for the rabbits to work freely among, a broken hilly country may generally be stocked with advantage; provided a tolerable market for the carcasses can be had within reach. He thinks there are, perhaps, few sandy or other loose-foiled hills, which would not pay better in rabbit-warrens, than under any other course of husbandry that could be introduced on them. And it is afterwards stated, in a minute, that on a considerable part of a farm which lies towards the coast, being hilly and very badly foiled,—more especially the tops and sides of the hills, which have always been full of rabbits in spite of all endeavours to destroy them,—the tenants last year (1782) applied for leave to convert this part, about ninety acres, into a rabbit-warren. Leave was given, and an allowance made them of half the estimated expense of raising a foot-wall fence round these ninety acres. He adds, that the fence was nearly finished, and the warren had, that year, turned out beyond expectation; it was valued by one who ought to be the best judge of its worth, at forty pounds a year; which is nine shillings an acre. And that, as the part of a farm, these ninety acres were not worth five shillings an acre; at the then prevalent price of barley, they were not worth more than four shillings an acre. It is, therefore, observed, that for ten pounds a real improvement of twenty pounds a year has been made and secured; for the warren will, through necessity, hereafter keep the fence in repair for his own advantage. He remarks, that the fence is made about four feet high, and three feet thick; faced with greenwood; and capped with furze, so as to project eight or ten inches over the face. Some of it was done for a shading a rod; but the spring putting in, fourteen or fifteen pence a rod of seven yards was obliged to be given. And a neighbouring warrenner, that winter, gave me some notice of the wall without the capping; which he does not mean to put on till the wall be thoroughly settled. This is very judicious; as several rods of that above-mentioned shot down in different places, as is often the case in such fort of work. It is further observed, that there are several patches in the valleys and some on the tops of the hills which have usually been tilled. Some of these were last year (1781), and some of them ought to be every year, cultivated for the rabbits; thus, while they get field or moly should be ploughed up; fallowed, fowing turnip-feed for present feed, (they will not let rape get up,) and to prepare the soil for barley and grass-feed the ensuing year. Thus a regular succession of feedage might be kept up for the use of these animals. And in the Rural Economy of Yorkshire it is lamented, that at Dalby there are two pretty large warrens. At Lockton there is one now (the time of writing) planting. And there are other parts of these heights which might be profitably stocked with rabbits. In general, however, property is too much intermixed to admit of an improvement, which is singularly adapted to the nature of these high grounds. And, that in situations where the ground, as well as the soil, is suitable to rabbit-warrens, and where an extent of it, sufficiently large, can be collected together in one property, there is a very strong reason why it may be profitably stocked with rabbits. It is added, that one of the warrens of this district contains eighteen hundred acres of surface; most of it covered with a black moreland soil; part of it a barren gravel; some little of it a thin lime-flone loam; not worth perhaps, on a par, for the common purposes of husbandry, a shilling an acre; nevertheless, these eighteen hundred acres are let, as a rabbit-warren, for three hundred pounds a-year! He will not pretend to say, that this warren is worth three hundred pounds a-year, nor affirm that it is not worth a shilling an acre to a husbandman. If it be worth two hundred and fifty pounds, as a warren, and supposing it to be worth even two shillings an acre, as a farm, it will be sufficient evidence of the profitableness of rabbit-warrens, in proper situations.

And in speaking of the wolds, be observes, that the warrens are numerous, and some of them very extensive. Coldham warren is at present, he believes, the largest upon the wolds; and, probably, the most valuable warren in the island. The Coldham farm contains about nineteen hundred acres; and, speaking generally, it is all warren; nor, however, wholly appropriated to rabbits, a flock of from six to eight hundred sheep being kept within the warren walls; principally, however, on one side of the warren, away from the burrowing grounds. And this appears to be a practice peculiar to the wolds of Yorkshire and Lincolnshire, whose hills likewise abound much with rabbit-warrens, and where better soil is appropriated to rabbit-warrens, than is perhaps in any other part of the island. The Coldham warren, in point of soil, is most of it worth from ten to twelve shillings an acre; some of it fifteen or sixteen shillings. But the present bleakness of the situation renders it of little more than half the value. As these better parts become moisy, they are inclined by a foot-wall, the surface pared and burnt, and the soil broken up for arable crops. Having afforded a succession of crops of corn, turnips, &c., they are now given with graze-feeds, and again thrown open to the rabbits and sheep. In 1783, there were about two hundred acres of this farm under the plough, besides some little sheep-walk which lay without the warren walls. The warren therefore, at that time, contained from fifteen to sixteen hundred acres; and, adjoining to Coldham, are two more considerable warrens; so that there are, perhaps, three or four thousand acres of tolerably good land, lying together, and appropriated principally to rabbits.

But it is remarked in respect to soil, that there is a disadvantage in flocking a rich soil with rabbits; a fough of graze, after a dry season, is found to produce a fcurring; which sometimes carries off great numbers. With regard to the burrows on the high wolds, they are mostly on the sides of hills; at Coldham, principally in one deep valley; whose fides are steep; giving the rabbits great freedom in working. The soil, in this case, is about eight or ten inches deep, under this a chalky rubble, of some inches thick, lying on a chalk-flone rock. The burrows are in the sub-flone.
between the foil and the rock, and chiefly towards the tops of the hills. And thousands of daws build their nests in the burrows, to the great annoyance of the rabbits. But at Driffieldgreets, near Driffield, where there are two large warrens, the surface is a dead flat; nevertheless, the warrens are well flocked and productive; a proof that a flat surface may, in some cases, be profitably flocked with rabbits. The soil, in this case, is a light land or gravelly loam, which is very proper for the purpose to which it is applied.

In some of the very southern districts, rabbits occupy the different sandy hilllocks, and many of the rocky wales; but there is nothing of any great importance in the management of them. Both the grey and black forts prevail in some instances. The writer of the Suffex Report on Agriculture thinks, that this fort of flock is the nuisance of a county; it increases and multiplies in proportion to the size of the wales, and is, of course, productive in this county.

From Horsham forest, Ashdown, and other parts, very considerable quantities of rabbits are sent to be disposed of in London.

In some of the midland counties they are found to be sufficiently abundant upon the sandy parts of wale lands; in inclosed level land, it is thought that they are not better than vermin, and that should the commons be properly generally inclosed, they must be in a great measure exterminated to make way for a better fort of flock; in inclosed land, they can only be kept with propriety, even in small warrens near the house, well fenced in, for family consumption; or on sandy or rocky precipices, impracticable to the plough, where they should also be fenced in. It is well known, that in the neighbourhood of commons abounding with them, great pains and expense are often used to fence the inclosed adjoining lands from their depredations. Rabbits are certainly a fort of flock unworthy of being cultivated, or bred in any considerable numbers, on inclosed and cultivated land; yet doublets deserving considerable attention on impracticable sandy or rocky steeps, which may at the same time be planted; and when properly fenced in, and thus fenced, such land seems in a system of the highest improvement of which it is capable.

In Cheshire many doubts have been entertained as to the advantages of encouraging the breed of rabbits, and many farmers are so utterly averse to them, that they would with the whole race to be entirely exterminated. Where land is inclosed, and applied to arable purposes, it seems agreed that by the injury they do to the fences, by the interfering with the cultivated land, and by the destroying of its produce, they are much more detrimental than profitable. It is, however, thought to be a question for consideration, whether, if a portion of weak fand, or dry heath land, was set apart for a rabbit-warren, well fenced, and kept distinct for this purpose; it might not, in some situations, be more profitably employed in this than in any other manner.

By some it is supposed, that it may be occasionally necessary to restrain them, on account of their astonishling succulence; but that to attempt to exterminate them, if it were possible, could not be politic or advisable, as they furnish food for foxes, which would otherwise prey on game and poultry.

This fort of flock is frequently met with in many other districts on tracts and spots of similar kinds of barren and uncultivable forts of land, and is probably the most convenient, appropriate, and beneficial description of any by which they can possibly be occupied and managed.

Stocking.—In the second of the above districts, it is stated, that in stocking a warren, whether the surface be flat or hilly, artificial burrows are made, to reconcile the rabbits to the ground, and to preserve them from vermin, until they have time to make their own burrows. And that in making these burrows, an improvement has lately, it is observed, been hit on. They are hewed with an auger, of a diameter large enough to make a burrow of a sufficient width. In a level warren, these augers may, from time to time, be found useful in forming such holes. They, however, in most cafes, are capable of making burrows for themselves without any difficulty.

But in regard to flocking in Lincolnshire, according to the agricultural survey of that district, some of the warren lands are flocked in the proportion of three couple only to the acre; while in others, it is in a considerably larger proportion. And one buck or male rabbit is said to be there sufficient for one hundred does, or females; but this is certainly a much larger proportion of the latter fort, than is allowed in most other districts. On the whole warrens of Yorkshire, according to Mr. Marshall, one male is considered as sufficient for only six or seven females, and the nearer they can be brought to that proportion, the greater the flock of young ones that may be expected, it being the nature or economy of the males to destroy their young, especially when the proportional number is too great.

Fencing.—The fencing in these situations is sod-wall, capped with furze, or of late with thiff thraw, forming a kind of thatch. And it is supposed, that weed would be found admirable in this intention. The warrens near Driffield are fenced with paling; an expensive fence in the out-set, and always under repairs. A brook, though ever so deep, is found to be insufficient as a fence against rabbits; one side of Driffieldgreets warren is bounded by a brook; but it is nevertheless fenced with paling. When the rabbits can evade this, they readily swim the brook. The necessity of good fences is of course sufficiently evident in this view, as well as that of preserving them from the destruction of vermin, and birds of prey, such as eagles, kites, &c. which are taken in steel traps, placed on elevated mounds of earth, where they delight to sit. It is this kind of fencing and coping, or killing the top, together with food in winter, nets, traps, and other things for taking them, with charcoal for drying the skins, warreners' men for killing and carrying, horses for carrying them to market, &c. that constitute the great expense of this fort of management.

Different Breeds.—There are many different breeds or varieties of these animals, but those that are employed as stock for warrens are the common grey and silver-grey breeds; the former of which is found to be considerably more hardy and much better for the purposes of food; but the latter has greatly the advantage in the value of the skin. In the above warrens, till lately the common grey rabbit, probably the native wild rabbit of the island, was the only species. At present, the silver-haired rabbit is sought after, and has, within the few last years, been introduced into most warrens. The skin of the grey rabbit is cut; that is, the wool is pared off the pelt, as a material of hats; whereas, that of the silver-haired rabbit is dressed as fur; which, the writer understands, goes principally to the East Indies. The colour is a black ground, thickly interfered with single white hairs. The skins of this variety fell for about four shillings a dozen more than those of the common fort; a sufficient inducement for propagating it in preference to the grey fort in most cafes. If the white forts could be introduced they might be still more valuable.

Management, Expenses, Profit, &c.—This is a fort of flock that on the whole only requires a slight attention; it is, however, necessary to supply the rabbits with additional food in the winter season, when the weather is severe, such
such as fine green hay, fainfain, clover, turnips, and others of the same fort, which must be distributed over the warrens. It is iflupposed that turnips anfwer the fort in deep fows, as the rabbits can discover them by the fcent. This fort of food is given in the quantity of two or three large carfuls to a thoufand couple per day, and one load of hay in the fame time during a form. It is likewife sometimes the prac-
tice to distribute billets of new cut afh-boughs, gorfe or whins, and other finilar woods in the warrens, the bark and other parts of which is eaten, by which the proportion of
hay is lefTened in a confiderable degree. In great fows, it is
neceffary to clear them away from the ditches or fences, to
prevent the rabbits from getting over them.

It may be obferved, that the rabbit is a fort of flock that
begins to breed at an early age, as in eight, ten, or twelve
months, going only about thirty days with young; the young
being a little more than three weeks old before they appear
from the burrows, during which time they are fucked twice
in the day by the mother. It is therefore evident, that they
may breed three or four times in the course of the year under
good keep, as the does take buck almost immediately after
producing their young. In warrens that are inclofed, it is
however faid, that they seldom breed more than two or three
times in the year. The annual produce per acre, is moftly
estimated at from three or four, to eight or ten couple,
yielding a profit of from eight, ten, or even fifteen fhillings,
where they are conducted under a good fystem of manage-
ment. And the produce is, as has been feen, the largest
on new lands; however, much of the profit muft always
depend on situation, fo as to be near good markets.

These animals are in what is termed feaon from the
end of October to the beginning of January, in which period the beft fkins are produced: of course a large pro-
portion of them is killed in this feaon time. The farmer
often futfains great fufs in what by the purchasers are called
whole fkins, quarter fkins, and racks, sixteen of which are
only confidered as a whole skin. The rabbits are difpofed
of by the hundred, fix score couple being confidered as an
hundred.

The following statements are given in the Agricultural
Survey of Lincolnshire, on this fort of management. On
the authority of Mr. Chaplin, it is flated that on 1000
acres it is fair to kill 2000 couple, which are sold by the
hundred, as above; which have fold at 10/. on an average
of ten years; laft year 13/.; killing and looking after, 62/.
for 1000 acres. And on the warrens between Cayton and
Tathwell, filver skins have been from 15. even to 21s. a
dozent; but the common grey rabbit is fo much harder,
that if a warren be focked with both, there will, in a few
years, be nothing but greys. It is added, that from Louth
to Caflor, 18 miles, 10 of them are warrens, chiefly fifiers;
rent 2s. to 3s. an acre. They plough a part every year
for corn and turnips; and laying down again with feeds, let
down the fences for the rabbits to enter. Warrens are
reckoned profitable, fo that fome fortunes have been made
on them. It is further flated, that in point of fkins, thofe
bred about May-day undergo no change from their white
colour, but from a white rack become a whole skin; bred
at Lady-day, become black; in June, white; in July,
black; in November, white again: then in full feton, as
the cafes are alfo. The skins ought to have thofe colours
on the infide, when flayed, or ftriped off from the rabbits.
The writer further flates, that from 250 acres of land, that
were fainfain worn out, and planted with rabbits, the fol-
lowing was the account many years ago; but all prices,
rent, &c. &c. are calculated at the preffent rates; and it is
to be noted; that the ground being thus new to rabbits
was much more productive than old warren land is found
be, as they breed much better on fuch new than on old
land. Used to kill about 2000 couple; flock left about 700
couple. Sold banks that fell, thirty-five years ago, 1s. 2d.
a rood of feven yards, would now coft 2s.; fufse faggots
 were 7s. a hundred, that is, 5s. for the fuzce, and 2s. kid-
ing, now doubled. Banks will lafi about seven years, in
a middling way; from three to twenty: want facing once
in seven years, at half the firft expefses; want capping in
three years with the fuzce. Laying on, or capping, 3d. a
rood now. It was then reckoned that 250 acres would
clear 100/., besides rent, which then was 1s. an acre.

Fencing annually half a mile 800 yards 133 roods at 1s.
6/. 13s.; for facing fuzce, a kid will do a yard; 24 miles
kidding, at a kid a yard, 4400 yards and kids, at 1s.
now, for 250 or 27l. 10s., or per annum 9l. 3s. 4d. add
6/. 13s., it is 15l. 16s. 4d. per annum. A warrenier 35s.,
a cow, fuel, and houfe: in all 40/. Extra labour, killing
18s. a-week for sixteen weeks, 14l. 8s. Alfo for a month
18s. a-week, 3l. 11s. 6d. Traps 5s. a-year. The men who
kill will carry. Four horses for three weeks, 1l. 4s. a-week,
7l. 4s. Charcoal for drying fkins, 5s. A perfon to order
fkinns, that is, from feaon to feaon, drying, five weeks; a
ufeful woman would do it, 1l. Winter food (after three
days now it must be ferved) cannot be lefs than 10l. a
year on 250 acres.

Recapitulation.

But it is, notwithstanding this statement, fuggested,
that if he had a warren of his own, he would plough it up
for corn, &c.; thinking tillage now more profitable than
rabbits. And the author adds, that at Partney fair, meeting
with Mr. Grant of Withgul, and difcourfing with him upon
warrens, he informed him that a common flock in winter
was three couple per acre, and the produce five or fix
couple
RABBIT.

couple killed; that killing, carrying, &c. might amount to something more than 1s. an acre: the fort silver f wig, which will not do well in other counties, where they have been tried. He has now 1000 acres of warren; and upon 100 acres the stock is 2600 couple, and kill 3000 couple annually. New land is the most productive. On such a warren, the rabbits must have two loads of hay a day, in a storm, or two or three large waggon loads a day of turnips. The warrener has 20L a-year, and two cows; the killers 8L or 9L a-week, and board for ten weeks. Silver fkins now are 10L. a dozen; have been 14L to 15L.

Fences 6L a-year; no cres onc; no buildings. The immense occupation of Mr. Grant and his sons, being much the most considerable in the county, with the circumstances of making an ample fortune, make him devious of seeing him. It is added, that 10 acres, Dr. Gibbons had a warren of 12 or 1300 acres; and the rest of the farm including it, 300L a-year, which rent has been doubled by ploughing. And Mr. Kersaw observed, that the community received next to nothing from warrens; which is probably the cause, as has been seen above, where the land is capable of being managed under the plough, or the system of grass.

And the calculation of Mr. Parkinson, of a warren of 700 acres under warrens, in the same district, stands thus: rent 5L; standing stock 2000 couple of silver hair, valued to the incoming tenant at 2L 6d. a couple ten years ago, and demanding a capital of 142L; and carefully typed to catch all extra bucks, so as to leave only one-fourth of the total number of bucks.

It is stated by the writer of the above agricultural survey, that the warren of North Ormby, occupied by the late Mr. Atwell, is supposed to be one of the best managed in the county. The rabbits chiefly consist of silver-greys; the land of the yearly value from 2L 6d. to 8L, and some little of it 10L. the statute acre. The occupier was of opinion, that lately his warren lands would have paid him better, had they been applied to the purpose of growing corn, and grasfs feeds for keeping sheep. The rabbit produce he supposed to be from 8L to 10L. in some particular years they have paid from 15L to 21L. an acre; but to obtain any extraordinary profit, very great care must, he thinks, be taken in killing the many different kinds of vermin which depredate, and, without the utmost vigilance, will

It is noticed, that as the family is maintained out of the farm, the interest of the capital of about 1400L. is not charged, because the interest would be only 70L. per year, when they are maintained out of the farm, with a profit of 294L. 3s. 10d.

RABBIT.

will quite depopulate the warrens. A considerable expence also attends the neccessity there is for night-watchers, to protect them from the infinitely worse vermin, the poachers. With him the silver-grey skins have been sold from 8½ d. to 15 d. and 16 d. per skin; the last two years they have only brought from 10d. to 11d. per skin; but to obtain even these prices, they must be what is called full feaoned, whole skins, and of the choicest colours, with respect to which the fashion varies very greatly. The carcases, of late years, have not averaged net into pocket more than 4d. per couple, after the expence of drying them, and by means of light diligence carts, having them carried to markets 30, and sometimes more than 60, miles to obtain even that sum. This inconvenience is occasioned partly by its being necessary to kill eight or ten parts of a year's slaughter in so short a time, as between the second week in November and Christmas, on account of their skins being then only in full prime, and as they are also very soon subject to become putrid, much more so than hares; and their being obliged to be packed close together, very greatly increaseth the mischief.

The estimate of the warren on the estate at Thoreselfway of 1700 acres, as given by the tenant Mr. Holdgate, with the silver fort of rabbits, is this:

Or about 22d. per cent. (the 5 per cent. included) on capital employed. This the writer observes is very great, reckoned on the capital, but small reckoned by rent, as it amounts to only half a rent. But supposethat the gros produce of 1500, which he takes to be nearer the fact; then the account will stand thus:

or 45 per cent. on the capital.

But it is supposethat, in whatever way it is taken, it explains the reason of so many of these nuisances remaining. The investment of a small capital affords a profit or interest that nothing else will, and of course the proprietor will be sure never to convert them to better use. But, it is asked, what pays the public interest? Here are only 2000. expences to 600l. rent, what is the population, the industry, the improvement! The landlord gets the lowest of rents, the tenant makes a good profit, they divide all, and the rest of the world is little or no better for them.

Rabbit-warrens are met with in most other districts of the kingdom, both towards the southern and northern parts of it; but more abundantly in those of the north. In the south they have in most places been got out of from any tolerable fort of land which is capable of affording any other better kind of useful produce, but in some parts of the north they still occupy spaces of ground which are of a good quality, and which might be converted to better purposes with great advantage to the proprietors, as well as farmers. Warrens of this nature, in some cafes, in both these situations, however, Hill continue to be well stocked, and, in the latter, are in particular instances of pretty considerable extents.

In Cheshire, the principal rabbit-warrens are on Delamere forest, though on several of the heaths and sand-lands these animals are frequently met with, but not in such numbers together as to constitute warrens.

In the north riding of Yorkshire, also, a few rabbit-warrens are met with on the detached moors, as well as on the skirts of the higher moors; but they are not so extensive as to make them an object of much attention. The kind of rabbits here are more thinly the common grey, with the exception of the flock on a warren at Nappa, in Wenley-dale, of about one hundred and fifty or two hundred acres, which consists of silver-greys, and is the only warren which is known in this district, to be entirely stocked with this kind: they are flatted to have been brought some years since from a warren in the above noticed district of Lincolnshire, to which they had been originally introduced from Ireland. The skins of this kind of rabbits are supposed to be worth double those of the grey; they are not used for felts, as the last, but dressed as furs, and ultimately exported in that state for the China market, where they are worn by the principal people; an use which has been already noticed and confirmed in regard to the demand which it creates.

But in the northern parts of Lancashire, warrens of this kind are more frequent. At Rossall-hall, in the tract called the Fild, one of great extent has exiled for a very great length of time; but the present proprietor, B. F. Hilketh, esq. has, with great propriety, lately reduced it very considerably, by taking two large lime farms from it, so that it now consists only of about a hundred acres of the most sandy barren part.

This warren formerly supplied a great number of rabbits for sale in the markets and hat manufacturies of the neighbourhood, and of course became a source of profit to the owner, though the management was very imperfect. The farms taken from it will, however, become far more advantageous to him.

The stock here was formerly of the grey rabbit kind, and it is still the same on the warren which remains, which is however far from being sufficiently stocked.

There was formerly no fort of green food ever cultivated for this fort of stock; nor has it been yet attempted on the present warren, but the proprietor intends to have it done in an effectual manner. Nor have the rabbits ever been fed in the winter season with either hay, bark, or any other fort of
of food; their being so near to the sea-coast perhaps renders it unnecessary.

The only mode of taking the rabbits here has hitherto been in nets, by what is termed running them by means of dogs.

At Heysham the Rev. Mr. Clarketon has a tract of coarse fenly land above his house, of about twenty acres, which has a great number of grey rabbits in it, and is well suited for a rabbit-warren, as it is incapable of being converted to any better purpose on account of the severity of the cold winds, and the effects of the sea-spray thrown up by them, as well as its rocky, whiny nature.

The principal rabbit-warrens in this county are, however, those in the sandy tracts in the south and north ends of the island of Walney, and in the neck of land from which it seems to have been separated. The rabbit-warren at the north end of this little island occupies a considerable space of ground of this barren sandy quality, as well as that at the southern point. The former is stocked wholly with rabbits of the grey kind, this fort being in most demand. There is much expense attending these warrens in many cases.

The expense of flocking in order to keep them up is sometimes very considerable. In this instance the farmer has upwards of two miles of dike fence composed of sod and flone to keep up and in repair, which costs from five to six fillings the rod of seven yards. The expense of a man constantly to look after the rabbits, and keep the dike fences in proper order and repair. That of the purchase of the traps or types, which cost 37. a-piece, and eighteen are required; but they last long, and cost little in repairs.

The providing net and dogs, which is annually about 10£.

The charge of taking the rabbits to Ulverlton, twice in the week, during ten weeks, which is 5£. each time.

The sale of rabbits is annually from one hundred and fifty couple upwards, at the rate of 21. 6d. each couple. They are usually sold to Lyons of Prefton, who takes the charge of them after they have been delivered at the above-named place.

Not any sort of dry or green food is ever given to the rabbits in this warren during the winter season; but there is not any snow, and very little frost taking place; in consequence of the situation being so surrounded by the sea.

The warren at the fourth end of the same little island is of similar extent, and exactly under the same fort of management; but it is said to be earlier, by a month at least, in the breeding of the rabbits, and the quality of their fur; which is supposed to arise from its being more fully exposed to the influence of the morning sun, in which the rabbit delights, and by which it is greatly benefited.

The rabbits are here likewise offered to sell for a higher price, as 37. the couple, than in the warren at the north end of it.

The rabbit-warren at Sand Scale is another farm of this fort in this neighbourhood, under similar regulations, but somewhat smaller than those in the Isle of Walney; and there is a still smaller one attached to a farm at Roanhead, the property of Mr. Sanyes, Esq., of Graythwaite, which is conducted in much the same manner, and with the same results as in the above cafe.

It may be noticed that this fort of flock is mostly taken by nets or traps, set in the form of a fold between the places where they run, and those where they feed, the rabbits being hunted into them as they return from feeding. But the wold warreners, Mr. Marshall says, have three ways of catching their rabbits; with fold-nets, with spring-nets, and with "types," a species of trap. The fold-nets are set about midnight, between the burrows and the feeding-grounds; the rabbits being driven in with dogs, and kept inclosed in the fold until morning. But the spring-net, when used, is, he believes, generally laid round a hay-stack, or other place, where rabbits collect in numbers. It is added that the trap is a more modern invention. It consists of a large pit or ciftern, formed within the ground, and covered in with a floor: or with one large falling door, having a small trap-door towards its centre, into which the rabbits are led by a narrow muce. And this trap, on its first introduction, was set molly by a hay-stack; hay being, at that time, the chief winter food of rabbits; or on the out side of the warren wall, where rabbits were observed to scratch much, in order to make their cleftes. Since the cultivation of turnips, as a winter food for this species of flock, has become a practice, the situation of the trap has been changed. Turnips being cultivated in an inclosure within the warren, a trap is placed within the wall of this inclosure. For a night or two, the muce is left open, and the trap kept covered (with a board or triangular rail), in order to give the rabbits the requisite haunt of the turnips; which having got, the trap is barred, and the required number taken. He adds, that in emptying the ciftern, the rabbits are forced; those which are fat, and in season, are slaughtered; those which are lean, or out of condition, are turned upon the turnips to improve. And that, at the close of the season, the bucks and the does are forced, in a similar way; the bucks are slaughtered, the does turned loose to breed.

Mr. Marshall also remarks, that great caution is requisite in the use of these traps. If too many rabbits be admitted at once, and the ciftern be kept close covered only for a few hours, suffocating and inordinate heat takes place, and the carcase, at leaf, are spoiled. Many thousand carcases have been wasted through this means. The traps are therefore watched; and when the required number is caught, the muce is stopped, or the trap covered in a proper manner.

And it is observed, that some notion may be formed of the produce of the wold warrens, from the great numbers which are frequently slaughtered at once; five or six hundred couple having not unfrequently been slaughtered in one night; and, it is said, that when the two Driffield warrens lay together, there was once an instance of fifteen hundred couple being killed at one time.

There is often much inconvenience in this fort of flock, from their getting out of their inclosures, and destroying the young corn-crops, new fowl graffes, young turnips, and the quick hedges as well as young plantations of apple-trees that may be in the neighbourhood. This forms a material objection to this fort of flock by the farmer.

Tame Rabbits,—In respect to breeding and rearing tame rabbits with the view of profit, those who are engaged in the business perform it in hutches, which must be kept very neat and clean, otherwise the rabbits will be subject to disease. Care must be taken also to keep the buck and does apart, till the latter have just kindled, then they are to be turned to the bucks again, and to remain with them till they fatten and run from them.

And the general direction for the choising of tame rabbits, is to pick the largest and flemmest: but the breeder should remember, that the skins of the silver-haired and white farts fell better than any other. The food of the tame rabbits may be colewort and cabbage-leaves, carrots, parsnips, green corn, and vetches in the time of year; also parsley, grafs, green leaves, milk, and cow-thistles, and other fimaliar plants, but with these moilt foods they must constantly have a proportionable quantity of dry food, as hay, bread, oats, bran, and other fimaliar matters, otherwise they grow pot-bellied, and die. Bran and grain mixed together have been found
RABBIT.

It is remarked, that the author of the Treatise on Agriculture and Gardening, has bred these animals with much success and ornamental effect in a small artificial Warren, in a lawn in the garden, made in the following manner:—

"Pare off the turf of a circle, about forty feet diameter, and lay it on the outside; then dig a ditch within this circle, the outside perpendicular, the inner sloping, and throw earth sufficient into the middle to form a little hill, two or three feet higher than the level of the lawn; the reed must be carried away. Then lay down the turf on the hill, and beat it well to lette. The ditch at bottom should be about three feet wide, and three and a half deep, with two or three drains at the bottom, covered with an iron grate, or a stone with holes, to carry off the daily rains, in order to keep the rabbits dry. In the outside bank should be fix alcoves, the sides and top supported, either by boards or brick-work, to give the rabbits their dry food in; by their different situations, some will always be dry; fix boxes, or old ten-chests, let into the bank, will do very well. If the ground be very light, the outside circle should have a wall built round it, or some flakes driven into the ground, and boards or hurdles nailed to them, within a foot of the bottom, to prevent the bank from falling in. The entrance must be either by a board to turn occasionally across the ditch, or by a ladder. The turf being settled, and the grass beginning to grow, turn in the rabbits, and they will immediately go to work to make themselves burrows in the sides, and in the hill. By way of inducing them rather to build in the sides, to keep the turf the neater, make a score of holes about a foot deep, and they will fill them to their own mind; and if there be a brick-wall round it, it should be built on pillars, with an arch from each, to leave a vacancy for a burrow." But there is, he says, another way that may be practised, which is, "to dig the ditch only about two feet deep, which will yield about earth enough to make the hill; put some pales, about a foot high, on the outside, for that will be a sufficient height to keep the rabbits in. Feed them as other tame rabbits are fed; and in wet weather sprinkle sawdust at the bottom, by which means the quantity of manure will be increased; once a week is often enough to take it away; the quantity will be surprising, nor will the smell be in the least offensive, even though it be quite close to the house. In a very large lawn, two or three of these hills, with the rabbits feeding on the tops, will not be unpleasing objects. If the hucks happen to be mischievous in killing the young ones, they must be chained in an alcove; or else have their liberty as in a Warren. After a great snow they will want some assistance early next morning; because the ditch will be nearly filled, and perhaps the alcove, where the hay is, will be blocked up."

He adds, that "it is a great improvement to castrate the young bucks, and keep them till they are full grown, before you kill them; the flesh will be amazingly finer, whiter, and tenderer. But then it will be bett to take them away, and keep them in another Warren, lest they should be too numerous, and disturb the breeding does; or else have a few hutches in the alcove to fatten them in."

It is suggested, that "as oil-cakes are found of great use in fattenings cattle, it is probable they would be useful in fattenings rabbits: and it is affirmed, that some of the oil mixed with the pollard or buck-wheat, is cheaper than the cakes; but having never made the experiment, he cannot ascertain its superior advantages."

In this mode, attention should be had to the breeding those forts of rabbits whose skins are in the greatest esteem with the furriers and hatters. These skins are generally of more value than the flesh, especially in the winter, against which time contrive to have the greatest quantity of these fattened hucks.

Profs.—It is remarked, in respect to profit in this way, that where does are kept in hutches, they are supposed to breed fix times a-year, and only five young ones are left to each, which is thirty from each doe; but these are in a more natural way, and the young ones difficult to be gotten at, let us suppose about thirty-fix to be produced from each doe, reckoning only seven-pence for each; there is a guinea profit from each doe; as the additional value of the skins in winter, and the dung, will more than pay the expense of food and attendance on them. And it is quite necessary that those who keep many rabbits in this way, should cultivate some lucern, parsley, and carrots, as no other vegetables are such proper food for them as these; they should also be fed upon some of the best upland pasture hay; for if it be coarse, so far from eating, they will waste it. Lucern hay is very proper for them in these cases.

In some districts very considerable profits and advantages are derived from the breeding and keeping of white tame rabbits. The skins of this fort having lately been much employed in trimmings, have sold at a much higher price than those of the common kinds. Their dung is also found of very great utility in the cultivation of large farms.

Diseases.—When kept in this way, rabbits are subject to several diseases, as the rot, which is caused by the giving them too large a quantity of green food, or the giving it fresh gathered, with the dew or rain hanging in drops upon it, as it is over-moisture that always causes the disease; the green food should, therefore, always be given dry, and a sufficient quantity of hay; or other dry food, intermixed with it, to counteract the bad effects of it. And a sort of madness often feizes them; this may be known by their tumbling about; their heels upwards, and hopping in an odd manner into the boxes. This distemper is suppos'd to be owing to the rankness of their feeding; and the general cure is the keeping them low, and giving them the prickly herb called tare-thistle to eat as much as possible. They are also subject to a sort of scabby eruption, which is seldom removed. These should, however, be directly separated from the rest of the flock.

It is noticed that the profit in this mode of management cannot, however, be well ascertained, as much will depend on the care which is taken in the feeding, and other manage-
RAB

Rabbit-Warren Farm, that fort which is chiefly managed under the rabbit fylem. These sorts of farms are now much less common than formerly, but in some instances, as has been seen, they afford the best and most advantageous means by which lands can be turned to any account in the way of cultivation. They, however, in most cases require no little capital, exertion, and attention, to manage them in the best and most profitable methods. See Rabbit.

Rabbit Manure, that which is collected from the dung of these animals, and which is said to be very valuable. See Manure.

It is found beneficial in different modes of application, as by being intimately mixed and blended with the manure of cows, or fよりも arable lands, and by being sown by the hand, only over the surface of it, in the way of a top-dressing, when they are in a flate of crop. When used in the last manner, it is likewise highly advantageous on most sorts of grass land; and in both these cases of top-dressing with it, there is a very quick and powerful state of vegetation produced in the crops, which can hardly be gained in any other way. See Quick Manure, and Top-Dressing.

In Oxfordshire, Mr. Fane has raised a small building for keeping rabbits in hutches, for the sake of the manure; he is said to have some hundreds, and to meditate the erection of a second building for keeping double the number; the present quantity make a load of manure in the course of the week; and as two loads manure an acre, they are the means of fully dressing twenty-fix acres annually; it is not conceived by him that they produce any other profit, nor is it necessary; for to be able to sell so much food at home, and pay attendance, the profit of manuring such a breadth of land, it is supposed, must be considerable. Three dozen of rabbits in the week are mostly sent to the London market during the season in which they can be used.

This is a sort of dung or manure, which has yet been but little subjected to chemical examination, consequently its real properties, or constituent principles, are very imperfectly known or understood; it would appear, however, from the effects which it produces, that it may be employed with the most advantage, when laid upon the land, in its more raw, crude, or fresh state, before it has undergone much decomposition by the processes of fermentation or putrefaction. It has, perhaps, never yet been kept dry and reduced into a powdery condition, so as to be put in along with the seed, in the manner of rape-duff, though it seems probable that it would go farther, and be more beneficial, in some cafes, if used in this way. See Dung.

RACBACADO, in Ornithology, the name of an American bird, described by Nieremberg with many fabulous circumstances. All that seems certainly known is, that its tail is very remarkably forked.

RABA, in Geography, a town of Arabia, in the province of Yemen; 30 miles N.W. of Sana.

RABDIUM, in Ancient Geography, Tur-Rabdia, a town of Asia, upon a mountain, some distance from the Tigris, south of Tigranocerta, and east of Niβis.

RABDOIDES. See Rabdoidea.

RABDOLOGY. See Rabdology.

RABDOMANCY. See Rabdomancy.

RABEOBA, a name given by some to the roots of the flammula major.

RABELAIS, FRANCIS, in Biography, was born about the end of the fifteenth century at Chiron, in Touraine. At an early period he entered himself among the Cordeliers, and became well skilled in the learned languages, and the literature of the age. He acquired a good share of popularity as a preacher; and what he gained by his sermons, he expended in the purchase of a small library. His private life was not so exemplary as his public discourses were dignified; and for some misconduct, which caused scandal in the monastery, he was imprisoned in his cloister. By his wit and facetiousness he obtained his liberation, with the pope's permission to quit his order, and remove to that of St. Benedict. Not being able, however, to bear any kind of restraint, he laid aside his religious habit, and, in 1532, went to Montpelier to study medicine. After some time he repaired to Lyons, where he printed a collection of pieces of Hippocrates and Galen. Here he likewise published several other works, among which were some of the books of his History of Pantagruel, which gave him so distinguished a place among burlesque writers. In 1533 he went to Paris, and waited on cardinal John de Bellay, to whom he had been known when they refided in the same convention; and he now made himself so agreeable to his old friend, that he was taken into his house in the several capacities of physician, reader, librarian, and steward. Du Bellay, in the following year, going out as ambassador to the court of Rome, took Rabelais with him, where his wit so much interested the pope and cardinals, that he very readily obtained a full abolition for the crime of apotheosis. In 1537 he took his doctor's degree in physic at Montpelier; and returning to Paris soon after, his friend the cardinal presented him with a prebend in the chapter of St. Maur. He was afterwards made the cure of Meudon, which office he held from 1545 to his death, in 1553, being, according to one of his biographers, in the 63d, and according to another, in the 70th year of his age. His Pantagruel, which was finished about the time that he accepted the cure of Meudon, brought upon him the hostility of the monks, whom he had severely satirized, and who procured its condemnation by the Sorbonne and the parliament; but it caused his company to be much sought after, as the witful writer of his time. The want of decency was easily pardoned at that period, and Rabelais had some estimable qualities, and poffeied extensive and various erudition, with a ready eloquence, and an inexhaustible store of ludicrous ideas. "The Pantagruel and Gargantua of Rabelais," says a critic, "are to be regarded as comic fables, often concealing, under a whimsical extravagance, attacks upon follies which it would not have been safe seriously to expose. It is in vain, however, that commentators have attempted to find out the meaning in much that is mere ribaldry and nonfence, and even to discover real history veiled in the allegory of burlesque, where the author meant nothing more than to make his reader laugh or wonder. His satire, where it is intelligible, is often just and ingenious; but the obscurity of his language, and eccentricity of his conceptions, render the perusal of his works, to a modern at least, rather a task than an amusement." The most complete editions of his works is that published in Holland, in 5 vols. 8vo., 1715, with notes by Ducht; and that at Amsterdam, in 3 vols. 4to., 1741, with plates by Picart. The letters of Rabelais were published in an octavo volume, with notes by St. Marthe. The memory of Rabelais is perpetuated in the medical school of Montpelier, where bachelors are invested with a scarlet robe, said to have been the very robe which that wit himself wore.

RABHELHORST, in Geography, a town of the duchy of Holstein; 5 miles W.N.W. of Cimmar.

RABENAU, a town of Saxony, in the margravate of Meffen;
Meissen; 8 miles S.S.W. of Dresden. N. lat. 50° 52'. E. long. 13° 36'.

RABENECK, a town of Bavaria, in the bishopric of Bamberg, 2 miles S.W. of Weifchenfeld.

RABENER, Theophilus William, in Biography, a celebrated German writer, was the son of an advocate at Leipzig, and born at Wachau in 1714. He was educated at home, by tutors employed for the purpose; but when he was 14 years of age, he was sent to the college of Meissen, where he had for fellow-students Grabner, Gertner, and Gellert, with whom, and particularly with the last, he formed a friendship which continued through life. In 1735 he went to the university of Leipzig, where he applied himself chiefly to the study of jurisprudence, without entirely neglecting the Muses. In 1741, professor Schwebe having begun a journal in the German language, entitled "Amusements of Reafon and Wit," Rabener became one of his principal coadjutors, and continued to affiliate him by his contributions till the year 1744. He is chiefly known as a writer in the first volume, by a humorous piece entitled "Proofs of the Necessity of employing Rhyme in German Poetry." This periodical work was, for some time, carried on with spirit and success; but at length it became degraded by literary disputes, which finally put an end to it; and another was established, under the title of "Contributions of Bremen." The writers engaged in this were all the most celebrated persons who flourished at that period, among whom were Gertner, Schmidt, and Rabener, to whom were united Gellert, Klopflock, and others. The Journal of Bremen forms an epoch in the history of the German literature, as it introduced into the country a better taste, and tended greatly to improve the language, which, previously to this, had been much neglected. Rabener had before this been appointed controller of the taxes in the circle of Leipzig, a place of great labour, and which required an exact knowledge of the laws of the country, and the most inflexible integrity. Notwithstanding, however, the attention which the duties of this office required, he found leisure to continue his literary pursuits; and towards the end of 1751, composed his satirical letters, in which he introduces persons of every state and character, all of whom speak in the language suited to their condition. In 1753 he was appointed chief secretary to the directors of the taxes at Dresden; and two years afterwards he published the fourth and last volume of his Satires, which contains "A Burlesque Explanation of the Proverbs of Sancho Panza," the "First of April," and the "Exhibit and Reparation." After this he began to write for the stage, and composed a comedy in four acts, entitled "The Freethinker," which, with many other papers and letters, were burnt, together with his house, during the siege of Dresden, in 1760. He now abandoned his literary labours, but his friends obtained from him a collection of letters, which were afterwards published by Weis. These were never intended for the public, but they are written with so much truth and sincerity, and exhibit a more correct picture of the author than any pen could have drawn. His health began to decline soon after his loss in 1760, and in 1767 he experienced a paralytic stroke, which was repeated in 1769; but he lingered out till March 1771, when he died. "He was," says his biographer, "among the small number of those privileged men, whom nature has endowed with every quality necessary to their state. He thought and spoke in a manner peculiar to himself: his pleasantries flowed as from an abundant source; he never sought for them; and they appeared so natural, pleasant, and lively, that it was impossible not to be struck by them. But he displayed his wit only among his friends: he never lavished it on the rich and great; on the contrary, he concealed it, when invited merely for the purpose of being heard. He always spoke the truth, without regard to persons or rank." Rabener, says he, was the favourite author of Germany, who wrote poetically in prose, whole satirical, sportive genius polished with a gall. Rabener's works are generally known throughout Europe, having been translated into the French, English, Dutch, and Swedish languages. Gen. Biog.

RABENSPURG, in Geography, a town of Austria; 8 miles N.E. of Liferdorf.

RABENSTAIN, in Geography, a town of Austria, on the river Bieich; 8 miles S. of St. Polten.

RABENSTEIN, in Geography, a town of Bohemia, in the circle of Leitmeritz; 40 miles E. of Prague. N. lat. 52°. E. long. 13° 26'.—Allo, a town of the duchy of Storia; 11 miles N.N.W. of Gratz.—Allo, a town of Bavaria, in the bishopric of Bamberg; 2 miles S. of Weifchenfeld.

RABIA PRIOR, in Chronology, is the name of the third month of the Arabic year, consisting of thirty days; and Rabia posterior is the name of the fourth month, consisting of twenty-nine days.

RABICH, a name given by Leo Africanus to a tree or shrub growing very plentifully in many parts of Africa, the fruit of which is much esteemed by the natives. He says that the tree rabich is prickly, and that the fruit is round, and like a cherry, but smaller, and of the taste of the piqua.

RABIEL, a name given by some authors to dragon's blood.

RABIES, in Medicine, that peculiar state of the nervous system, which is produced by the bite of a rabid animal, and which is commonly, but improperly, called madness. As the dog is the principal source of this disease, the word rabies is commonly united with the epithet canina. See HYDROPHobia.

RABINA, in Geography, a town of Mexico, in the province of Vera Paz; 40 miles S.S.W. of Vera Paz.

RABINET, a name formerly given to a small piece of ordnance, between a falconet and a bafe. Its dimensions, &c., see under CANNON.

RABIRA, a word used by some of the chemical writers to express tin.

RABISHI, in Geography, a river of the island of St. Vincent, forming a bay on the eastern coast, near the southern extremity, where it runs into the sea. N. lat. 19° 5'. W. long. 61° 11'.

RABLAY, a town of France, in the department of the Maine and Loire; 9 miles N. of Villiers.

RABLES, Ilea aux, a cluster of small islands at the entrance of lake Superior, in Upper Canada, and at the east end of it, cast of Whitefish island, and pretty close to the main land.

RABNABAD, a town of Hindoostan, in Bengal, at the mouth of the Ganges; 90 miles S.S.W. of Mahomedpore.—Allo, a small island on the coast of Bengal, at the mouth of the Ganges. N. lat. 22°. E. long. 90° 30'.—Allo, one of the mouths of the Ganges, which opens into the bay of Bengal. N. lat. 22°. E. long. 92° 26'.

RABNITZ, a river of Hungary, which runs into the Danube, a little below Raab.

RAGO, a town of Arabia, in the province of Yemen, near the coast of the Red sea, where the Arabs live in huts; 105 miles S.W. of Medina.

RABOLANE, in Ornithology, a name given by many to the lagopus, a bird found on the snowy mountains, and called by some the white partridge.
RABRI, a name given by some authors to bole armenic.

RABUEL, Claude, in Biography, a French Jesuit and able mathematician, was born at Pont-de-Veyle, in the county of Breils, in the year 1668. About the age of 18 he was entered into the society of Jesuits, and principally distinguished himself by his proficiency in mathematical learning, of which he became the professor in Trinity college at Lyons, performing its duties with great reputation and success. He died in 1725, in the 66th year of his age. His chief work was "A Commentary on the Geometry of Descartes," which was published after his death in 1735, under the care of father J. Elomnade. This was the first publication of the whole of that work, which had been given to the public. The labours of Fermat, De Witt, and others, extended only to particular parts of it. Rabuel left behind him other works on algebra, the conic sections, and the geometrical loci of the differential calculus, and of the integral calculus; and he was one of the few instances of persons who, with a passion for the mathematics, had a fine taste for polite literature.

RABUTAH, in Geography, a town of Africa, in the kingdom of Senaar; 33 miles S.S.W. of Senaar.

RABUTIN, Francis de, in Biography, who flourished in the sixteenth century, was of an ancient and noble family in Burgundy, and served in the army with the duke de Nevers, under Henry II. and Charles IX., with a high reputation for valour and fidelity. He was living in 1581, but nothing is known of him beyond that period. He was author of "Commentaires de diverses Guerres du Roi Henri II. et de l'Empereur Charles Quint," first printed in 1555; a continuation was printed afterwards, in 1558; and the whole work together in 11 books, in 1574. It contains a history of the wars in the Low Countries, from 1550 to 1558, and is said to be written in a simple style, with a great appearance of vivacity.

RABUTIN, Roger de, count of Buffi, a very distinguished character in the reign of Lewis XIV., was born at Epy, in the Nivernois, in 1618. He entered very young into the army, in his father's (Leonor Baron of Buffi) regiment, of which he became colonel. After serving in a number of battles and sieges, he ref: to the rank of mellede-camp of the light horse, and lieutenant-general of the Nivernois. He looked for still higher honours, and being disappointed, engaged in hampoons upon persons about the court, which drew upon him the king's displeasure; and in 1665, in which year he was admitted a member of the French academy, a manuscript history of the amours of two court ladies, of which he was the writer, being handed about, under the title of "Histoire Amoureuse des Gautes," a complaint was laid before his majesty, in consequence of which he was sent to the Baillie. Imprisonment had nearly proved fatal to him, and he was liberated, but was obliged to resign the office which he held under government. After this he was exiled to his country-seat, where he remained 17 years, during which he did not cease to implore the king to be allowed to return, by letters conceived in terms of abject humility and base adulation. In 1682 he was allowed to return to court, but finding himself generally neglected, he retired of his own accord to his estates. He died at Autun in 1693, at the age of 75. He was author of several works, among which were "Difcoveries a fez Enfants, fur le bon Usage des Adverfaries;" "Memoires," published first at Paris in two, and afterwards at Amsterdam in three volumes, 4to.; "Lettres," 7 vols. 12mo.; and "Histoire Abregee de Louis le Grand." His fon the abbe de Buffi became bishop of Lucon in 1723, and was a learned and ingenious member of the French academy.

The sifter of the bishop, a nun, published an abridgment of the life of Madame de Chantal, and of the life of St. Francis de Sales.

RABY, in Geography, a small township of America, in New Hampshire, in Hillborough county; about 65 miles W. by S. of Portsmouth; incorporated in 1790. Its name has been since changed.—Also, a town of Bohemia, in the circle of Prachatitz, containing a citadel, at the siege of which, Ziska, general of the Hussites, lost his only remaining eye; 4 miles S. of Horazdowitz.—Also, a town of Sweden, in Sudermanland; 7 miles N. of Nyköping.

RACA, or RACHA, a Syriac term, found in the Gospel of St. Matthew, chap. v. 22. and preferred in most translations.

Father Simon oberves, that the Greek translator of St. Matthew's Gospel retained the Syriac raca, which he found in the original, because it was very common among the Jews. And St. Jerom, Luther, the English translators, those of Geneva, Lowain, Port royal, &c. still preserve it in their respective languages.

F. Bouhours chooseth rather to express the sense of it in a sort of paraphrase, thus: he that fays to his brother, "homme de peu de fens, mon petit entenduand," shall deferve to be condemned by the tribunal of the council, &c.

Molt translators, except the English, and F. Simon, for raca write racha; but the former orthography seems the best founded; all the Latin copies having raca, and all the Greek ones rachos, or, with Helricius, rachos, which is the same; all, we mean, but St. Ireneus, and Beza's copy, now at Cambridge, which have rachos. In effect, the origin of the word shows it should be raca, as coming from the Syriac "Ghac, raca, of the Hebrew rob, Gk, empty, feafem.

RACAISBONE, in Geography, a town of Hindoosan, in Aurungabad; 30 miles S. of Aurungabad.

RACAM, a town of New Mexico, in the province of Huaqui; 60 miles S.W. of Riochico.

RACAN, Honore de Bueil, Marquis de, in Biography, a French poet, was born in 1589, of a noble family, in Touraine. When very young, he had a place in the king's bed-chamber, under the duke of Bellegarde. From Malherbe, who was at that time domiciliated with the duke, he acquired a fondness for poetry, and obtained instructions in the art of versifying. He first bore arms, as a profession; but after a time he devoted himself to a life of leisure. He was one of the earliest members of the French academy, and though almost wholly without the advantages of education, he obtained reputation as a writer. His most popular work was entitled "Bergeries." He composed in various styles, and wrote translations of Psalms, and many sacred odes taken from the Psalms, and other scriptural poems. In prose he published "The Life of Malherbe;" "A Difcourse pronounced before the Academy;" and some "Letters." He died in 1670, at the age of 81. Of his works a new edition was given at Paris, in 1724, in 2 vols. 12mo.

RACCA, RACHA, Rika, or Racta-Rica, in Geography, a town of the Persian empire, in the province of Dari-bekir, and pashalic of Orfu, the capital of the district named Diar Medzar. It is situated on the eastern bank of the river Euphrates, at the mouth of a small river named Deles, (the ancient Billicha,) and was founded, according to Pliny, by Alexander the Great. It was first called Nicopolion, and afterwards Callinicum and Leontopolis, from Seleucus Callinicus and the Greek emperor Leo. It was the favourite residence of Haroun al Rafehid, the ruins
Olympic games, though Mr. Weet professes himself dissatisfied with the authority upon which they depend; and says that in the books which he has confulted, he can find no mention of any other race of riding-horses, besides those of the Celts and the Calpē. As to that particular branch of horsemanship, above described, Euthalophilus, in his comment upon Homer, tells us, that in the old scholia it is written, that Demetrius says he had seen a man, vaulting in the manner described by the poet, from the back of one horse to another, holding the bridles at the same time, and keeping the horses to their speed, without any interruption or incumbrance. This affersion implies that such a feat was very uncommon, and consequently that no such exercise could ever have been admitted into any of the games of Greece. The word Ἐνθαλητος, used by the poet in the beginning of this simile, says Mr. Weet, may possibly have induced some people to imagine, that the riders of the horses called Ἐνθαλητος, Celte, were accustomed to leap from one horse to another, as if that word was a term of the manage, of which the verses that follow were merely an explanation. It is certain, however, from a passage in the Odyssey (E. v. 371.) that by Ἐνθαλητος Homer meant to signify no more than a riding-horse, and consequently that by the word Ἐνθαλητος, which is derived from Ἐνθαλης, no more is to be understood in this place than simply to ride. This interpretation of Ἐνθαλητος, Celte, may be further confirmed by the authorities of Pindar and Paulyas, and particularly by a story related by the last mentioned author (lib. vi. c. 13.) of a mare, named Aura, belonging to one Phidolas, a Corinthian. This mare, says the historian, having accidentally thrown her rider soon after she had started from the barrier, continued the race of her own accord, and turned round the pillar as if the rider had been still upon her back; upon hearing the trumpet, she mended her pace, till coming in before her antagonists, she leaped over-against the judges of the games, as conscious of having gained the victory. The victory was accordingly adjudged to her master Phidolas, who, by erecting in return a statue to her honour, intimated to whom the merit of that victory was due. In this story, there is no mention of any other horse or mare, that shared the victory with Aura, and consequently that, in the race called Celte, each competitor made use of but one single horse. Moreover, the victorious Aura was of the feminine gender, and hence we may infer, that in all the races, as well of riding horses as of chariots, mares or horses were indiscriminately used; excepting in the race named Calpē, in which mares only were employed. And further it appears, that though the rider was thrown off in the very beginning of the race, yet the crown was awarded to Phidolas, the master of Aura; to whom certainly no less was due, than if his mare had conquered under the conduct and direction of her rider. It appears also, by the circumstance of Aura's mending her pace upon hearing the trumpet, that the trumpet either did not sound during the whole race, but at the last round only, or that it sounded differently in different periods of the course. There was, however, a meaning in the sound of the trumpet, which Aura, probably an old itager, understood.

The race of full-aged riding-horses was instituted in the 33d olympiad, and that of the Ἐθαλης, Kēnē, or under-aged riding-horses, in the 131th. It is a well-known fact that chariots were used in war above 1000 years before cavalry was introduced among the ancients. They seem to have had a terrible notion of being mounted upon the back of a horse, and have accordingly made monsters of those whom they first beheld in that attitude, to which they were not very speedily reconciled. Their amazement gradually diminished; and their intercourse with other nations not only 

---

RAC

ruins of whole palace, it is said, are still visible. The position of Racca, in the parallel of 36° N., was ascertained by the celebrated oriental astronomer Mohamed Ben Jaber, surnamed Al Batani, who passed many years of his life at this place. The town and adjoining country are inhabited by different tribes of wandering Arabs. N. lat. 36° 1'. E. long. 38° 50'.

RACCAN, a river on the north coast of Sumatra, which runs into the sea, N. lat. 2° 30'. E. long. 100° 15'.

RACCANATTO, a river of Naples, which runs into the gulf of Tarento, N. lat. 39° 47'. E. long. 16° 42'.

RACCONO, in Geography, see Raccoon.

Raccoon, in Geography, an island in the Atlantic, near the coast of South Carolina, nine miles long and one wide. N. lat. 33° 3'. W. long. 70° 22'.

RACCOON, a river of Pennsylvania, which runs into the Ohio, N. lat. 40° 38'. W. long. 80° 25'.

RACCOON, a small island in Ossabaw found, belonging to the Flate of Georgia. N. lat. 31° 47'. W. long. 81° 12'.

RACCOON KEY, a small island or rock in the gulf of Mexico, near the south coast of West Florida. N. lat. 29° 46'. W. long. 89° 21'.

RACCOON KEY, a cluster of small islands near the coast of South Carolina. N. lat. 24° 8'. W. long. 79° 15'.

RACCOURCY, in Heraldry, signifies the face as coupé, that is, cut off, or shortened; and denotes a cross, or other ordinary, when it does not extend to the edges of the effetecheon, as they always do when absolutely named, without such distinction.

RACE, in general, signifies running with others, in order to obtain a prize, either on foot, or by riding on horseback, in chariots, &c.

Racing was one of the exercises among the ancient Greekian games, which was performed in a course, containing one hundred and twenty-five paces; and those who contended in those foot-races were frequently clothed in armour. For a particular account of these races, see STADIUM.

There were properly but two kinds of horse-races at Olympia, namely, the chariot-race, introduced into those games in the 25th olympiad (for an account of which see CHARIOT); and the race of riding-horses, which was not admitted till the 33d. Although chariots were in use before riding-horses, as we may conclude from the testimony of Homer, among all horse heroes, Greek and Trojan, no one makes his appearance on horseback, except Diomedes and Ulysses mounted upon the horses of Rhéisus (II. x.), it is nevertheless plain, from this instance, that neither the heroes nor the horses were utter strangers to the art of riding; and it is also evident, from another passage in the 15th Hid., that horsemanship was carried even to some degree of perfection, at least in the time of that poet, who lived but in the next generation after the siege of Troy, according to sir Isaac Newton. This passage, extracted from Pope's Homer (II. xv. v. 822.) is as follows:

"So when a horsemans from the wat'ry mead
(Shall'd in the manage of the bounding steed)
Drives four fair couriers, practis'd to obey,
To some great city, thro' the public way:
Safe in his art, as fide by fide they run,
He shifts his seat, and vaults from one to one;
And now to this, and now to that he flies:
Admiring numbers follow with their eyes."  

Some authors (see Rollin's Anc. Hist. tom. v. p. 72. ed. Amst.) have introduced an exercise like this into the
rendered riding-horses familiar to them, but convinced them likewise of the advantages accruing from the use of cavalry. Hence it came to pass, that an order of equites, or horsemens, was instituted in most of their commonwealths; to whom, as in Athens, was allotted the second rank in the state. Upon the same principle, perhaps, the 

race, a sort of riding-horse, was admitted into the Olympic hippodrome, and held in such estimation, that although the race of riding-horses was neither so magnificent nor so expensive, and consequently not so royal, as the chariot-race, yet we find, among the competitors in this exercise, the names of Philip, king of Macedon, and Hiero, king of Syracuse. To the latter is ascribed the first Olympic ode of Pindar, in which honourable mention is made of the horse Phereclus, whose fleetness gained for him the master the Olympic crown. The race of the Calpæ was performed by mares. (See Calpæ.) The length of this race, and also that of the Celes, are not ascertained; but it is reasonable to suppose, that the latter, distinguished, as we have already observed, into two classes, one of full-aged, and the other of under-aged horses, con-

cluded of the same number of rounds as those of the chariots, distinguished in like manner into two classes. Mr. Web has not been able to determine the different ages that ranked the horses in one or the other class; nor whether the weights of the riders, or the sizes of the horses, were taken into consideration. These points seem to have been left to the discretion of the Hellanodicks, who were appointed to examine the young horses that were entered to run for any of the equilibrists (Pent. 1. iv. c. 24.), and who were sworn before the statue of Jupiter Horius, to give a true and impartial judgment upon the matters left to their examination, without taking any reward; and not to discover the reasons which disposed them to reject some, and admit others. Wett's Dissertation on the Olympic Games. 

Race, in Genealogy, a lineage, or extraction, continued from father to son.

The word is French, formed from the Latin radix, root; as intimating the root of the genealogical tree.

In several orders of knighthood, as in that of Malta, &c. the candidates must prove a nobility of four races or de-

ficients.

In some republics the magistrates are to prove themselves of plebeian race, to be qualified.

The French reckon their kings by races; as, the first race, the second race, the third race. We also say the race of the Ottomans, the Archidid, the Ptolæmies, &c.

Race, in Natural History. See Cibdelaophoria.

Race, the mark made on timber, &c. by a tool called a racing-knife.

Race, Cape, in Geography, a cape on the S.E. coast of Newfoundland. N. lat. 46° 40'. W. long. 53° 3' 30'.

Race Point, a cape on the coast of America, W. of cape Cod. N. lat. 42° 4'. W. long. 78° 12'.

RACEME, in Gardening, the long mode of cluster-

flowering and fruiting which takes place in some fomts of plants and fruit-trees, as in the grape vine, and the different kinds of currants. See Racemus.

RACEMIFEROUS, in Botany, denotes bearing in clusters.

RACEMUS, in Botany and Vegetable Physiology, a clus-

ter, is a mode of inflorescence, in which several flowers, each supported on its own proper stalk, are connected by one common stalk, either simple or compound. A bunch of Cur-

rants is a simple racemus; the inflorescence of the Woody Nightshade, Solanum Dulcamara, is a compound one. In the American plant called Alba racemosa, the clusters are simple, but aggregate. A racemus differs from a spica, or spike, in having a partial stalk, as above described, to each flower; it is moreover generally understood to be drooping or pendulous, and to have the flowers expand all nearly at one time. On the contrary, a spike is most frequently erect; the flowers open in very gradual succession, informly that the lowermost may have partly perfected their seeds, before the uppermost expand; and especially, they are indi-

vidually fesile, at least at the time of their expansion. To these characters may be added, that a spike is crowded or dense; a cluster lax or scattered. It must also be allowed that botanists, even of the first rank, are incorrect in the application of these terms. The male inflorescence of Quercus, the Oak genus, because drooping and loosely disintegrated, with all the flowers in perfection nearly at the same time, is termed a racemus; though it possesses the most essential character of a spica, fesile flowers. On the other hand, Veronica spicata, having a dense upright series of flowers, expanding gradually, is said to be spicoid, though each separate flower has a partial stalk. A little latitude must necessarily be allowed, though it is very deirable that botanists should be more exact in the use of these and other terms, than they sometimes are. See Spica and Inflo-

rescence.

RACER, in Gardening, a name applied to a sort of fward-cutter, or cutting implement, used in running out or cutting through the surface of grass of fward, and dividing it into proper widths, lengths, and thicknesses, for turf intended to be cut up for laying in pleasure-grounds, or other places, and always necessary preparatory to the work of flaying or cutting up the turf with the turfing-iron. It is also useful for cutting and straightening the edges of grass verges in such grounds, as well as for many other purposes.

It is a tool which is very simple in its construction, merely consisting of a strong wooden handle, about four feet long, having the cutter fixed at the lower end, in the form of a half moon, with the edge downward, to cut into the fward; the handle should be about an inch and a half thick, growing gradually thicker towards the lower end.

In using the tool, it is pushed forward so as to cut or race out the fward in an expeditious manner. And in cutting turfs with it, it is necessary first to mark out on the fward the width of the turf intended, which should generally be a foot wide, and a yard long, and about an inch or inch and a half deep; then draw a line tight, right lengthways, striking the cutter into the fward close to the line, running it along expeditiously, so as to cut its way, and divide the fward to a proper depth, afterwards placing a line a foot farther, and racing it out as before, and so on, to as many widths as may be wanted; and then, with the line placed crofs-ways, to race out the fward accordingly in yard lengths. The fward being thus raced out, the turf-cutter with the turfing-iron should proceed to cut them up and flay them off from the ground. This small implement is likewise very convenient for many other little purposes about pleasure grounds and gardens, as those of cutting the edges of the verges which are laid with turf, and straightening the edges of the borders in different parts. See Turf.

RACHA. See Raca.

RACHA, in Geography, a town of Bohemia, in the circle of Leitmeritz; 6 miles E. of Leitmeritz.

RACHELSDORF, a town of Bavaria, in the bishopric of Bamberg; 15 miles N. of Bamberg.

RACHEMTUM, from the Fr. raccht, redimere, the compensation or redemption of a thief.

RACHIA,
RACHIA, in Geography, a town of Iliria; 7 miles N.E. of Pedena.

RACHIALGIA, in Medicine, a term given by Alitrae, and adopted by the nosophists, to denote certain colicky pains in the bowels, which were supposed to originate from the nerves of the spine, and especially the colic from the poison of lead, or Concha Platinum; which see. The word is from παχύς, the spine, and αἰγῶν, pain. See Sauvages Nofiol. Meth. class vi. gen. 29.

RACHIS, or rather Rhachis, in Botany, from δρακος, the back-bone, is the common stalk, or receptacle, of the florets, in the spikelets of grasses; or of the spikelets themselves in Leptom, Triticum, Secale, Hordeum, Rattilola, &c. The same term is applied to the rib, or leaf-stalk, of ferns, which is often winged or bordered. The Rachis in both these inflances is frequently jointed; by which in the former, the spike heads of such grasses, wrapped up in their husks, are the more readily dispersed. The part in question being in some cases smooth, in others variously hairy or bearded, affords excellent specific distinctions; witnessing the genus Avena.

RACHISAGRA, a term used by some physicians for the goot in the spine of the back.

RACHITIS, in Medicine, from παχύς, the spine, (because the spinal marrow was supposed to be the seat of the disease,) a malady corruptly termed in English the Rickets: which see.

RACHOK, in Geography, one of the Kuril islands or the Eastern Pacific ocean; distant from Murfyer, another of the said islands, about 120 versts. Its length is about 20 versts, and its breadth the same, and it presents the appearance of a solitary mountain rising upwards from the sea. It was formerly covered with verdure, with shelves of rocks, where sea-fowl in great number made their nests; but these rocky shelves have been demolished by the eruption of subterraneous fires, which split the summit of the mountain, throwing up vast quantities of stones and ashes; and since that time, the island has always continued burning. At this eruption those places on the shore where formerly they had thirteen fathom water, were filled up with rubbish and ashes into holes and banks.

RACLIN, in Ancient Geography, the Rivina of Ptolemy, near the N.E. coast or Ireland, memorable as the retreat of Robert I. of Scotland.

RACOL, in Geography, a town of Hindoostan, in Soonda; 16 miles S.S.E. of Goa.

RACHORE, a district or province of Hindoostan, in Golconda, bounded on the N. by the Kiltnah, on the E. by Canoul, on the S. by Adoni, and on the W. by Sanore.—Allo, a town of Hindoostan, and capital of the above-mentioned province, on the S. side of the Kiltnah, and not far above the confluent of the Tomuaddra with it, and below that of the Beemah, belonging to the Nizam. It is four days' journey from Adoni, reckoning a day's journey at 22 British miles in road distance, and 17 or 18 geographical miles; 91 miles S.W. of Hyderabad. N. lat. 16° 24'. E. long. 78° 2'.

RACHOSIS, from παχύς, lacero, a disease, in which the fomentum is relaxed and excoriated.

RACHOUR, in Geography, a town of Hindoostan, in the barier of Gurry Mundella; 20 miles S.S.W. of Gurrumiah.

RACHOUR, a town of Hindoostan, in Myfore; 20 miles S. of Gurramunda.

RACHOW, a town of Poland; 36 miles S.S.W. of Lublin.

RACINE, John, in Biography, an eminent French poet, was born in 1639. He was educated at the convent of Port-Royal, near Paris; after this he went through a course of philosophy at the college of Harcourt, and then made his appearance before the public in an ode on the king's marriage. This effort was, through the interest of Colbert, rewarded with a present and a small pension. Elated with the success which crowned his first effort, he determined to follow poetry as a profession; and, rejecting the offer of an uncle, a prior, who offered to resign his benefice to him, provided he would enter into holy orders, he fixed his residence at Paris. In 1663 he brought upon the stage his first tragedy, entitled "Le Thébaïde ou les Fries ennemis." It was written in the manner of Corneille, which he soon after quitted for one of his own; a judicious change, says a critic, since the characteristics of these two masters of the French drama were extremely different. He next published his "Alexandre," which was followed by his "Andromaque." About this time he was prevailed to the priory of Epinay, but not being in orders, he was, after a law-suit, obliged to quit. His "Andromaque," which established his character as a tragedian, was soon followed by the comedy "Les Plaideurs," which, though it obtained for him the praise of Molière, and was well received at court, was his only attempt in that walk. Between the years 1679 and 1679, he published his "Britannicus," "Berénice," "Bajazet," "Mithridate," "Ephigène," and "Pïèdre." His popularity and well-earned reputation excited a strong party against him: the chagrin which he underwent from the arts of his enemies, and the over-feeling to criticism, which led him to confess, in the confidence of friendship, that the worst criticism made upon his works caused him more uneasiness than the greatest plaudits had given him pleasure, inspired him with the resolution of renouncing poetry and turning Carthusian. He was, however, persuaded to change his plan, and to marry: he accordingly formed an alliance with the daughter of a gentleman in the treasury of Aniens, by whom he had several children. At the same time he ceased to write for the stage, and thereby reconciled himself with his old friends of the Port-Royal. Racine now became a courtier, and obtained the situation of gentleman in ordinary to the king, to whom he made himself very useful. He was also appointed to the office of historiographer-royal, in conjunction with his friend Boileau, which they made a complete sinecure. He was prevailed upon by Madame Maintenon to write a dramatic piece on a scriptural subject, for the ladies of her foundation of St. Cy, and his "Either" was performed by them in 1689, with great applause, in the presence of the whole court. He followed it with "Athalie," acted by the same ladies in 1691. Madame Maintenon, deeply affected with the infirmities of the people in the latter years of Lewis's reign, engaged Racine to draw up a memoir on the subject. This he delivered in a manner, as to give great offence to the king, who happened to obtain a sight of it from a lady to whom it had been lent. Racine was excluded from the court, a circumstance that proved upon his mind, that he fell into a state of melancholy, of which he died in 1699, at the age of 60. For a character of this writer we shall be indebted chiefly to the General Biography. He was polite in his manners, with the affected froth of a courtier, which was, however, a mask to his actual disposition, for, in reality, he had much gall and epigram in his character. Religion, however, corrected, in a good measure, these defects, and in all the relations of domestic life he was exemplary. As a dramatic writer he is supposed to have ranked with Corneille, though in many points he even surpassed him. His characteristics are tender-
nef, elegance, correctness, good taste, refined sentiments, and the art of verifying in a supreme degree, so that his countrymen find a charm in his lines, which distinguishes them from other French poets. The critiques of Boileau contributed much to his excellence in this particular, and he is said to have taught him, as a great secret, to write the second line of a couplet first. With respect to the proper dramatic merit, Racine must be judged by those who are formed to the French school, and are not readily wearied with long speeches, rather descriptive of feeling than expressing it, and all refinements of the tender passion, often applied to characters, to which it is historically unfitful. Many parts of his best pieces, however, prove that his mind was well furnished with elevated and dignified sentiments, which he probably derived from an affidious study of the ancients. Besides his dramatic works, Racine was author of "Cantiques," replete with the union of tender devotion; "L'Histoire de Port-Royal;" "Idylle sur la Paix;" "Epigrams;" "Letters;" and some "Opuscules." He was member of the French academy from 1673, and as director of that institution he pronounced the eulogy of Corneille. The best edition of his works is in seven vols. 8vo. 1768.

RACINE, LOUIS, son of the preceding, also a distinguished poet, was born at Paris in 1692. He was, however, not more distinguished for his poetry than for his pithy, and adopted the ecclesiastical habit. In a state of retirement, in 1720, he published his poem "On Grace." The chancellor d'Augusseau, during his own exile at Freines, brought Racine again into the world, and cardinal Fleury afterwards gave him a place in the finances. He married, and lived very happily in his family, till the los of an only son threw him into a deep melancholy. His religious sentiments took full possession of his soul, the fervour of which may be exemplified by the line from Thibault which he inscribed on the crucifix which ever accompanied him:

"Te fpecem suprema mili cum venerit hora,  
Te teneam moriens deficienite manu."

He died in 1763, at the age of 71. His poetical writings are "Poems on Religion and Grace;" "Odes," of which the diction is splendid, and the sentiments elevated; "Epistles," and a "Translation of Milton's Paradise Lost." In prose he wrote "Reflections sur la Poésie;" "Memories sur la Vie de Jean Racine;" "Remarques sur les Tragedies de J. Racine;" besides these he contributed several dissections to the Memoires of the Academy of Inscriptions, of which he was a member. His works were collected and published in 6 vols. 12mo.

RACINE, BONAVENTURE, a learned French priest and ecclesiastical historian, was born at Chauny, in the diocese of Noyon, in the year 1708. He received an excellent education at the Mazars college at Paris, where he not only studied the ancient languages, but entered pretty fully into the different branches of philosophy, divinity, and the studies connected with ecclesiastical history. At the age of twenty-one he was enticed by the archbishop of Alby, as a fit person, to re-establish the college of Raballens, a town in his diocese. To this design he devoted his talents with unwearyed zeal and industry, and was abundantly compensated by the success which attended his labours. The institution, was, in a short time, crowded with students, who imbibed from his lectures a taste for science and literature. Thus usefully engaged, he became an object of the jealousy of the witty Jefuits, who caused him to be banished from Raballens. He retired to Montpelier, where M. Colbert engaged him to undertake the direction of the college of Luneil: from this place he was also driven by the fame per-
RACING.

ing the snaffle backwards and forwards in his mouth, and by that means forcing him to open his mouth, which will give him wind, and be of great service. If there be any high wind flirring in the time of riding, the artful jockey will let his adversary lead, holding hard behind him, till he sees an opportunity of giving a looke; yet in this cafe, he must keep to close behind, that the other horse may keep the wind from him; and that he, fitting low, may at once shelter himself under him, and affift the strength of the horse. If the wind happen to be in their back, a fuit contrary method is to be taken with it; the expert jockey is to keep directly behind the adversary that he may have all the advantage of the wind to blow his horse along, as it were, and at the fame time intercept it in regard to his adversary.

When running on level carpet-ground, the jockey is to bear his horse as much as the adversary will give him leave, because the horse is naturally more inclined to spend himself on this ground: on the contrary, on deep earth he may have more liberty, as he will then spare himself.

In riding up hill the horse is always to be favoured, by bearing him hard, for fear of running him out of wind; but in running down hill, if the horse’s feet and shoulders will bear it, and the rider dares venture his neck, he may have a full looke. If the horse have the heels of the reef, the jockey must always spare him a little, that he may have a referee of strength, to make a pull at the fall poft.

A great deal depends on the jockey’s knowing the nature of the horse that is to run against him; for by managing accordingly, great advantages are to be obtained: thus, if the opposite horse is of a hot and fiery disposition, the jockey is either to run just behind him, or check by jowl with him, making a noife with the whip, and by that means forcing him on faster than his rider would have him, and consequently fpending him fo much the sooner; or else keep just before him, in fuch a flow gallop, that he may either over-reach, or by treading on the heels of the fore horse, endanger tumbling over.

Whatever be the ground that the adversary’s horse runs on, the cunning jockey is to ride the moft violently over; that by this means it will often happen, that in following he either fumbles or claps on the back finews. The feveral corrections of the hand, the whip, and the spur, are all to be observed in the adversary, and in what manner he makes use of them: and when it is perceived, by any of the fymptoms, of holding down the ears, or whifling the tail, or ftrechting out the noife like a pig, that the horse is almoft blown, the bufinefs is to keep him on to this fpeed, and he will befoon thrown out, or diftanced. If the horfe of the opponent looks dull, it is a fign his strength fails him; and if his flanks beat much, it is a fign that his wind begins to fail him, and his strength willfoon do too.

After every heat for a plate, there must be dry straw, and dry cloths, both linen and woollen, ready to rub him down all over, after taking off the sweat with what is called a fweat-knife; that is, a piece of an old fword-blade, or fome fuch thing. Some advice the fleeping of the cloths in urine and falpetre the day before, and letting them be dried in the fun for this occafion. After the horfe has been well rubbed with thefe, he fhould be chafed all over, with cloths wetted in common water, till the time of starting again. When it is certainly known that the horfe is good at the bottom, and willlick at the mark, he fhould be rid every heat to the beet of his performance; and the jockey is, as much as poiffible, to avoid riding at any particular horfe, or faying for any, but to ride out the whole heat with the bell fpeed he can. If, on the contrary, he has a fiery horfe to ride, and one that is hard to manage, hard-mouthed, and difficult to be held, he is to be flarted behind the reft of the horfes with all imaginable coolnefs and gentleneff; and when he begins to ride at home command, then the jockey is to put up to the other horfes; and if they ride at their cafe, and are hard held, they are to be drawn on falter; and if it be perceived that their wind begins to rake hot, and they want a fob, the bufinefs is to keep them up to that fpeed; and when they are all come within three quarters of a mile of the poll, then is the time to pull for it, and use the utmost fpeed in the creature’s power.

When the race is over, the horfe is immediately to be clothed up, and rode home; and immediately on his coming into the stable, the following drink is to be given him. Beat up the yolks of three eggs, and put them into a pint and a half of new milk made warm; let there be added to this three pennyworth of fallof, and three spoonfuls of falhald-oil, and let the whole be given with a horn. After this he is to be rubbed well down, and the faddle-place rubbed over with warm fack, and the places where the furps have touched, with a mixture of urine and falt, and afterwards with a mixture of powder of jet and Venice turpentine; after this he fhould have a feed of rye-bread, then a good muff, and at fome time after that as much hay and oats as he will eat. His legs, after this, fhould be bathed some time with a mixture of urine and falpetre.

For the preparation of the horfe before running, &c. see Plate.

We shall here observe, that horfe-races were a species of amufement known in England in very early times. Fitz-Stephen, who wrote in the days of Henry II. records the great delight which the citizens of London took in the diversion. Races appear likewife to have been in vogue in the reign of queen Elizabeth, and to have been carried to fuch excess as to have injured the fortunes of the nobility. Lord Herbert of Cherbury (see his Life by Mr. Walpole, p. 51.) enumerates thefe among the sports which he thought unworthy of a man of honour. “The exercife,” says he, “I do not approve of is running of horfes, there being much cheating in that kind; neither do I fee why a brave man fhould delight in a creature whose chief ufe is to help him to run away.” Jarvis Markham, who wrote on the management of horfes in 1599, mentions running horfes; but at this time there were only private matches, made between gentlemen, who were their own jockeys, and rode their own horses. However, in the following reigns: James I., public races were established; and Garrowby, in Yorkshire, Croydon, near London, and sometimes Leobald’s, near Enfield-chace, where the king relided, were the courses in which they were performed. The horfes at this time were prepared for running by the discipline of foot, phyle, airing, and feats and clothing, which compose the present fystem. The weight also which each horfe was to carry was rigidly adjusted: the usual weight of the riders being flated at ten flones, who were put into foales, and weighed before they flarted. Most of the celebrated races in the kingdom were called bell-courfes, the prize and reward of the conquering horfe being a bell. To this purpofe, Camden fays, that in 1607 there were races near York, and the prize was a little golden bell. Upon this Bengen offers a conjecture, whether the phrafe of bearing the bell, which implies being comparatively the bell or moft excellent, and corresponds with the expreffion of bearing the palm among the ancients, as a reward decreed to the twifeft horfe in a race, is not more aptly deduced from this custom,
frequently than from the method of tying a bell round the
neck of the sheep, which leads the flock, and is, therefore,
counted the bell.

About the latter end of the reign of Charles I. it was
customary to have races performed in Hyde Park. See the
Comedy of the Merry Beggars, or Jovial Crew, written in
1641, in Doddley's Collection of Old Plays.

Racing was much encouraged by Charles II. after his
restitution: he gave public rewards and prizes, and ap-
pointed races for his own amusement at Datchet Mead,
when he resided at Windsor. But the most distinguished
spot for those exercises was Newmarket, which was at first
frequented for the purpose of hunting, and seems not to
have been defined to be a horse-courte till some time be-
fore the troubles of the reign of Charles I., when races were
discontinued: but they were revived soon after the
Restoration. The king attended in person, and established
a house for his accommodation, and kept and entered horses
in his own name. Instead of bells, a silver bowl or cup,
of the value of a hundred guineas, was allotted for a prize;
and upon this royal gift the exploits of the successful horse,
and his pedigree, were generally engraved. The sum of
a hundred guineas is now given in lieu of the silver bowl.

When William III. was advanced to the throne, he not
only added to the plates given to different places in the
kingdom, but founded an academy for riding. Queen Anne
continued the bounty of her predecessor, with the addition
of several plates. George I., towards the end of his reign,
discontinued the plates, and gave the sum of a hundred
guineas in their room.

In the thirteenth year of George II. an act was passed
for the suppression of races by ponesies, and other small and
weak horses, by which all matches for any prize under the
value of 50l. are prohibited, under a penalty of 100l., to
be paid by the owner of each horse running, and 100l. by such
as advertise the plate; and by which each horse entered to
run, if five years old, is obliged to carry ten stone; if six,
eleven, or if seven, twelve. It is also ordained, that no
person shall run any horse at a courte, unless it be his own,
or enter more than one horse for the same plate, upon
pain of forfeiting the horses: and also every horse-race must
be begun and ended in the same day. Horses may run for
the value of 50l. with any weight, and at any plate. 13 Geo. II.
cap. 19. 18 Geo. II. cap. 34. Pennant's Brit. Zool.
vol. i. p. 6, &c. Berenger's Hill. and Art of Horlemam-
ship, vol. i. p. 185, &c.

We shall here add, that at Newmarket there are two
courtes, the long and the round: the first is exactly four
miles, and about three hundred and eighty yards, i. e.
seven thousand four hundred and twenty yards. The
second is fixed thousand fix hundred and forty yards. Chil-
ders, the twentith horse ever known, has run the first courte
in seven minutes and a half, and the second in seven minutes
forty seconds; which is at the rate of more than forty-nine
feet in a second. But all other horses take up at least
seven minutes and fifty seconds in completing the first and
longest courte, and seven minutes only in the shortest,
which is at the rate of more than forty-seven feet in a
second, and it is commonly supposed that these courters
cover, at every bound, a space of ground in length about
twenty-four English feet.

RACITZA, in Geography, a town of Bukovina; 7
miles N. of Czernauci.

RACK, a small island near the coast of Virginia. N.
lit. 37° 19'. W. long. 75° 51'.

Rack, Lower and Upper, two small islands near the coast
of Virginia; the former in N. lat. 37° 20'. W. long. 75°
50', and the latter in N. lat. 37° 26'. W. long. 75° 45'.

Rack, an engine of torture furnished with cords, &c.
for extorting confession from criminals.

The duke of Exeter, confable of the Tower under
Henry VI., with the duke of Suffolk, and others, having a
design to introduce the civil law into England; for a
beginning, the rack, or brake. allowed in many cafes by the
civil law, was first brought to the Tower, where it is still
preferred; in those days the rack was called the duke of
Exeter's daughter. 3 Iatt. 35.

It was occasionally used as an engine of statute, not of law,
more than once in the reign of queen Elizabeth. (Barr. 92.
495.) But when, upon the affiliation of Villiers, duke of
Buckingham, by Felton, it was proposed in the privy-
council to put the statute to the rack, in order to discover
his accomplices; the judges being consulted, declared unani-
mously, to their own honour, and the honour of the English
law, that no such proceeding was allowable by the laws of
England. The uncertainty of this punishment, as a tatt
and criterion of truth, was long ago very elegantly pointed
out by Tully (pro Sulla, 28.) though he lived in a state in
which it was usual to torture slaves, in order to furnish
evidence. "Tamen," says he, "illa tormenta gubernat
dolor, moderatur natura cufqueque tum animi tum corporis,
regit quantum, flecit libido, corruptum ipes, infirmat metus;
ut in tot rennum angustius nihil veritati loci relinquatur."

The marquis Beccaria (ch. 16.), in an exquisite piece of
raillery, has propoosed this problem, with a gravity and
precision that are truly mathematical: "the force of the
muscles, and the sensibility of the nerves of an innocent
person being given, it is required to find the degree of pain
necessary to make him confess himself guilty of a given
crime."

Rack, in the Manege, a pace in which a horse neither
rots nor ambles, but shuffles, as it were, between both.
The racking pace is much the same as the amble (which
fee); only that it is a twitter time, and a shorter tread.

Rack is also a wooden frame, made to hold hay or fodder
for cattle. There has lately been much improvement made
in the forming of all sorts of racks, both for the stable,
cattle-heds, and field. See Cattle-heds, Stable, and
Sieve-bowes.

Rack, in Rigging, a short thin plank, with holes made
through it, containing a number of belaying-pins, used in
stead of cleats; it is nailed to the throuds, and nailed over
the bowsprit or windlass.—Also, a long shell, containing
a number of sheaves, formerly fixed over the bowsprit to lead
the running rigging. At present, wooden saddles, containing
holes in them, are nailed on the bowsprit for this purpose.
Being more out of the way, and less liable to be out of order.
See Shot-rack, and Shiold-rack.

To Rack Wines, &c. is to draw them from off their lees,
after their having stood long enough to clear and settle.
Hence.

Rack-Vintage, is frequently used for the second voyage
our wine-merchants used to make into France for racked
wines; whence they used to return about the end of
December.

Rack-Holder, such tenants as hold their lands under
such leases.

Rack-Leafer, are such sorts of leases as are granted for
one or more lives, at the full rack rents, as in Cornwall,
and some other counties. See Leases of Land.

Rack-Rent, is the full yearly value of land let by lease,
payable by tenant for life or years, &c. See Rent.

Rack-
RACK, Sheep, a sort of long narrow crib, fixed upon wheels, for containing hay for sheep, having a lid or covering on the top. It is very useful in bad weather, in the winter season, as preventing the hay from being walked on and admitting the sheep to feed conveniently.

RACKAMA, in Geography, a lake of Syria, south of Hella and the ancient Babylon, is about 30 miles long, and flows into the Euphrates.

RACKEBY, a town of Sweden, in West Gothland; 40 miles N.E. of Uddevalla.

RACKET, a kind of bat for striking the ball at tennis; consisting usually of a lattice, or net-work, of cat-gut, strung very tight over a circle of wood, with a handle or shaft of a moderate length.

The word is formed from the French raquette, which Menage derives from the Latin reticula, a diminutive of reticulum; whence also reticulae, and reticulum.

Parquier observes, that anciently they used no rackets at tennis, but played with the palm of the hand; and hence he conjectures it is that the French call tennis play, jeu de paume. He adds, that rackets were not introduced till a little before his time.

Racket is also a machine which the savages of Canada bind to their feet, to enable them to walk more commodiously over the snow; made much in the manner of a tennis-racket.

Its figure is a lozenge, of which the two obtuse angles are rounded off. It is bound about with very fine thongs of leather, and the meshes of it are much smaller and closer than those of our rackets.

In the middle is fitted a kind of shoe, lined with wool, or hair; to be tied on to the ankle: by which means the feet are prevented from sinking in the snow. Rackets oblige the perfons to take very long steps, and, as we say, to walk a great pace, to keep them from knocking against each other.

Racket, in Geography, a river of New York, which runs into the St. Lawrence, N. lat. 45° 13', W. long. 74° 42'.

RACKIBIRN, the name of a small island on the N.W. coast of Ireland, situated near Tiellen head, in the county of Donegal. N. lat. 54° 39', W. long. 8° 44'.

Racking, in Sea Language, denotes the falfening of two opposite parts of a tackle together, so as that any weighty body suspended by it shall not fall down, although the rope, which forms the tackle, should be loosened by accident or neglect. This expedient is chiefly practised when the boats are hung up to the ship's side in the night, in an open road or bay, left the rope of the tackle should be untied by the inattention of some of the crew, by which accident the boat might be considerably damaged, and probably lost or dashed to pieces. Falconer.

Racking Fruit Liqueur, the operations of fining and drawing it off. See Cyder.

Racilia, in Geography, a small rocky island in the Grecian Archipelago, inhabited by two or three poor monks, who take care of a few sheep and goats. N. lat. 36° 53', E. long. 25° 38'.

Racknit, a town of the duchy of Carinthia; 3 miles S. of Saxonburg.

Rackoon, or Raccon, the urus lotor of Linneus, in Zoology, the name by which we commonly know an American animal, called coati by the Brazilians. It is something smaller than the beaver, and is of the shape of the beaver in the body, and its legs are as short as in that creature. The face, cheeks, and chin are white; the upper part of the body is covered with hair, long, soft, and thick; black at the ends, whitish in the middle, and ash-coloured at the root. Sometimes from this mixture of colour the back appears plainly grey; and Maregraves mentions another species, which is of a deep yellow or ochre colour.

The head is very like that of the fox in shape; but that the ears are shorter, roundish, and naked, and it has from the forehead to the nose a fleshy line. The eyes are large, and surrounded with two broad patches of black; the nose is black and sharp-pointed; its tail is very bushy, and annulated with black. Its feet are each divided into five slender toes; by the help of which it climbs trees as expertly as a monkey, and uses the fore-feet as hands, to reach up its food to its mouth. It is a very cleanly animal; and if there be no water near, it always washes its food, be it what it will, before it eats it. It feeds on vegetables, but is also very fond of eggs, and will even feed birds if it can catch them. It is also very fond of sweet things and strong liquors, and will get exceedingly drunk: at low-water it feeds much on oysters, watching their opening, and with its paw in the fish, and is sometimes caught in the shell. It is very common in the warm and temperate parts of America, in the mountains of Jamaica, and in the isles of Maria in the South sea, and is a creature easily tamed. It is hunted for its flesh, the fur, next to that of the beaver, being excellent for making hats. Ray and Pennant.

Racle, Fr., to scrape, to rasp, or file a hard body. It is said, in derision of a bad performer on the violin, or any other instrument played with a bow, that he rasps or scrapes the strings; because, in fact, he draws a harsh and disagreeable tone from his instrument, which resembles that produced by scraping or filing a hard body. Even good players on the violin sometimes scrape a little in the forte parts of their performance. Suppl. to Encyc., 1st ed.

Racularguine, in Geography, a town of Bengal; 50 miles N.W. of Burdwan.

Raconigi, a town of France, in the department of the Stura, containing four gates, with as many faubourgs, well peopled. The king of Sardinia had a palace here. The police is conducted by fifteen counsellors, from whom two syndics are chosen every four months, who act as bailiffs or mayors of the town. It has two parishes, and several religious houses. The habitants are industrious, and much employed in making gauzes and silk stuffs; 6 miles N. of Savigliano.

Racopilum, in Botany, from réx, a rent in a garment, or a wrinkle, and stip, a hat or cap, the name of one of Palafiat de Beaucloit's genera of mosses, whose veil is torn at the side. It ought to be written Rhacopilum.

Racoubea, a name of Aublet's, of which we find no explanation. See Homalium.

Racow, Catchifim, in Ecclesiastical History, a system of theology compiled by the most eminent Socinian doctors, and first published at Racow, or Rakow, in Poland, in the year 1609, with a dedication to our king James I. This catchifim, or a translation of it, was committed to the flames in England, in the year 1653, by order of parliament. A new edition of it, corrected and enlarged, was published at Stauropolis, in 1684. The Socinians consider this catchifim as the great standard of Socinianism, and an accurate summary of the doctrine of that sect. However, Moheim observes, that it is, in reality, no more than a collection of the popular tenets of the Socinians, and by no means a just representation of the secret opinions and sentiments of their doctors. Hence he says it never obtained among them the authority of a public confession or rule of faith; and hence the doctors of that sect were authorised to correct and contra-
rad it, and to substitute another form of doctrine in its place. But to this account it has been replied, that it would have been inconsistent with the liberty, for which they argue in the preface to this catechism, to have limited their religious inquiries to this standard; and by treating it as a rule of faith, they would have violated their express declarations, that they dictated to no one, and affirmed no authority. Moh. Eccl. Hist. 'See RAKOW.'

RACSON-COMPON, in Geography, a mountain of Thibet. N. lat. 31° 50'. E. long. 86° 14'.

RADA, a town of Sweden, in Warmeland; 33 miles N. of Carllstadt.—Alfo, a town of Sweden, in Warmland; 35 miles S.E. of Carllstadt.—Alfo, a town of Sweden, in Weft Gothland; 5 miles W. of Gothenburg.—Alfo, a river of Weftphalia, which runs into the Ocker, 5 miles N.E. of Gollar.

RADANAGUR, a town of Hindooftan, in Bahar; 32 miles E. of Ramgur.

RADANI, a town of Sweden, in Weft Gothland; 16 miles N. of Udevalla.

Radar, a town of Perfo, in the province of Chorofan; 48 miles N. of Mefohid.

RADASALMI, a town of Sweden, in the province of Savolax; 20 miles N.N.W. of Nyfhot.

RADAVITZA, a town of Prufia, in the palatinate of Culm; 22 miles E.S.E. of Culm.

RADAIN, a town of Aulaia; 6 miles W.S.W. of Vienna.

RADAUTZ, or Radentz, a town of Bohemia; 22 miles W.S.W. of Saczava.

RADAWAIR, a town of Hindooftan, in Candeif; 14 miles S.W. of Burhanpour.

RADBUZA, a river of Bohemia, that rises in the S.W. part of the circle of Pilien, and runs into the Miza, near the town of Pilien.

Radcliffe, John, in Biography, an eminent and eccentric physician, was born at Wakefield, in Yorkshire, where his father profefTed a moderate eftate, in the year 1650. He received the rudiments of his classical education at a school in that town; and at the age of 15, was lent to complete his studies at University college, in Oxford. He took his bachelor's dege in arts in 1669, and removed to Lincoln college, where he was elected to a fellowship. Having determined upon the profefion of phyfic, he went through the courtes of botany, chemistry, and anatomy, and was distinguished by the rapidity of his attainments in all those pursuits. Nevertheless he did not apply with zeal or indufly to the studies of the clofet, and recommended himself rather by his vivacity, acutenefs, and wit, than by any extraordinary acquisitions in any department of knowledge. In the prosecution of his medical inquiries, he contented himself with looking into the works of Dr. Willis, who was at that time prafticing in London with much reputation. He was polifTed, indeed, of very few books; infomuch that when Dr. Bathurst, head of Trinity college, asked him once with surprife where his rudy was? he pointed to a few vials, a skeleton, and a herbal, and faid, 'Sir, this is Radcliffe's library.' He took the degree of Master of arts in 1672, and in 1675 he proceeded bachelor of medicine, and immediately began to praftice in Oxford. He profefTed to pay very little regard to the rules which were generally followed, but confined them on many occasions with great freedom and acufon; a conduct which did not fail to draw upon him the envy of all the old practioners. Nevertheless his reputation and his praftice rapidly increafed; and before he had been two years in the world, he was very generally confulted, even by those of the highest rank. About this time, in confequence of some Witticisms, which he had launched with his accufed freedom againft Dr. Marshall, rector of Lincoln college, the latter unkindly oppofed his application for a difpensation for taking holy orders, which the Statutes required, if he retained his fellowship, and fhewed other tokens of invifibility; which induced Radcliffe to refign his fellowship, quit the college, and take lodgings in the town. He continued to praftice at Oxford, increafing alike in wealth and reputation, until 1684, when he determined to remove to London, and settled himfelf in Bow-street, Covent Garden.

His successes in the metropolis was unufualy rapid; and doubtlefs his wit and pleasantry, which rendered him a moft entertaining companion, contributed farceably lefs than his reputed skill in his profefion to forward his progres. In lefs than a year he was in full praftice; and in the second year, he was appointed physician to the princeses Anne of Denmark. In 1688, when prince George of Denmark joined the prince of Orange, and the princes retired to Nottingham, in a state of pregnancy, he was prefied by bishop Compton to attend her, in quality of his office; but he excufed himself on account of the multiplicity of his patients. After the revolution, he was confulted by king William and the nobility about his court; an honour which he mufT has owed entirely to his high reputation, for he never fliwed any inclination to be a courtier. By his rough independence of spirit and freedom of language, indeed, he ultimately loft all favour at court. In 1699, when king William returned from Holland in a state of fervor infpiration, he fent for Radcliffe, and fweing him his twelfon ankles, while the rel of his body was emaciated, faid, 'What think you of thefe?'—'Why truly,' replied the phyfician, 'I would not have your majesty's two legs for your three kingdoms.' This freedom was never forgiven by the king, and no interceffions could ever recover his favour towards Radcliffe. In 1694, when queen Mary caught the small-pox, and died, Radcliffe was accufed, bishop Burnet fays, of negligence and unkindfefs. He soon afterwards lost the favour of princes Anne, by neglecting to oblige her call from his too great attachment to the bottle, and another physician was appointed in his place. When queen Anne came to the throne, the earl of Godolphin exerted all his endeavour to reafign him to his former poet of chief phyfician; but he refused, alleging that Radcliffe would fend her word again, 'that her ailments were nothing but the vapours.' Nevertheless he is said to have been confulated in all cafes of emergency, in a private way. In 1703 Dr. Radcliffe had an alarming and dangerous attack of pleurisy, which he refufed, and increafed in the outlet by drinking a bottle of wine; he had, however, 100 ounces of blood taken from him by Mr. Bernard, the furgeon; and the next day, in spite of all interceffions, was carried to Kenilworth. His escape was almoft miraculous. The quefion asked Mr. Bernard how he did? and when he told her that he was unconfultable, and would obferve no rules, she anfwered, that then nobody had ravon to take any thing ill from him, for he was plain he used other people no worse than he used himfelf. During this illness he made a will, by which he diaposd of the greater part of his property for charitable purpofes, approprating particuJarly several thoufand pounds for the relief of fick leamen on fcore. He recovered, however, and continued in full occupation in his profefion, increafing in wealth and infeftance to the end of his days, and wagging a perpetual war with his brethren; who, in their turn, reprefted him as an active, ingenious, adventurous empiric, whom coufiant praftice
practice had brought at length to some skill in his profession. His caprice in the performance of his professional duties appears to have been unbounded; and many anecdotes are related of his refusal to attend on persons of distinction, if he happened to be engaged in pleasant company, or had any personal pique against the individuals, or if he conceived himself in any way affronted. Thus he set off suddenly for Bath in 1704, while attending the lady of Sir John Trevor, because that gentleman sent to Oxford for Dr. Breach to consult with him; which he had done as a compliment to Radcliffe, rather than join any of the London physicians with him. When Mr. Harley was visited by Swift, Swift complains, that by the caprice of Radcliffe, who would allow none but his own surgeon to be admitted, "he had not been well looked after," and adds in another place, "Mr. Harley has had an ill surgeon, by the caprice of that puppy Dr. Radcliffe, which kept him back so long." On the other hand, he attended the lady of Sir John Holt in a bad illness, with unusual diligence, out of pique to the husband, who was not supposed to be very fond of her. In the last illness of queen Anne, he was sent for to his country-house at Carshalton about noon; by order, as one account affirms, of the privy council; but he returned an answer, that "he had taken physic, and could not come." It has been stated, however, on the contrary, that he was only sent for on this occasion by lady Marham, without any order from the queen or the council, which is contrary to the following circumstances. On the 5th of August, four days after the queen's death, a friend of the doctor's moved in the house of commons, that he might be summoned to attend in his place, (Dr. Radcliffe had been elected a member for Buckingham in 1713,) in order to be excused for not attending on her majesty. A letter is preferred, said to have been written by the doctor to one of his friends, on this occasion, in which he says, "I know the nature of attending crowned heads in their last moments too well, to be fond of waiting upon them, without being sent for by a proper authority. You have heard of pardons being signed for physicians before a sovereign's demise; however, ill as I was, I would have went to the queen in a horse-litter, had either her majesty, or those in the commissary next her, commanded me to do." Whatever was the truth of the case, it is certain that Dr. Radcliffe became so much the object of popular resentment, that he was apprehensive of being assassinated, as appears from a letter addressed by him to Dr. Mead, which is extant. "Nor shall I be at any time, " said, "because I have received several letters which threaten me with being pulled to pieces, if ever I come to London." He survived the queen but three months, and died at Carshalton on the 23rd of November, 1714, the age of 64. It was believed, that the dread which he had of the populace, and the want of company in his retirement, which he did not dare to leave, contributed to accelerate his death. He was buried at Carshalton, and not at St. Mary's church in that city. It does not appear that Dr. Radcliffe ever attempted to write, and probably he would not have succeeded as an author. He was observed, indeed, to have been very little conversant with books; which made Dr. Garth humorously say, that "for Radcliffe to institute a library, was as if an enchanter should found a Farago." He was often the subject of the attacks of ridicule from poets and wits, and even was not spared on the stage, having been severely satirized in a piece acted in 1704, from a legal dispute with an apothecary, which was attended by the ladies of the court, and in which the paffages alluding to the doctor were much applauded. Swift, in Martinus Scriblerus, and Steele in the Tatler, levelled their ridicule at the doctor; and the following severe portrait of him was drawn by Dr. Maudclle, in his Essay on Charity Schools. "I That a man with small skill in physic, and hardly any learning, should by vile arts get into practice, and by up great wealth, is no mighty wonder; but that he should to deeply work himself into the good opinion of the world at to gain the general esteem of a nation, and establish a reputation beyond all his contemporaries, with no other qualities but a perfect knowledge of mankind, and a capacity of making the most of it, is something extraordinary. If a man arrived to such a height of glory, should be almost distracted with pride, sometimes give his attendance on a servant, or any mere person, for nothing, and at the same time neglect a nobleman that gives exorbitant fees; at other times, refuse to leave his bottle for his business, without any regard to the quality of the persons that lent for him, or the danger they are in; if he should be furious and morose, affect to be a humdrum, treat his patients like dogs, though people of distinction, and value no man but what would defy him, and never call in question the certainty of his oracles:—if he should infult all the world, affront the first nobility, and extend his insolence even to the royal family:—if, to maintain as well as to increase the fame of his sufficiency, he should scorn to consult with his better's on what emergency forever, look down with contempt on the most deserving of his profession, and never confer with any other physician but what will pay homage to his superior genius, creep to his humour, and never approach him but with all the stolid obsequiousness a court flatterer can treat a prince with:—if a man in his life-time should discover, on the one hand, such manifest symptoms of superlatite pride, and an infatiable greediness after wealth at the same time; and on the other, no regard to religion, or affection to his kindred, no compulsion to the poor, and hardly any humanity to his fellow-creatures:—if he gave no proofs that he loved his country, had a public spirit, or was a lover of arts, of books, or of literature:—what must we judge of his motive, the principle he acted from, when after his death we find that he has left a trifle among his relations, who flood in need of it, and an immense treasure to an university that did not want it."

Whatever may be the motives of the endowers of splendid institutions for the public use, the nation is at all events benefited for ages, by such noble establishments as the library and infirmary which he founded at Oxford, and which bear his name. He also endowed two travelling fellowships, with an annual income of 300l. attached to each. He had previously caused the beautiful east window, over the altar, in University college, to be put up at his own expense; and likewise given the money, which was paid for the erection of the master's lodge there, making one side of the eastern quadrangle. He was certainly avaricious to the extent almost of spining, and never could be induced to pay bills without much following and importunity. A piece of waggery would sometimes conquer this diffidence. A pavior, after long and fruitless attempts, once caught him just getting out of his chariot, at his own door, in Bloomsbury square, and let upon him. "Why, you rascal," said the doctor, "do you pretend to be paid for such a piece of work? Why, you have spoiled my pavement, and then covered it over with earth, to hide your negligence!"—Dr. Doctor," said the pavior, "mine is not the only bad work the earth hides."—"You dog you," said the doctor, "are you a wit? You must be poor; come in," and he paid him. He told Dr. Mead, that the great secret by which he might make his fortune was to make all mankind ill." Dr. Mead, however, adopted the
contrary axiom, and succeeded even beyond his adviser. Notwithstanding that Radcliffe seems to have literally practised this principle, in his dealings both with his patients and his brethren; and notwithstanding the severe accusations of ignorance and empiricism, which were everywhere leveled against him; the universal reputation, which he acquired and maintained, seems to justify the testimony of Dr. Mead, that "he was deservedly at the head of his profession, on account of his great medical penetration and experience." See Atterbury's Epistolary Correspondence. The Richardsoniana. Pope's Works, vol. vii. Swift's Works, vol. v. Hutchinson's Biographia Medica.

RADDEBURG, in Geography, a town of Saxony, on the east coast; 5 miles N.E. of Trebnitz.

RADDEINSDORF, a town of the duchy of Holstein; 6 miles E.S.E. of Eutyn.

RADDE, in Agriculture, a red ochre of iron, which, according to Dr. Darwin, has been found useful as a manure in the northern parts of Staffordshire. Its properties have not, however, been yet chemically examined as they relate to manure. See REDDE.

RADEBURG, in Geography, a town of Saxony, in the margravate of Meissen; 10 miles N.E. of Dresden. N. lat. 52° 15'; E. long. 15° 23'.

RADECHAU, a town of Bohemia, in the circle of Koniggratz; 9 miles S.E. of Trautenau.

RADEGATZ, a town of Germany, in the principality of Aschant-Della; 13 miles S.S.W. of Della.

RADEGURRY, a town of Hindoostan, in Canara; 24 miles S.S.E. of Mangalore.

RADERHAL, a town of the duchy of Carinthia; 13 miles E. of Saxenburg.

RADERAN, a town of Bohemia, in the circle of Kaurzim; 3 miles N.E. of Kaurzim.

RADERMACHIA, in Botany, a name originally given to the Bread-fruit, (see Artocarpus,) by Thunberg, in honour of one of his great patrons, Joachim Cornelius Matthew Rademaker, a member of the Dutch council, and President of the Society of Sciences, at Batavia. The author, in his Nova Genera, p. 25, represents this gentleman as a most distinguished Marina, and eouragecr of Natural History. Nevertheless, the above name has, by common consent, given way to the expressive one of Forrer, Artocarpus, which is properly synonomous with Bread-fruit.

RADERSBERG, in Geography, a town of Germany, in the principality of Cuiambach; 7 miles E. of Bayreuth.

RADES, a town of Tunis, on the N.E. coast; 5 miles S.E. of Tunis.

RADESCHE, or Ratschach, a town of Lower Carniola, on the Save; 10 miles N.W. of Gurkfeld.

RADHA, in Mythology, is the name of the consort of the Hindu deity Krishna. As Krishna was an avatar, or incarnation of Vishnu, so Radha is underfoot to be similarly an avatar of Vishnu's consort Lakshmi; thus incarnated to accompany her lord in this, his most splendid terrestrial manifestation. Under the names of Krisha and Lakshmi some notice will be found on the subject of this. Radha is seen very frequently portrayed and alluded to in the paintings and writings of India: Krishna is, indeed, seldom seen without her. She is repreented of perfect beauty, and is warmly celebrated in the amatory poesies of Hindoostan. In the elegant work of Jayadeva, entitled Gita Govinda, a pastoral drama exhibiting the loves of Krishna and Radha, the lovely nymph is thus described after a quarrel with her frolicsome and fickle lord, in the morning after the night of reconciliation, when affection ceased, and enmity crowned the recollection of past forrows. "In the morning the aurore, disarrayed, and her eyes betrayed a night without slumber, when the yellow-robed god, who gazed on her with transport, thus, in his heavenly mind, meditated on her charms: 'Though her locks be diffused at random; though the luster of her lips be faded; though her garland and zone be fallen from their enchanting tinsel; and though she hides their places with her hands, looking towards me with baulful glance; yet ever thus disarrayed, she fills me with ecclatic delight.' But Radha, preparing to array herself before the company of nymps could see her confusion, thus with exultation to her obliquious lover.

Place, O Ion of Yadu! with fingers cooler than faunal wood, place a circlet of mukh on this breast, which resemles a vale of coniferous water, crowned with fresh leaves, and fixed near a venerable bower to propagite the god of love. Place, my darling: the glossy powder, which would make the blackest be envious, on this eye, whose glances are keener than arrows darted by the husband of Reti. (See Reti.) Fix, O accomplished youth! the two gems, which form part of love's chain, in these ears, whence the antelopes of thine eyes may run downwards and sport at pleasure. Place now a fresh circlet of musk, black as the lunar spots, on the moon of my forehead; and mix gay flowers on my trefoil with peacock's feathers, in graceful order, that they may wave like the banners of Kama. Now replace, O tender hearted! the loft ornaments of my vulture; and relax the golden bells of my girdle on their destined station, which resemles those halls where the god with five heads, who destroyed Sambara, keeps his elephant ready for battle. While the spake, the heart of Yadava triumphed; and obeying her imperious benefice, he placed musky spots on her bosom and forehead; dyed her temples with radiant hues; embellished her eyes with additional blacknefs; decked her braided hair, and her neck, with fresh garlands; and tied on her wrists the looofed bracelets, on her ankles the beany rings, and round her waist the zone of bells, that founded with ravishing melody."

But we must recollect, says the author of the Hindu Pantheon, whence this article is chiefly taken, that the seemingly amourous conflicts of these ardent lovers are mere mythical defiptions of "the reciprocal attraction between the divine goodnefs and the human foul." This is the emblematical theology that Pythagoras admired and adopted; that the Sufi poets, Hafez, Sadi, and many others among the Persians, and Solomon also, in his fine Song, so beautifully inculcates. Like the enthuafias of other days, and in a manner not easily comprehended by the unenlightened, nor believed by them to be permanently chaitte, however innocent its commencement, "they profess eager desire, but without carnal affections; and circulate the cup, but no material goblet: in their feet, all things are spiritual, all is mystery within mystery." See Sir W. Jones's admirable Essay on the Mystical Poetry of the Persians and Hindoos, in the third volume of the Asiatic Recherches, in which a translation of the Gita Govinda of Jayadeva is introduced. Under the article JAYADEVA of this work is a brief notice of his poem; and under MAHESA is an extract from it, descriptive of the persons and loves of this interestine couple. (See also Prafulla.) The reader defiers of seeing what has been said and believed on the curious subject of mythical or emblematical theology, may consult our articles under MYSTERY, MYSTICS, and those there referred to.

Returning to Radha, we have to observe that among the sect of Gokalatha (see Sects of Hindoos) she is deemed a personification of religion, and sometimes called Rukmini.
(See that article.) There is a sect fond to worship her exclusively, and called Radha-ballabhi: they consider her as the Sakti, or active power of Vishnu or Krishna. (See Sakti.) The followers of this sect have ascribed to them the singular practice of making their own wives perforate Radha, and of preserving to or through them the oblations propitiating the goddess, or Lakshmi, of whom, as before said, she is an incarnation. There is no end to the whimsicalities in the modes of human worship, to give them no harsher name, wherever, to use an oriental expression, we suffer our necks to slip out of the collar of reason. Thus in India, as hath been the case in other countries, there is, with several sects, a right-handed and a left-handed mode of worship; one meaning a decent, the other an indecent mode. Those among the sect in question, who follow the left-handed path, require their wives to be naked, when attending them at their devotional abominations. She is sometimes called Radhika, and Krishna, Radhikdeviwar, or Lord of Radhika; and sometimes the name of Kamatani is given both to her and Rukmini. See RUKMINI AND YONI.

In Radha may be recognized the Grecian Juno, and of course in her husband Krishna, or Vishnu, the amorous Jove of that imitative race. On this point we shall quote a paragraph from the Edinburgh Review, No. xxxiv.

"We translate a passage from the Purana, entitled Brahma Vaivartica, to demonstrate the identity of character ascribed to Jupiter and Vishnu; only premising, that in conformity to the peculiar tenets of its author, Vishnu is here filled Krishna, and his goddess, Radha, Gangâ (the Ganges) was originally a nymph of wonderful beauty, who inhabited Paradise. She became enamoured of Krishna, and, concealing her face with her robe, flied invisible in his presence, her eyes fixed on his radiant countenance. The jealousy of Râdhâ (Juno) was excited. Followed by her innumerable attendants, she repaired to the presence of the god, and seated herself on his throne of gems. The timid Gangâ trembled at her aspect, and dissolved with terror. The goddess speaks: "Who is this nymph, lord of the universe, who, with half concealed visage, and eyes sparkling desire, thus gazes on thy sacred form?" This is not the first time the likes have witnessed the infidelity of their lord. When I detected thee dallying in a grove of sandal with Vîjaya, the figure of a quadruped concealed thy shame, and she was changed into a river. Still pursued by thee she became the mother of the mighty ocean. The fame forest was the scene of thy amours with the nymph Sôbhâ, (beauty). Again thou assumedst the form of an animal; whilst her spirit fled to the moon, and thou dividedst her body amongst gems, flowers, and black-eyed damsel. The woods of Vîrîsâvan afforded thee a retreat with the shepherdess Prabhâ (Juliet.) On my arrival, her spirit transmigrated to the solar orb; of her body thou madest a distribution: the god of fire obtained a part; and fome, as gold, gave brightness to the crowns of the kings of the earth. When I found thee, unexpectedly, on a bed of viral buds, reclined in company with the fair Xami (patience), alarmed at my voice, thou gatheredst as they lay dispersed, thy yellow robes, thy lyre, thy necklace of flowers, and thy cedr of gems. Then I forgave when thou belittledst a portion of thy body on the pious anchoret, a portion on the sick, and a portion on the glutton.

Such of our readers as have obtained a share in the latter portion, may, in the endeavour to expound this solar allegory, be repaid perhaps for their pains; in perusing the Gita Govinda and the article in which it is comprised, above referred to, they assuredly will.

RADHICA, a name of Radha, comfort of the Hindu deity Krishna, as sufficiently noticed under those articles.

RADHOST, in Geography, a mountain of Moravia, in the circle of Prerau; 12 miles E. of Melitch.

RADHUA, a mountain of Arabia; 30 miles W. of Medina.

RADIÆUS, in Anatomy, an epithet applied to parts about the radius, and equivalent to radialis; which see. See RADIAL CURVES. See CURVES.

RADIALIS, in Anatomy, a name given to parts in the fore-arm, situated near the radius. The adjective radial is also employed to denote the edge, surface, or aspect of any part, which is towards the radius; and in this way, with the term uhmar, affords the means of denoting the organs more accurately and intelligibly, than the indefinite expressions of outer and inner, which vary constantly in the changing attitudes of the limb.

RADIALIS Arteria, is the artery of the wrist, in which the public is commonly felt. See ARTERY.

RADIALIS Carpi Externus, Longior & Brevior. See CARPI.

RADIALIS Carpi Flexor. See CARPI.

RADIALIS Externus, Longior & Brevior, synonyms of the extensors carpi radiales, longior & brevior. See CARPI.

RADIALIS Internus, a synonym of the flexor carpi radiantis. See CARPI.

RADIALIS Nervi. The large nerve which goes behind the humerus, between two heads of the triceps, is called radial by some anatomists; others give this name to the nerve which lies parallel to and over the brachial artery. The first of these is called also the muscular spiral nerve, the second the median. See NERVE.

RADIALIS Vena, the vein corresponding to the radial artery. See VEIN.

RADIANT Heat. See HEAT.

RADIANT Point, or Radiating Point, is any point of a visible object, whence rays proceed.

Every radiant point diffuses innumerable rays all round; but only those radiants are visible, from which right lines may be drawn to the pupil; because the rays are all right lines.

All the rays proceeding from the same radiant continually diverge; the crystalline collects or reunites them again.

RADIATED, in Botany, an epithet applied to round flat flowers, consisting of a disk, and a single row of longish pointed leaves, ranged all around it in manner of rays, or spokes.

Radiated flowers are properly such as have several semioflets set round a disk, so as to resemble a radiant star; such are daises, chamomile-flowers, fun-flowers, &c. These are sometimes also called radiated diffuse flowers.

A radiated flower has two parts; its middle part, which is called the disk, and which is wholly made up of florets; and the other part, which is called the circle or border, which is wholly made up of semi-florets, or elf of plain flat leaves; but that is left common. The florets and semi-florets both usually adhere to the embryos, and to the thalamus of the flower, being contained in one general cup. These embryos finally ripen into seeds; sometimes furnished with down, sometimes with foliaceous heads, and sometimes without either, and sometimes margined. Of these seeds some are wrapped round with a kind of case or capsule, others are separated from one another by small perpendicular leaves.

RADIATED Leaf. See LEAF.

The word is also used in speaking of medals, and in heraldry,
It is, in fact, the main organ of medium of nutrition, and the means by which food is imbied or drunk up from the surrounding soil or earth. The radicles, together with the leaves, therefore, confitiate the absorbent organ of plants. See Radicula, and Root.

Radicofani, in Geography, a town of Etruria, near which are two castles, one built by Didier, left king of the Lombards, and the other by Colino I.; 55 miles S. of Florence.

Radicondoli, a town of Etruria; 24 miles N.E. of Florence.

Radicula, in Botany and Vegetable Phytology, the radicle, or fibre of the root. (See Root.) This term is used by Dillenius, in his Nova Genera, 121. t. 6, as a generic name, for a set of plants referred by Linnaeus to Sisymbrium. See that article.

RADIOLI, a muscule of the fore-arm. See Pronator.

RADIOLAR, Tares. See Pronator.

RADII Supinator, muscles of the fore-arm. See Supinator.

Radin, a little fender bones supporting the membrane, forming the fins in fishes, and called by Artedi officula radiata pinnarum, from their running from the base to the summit in the form of rays. See Fin, and Anatomy of Fish.

Radin, in Geography. See Radin.

Gen. Ch. Cal. Perianth inferior, of one leaf, cut about half down into four equal, permanent, wedge-shaped segments, each of which is three-cleft. Cor. Petals four, obvate, about the length of the calyx, alternate, with its principal segments. Stain. Filaments four, awl-shaped, ereft, the length of the calyx; anthers roundish, of two lobes. Pif. German superior, roundish, with four grooves; styles four, terminal, very short; stigma capitale. Peric. Capsule roundish, bluntly five-ribbed, of eight cells and eight valves. Seeds solitary, elliptical, compressed, very smooth.

the generic character and name, as well as in his reference to Linnaeus. The *catyxs* is many-cleft, not composed of four distinct leaves; the plant has hardly any thing of the aspect of a *Linum*, and therefore cannot properly be called *linclades*; neither has it been published as a genus, under the name of *Radiole*, by Linnaeus, as Gmelin's reference to the 12th edition of *Syll. Nat. indicates.

**RADIOMETER**, a name which some writers give to the *radia hisnomys*, or Jacob's staff. See FORE-STAFF.

**RADISH**, in Botany. (See RADIUM.) The radish is much grown, according to the author of the Agricultural Survey of the County of Kent, on the belt rich loamy foils of the Isle of Thanet, and in East Kent, for the supply of the London feedmen. The roots usually cultivated for this use are, the early short top, the falkon, and the turnip-rooted radish.

The land for the growth of this sort of crop should be in a fine state of preparation, by being ploughed to a great depth in the early part of the winter, and broken down well by harrowing, so as to render it perfectly clean from weeds, being previously filled with well reduced manure. The ground being brought into this fine condition, the seed is sown on furrows about ten inches apart, in a dry time in the month of March, about two or three gallons per acre. And as soon as the plants appear, every other row is cut up with a horse-hoe, leaving the rows twenty inches apart. When the plants get two or three rough leaves, they are hoed out in rows, and are then kept clean by repeated horse and hand-hoeing, when necessary, leaving the plants at about eighteen inches distance. It is added, in the above Report, that the crop is seldom fit to reap till October, and sometimes is out in the fields till Christmas, without receiving injury from wet weather; it being necessary that it should have much rain to rot the pods, that it may thral well. In respect to the produce, it is from eight to twenty-four bushels per acre; and it is sold to the London feedmen, who send it to all parts of the kingdom for retailing to the gardeners.

It is probable that this sort of crop might be grown in many other districts near the metropolis, or other large towns, with equal success, where the soil is of a rich loamy nature, as it is very easy in its culture, and requires but little labour or trouble. As it is necessary for it to remain out such a length of time, however, it will be proper, especially in wet locations, to keep the stems from falling too much upon the ground, as they and the seed may be injured by being too much in contact with it. If kept up in this way, the flanks, feed-hulls, and other offal parts, may also form a good cut food for some sorts of live-flock, as is the cafc with some other similar sorts of crops.

**RADISH, Horf.** See COCHLEA. ARMORICA.

**RADIUS**, in Anatomy, that bone of the fore-arm which extends from the humerus to the wrist, in the line carried from the external condyle of the former bone to the thumb. See EXTREMITIES.

**Radius, Diflocations and Fractures of.** See Fracture and Luxation.

**Radius**, in Botany and Vegetable Physiology, means the aggregate marginal flures, of compound flores, each generally in an oblong form, and all spreading from the centre, or disk, like rays. Such are the white flures of the Daffy, and blue, purple, or red ones, for the most part, of the *Allia*. The usual shape of the limb or border of such flures is ligulate - either linear, or elliptical; rarely, as in *Achillea*, short and roundish; in some compound flures the radius consists of tubular flures, as in *Centauera*; and those are neuter, definite of organs of fructification. The ligulate radiant flures above-mentioned are either female, producing perfect seed; or they are abortive, with more or less imperfect traces of a pistil. Many of them have no sign of a style or stigma, but none is without so much of a germen, as serves for the basis, that supports the petal itself.

A radius is occasionally assumed by some flowers, naturally dentate of one, as in the genus *Bidens*, each species of which, by such an acquisition, becomes a *Corolla*, and changes its order in the *Symphyxia*, from *Polygonia aculeata*, to *P. jprofusia*. This change is an approach towards a double flower, in that class; being a transformation of a certain number of the perfect, or united, flores into female ones. If such a transformation be total, and all the tubular flures become ligulate, the whole flower is double, and unproductive of seed, like the double Chamomile.

**Radius, Ray, in Geometry, the semidiameter of a circle;** or a right line drawn from the centre to the circumference.

The word is derived from the Greek *ράδιον*, rod. Flota uses the word radius, for a furrow.

The radius is also called, especially in trigonometry, *sinus totus*; the whole line.

It is implied in the definition of a circle, and it is apparent from its construction, that all the radii of the same circle are equal.

**Radius, in the Higher Geometry, Radius of the evolute, Radius curvatus, or Radius of a given circle,** is a right line representing a thread, by whose evolution from all the curve on which it was wound, the curve is formed; or it is the radius of a circle that has the same curvature in a given point of a curve that with of the curve in that point. See Curvature and Evolute, under which articles the method of finding this radius may be seen.

**Radius Afronomicus, an instrument usually called Jacob's staff, the cross-staff, or fore-staff.**

**Radius, in Optics.** See RAY.

**Radius, in Mechanica, is applied to the spokes of a wheel;** because illuming like rays from its centre.

**Radius Vector, is also used for a right line drawn from the centre of force in any curve in which a body is suppos¬

ed to move by a centripetal force, to that point of the curve where the body is suppos'd to be. See CENTRAL FORCES.

**Radius, among the Romans, a name given to the iron rod with which the boys rolled the trocheus.**

**Radius Aridinius, in Natural History, a name given by Mellius, Gmelin, and some other authors, to a kind of figured foliis, of which there are a great many very different species, some of which have been described by authors among the belemnites, under the names of *alveol belemnifer*um. Mr. Gmelin, who has taken great pains to inform himself, as well of the nature and figure of these flures, from the subjects themselves, as of their history, and the various accounts of them from other authors, observes, that the place where they are most frequent is Sweden, and that there they are no where so common as in the isle of Oeland. Volkman figures some also which he found in Silex's, and Helwing others which he collected in Prussia: he also found great numbers of them himself in Rudio.

They are usually imdered in lime-stone, and though at first sight they may all appear alike, yet, on a careful examination, they will be found to differ very greatly. The most obvious general distinction, established by Gmelin, is that some of them are straight, and others crooked. The straight ones may be divided into two genera. The first of these comprehend, according to this gentleman, two speeces; the first smooth, and with a converging alveolus. The
The regular and nice configuration of these bodies shews very plainly that they cannot be of mineral origin; but the several paterne of which each is composed, the sphinculus of communication, obvious in several, and the flisy matter yet found remaining on many, prove them to have been once shell-fill of the univalve or tubular concamcrated kind; the description of which, so far as it can be gathered from these remains, must have been this. The shell must have been either cylindric or conic in figure, of a smooth surface, and divided into several chambers or cells; but this so that the lepta which form the concamcrations are not continued and whole, but in some part of the periphery are cut in, in the figure of a crescent. Through these crescents, which, standing all together, make a continued canal, there has pailed another sely body of a cylindric or conic figure, also divided into concamcrations, and that in such a manner, that the lepta which form the cells are pierced with a small aperture on one side, which grows gradually smaller as the shell extends in length; and finally, through these apertures, in the concamcrations, there palles another shell pointed at the end, and, like the ret, divided into its concamcrations, and pierces along its middle with a sphinculus.

Mem. Acad. Petrop. vol. iii. p. 263.

This shell is, therefore, a compages of three sely bodies, enclosed one within another; and, it must be supposed, in order to carry an analogy with other shell-fills, these three sely bodies have communication with one another, by means of certain flips or perforations. The communication of these, one with another, seems all evident, from their being all found in their foible flate, filled with the fame flony matter; this has, doubtless, been all received in at the sphinculus of the inner shell, and thence has been thrown into the second, and from this into the third shell, so as to fill up all the concamcrations of the outer, as well as of the inner parts. This must have been the cafe with thefe; and the several various species that are at this day found foible, must have owed their origin to as many different species of the shells. The crooked and twisted, or wrecked kinds, which have the sphinculus usually placed near the sile, greatly approach in their structure to some of the corn commons.

RADIX, in Botany and Vegetable Physiology. See Root.

RADIX is used among some anatomists for the foile of the foot.

RADIX Carlo Santea; this root is found in temperate foils, in Mechoacan, a province of America. Its bark is easily separated from it, is of an aromatic smel, and of a bitter and somewhat acrid taste. The root itself consists of very slender fibris, which are easily separated from each other. The bark is accounted fudoric, and corrodates the stomach and gums: if chewed, it procures an agreeable breath. It is good for scurvy, catarrh, epilepsy, habitening deliveries, and removing hernias, and the small-pox, if taken either in powder or in the form of a decoction. The Spaniards have called it by the name of St. Charles, on account of its uncommon virtues.

RADIX Eutrochus, the root of the entroch, a name given by some authors to a foible substanve, usuall found among the entrochi, and seeming to have been the basis from which they have grown. It is plainly a part of the stella marina arborescentes petrifed, as these foiles also are. This foible is rarely found whole, but the fragments of it are very common. When entire, it is about the size of a walnut; the top of it being flat, and in some degree resembling the end of an entrochus, with a central hollow, but not having the least appearance of the rays of those foiles. These foils, though not properly judged of as to their origin, have yet been described by a great number of authors. Agrius, in particular, compares the form of them to a wheel. The body of this well resembles indeed the nave of a wheel, the fhape of it being conical toward one end, till you come to the top, and then a little flattened, with a hole in it. There is also a hole in the opposite end of the same foil, seeming fit for an axe to pass through; and there are five hollow flits, or feet, siling sidewayes, at equal distances from the broad bottom, and equally carried on in the fame direcon, so as not to misfit represent the foiles. At the end of each of these rays or foiles, there is a hollow, of the fame nature with those in the middle of the common entrochi, but this is cut acrois, by a seam, or break of the same foile, which palles directly over its centre, and covers about a third part of it; this goes no farther than the mouth of the hole, but it cuts it into two, and shews it in the form of two eyes. These radii or foiles are very seldom found so perfect as here described. Lifer mentions them as being formed like crescents at the end, which may very easily happen from the breaking off a part of the terminating portion.

Phil. Tranf. N° 129.

RADIX Alba, a word used by Diocedes, to exprass the root of the dracunculus.

RADIX, among Grammarians. See Radical, and Root.

RADIX, in Mathematics, the fame as root; but used in a different fenfe by different authors: we say the root of an equation, but the radius of a system of logarithms, the radius of a series, the radius of notation, &c. meaning in all these cafes the fundamental quantity on which the system is constructed, or that whence it has been derived, or that by means of which all other things of a like kind are compared.

RADIX of a System of Logarithms, is that number which involved to the power denoted by the logarithm, is equal to that number. Thus, under the article Logarithms it is shewn, that if \( r' = a \), then \( x \) is the logarithm of \( a \), and \( r \) is called the radius of the system. This radius in the common or Briggs’s logarithms, is 10, and in the Neperian or hyperbolic logarithms, it is 2.718281828, &c. and generally the radius of any system of logarithms, is that number whose logarithm in that system is unity.

RADIX of a System of Notation, is that number which indicates the local value of the figures, and is in all systems represented by a unit and cipher (10), which is ten in the common system, two in the binary system, three in the ternary, twelve in the duodecimal, and so on. See Notation.

RADIX of a Series is used, by some authors, as a term of comparison between any finite function, and its expansion or development: thus, the radix

\[
\begin{align*}
\text{of } 1 - r + r^2 - r^3 + r^4 & \quad \text{&c. is } \frac{1}{1 + r} \\
\text{of } 1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} & \quad \text{&c. is } \frac{1}{1 + \frac{1}{2}} \\
\text{of } 1 - 1 + 1 - 1 + 1 & \quad \text{&c. is } \frac{1}{1 + 1} \\
\text{of } 1 - 2 + 4 - 8 + 16 & \quad \text{&c. is } \frac{1}{1 + 2} \\
\text{of } 1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} & \quad \text{&c. is } \frac{1}{2 + 1} \\
\text{of } 1 + x + x^2 + x^3 + x^4 & \quad \text{&c. is } \frac{1}{1 + x}
\end{align*}
\]
of $1 + 2x + 3x^2 + 4x^3 + 5x^4$ &c. is $\frac{1}{1-x}$

of $1 + \frac{x^2}{2} + \frac{3x^3}{8} + \frac{5x^4}{16} +$ &c. $\sqrt[4]{\frac{1}{1-x}}$

See Dr. Hutton's Tracts, vol. i. p. 9. See also our article SERIES.

RAD-KNIGHTS. See REDMANS.

RADL, in Geography, a mountain of Stiria; eight miles S.S.W. of Landberg.

RADLER SEC, a lake of Carinthia; six miles N. of Saxenburg.

RADLSTEIN, a town of the duchy of Carniola; six miles W. of Landlraf.

RADLSTHAL, a town of Austria; nine miles E. of Krottan.

RADMANS. See REDMANS.

RADMANSO, in Geography, a small island in the Baltic, near the coast of Sweden. N. lat. 59° 45'. E. long. 18° 44'.

RADNAGUR, a town of Bengal; 32 miles S. of Burdwan.

RADNITZ, a town of Bohemia, in the circle of Pilen; 10 miles N.E. of Pilen.

RADNOR, New, or Most-Yfed, a borough and market-town in the wonym of Swydd Wynogyn, Caerfyl Chwaddl, (now called the liberties of the town of New Radnor,) county of Radnor, South Wales, is situated near the river Somergyll, at the distance of seven miles N.W. from Kington, and 156 miles W.N.W. from London. In remote times, this town was a place of great importance, as appears from its having given name to the county, but it has now dwindled into comparative poverty and insignificance. Caradog informs us, that about the year 992, Meredydd ab Owain destroyed Radnor, in a ferocious contest with his nephew, who had been affilling the English to ravage South Wales. It was recovered, however, from this disaffair, and continued to flourish till the union of Wales with England, when it began to decline, in consequence of its ceasing to be fortified and garrisoned as a frontier town. Before that period, it was surrounded by a lofty wall, and a deep moat, some remains of which are distinctly visible on the west and south sides. The walls, when standing, are traditionally said to have been of great height. The area inclosed by them was an oblong square, containing about twenty-six acres of ground, laid out into three longitudes of streets, which were intersected by five tranverse ones. Of these at present several have no buildings; and others are only foot paths. But though thus decayed, Radnor still preserves its privileges as a borough. The corporation consists of a bailiff, twenty-five capital burgesses, two aldermen, a recorder, a coroner, a town-clerk, and other inferior officers. The bailiff and aldermen are chosen annually from among the capital burgesses, and are justices of the peace. The bailiff of the preceding year is also a justice of the peace; and there besides three additional persons nominated out of the capital burgesses, who are invested with similar authority. The district over which they preside, and superintend the jurisdiction of the county magistrates, is considerable; comprehending a circle round the town nearly ten miles in diameter. The bailiff's courts and the petty felions are regularly held every Monday, when the bailiff, aldermen, and town-clerk attend to transact business relating to the borough, and have power to determine all suits for sums under forty shillings. The quarter-felions for the borough are held on the Mondays after the quarter-quarter-felions at Presteigne; and the sheriff's county courts for the recovery of small debts, are held every alternate month here, and at the town last mentioned. The representative for the borough is chosen by the burgesses of New Radnor, in conjunction with those of the boroughs of Knighton, Rhayader, Cenf Llys, and Clynclas; the bailiff being the returning officer. As nothing but the circumstance of receiving parochial relief disqualifies any person from becoming a burgess, the number of voters is considerable; those of New Radnor are supposed to exceed 500, and the whole number, including those of the contributory boroughs, is estimated to be about 1500. To be a capital burgess of New Radnor, however, actual residence within the jurisdiction is essential, which is not the case as to the contributory boroughs: and if a capital burgess becomes non-resident he loses his privileges as such. A benefice society, established here in 1778, at present consists of above 100 members, who hold their annual meetings on the 6th of January.

Weekly markets were formerly held here on Tuesdays, but these are, at present, only nominal, notwithstanding some late attempts to restore them. There are still, however, five annual fairs, and there is also an annual wake on the third Sunday in the month of August. The parish of Radnor is divided into three portions, of which the town of New Radnor is the principal, containing, according to the parliamentary returns of 1811, 77 houses, and 380 inhabitants. The public buildings here are the town-hall, the prison, and the church. The last consists of a nave, south aisle, and chancel, with a tower at the west end.

Radnor castle, and on an eminence commanding the town. Of this once majestic pile, a few fragments of walls only remain, but the entrenchments are still entire; the outer ward, called Balli-Glas, or the Green Court-Yard, is yet distinct from the inner one, or keep, and is nearly in its original form. In 1773, on digging within the area of this castle, six or seven small "Gothic arches of good masonry were discovered," besides a variety of ancient instruments. The forest of Radnor extends several miles to the north of the town, covering the slope of a lofty eminence, from the summit of which are very extensive prospects. The principal seats in the vicinity are Downton-hall, the seat of Percival Lewis, esq. and Harpton-court, a seat belonging to Thomas Frankland Lewis, esq. Both these mansions are surrounded by beautiful scenery, and are highly ornamental to this district. About two miles westward from the town is a celebrated water-fall, called Water-break-its-neck, seventy feet in perpendicular height; but it is extremely defietive in water, except during the time of floods, when the effect produced is truly grand. At the western extremity of the parish is an intrenched dyke, which formerly extended across the whole vale of Radnor. War-cloaks, a field to the eastward of the town, is traditionally said to have been the scene of some military contest, but no particulars respecting it are preferred.

Old Radnor, or Pen-y-Cragg, is a small village, situated about three miles to the south of New Radnor. Camden supposes it to have been the Magnes of Antoninus, which was garrisoned by the Phacienian regiment in the reign of Theodosius the younger; and there seems every reason to believe that it was a place of note in the Romo-British period. The Roman road passed close to the base of the hill upon which the village stands. The church here is a venerable old edifice of stone, with a massive square tower at one end. A curious screen, richly carved in wood, extends across the nave and side aisles. Here are various monuments to the memory of members of the Lewis family of Harpton. Carlile's Topographical Dictionary of Wales, 410. 1813. Lipcomb's Tour through Wales.
Radnor, a small pleasant town of America, in Delaware county, Pennsylvania. The place was originally called "Amilel" by the Dutch, who began to build here. The number of inhabitants is 925.

Radnor, a town of South Carolina; 10 miles S.W. of Edmondbury.

Radnorshire, an inland county of South Wales, is bounded on the north by the counties of Montgomery and Salop, on the east by the county of Hereford, and on the south and west by the counties of Brecknock and Cardigan. According to Mr. Clarke, it contains 510 square miles, or 346,000 acres, and is politically divided into five hundreds, and fifty parishes; some of which are within the diocese of Hereford, and the remainder within that of St. David's. The parliamentary returns of 1811 state the number of its houses at 4154, and of its inhabitants at 25,900.

It sends two members to parliament; one for the county, and one for the borough of New Radnor, with its contributory boroughs. The face of the country is extremely mountainous and bleak in every part of it, but it is intersected by several valleys, which are watered by the Wye, the Teme, the Lugg, the Ithen, the Eddow, and their respective sub-fidian streams. These valleys afford a considerable extent both of meadow and arable land; especially the Vale of Wye-Side, and the Vale of Radnor, some portions of which are very fertile, and have a good soil and a congenial climate. In the other parts of the county, however, a barren soil, and a chilly atmosphere, are the predominant characteristics. Nearly two-thirds of its whole extent being either in a state of commonsage, or lying wholly waste, agriculture has hitherto made little comparative progress here. Cattle and sheep consequently constitute the chief produce of the county. The number of the latter is indeed very great. Hence Radnorshire is famed for its supply of wool; but notwithstanding this circumstance, singular to say, the manufacture of woollen goods is totally disfigured. The raw material is sold to the manufacturers of the north, by whom the inhabitants of this county are in return furnished with cloth.

Radnorshire contains three market-towns; Presteigne, Rhaiadr, and New-Radnor. The market at the last, however, is only nominal. The county courts are held at Presteigne, which is now the most important and flourishing town in the county. (See Presteigne.) The chief remain of antiquity within its limits is Offa's Dyke, which commencing at the river Wye, near Hay, skirts the counties of Radnor and Hereford, and passes into Montgomeryshire at Powell-y-Ppoid, a hamlet on the road between Bishop's-castle and Newtown. The only religious house in the county was the Abbey of Cwm Hir, founded in 1143, for monks of the Cistercian order, by Cadwathelan-ap-Madoc, which, at the dissolution, was valued at £28. 17s. 4d. per annum. Of this monastery a considerable part of the buildings is yet standing, though in a very ruinous and dilapidated condition. Leland, in his Itinerary, (vol. v. p. 153) speaks of its church as the longest in Wales, and informs us, that it was "spoiled and defaced by Owen Glendower." The principal castles in Radnorshire were those of Colveyne, Tynybont, Aberedow, Aber-Eddyw, Ewenlles, Radnor, Rhaiadr, and Pain's-castle. Several antiquities, among whom are Cadern, Gale, and Ward, place the Roman Itation Magnos, or Magna, at Old Radnor, as is mentioned above; but Baxter contends that it should be fixed at Ledbury, in Herefordshire, and Harris at Gaer, near Brecknock. In this county, particularly on the summit of Gwafedin hill, are several of those collections of flomes called in South Wales Larnes, in North Wales, karnadhen, in Scotland, cairns, and in Ireland, dunt.

Radnor was erected into an earldom by Charles II., in the person of John Robarts, lord Robarts of Truro, but that title became extinct in 1757. It was revived, however, in 1765, in the person of William Bouverie, baron Longford, and vicompt Fofkiphone, whose son Jacob, now earl of Radnor, enjoys his privileges. General View of the Agriculture of the County of Radnor, by John Clark, 4to. Skrine's Tours in Wales. Camden's Britannia. Pennant's Tour in Wales. 8vo.

Radnott, a town of Transylvania, on the river Marce; 23 miles W. of Scherburg.

Rade, a small island in the North Sea, near the coast of Norway. N. lat. 60° 35'.

Radoffin, a town of Moravia, in the circle of Iglau; 21 miles E. of Iglau.

Radowitzell, or Ratzdorf, or Zell, a town of Germany, in Austrian Swabia; situated on the Untere, or lake of Lille; 10 miles N.W. of Conflance.

Radowitz, a town of Poland, in the patalinate of Sandomir; 50 miles N.N.W. of Sandomir.

Radomischl, a town of Bohemia, in the circle of Prachatitz; four miles N. of Strakonitz.

Radomisl, a town of Poland, in the patalinate of Lublin; 45 miles S. of Lublin.—Alfo, a town of Poland, in the patalinate of Kiev; 56 miles N.W. of Kiev.

Radomsk, or Radomiski, a town of Poland, in the patalinate of Sirdia; 32 miles S.E. of Sirdia.

Radonitz, a town of Bohemia, in the circle of Saatz; 13 miles W.S.W. of Saatz.

Radoschitsch, a town of Poland, in the patalinate of Sandomirz; 20 miles N.E. of Malogozec.

Radouski, a town of Pruffia, in the patalinate of Culm; 10 miles W. of Lautenburg.

Radstadt, a town of the archbishopric of Salzburg; 36 miles S.S.E. of Salzburg.

Radt vor dem Waale, a town of the duchy of Berg, where Roman Catholics, Lutherans, and Calvinists, have, each of them, a church; 25 miles E. of Daffeldorp.

Radula. See Raspatory.

Radunpour, or Radimpor, in Geography, a town of Hindooflan, in the country of Agimere, on the river Puddar, or Butflas; 171 miles N. of Surat. N. lat. 23° 58'. E. long. 71° 48'.

Radzanow, a town of the duchy of Warrafaw; 30 miles N.E. of Ploczkno.

Radzieczow, a town of Poland, in the patalinate of Belez; 24 miles W. of Belez.

Radziejow, or Rodschowa, a town of Poland, in the patalinate of Brzefly; 25 miles W. of Brzefly.

Radzivilow, a town of Lithuania; 50 miles E.N.E. of Minik.

Radzymin, a town of the duchy of Warrafaw; 12 miles N. of Warrafaw.

Raemsdonck, or Ramsdonck, a small but frong place of Brabant; three miles E. of Gertrudenberg.

Raeopour, a town of Hindooflan, in the cincar of Gohud, on the Junna; 38 miles E.N.E. of Lahaar.

Raerdorp, a town of Holland; five miles N.E. of Amsterdam.

Rätvik, a calcareous mountain of Sweden, the height of which is ellimated by Bergman at 6000 feet above the sea, observing also, as a singularity, that upon this mountain, and that of Rodaberg, are found vast blocks of reddish felfpar, mingled with quartz and brown mica.

Rafael, Cape, a cape on the E. coast of the island of Hifpanola. N. lat. 19° 2'. E. long. 69° 46'.

Rafael, St., a town of South America, in the province of
of Caracass; 40 miles S. of Caracass.—Alto, a town of South America, in the province of Moxes; 120 miles E. of Santa Cruz de la Sierra la Nueva.—Alto, a town of New Navarre; 155 miles S.W. of Cafa Grande.

**RAFAH,** a town of Egypt; 57 miles N.E. of Caiieh.

**RAFALSO,** a small island in the gulf of Finland. N. lat. 60° 20'. E. long. 26° 12'.

**RAFFAELE DA URRINO,** in Biography. See **RAFAEL.**

**RAFFLING,** a sort of game with three dice, in which he who throws the greatest pair, or pair royal, in three casts, wins the prize or flake.

The word probably comes from the base Latin, *risere,* to *risere,* to *risere,* *risere,* take all away.

The raffle is properly the doublet or triplet: a raffle of aces, or dukes, carries it against mere points.

**RAFFLING** is also used when a company of persons club to the purchase of a commodity, or make small deposits, amounting in the whole to its full value; and he that throws the highest on three dice, or who has the highest number by means of balls thrown on a bagatelle or porto-bello table, takes it.

**RAFICA,** in Geography, a town of Asiatic Turkey, in the government of Dzirbekir; three miles S. of Raca.

**RAFLUNDA,** a town of Sweden, in the province of Skone; 17 miles S. of Christiana.

**RAFINA,** in Botany, a genus of plants, separated from the Linnean *Crotalaria* and *Lupina,* augmented with several new species from the Cape, and named by its author, professor Thunberg, in the second part of the preface to his *Prodromus Plantarum Capensis.* De Thoess is completely in the dark as to the person commemorated in this name, who can be no other than Mr. C. G. Rafin of Copenhagen, author of a *Flora of Denmark and Holstein,* in the Danish language, published in the years 1796 and 1800; in octavo, making two volumes, which include the first ten classes of the Linnean system. We know not whether any more has appeared. The same botanist has written a work on the phytology of plants; and several papers for the Academy of Sciences at Copenhagen. See Sims and Konig's Ann. of Bot. v. i. 6.—Thunb. Prodr. 235. perf. n. 48. Willd. Sp. Pl. v. 3. 949. Ait. Hort. Kew. v. 4. 261.—Clas and order, *Diadephia Decandria.* Nat. Ord. Papilionaceae. Linn. Leguminosae, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, five-cleft, ringlet; the upper lip in two broad ditangents; lower divaricated, in three acute ones, the middle one smallleaf. *Cor.* Papilionaceae. Standard large, heart-shaped, acute, spreading, depressed at the fides. Wings ovate, about half as long as the standard. Keel acute, the length of the wings. *Stam.* Filaments ten, all united into a linear tube, split along the base; five of them rather the shortest; anthers simple. *Pist.* German flaked, linear; stile simple, bent upwards at nearly a right angle; stigma obtuse. *Peric.* Legume flaked, oblong-lanceolate, compressed, of one cell and two valves. *Seeds* several, flaked, roundish-kidney-shaped.

Eff. Ch. Stamens all united. Calyx ringlet; upper lip divided; lower divaricated, in three segments, the middle one smallleaf. Legume flaked, lanceolate, compressed.

Obf. The first species in Willdenow, *pseudolata,* *Crotalaria pseudolata* of Linnaeus, figured in Smith's *Insects of Georgia,* v. 2. t. 67, is *Baptisia pseudolata* of Brown, in Ait. Hort. Kew. v. 3. 5, a genus adopted from Ventenat, and belonging to the *Decandria Monogynia.*

1. **R. amplexicaulis.** Orbicular Rafinia. Thunb. Prodr. 123. Willd. n. 2. (Crotalaria amplexicaulis; Linn. Sp. Pl. 1503. Genista perfoliata, orbiculata foliis; Ser. Theaur. v. 1. t. 124. f. 5. Lin.)—Leaves reticulated, orbicular, clasping the stem, alternate; the floral ones opposite, coloured.—Native of the Cape of Good Hope. A smooth, handsome, branched flowered, clothed with entire leaves, from one to two inches across, finely reticulated with innumerable veins; the upper ones, which accompany the flowers, smaller, and pale yellowish. *Flowers* solitary, nearly felifte, yellow, smaller than the floral leaves.

2. **R. elliptica.** Elliptical Rafinia. Thunb. ibid. Willd. n. 3, excluding the reference to Andrews.—Leaves slightly veined, elliptic-ovate, acute, alternate; the floral ones opposite, not longer than the flowers.—Native of the Cape. Confounded by Linnaeus with the foregoing, from which it differs in having much smaller leaves, felifte, not clasping the stem, quite different of reticulated veins. *Flowers* of a deeper yellow, as long as the floral leaves.

4. **R. triflora.** Three-flowered Rafinia. Thunb. ibid. Willd. n. 5. Ait. v. 1. Venten. Malsar. t. 48. (Crotalaria triflora; Linn. Sp. Pl. 1504. Curt Mag. t. 482. Borbonia cordata; Andr. Repol. t. 31, excluding the synonym.)—Leaves ovate, smooth. Branches angular. Stalks single-flowered, three together.—Native of the Cape, where it was gathered by Sparrmann and Thunberg, and from whence its seeds were sent to Kew garden, in 1786, by Mr. Francis Masson. The plant is biennial, requiring to be sheltered in winter, and flowering in June and July. Stem branched, about a yard high, most leafy in the upper part, smooth, and of a glaucescent green, as well as the leaves, which are numerous, alternate, almost Isis, more or less exposed, but varying in size and breadth. *Flowers* abundant at the summits of the branches, large, yellow, axillary, flaked, three together, the floral leaves smaller than the rest, and often tinged with purple.

5. **R. opposita.** Opposite-leaved Rafinia. Thunb. ibid. Willd. n. 6. (Crotalaria opposita; Linn. Suppl. 322. Liparia opposita; Linn. Syd. Veg. ed. 13. 554. Spartium capenfe; Sp. Pl. 995. Cytisus capensis; Berg. Cap. 171.)—Leaves elliptic-lanceolate; the upper ones most opposite. *Flowers* lateral, on short solitary stalks.—Native of the Cape, apparently unknown in our gardens. Linnaeus and his son confused many different things under this species, some of which being marked in their herbarium as having been gathered by Thunberg, we presume to be among those he has defined; yet it is not possible to determine them all by his short characters, several of which unfortunately contradict the specific names. The *flora* of the present is described by the younger Linnaeus as *flora-fulo* the copious, alternate, leafy branches, three or four inches long, on which one or two pair of the lower leaves are opposite; the proper floral leaves, like those of the stem, being alternate; all the leaves are elliptic-lanceolate, or somewhat ovate, acute, entire, single-petalled, an inch or more in length. *Flowers* either lateral or axillary, among the uppermost leaves, solitary, each on a simple stalk about the length of its calyx. Corolla yellow, not half so large as the last species.

They have one mail, on which is hoisted a large square sail; and a pair of oars, whole heels rest on each side the raft. When a fore-and-aft sail is set, a pair of oars is rigged forward. These rafts were the first conveyance by water, no doubt, long before vessels of a better construction were thought of; and what is rather surprising they are made to sail with foul winds, and steer, as well as any other kind of vessel, by means of an invention similar to, and perhaps the original of, that which is now called "a flying-keel." They have for this purpose planks about ten feet long, and fifteen to eighteen inches wide, which slide vertically in the spaces between the trunks which form the raft. It is only necessary to immerse them more or less, and put down a greater or less number at the fore or after part of the raft, to make it either hump-to, or fall-off from the wind, tack, veer, lie-to, and perform every necessary manoeuvre. The number of these planks is five or six, and if one of these planks be drawn up forward, the raft will keep away; and, if one is raised abait, it will come to the wind. This fort of raft, from the simplicity of its construction, might perhaps be well adapted to many cases of emergency, after shipwreck upon coasts, defitute of all other materials for ship-building.

RAFT-PORT, in a Ship, a square hole cut through the forecastle of some ships, immediately under the counter, to receive the planks or pieces of timber which are brought to lade her for transportation; and which, on account of their great length, could not be received aboard otherwise.

RAFTERING, in Agriculture, a provincial term used for a fort of ploughing in narrow ridges, or small ridgets. It is useful for expounding a large surface of earth to the influence of the atmosphere.

RAFTERS, in Building, are pieces of timber, which, standing by pairs on the rafters-piece or rafter-piece, meet in an angle at the top, and form the roof of a building.

It is a rule in architecture, that no rafters should stand farther than twelve inches from one another.

For the sizes or scantlings of rafters, it is provided by act of parliament, that principal rafters from 12 feet 6 inches to 14 feet 6 inches long, be 5 inches broad a-top, and 8 at the bottom, and 6 inches thick. Those from 14, to 18, 6, long, to be 9 inches broad at the foot, 7 a-top, and 7 thick. And those from 18, 6, to 21, 6, to be 10 inches broad at the foot, 8 a-top, and 8 thick.

Single rafters, 6 feet 6 inches long, to be 4 and 3 inches in their square.

RAFTY, a provincial term signifying damp and musty, as corn or hay in a wet season.

RAG, or RAKE, among Hunters, denotes a company or herd of young colts.

RAG, or RAG, Rowley, in Mineralogy. See Ferrite.

Rag, a torn piece of cloth of any sort. See the next article.

Rags, Woolen, as well as the clipings of pitch marks upon sheep, are good manure. The rags should be chopped small, about an inch or two square, and scattered on the earth at the second ploughing; for being thereby covered they will begin to rot by feed-time. They imbibe the moisture of dews and rain, retain it long, and, according to Dr. Home, keep looee dry soils in a moot state. They formerly coilt about fourpence a bushel at London, from whence many loads were sent every year to Dunshtuble, which is thirty-three miles, where they are laid on even little lands, just after the fowing of the corn, allowing to the acre four facks, of six bushells each; they are much higher now, at more than double
double this price, and no quantity of any great account to be procured. See Manure, and Toy-dressing.

The farmers in Oxfordshire make use of rugs of this sort, procuring them from London and other places, at the rate of from eight to nine pounds the ton, which, with the carriages, load them in upon the farms from nine pounds ten shillings to ten pounds. By some they are spread upon the clover lands, lay or layers for wheat, in the proportions of from three or four to fix hundred weight to the acre. Tried with dung in this way, in the quantity of seven hundred weight to the acre, the dung is found the better dressing. They are also applied for turnips, for which crop they are ploughed in before the winter, as soon as the wheat-owing is over; if ploughed in at the time of sowing turnips, they will not work for that crop. Some for this crop give half a cost of rags, and half a cost of sheep-fold. When applied on the clovers they seldom last longer than two years. Others think that half a cost of rags, and half a coat of dung, is the most beneficial method of applying this sort of manure. Some think rags are more durable than any other manure. Rags are occasionally bought from Whitney to this district, at from seven shillings and sixpence to eight shillings and sixpence the hundred weight, and five hundred weight spread upon the acre; they commonly last only one crop, but sometimes for two, and are found superior to any thing for wheat. They are ploughed in; and if the weather be very dry, do not answer so well. They are supposed to do better on a summer fellow for that crop.

In Suffolk rags are chiefly of service in the hop grounds, for which they are thought an excellent manure. Very great benefit is said to have been derived from the application of these rags, in contributing to preserve for the purpose of plantation in a state of constant moisture and vegetation in the dried oras, when grown which has been manured with dung, have been dried up, and the hop crops have failed. Rags have likewise been found very useful on the mowing grounds in some parts of Lancashire, where laid upon them in a pretty full proportion. When cut or chopped sufficiently small, they readily sink down upon the surface of the land, and do not afford any sort of interruption to the sowing, while they absorb and keep in the moisture, which is of material benefit tosuch groafs lands as are inclosed to be dry.

Rag, in a Ship. See Bolts.

RAGAL, in Geography, a town of Germany, in the county of Pludzenta; 10 miles E. of Pludzenta.

RAGALBUTO, a town of Sicily, in the valley of Demons; 23 miles S. of Cefalu.

RAGALMATO, a town of Sicily, in the valley of Mazara; 8 miles N. of Naro.

RAGAMMEE, a town of Ceylon, near the W. coast; 38 miles S. of Columbo.

RAGANELLO, a river of Naples, which runs into the gulf of Tarento, near Civa Mandonia.

RAGAPILLY, a town of Hindostan, in Golconda, near the left bank of the Godavery; 5 miles S.E. of Badia Scillian.

RAGATZ, a town of Switzerland, in the county of Sargans; 5 miles S.S.E. of Sargans.

RAGAY, a town on the S. coast of the island of Luzon. N. lat. 13° 50'. E. long. 122° 40'.

RAGGED, in Heraldry. See Raguled.

Ragged Hawk, in Falconry, is a hawk that hath its feathers broken.

Ragged Robin, in Botany. See Lychins.

Ragged Harbour, in Geography, a bay on the E. coast of Newfoundland, being a part of Catalina bay; 2 leagues N. of Catalina harbour. N. lat. 49° 45'. W. long. 53° 40'.

Ragged Helmet, a small island in the Mergui Archipelago. N. lat. 10° 0'.

Ragged Island, a small island in the East Indian sea, near the island of Paraguay. N. lat. 11° 24'. E. long. 119° 30'.—Also, a small island among the Bahamas. N. lat. 22° 27'. W. long. 77° 16'.

Ragged Point, a cape on the E. coast of the island of Borneo. S. lat. 2° 13'. E. long. 110° 43'.—Also, a cape on the N. coast of the island of St. Christopher. N. lat. 17° 30'. W. long. 62° 42'.

RAGGIOLINO, a town of Italy, in the department of the Mincio; 19 miles S. of Mantua.

RAGH, in Hindoo Mythology, is the name of the ancestor of Rama, one of their deified heroes, who is hence sometimes called Raghu, or son of Ragh. Budha, or Boodha, another of the Indian deities, is laid to have had a son also of this name.

RAGHUNA, a name of the Hindoo deified hero Rama, signifying a descendant of Raghu, a warlike character. All these names are still very common among Hindoos: whether confined to the sect who, as chiefly worshipping Rama, are called Ramuanuj, or more extensively given, we are not informed. See Rama.

RAGLAN, in Geography, a town of Peria, in the province of Fariftan; 130 miles N.W. of Sehiras. N. lat. 30° 40'. E. long. 50° 8'.

RAGLAND, a small village of Monmouthshire, here mentioned on account of its castle, the ruins of which excite its grandeur and magnificence, command the attention of travellers. During the rebellion it was held for the king, and defended to the last extremity by the marquis of Worcester; 8 miles W. of Monmouth.

RAGMAN'S Roll, or Ragumand's Roll. See Roll.

RAGNIT, in Geography, a town of Pruflian Littimana, on the river Memel, endowed with the privileges of a town in the year 1722. Its ancient castle was famous even in the times of Paganism. The knights of the Teutonic order rebuilt it, with additional works, in 1555; but being destroyed in 1555, it was rebuilt a second time, and called Landshut; but afterwards it obtained the name of Ragnit from the river which pas ses by it; 36 miles E.N.E. of Königsberg. N. lat. 55° 5'. E. long. 22° 18'.

RAGOGNA, a town of Italy, in Friuli; 16 miles N.W. of Udine.

RAGOOGUR, a town of Hindostan, in the Malwa country, and circuit of Kitchewana; 116 miles N.E. of Oudega. N. lat. 24° 23'. E. long. 77° 30'.

RAGOTSKI, Francis, in Biography, the second of the name, prince of Transylvania, distinguished by his courage and patriotism, was born in 1676, at the castle of Borså, in Hungary. When he was only a year old he lost his father, prince Francis, and was left to the care of his mother, Helena Sereni, who afterwards married count Tékeli. During his education he was carefully watched by the house of Austria, and his correspondence with his mother, who had retired to Constantinople, was entirely broken off. He was now suffered to travel to most of the courts of Europe, and to contract a marriage with the princess of Hesse Rhin-lids. Zealously attached to the independence of his country, which was kept in a state of great devastation by the Imperialists, he secretly entered into negotiations with the French king, Lewis XIV., but being betrayed by one of his confidants, he was arrested, and a charge of treason was preferred against him. The sentence of guilty was soon pronounced, and he was committed to the custody of an officer,
officer, who, however, connived at his escape, and he arrived in a dragoon's habit at the frontiers of Poland. Here he received assurances of alms from France, and immediately published an eloquent manifesto, calling upon the nation to free itself from the Austrian yoke. Numbers joined him; being, however, but half armed, he was fearful of trusting his cause in their hands, and withdrew to the frontiers of Poland, where he was joined by fresh recruits. With these he ventured to make some progress; formed several fortresses; and took a severe revenge upon the Imperialists, who had given no quarter to the Hungarian insurgents.

At this period the crown of Poland was vacant, through the deposition of Augustus by Charles XII. of Sweden, and the Polish chiefs were deficient in placing it upon the head of Ragotki. But he had no such ambitious views: his great object was to liberate his country, and he refused to desert its cause for any other prospects. He accordingly pursed his success, and by the reduction of Tokay, obtained the submissio of almost the whole of Lower Hungary. So high was his reputation, that the diet of Alba Julia, in 1704, proclaimed him prince of Transylvania, with which dignity he was afterwards solemnly invested. He obtained likewise the title of protector of Hungary, and Lewis XIV. sent to him a public embassy. He soon began to feel the difficulty of supporting a popular insurrection against the arms and policy of a powerful sovereign, as well by the aban donment of some of his allies, as by the defection of his troops. He had another opportunity of giving a refusal to the crown of Poland, which was offered him by the czar Peter, fleeing thereby his sincere attachment to the cause of his country, and he employed all the resources of valour and good conduct to support a declining cause. In 1711, a treaty was concluded between the Hungarian Rates and the emperor, into which he refused to enter, although the first article secured his life and property, with the title of prince of Transylvania. Mortified by the failure of his patriotic exertions, he withdrew to Turkey, renouncing his great estates, and preferring an honourable poverty to a splendid servitude. He afterwards passed some time in France, then returning to Turkey, he fixed his final residence at the castle of Rodoto, on the sea of Marmora. "There," says his biographer, "a Christian among Mahometans, and a philosopher among barbarians, he tranquilly closed his life in 1733, at the age of 61." He left "Memoirs of his Life," which were published in the "Revolution of Hongrie," printed at the Hague in 1739. In 1751 there appeared a work, entitled "Testament politique et moral du Prince Ragotki," the authenticity of which is doubted. Mereri.

RAGOUT, or Rago, a sauce or seafoning, intended to increase or recover the appetite when languishing, or loth.

The term is French, but naturalized. It is also used for any high-flavoured dish, prepared of beef, fish, greens, or the like, by stewing them with the addition of bacon, salt, pepper, cloves, and the like high-flavoured ingredients. We have ragouts of beef, of cray-fish, of giblets, of apricots, of endive, of coxes-combs, of gammon, of celery, &c.

The ancient had a ragout, called garum.

RAG-PAVING. See Paving.

RAG-STONE, a name given by our artificers to a kind of flone, which they use for setting an edge upon knives, chisels, and other tools. It is a greyish-coloured flone, containing a large quantity of talcgy particles, and splits easily into thin flakes. It is a soft flone, and is used only to finish the setting an instrument after the edge has been prepared by grinding or rubbing the tool upon some other flone of a coarser texture. We have this from Newcastle and many other parts of the north of England, where there are very large rocks of it in the hills. This kind of flone is in some districts considerably blended and intermixed with the sub-foil, rendering it of a more barren and unfertile quality.

RAGUENET, L'Amour, in Biography. In 1702 the publication of a pamphlet, entitled "Paradise des Italiens et des Francois en ce qui regarde la Musique et les Operas," by this author, a man of arque and intelligence, who had refided some time at Rome, gave birth to a long, but ineffectual controversy, concerning the degrees of perfection, and superiority of French and Italian music. The book was licenced by Fontenelle, who laid in his testimony, that "he thought it would be very agreeable to the public, provided they were capable of equity." This declaration, however, did not prevent Fraycule, the continuator of Bonnet's "Histoire de la Musique," from attacking the author and Italian music in a most furious manner, treating both with equal contempt and obloquy.

The French, after this period, seem to have enjoyed their lyric fonnules in great comfort and tranquillily till 1732; when the perfonage of Pergolesi's "Sarva Padrona" at Paris, by a company of burletta figures from Italy, let the musical republic in a flame which has not yet been extinguished.

There had, indeed, been a fentiment excited, that was rather turbulent, and tending to a civil war, on the first appearance of Rameau as a dramatic composer in 1733, who, by new harmonies and accompaniments, had given offence to the true believers in the worship of Lulli; but this soon fubfided, and the nation not only heard his compositions with rapture, but reverence him as "a theoorist, to whom music was as much indebted as physics and philofophy to Newton."

This little work was published in English in 1739, and has been fated to be tranflated by Galliard. If this worthy profeffer was the translator, it was before he had committed himself to complete matter of the English language as he appeared to be afterwards, in his tranflation of "Te French and Song."

The English of this paraphrase is doubtless good; many of the notes, however, are good and original; a person who had been in Italy, and well known with Ragul music in that country, as well as in England, at the beginning of the last century, during our first attempts at operas, before the arrival of Handel.

RAGUIER, Le, the name given by the French sailors to a wind peculiar to the gulf of Alexandretta or Scanderoon, which, rushing from the snowy summits of the mountains, frequently forces ships to drag their anchors several leagues.

RAGULED, or Ragued, in Heraldry, is applied to an ordinary, e. gr. a crof, whose outlines are jagged or knotted.

He beareth fable, a crof ragued, or, by the name of Slayry.

Ragged differs from indented, as the latter is regular, and the former not.

The bearing is very ancient: Julius Caesar gave for his badge, a bear's head, on a ragged staff.

Ragued is sometimes also used in the fene of truncated, or cupped, and applied to a branch that is sawed from the tree; or a Rock fawed from its root.

RAGUN, in Geography, a town of Germany, in the principality of Anhalt-Dessau, on the Mulda; 9 miles S. of Dessau.

RAGUNDA, a river of Sweden, which rises in the lake
lake Storfo, and in the province of Medelpadia, changes its name to Lindal.

RAGUSA, a small republic, situated on the eastern shore of the Adriatic, and nevertheless regarded as an Italian State. It has a population of about 36,000 persons, on an extent of 352 square miles. As this State is adjacent to the territory formerly belonging to the Venetians in Dalmatia, its government was formed on the model of the Venetian arithocracy. Its religion is the Catholic, and its language the Slavonic, though most of the inhabitants speak Italian.

The fee is archiepiscopal, with six suffragans, and its commerce is considerable. The chief magistrate of the arithocracy in this island, called the "rector," is changed every month. Here is also a council of ten, and a great council composed of all the nobles above twenty years of age, and these nominate the "Pregadi," a female of fifty, which superintends all State affairs, receives and deputes ambassadors, and confers offices. The revenue of Ragusa was formerly estimated at a ton of gold, or about 15,000 florins. This small republic has found it necessary to engage the protection of the Turks, for which it pays a tribute of about 20,000 sequins; though the commerce is beneficial to the Ottomans, in supplying them with ammunition. Jealousy of their neighbours induces the Ragufans to fortify the gates of their city, except for a few hours in the day. The capital is Ragusa; and it has been lately annexed, together with Dalmatia, to the kingdom of Italy. It now (1814) probably awaits for a new allotment. The Ragufans have many country-houses at Gravofa, another sea-port town. Stagno is another little town, subject to Ragusa. Of the Ragusan fields, the chief is Milet, or Melada, fertile in oranges, lemons, and good wine. On the north there is a tolerable haven, with a town of the same name. Three or four little islands in that neighbourhood also acknowledge the sovereignty of Ragusa.

Ragusa, the capital of the above-mentioned island, is an ancient city, being the Ragusium of the Romans, and in the tenth century it became the metropolis of Dalmatia. In the 15th century it was conquered by the Venetians, and afterwards for a time subject to the crown of Hungary. It is a well-built city, and its commerce is not inconsiderable. The harbour might be rendered capable of a firm defence; and the circumjacent islands are beautiful by nature and art. Earthquakes, however, have been terrible; and that of 1667 destroyed 6000 persons; 248 miles N.W. of Salonsiki. N. lat. 42° 58'. E. long. 18° 18'.

Ragusa keeps accounts in ducats of 40 grostetti, each grostetto being divided into 6 foldi; but at the public offices accounts are mostly kept in perperi of 12 grostetti. Formerly the ducat represented a real coin struck at Ragusa, and had a fixed value; but since it has become a money of account, it is always equivalent to the Turkish piaster, and therefore liable to a change of value. At Ragusa no gold coins are struck; its silver are the old tallari or danars, commonly called Villini or Ragusini, weighing 1 oz. 7 car. (Ragusa wt.), containing 17 parts of pure silver to 13 of alloy, and reckoned at 1/2 ducat, or 60 grostetti; but on account of the depreciation of the ducat, the value of the tallari has been proportionally raised in weight. The new tallari, called libertin, weighing 1 oz. 10 car. and containing 9 parts of pure silver to 5 of alloy, was valued at 80 grostetti. But since the year 1796, ducats have been coined of 40 grostetti, weighing 22 an ounce; also perperi of 12 grostetti, weighing 20 carats, and half perperi in proportion; these three coins contain 9 parts of pure silver, and 11 of alloy. The grostetti, none of which have been lately coined, are still in circulation; they weigh the 6th part of an ounce, and bear the same value with the paras of Constantinople. The ducat of 1796 is worth 13.4 florins, which is nearly the value of the Turkish piaster. The tallarico or Ragusini of 1759, is worse than the English standard 4 oz. 2 dwt.; its weight is 18 dwt. 7.4 gr., content in pure silver 256.4 gr., and its value in florins 22. 14.4. That of 1794 is worse 3 oz. 19 dwt., its weight 18 dwt. 17.4 gr.; its content in pure silver 267.6 gr., and value in florins 30. 12. The ducat of 1797 worce 5 oz. 11 dwt.; its weight 8 dwt. 17.4 gr., content in pure silver 97 gr., and value in florins 12. 11.4. The tallarico or Ragusini has upon it the head of the chief magistrate, or rector; legend REXIP. HICAGIUS; reveres, arms of the city, legend, DUCAT ET SEM. REIP. RAC. i.e. ducat and half of the republic of Ragusa. Pieces of 1794. &c. bear the head of a woman, with REVPL. RICAGIUS, reveres, a shield, with the word LIBERATAS, inclosed by two branches, over which is a crown, legend, DUCAT ET SEM. REIP. RICAGIUS.

The pound with which gold and silver are weighed at Ragusa consists of 12 ounces; the ounce is divided into 6 faggis; the faggio into 22 carats, and the carat into 4 grains. But the pound of commercial weight is equal to 567 English grains, or 12 oz. 13 dr. avoirdupois; the former being 560.62 English grains. The ell of Ragusa measures 22.5 French lines, or 20.4 English inches. Kelly's Un. Camb. 248. 47. 20. 12. 20. 40. 20. 4.

RAGWORT, in Botany. See OTHONIA, SENECIO, and SOLIDAGO.

Ragwort, in Agriculture, a very pernicious plant of the weed kind, which is sometimes termed feagrime. It has a green stalk in its early state, but, as it advances in age, inclining to violet or purple, especially downwards. Its flowers are yellow, and thick-set, and composed each of a number of small pointed leaves. It runs to seed in the latter end of summer. The smel, both of the stalk and leaves, which are jagged, as well as the flower itself, are so offensive to animals, as that hardly any will feed upon it, except when almost starved.

It has been proposed to destroy it by picking out the roots, and feeding the land close with sheep. It most affects meadows and pasture lands when the foils are good.

RAHA, in Geography. See JERICO.

RAHABA, or RABBA, town of Arabia Deserta, near the Euphrates, on the road by which caravans travel from Syria to the Arabian Irak; 110 miles S.W. of Moful. N. lat. 35° 5'. E. long. 40° 21'.

Rahaba Melik Ben Tuk, a town of Asiatic Turkey, in the province of Diarbekir, on the Euphrates; 50 miles S. of Kerkefch. RAHABY, a town of the desert of Syria, containing about five or six thousand inhabitants, situated on a plain, surrounded with date-trees; 70 miles N. of Meqhid Ali. RAHANPOUR, a town of Bengal; 42 miles N.W. of Natore.

RAHAPA, a small island in the East Indian sea, near the E. coast of Borneo. N. lat. 45° 58'. E. long. 114° 4'.

RAHAS, in Ichthyology, a name given by some authors to the torpedo, or cramp-fish.

RAHEINA, in Geography, a bay on the W. coast of Mowhée, one of the Sandwich islands. N. lat. 20° 50'. E. long. 203° 19'.

RAHEMAT, a large lake in the Arabian Irak, 90 miles in circuit, near Meqhid Ali.

RAHENSTEIN, a town of Bohemia, in the circle of Saaz; 19 miles S.W. of Saaz.

RAHMANIE, a town, or rather village, of Egypt, built
built on the W. bank, at the entrance of the canal of Damascus, which is navigable only at the rife of the Nile; 9 miles S. of Damascus; which see.

RAHMETABAD, a town of Persia, in the province of Dera, 20 miles N. E. of Conwar.

RAHNI, or RANIS, a town of Saxony, in the circle of Neufstadt; 10 miles S.W. of Neufstadt. N. lat. 50° 33'. E. long. 11° 40'.

RAHNY, a town of Bengal; 25 miles N.W. of Dinagepoured.

RAHON, a town of France, in the department of the Jura; 6 miles S. of Dole.

RAHOON, a town of Hindostan, in the subah of Lahore; 108 miles S.E. of Lahore. N. lat. 31° 1', E. long. 75° 42'.

RAH, in Astronomy, is the Hindoo name of the planet of the ascending node, or dragon's head. Kutu is the name of the other node; and a table, in the usual style of mathematical allegory, is given under that article, of their origin and mistake. The malignant Rahu was decapitated, and Kutu was his head. In one painting of the Hindoo zodiac, the headless Rahu is represented of a black colour, in red clothing, mounted on an owl, and holding a lotus in his hand; in another, he holds a spear, and stands on a tortoise. In the table given under Kutu it is related that Vishu was the decapitator of Rahu: other accounts assign that office to Narayana. Among the Hindoos, as we have had occasion to remark in several articles, their feeces, as well as their history and religion, are enveloped in a mafs of mythological allegory: a farther instance of which, connected with the subject of this article, is seen under Eclipse (Note. A reference being made from the article Kutu to this, we take the opportunity of correcting two typographical errors in that article. In its early part, for Kasyapa, read Kasyapa; and in the fourth line of the second column, for or read a.)

RAHWAY, in Geography. See RAWA.

RAI, or RAI, an ancient town of Persia, in the province of Irak, before 1tpahan the capital of Persia. This was once a grand and proud city; and its ruins still cover a great extent of country. It holds a distinguished place in the annals of Persia: it is mentioned by Arrian and Dio, as the capital of the province of Rhages, fo called from the calamities brought upon this part of the empire by the earthquakes to which it formerly was, and is still subject. It is frequently mentioned in the wars of the renowned Haroun al Rishid; it was the capital of this part of Persia, in the reign of Alp-Arman, and continued to flourish until it was sacked by the generals of Genghis Khan. Its ruins are situated five miles S. of Tebriz, the present capital of Persia; and in the centre of them is a village, called Sheik Abdal Azzeem, from a son of the seventh Imam, to whose memory a noble mosque and mausoleum have been erected.

RAJA, denoting king, an appellation given in Hindostan, or the empire of the Mogul, to princes descended from those that ruled there before the conquest of the Mogul; who exercised all rights of sovereignty, only paying a tribute to the Great Mogul, and observing the treaties by which their ancestors recognized his superiority.

There are some rajahs who still retain a more independent sovereignty in the mountains; the Indians call them raj; the Persians, plurally, rajahs; our travellers rajahs, or rajas. They have under their command followers, called rajah-ports, or persons descended from rajahs, who are a robust and brave people, and who enter into the service of those who will pay them. The Great Mogul has several of these rajahs in his service.

The chief lords of the Moguls, viz. the vice-roys, governors of provinces, and chief ministers of state, F. Ca- trow observes, are called ombus; and the idolatrous rajahs, or Indian lords who governed petty states before the conquest of their country, held the same rank at court with the ombus.

All the difference was, that the children of the rajahs succeeded their fathers in the show of the sovereignty left them; whereas the children of the Mahometan lords live all in laying their fathers.

The Indians account four ages from the beginning of the world: and in the second, which lasted 1,296,000 years, they hold the rajahs or kehatras had their rise: a noble cait, though inferior to the Brahmins. Vice then, they say, began to creep into the world; men only lived 300 years, and their nature was reduced, &c.

RAIA, the Ray, in Ichthyology, a genus of fishes of the order Chondropterygia, of which the generic character is, that it has five oblique spiracles on each side, placed beneath the eye: the head is small, pointed, and not dilated from the body; the mouth is beneath the vertebral, toothed; the body is broad, thin, and flat. The individuals of this genus are all inhabitants of the sea only; they keep at the bottom, and in winter cover themselves with sand and mud: they feed on tereaceous animals, fish, or any animal substances which they may happen to meet with. They grow to a large size, sometimes exceeding 200 lbs. in weight. The females are the larger, and produce their young alive, only one at a time, which, like the shark tribe, are enclosed in a quadrangular, black, horne shell, the corners of which end in flender incurved points, but not extending intro long filaments, like those of the shark: the eyes are half covered with a thin membrane, oblong, placed on the upper part of the head: above thefe, in the place of the nostrils, is a broad luscus or groove, divided by a reticulate membrane, conflating of crissed folds, and clofed with a valve: behind this luscus are two small femiliar orfices: the tongue is very broad, short, and smooth. The ventral fins are covered with a thick skin, and surrounding the body: the ventral at the hafe are connected with the anal; the flesh is generally edible: the liver is large, and producing a great quantity of pure oil.

Of this genus there are nineteen species, divided into three sections: viz. A, comprising the electric ray, or torpedo and skates: these have sharp teeth. B, including the ling-ray and thornbacks, having obtuse teeth. And C, which are denominated uncertain, comprising five species, which inhabit the Red sea, or about the Cape of Good Hope, but which have not yet been sufficiently examined.

Section A. With sharp Teeth.

Species.

*Torpedo; Electric Ray. The body of this fish is entirely smooth and flat. The species inhabits the Mediterranean, and grows to a large size; some have been taken that have weighed from 60 to 80 lbs. each, but the average weight is less than 20 lbs. It is of a dirty clayish colour; the head and body are round, and but indifinitely separated. The body is extremely thin; behind the eyes are two wide foramina, which have been supposed to be intended by nature for conveying sound; they are best with six cutaneous fingers on their inner circumference, and communicate with the mouth. The torpedo can live about twenty-four hours out of the sea, and a short time longer, if put into fresh water;
water; it inhabits those places where the bottom is sandy, and
buries itself superficially by digging the sand over its
back with a fort of vibration, which it gives to its extremities.
It is in this situation that the torpedo surrounds and
terrifies the unwary pellager, who inadvertently treads upon it,
by the exertion of its electrical or bumbling faculty.
This power is serviceable to the animal in two important cases:
as a means of defence against voracious fishes, and
as a method by which he is enabled to procure his subsistence
from among the smaller tribes; for the former, when elec-
trified, are deprived of all possibility of seizing their prey;
and the latter, after having unwarily approached the tor-
pedo, and received the shock, are incapable of making their
escape. (See Torpedo.) The food of the torpedo is fur-
mullets and palfes; the former are so swift, that it is impos-
sible for the torpedo to take them by pursuit, and as this
fish has been found in its stomach, it is presumed that it was
taken by means of the electrical shock. The torpedo has
been taken off Pembroke, at Torbay, and near Waterford
in Ireland. It is caught like other flat fish, with the trawl,
and is commonly found in water forty fathom deep, in com-
pany with other species of this genus.

* Batitis, the Sharp-nosed Skate. This species is varied; the middle
of the back is smooth; the tail is becket with a single row of
spines; it inhabits the European ocean, and is thought to
be the largest fish of the genus; the body above is enormous,
sometimes with a few black lines, beneath white, with waved
lines of black dots; and the eyes are numerous small,
hooped spines; in the males the fins are full of spines. Of
all the larger fishes, the skates are the most numerous, and
their numbers are a great mavor owing to their size,
and to the protection afforded them by those frightful spines
which nature has afforded them. There is not one of the
rapacious tribes accepting, perhaps, the cachalot and white
shark, that has a sufficient size to receive them,
and even these are probably deterred from their purposes
of destruction by the armour with which their prey is covered.
Of some the size is such as to defy all powers of
destruction which even the shark himself possesses. I. Engand fauna
of the species have been found weighing upwards of two
hundredweight, but even this is far inferior to their enor-
mous bulk in other parts of the world. Near the island
Guadaloupe, a ray was killed more than twenty-five feet
long, and almost fourteen broad. After all, the fish of
this tribe probably attain a much larger size than that of any
individual which has ever yet been examined. It is only
the smallest of the kind that approach the shores; the largest
continue for ever prowling at the bottom in the unfathomable
caverns of the ocean, where they continue perhaps to grow
for a century.

The skins generate in March and April, at which time they
swim near the surface of the water, several males pursu-
ing one female. The females call their young parfa, as they
are called, in May, and continue to produce till September:
they are very prolific, not less than the hundred eggs having
been found in the body of a single female. The rays generally
frequent the note parts of the sea where the bottom is
black and muddy, where they devour every thing indiscrimi-
ately, but they are more delicate with regard to a bated
hook. They devour any putrid substances whatever, but
if the bait has been taken up and suffered to lie for any
time in the open air, they will not touch it; they appear
to perceive the line, and to dread it; but the impulsion of
hunger overcomes their caution, and even though they perceive
the danger, if the sharply hungry, they devour the bait, as
if regardless of the consequences. See Skate.

Oxyrhinclus; Sharp-nosed Ray. Varied; middle of
the back with ten spinous tubercles. This is similar in shape
to the skate, but with a longer and sharper snout; the col-
our of the whole upper part is cincereous, with several pale
or whitish spots, intermixed with a few light flaky streaks
or variegations; beneath it is white, with darkly or blueish
streaks; down the back and tail run a single row of spines,
and a few others are placed about the region of the eyes: the
spines are sometimes furnished with a row of smaller or weaker spines than those on the upper part; the
eyes are large, as is also the mouth. This species, the
skate, sometimes, but not often, is taken of a very con-
iderable size. It is a native of the Mediterranean
and Northern seas.

Mitaetus. This species has a smooth belly and back; it
has spines near the eyes, and a triple row of them on the
tail. It inhabits the Mediterranean; the body above is
marked with an oblique spot.

* Fulonica; the Fuller Ray. The back is covered with
spines; the eyes with a single row; pectoral fins and tail
with a triple row. It inhabits the European seas; grows
to a large size; the body above is cincereous, with numerous
black spots; beneath it is white. The front of this fish is
short and pointed; the pectoral membrane is fringed;
the teeth are small and sharp; and the tail is slender. It has
been thought by some authors that this is only a variety
of the next species.

* Rubir; Rough Ray. The back of this species has a
single spine; and the tail is becket with a triple row of spines.
This is greatly allied to the thornback, but covered with
more numerous spines, every part of the skin on the upper
surface being matted with sharp curved aculei of different
sizes; of these, one row of the largest runs down the middle
of the back, and three, or sometimes five, along the tail;
others are dispersed about the eyes and the flaps of the pectoral
fins; the general colour is a yellowish or whitish-grey,
sometimes variegated with dusky or brownish clouds and streaks;
the under side is white, and becket with very numerous scattered
spines, but less strong than those on the upper side.
It is about the size of a thornback. Mr. Pennant mentions
one that measured nearly three feet from the nose to the tip
of the tail. It is a native of the Mediterranean and other
seas.

B. Teeth obsolete.

Species.

Sephen. Body nearly round; tail twice as long as the
body, winged beneath, and with two long spines above, fer-
rate on each side. It inhabits the Red sea, and is sometimes
so large, as to reach three yards across; body above brown,
with three rows of large hemispherical tubercles down the
middle of the back; beneath it is quite flat and smooth, and
it is of a reddish-white. It is from the skin of this species
that the beautiful substanc called Calabash is prepared by
the French, and which, being coloured with blue, green,
or red, according to the fancy of the article, and afterwards
polished, is so frequently used for various kinds of boxes,
telecope tubes, &c. For this purpose the smaller or younger
specimens are preferred; the tubercles in the more advanced
or full-grown animals being too large.

There is a variety of this species; the length of the spec-
imen described by Dr. Raffles was about 9½ inches; the tail
is about two feet nine inches long; the colour of the whole
animal is a dull leaden above, with a deep blue tail; beneath
it is dusky white; on the middle of the back there are only
two pearl-formed tubercles instead of three; the tail is
furnished with a sharp spine and a fin beneath. It is a native
of the Indian seas.

X x

Agula.
AQUÍN. The body is smooth; the tail is pinnate, with a long pinnate spine. This species is of a rhomboidal shape, but with a considerable dilatation: the pectoral fins approach to a subelliptical form; the colour is cinerous above; pale or whitish below: the head is rather large, and the fin produced: the teeth are large and prominent, with yellow edges: the tail is long, slender, sharp-pointed, and furnished with the middle of a spine similar to that of the flag-ray. This species grows to a very great size, sometimes measuring ten, twelve, or even fifteen feet in length, and weighing upwards of three hundred pounds. It is found in the Mediterranean, Atlantic, and Indian seas, and is said to swim in a slower manner than most other rays. It preys on smaller fishes, and is supposed to strike and kill, or at least disfigure its prey with the caudal spine; when taken, it is observed to vibrate the tail with great strength and rapidity in all directions. It is not reckoned among the edible fishes; but the liver, which is very large, is said to be eaten, though it is more frequently used for the purpose of preparing from it a clear oil, which it affords in great plenty.

*PANTINACA*; Sting-ray. The body of this species is smooth; its tail has a long sharp spine, serrate on the fore part, and another on the back. There are two other variations, one of which has a smooth body; the back is beset with two spines, serrate on the fore part; the body of the other is covered with spots.

This species is described as having a body somewhat approaching to the ovate, the pectoral fins less pointed than in some other species of this division. The snout is pointed; the body more convex than usual; the colour of the whole animal above of a yellowish-brown, the back is sometimes found to approach to a blueish-brown; and the tail is a smooth, slender, and lengthy, a very thick at the base, and gradually tapering to the extremity, which is very slender; near the middle it is armed, on the upper part, with a very long, flattened, and sharp-pointed bone or spine, densely serrated in a reversed direction on both sides; with this the animal is capable of inflicting very severe wounds on fish as ingeniously as to handle it; and it answers the purpose both of an offensive and defensive weapon. This weapon is annually cast, and as it frequently happens that the new spine has arrived at a considerable size before the old one has been cast, the animal is occasionally found with two, in which state it has been sometimes erroneously confounded as a distinct species. This fish is said not to grow to a very large size. It is found in the Mediterranean, Atlantic, and Indian seas, and its number is numbered among the edible rays. On account of the danger attending the wounds inflicted by the spine, it is usual with the fishermen to cut off the tail as soon as the fish is taken. In some countries it is said to beillegal to sell the fish with the tail adhering to it.

It was formerly thought that the spine of the fish possessed a venomous quality, by infusing into a wound made by it some very acrid poison; this is now proved to be completely erroneous, and the effects sometimes produced by an asp entirely from the deepness of the puncture and laceration, which, if taking place in a tendinous part, or among the larger nerves and blood-vessels, have often proved fatal. It may not be amiss to observe, that some ancient writers have been deceived upon the effects of this animal's powerful weapon in terms of considerable luxuriance; it was supposed to be not only poisonous in the living animal, but to preserve its poison when taken from the fish, and affixed to the head of an arrow or a spear; it was said even to destroy the most healthy and flourishing plant by its touch, and even to cause trees to die by striking the bark with its point. It forms the head of the fatal spear presented by Circe to her son Telephus, by which he was rendered superior to his enemies, and with which he, at length, unconsciously, flew his father Ulysses. The general habits of this species are similar to those of the rest of the genus, often lying flat, and in ambush on the soft mud at the bottom of the shores which it frequents, and seizing its prey by surprise; at other times it will pursue it through the depths of the ocean.

*CLAVATA*; Thornback. The body of this species is pinnate; the teeth tuberculate; across the belly is a strong semilunar cartilage. This species grows to a very considerable size, though rarely equal in magnitude to the skate already described; in its general appearance it resembles that fish, but is somewhat broader in proportion, and is readily distinguished from the skate by the very strong, curved spines with which its upper surface is covered; there are more conspicuous down the middle and on each side of the back, where four or six, of much larger size than the rest, are generally seen; the remaining parts being furnished with many scattered spines of a smaller size, intermixed with still more minute ones, and the whole fish is of a rough and thorn-like surface; the back is marked with an uncertain number of pale or whitish round spots of different sizes, and which are commonly surrounded with a blackish or dark coloured edge; these spots are said to be caused by the shedding of the spines at different intervals; along the middle of the back runs a single row of strong spines, continued to the tip of the tail; the colour of the fish is a brownish-grey, with irregular blackish or dusky variegations; the under part is white, with a light call of flesh-colour, and about the middle of the body, as well as on the fins, are disposed several spines similar to those on the upper side, but less strong. The thornback is an inhabitant of the Mediterranean and other seas, and is held in some esteem as food, though not considered equal to the skate in goodness.

RHINOBATIS. Body long, tapering; snout lengthened. This is reckoned a very remarkable species, and is thought to connect in some degree the genera of raia and squalus, the body being much longer than in the preceding kinds of ray; the snout is lengthened, but not very sharp; and the body, which is moderately convex above, flat beneath, gradually tapers from the shoulder to the tail, which is furnished above with two fins, of an oblong shape, and situated at a considerable distance from each other; the tip of the tail is also dilated into an oblong fin. The colour of the whole fish is of a dull earthy brown, paler beneath, and the skin is every where roughened by minute tubercles. This fish is said to grow to a length of about four feet, and is native of the European seas. It is very frequently seen about the coasts of Naples.

DJDIDENS. Tail-fin two-lobed; spines in a triple row at the beginning of the back, and afterwards in a single row; the first dorsal fin is above the ventral. It inhabits the Red sea, and is about two yards long. The body is a little rough, and of a pale ash colour; above it is varied with whitish spots; beneath it is whitish; behind the vent are a few brown and white stripes.

LYMMA. Body oval, smooth, tesselated, with blue spots; pinnate tail with a single spine. It inhabits the Red sea; is hardly a foot long; the spots oval, unequal, beneath whitish. It is much allied to the eagle-ray, and is of a reddish-brown colour above; the tail is somewhat longer than the body, marked above, for half its length, with two longitudinal blue stripes, and is furnished about the middle with one, and sometimes with two, large and serrated spines, which
which are covered at their base by a bluish-brown skin; the under part of the body is pale or whitish.

Arrak. Body orbicular, silvery; tail round, without a fin, and furnished with two spines. It inhabits the Red sea; the teeth are granulate.

C. Uncertain.

Ommessonchus. Tail round and spotted. It inhabits the Red sea, and very much resembles the R. pinnacea.

Tajara. Tail round; body beneath snowy. It inhabits the Red sea. When just taken, it beats violently with its fins.

Schouler. Body with a few remote spines. It inhabits the Red sea. The Arabinans make fishbreads for their swords out of its skin.

Mula. Beneath snowy; tail round, variegated. It inhabits the Red sea, and approaches the shores by night. The spine on its tail inflicts a dangerous wound.

Rapensis. Back with a single fin; the tail is short, pinnate at the end; the body is smooth and unarmed; and the mouth is a little obtuse. It inhabits near the Cape of Good Hope, is shaped something like the torpedo, except that it has a fin on the back. The body is small and orbicular; above it is convex, beneath flat.

RAJABERRY, in Geography, a town of Bengal; 10 miles S. of Dacca. N. lat. 23°. 24°. E. long. 90°. 36°.

RAJACOTTY, a town of Thibet; 60 miles N.N.W. of Srinagar.

RAJAGUNGE, a town of Allam; 16 miles S. of Gentia.

RAJAGUR, a town of Hindoostan, in Bahr; 35 miles W.S.W. of Gayah.—Alfo, a town of Hindoostan, in Guzerat; 10 miles N.E. of Champanear.

RAJAHUN, a town of Hindoostan, in the circuit of Ciacole; 12 miles W. of Ciacole.

RAJAKERA, a town of Hindoostan, in the province of Agra.

RAJAMUNDRY, a circuit of Hindoostan, bounded on the N. by the circuit of Ciacole and Golconda, on the E. by the bay of Bengal, on the S. by the circuit of Elleore, and on the W. by Golconda. It is crofterd by the Bain Gonga from N. to S.—Alfo, the capital of the above-mentioned circuit, intuated between Elleore and Ciacole, on the Godavery. Its principal riches confit of forests of teak-wood, N. lat. 17°. E. long. 81°. 57'.

RAJANAGUR, a town of Bengal; 25 miles S. of Dacca.—Alfo, a town of Hindoostan, in the circuit of Rajamundry; 7 miles N.E. of Rajamundry.

RAJANIA, in Botany, fo called in honour of our immortal naturalift, the Rev. John Ray, the moft accurate in obervation, the moft philosophical in contemplation, and the moft faithful in decription, amongst all the botanifts of his own, or perhaps any other, time. His life will be given hereafter, in its proper place. Plumer, who established this genus, finding the name Raja proccupied by zoologists, contrived to call the plant Jan-Raja; which Linnaeus turned about into Rajania, till retaining the idea of the Christian name, combined with the other. But such an idea is ludicrous to English ears, and is happily not, in general, perceived. We prelume to alter the orthography in one letter, writing the word as it is always pronounced, and deducing it regularly from the Latin RADIUS, by which name the person commemorated is known all over the literary world.—Plum. Gen. 33. t. 29. Linn. Gen. 525. Schreb. 692. Willd. Sp. Pl. v. 4. 788. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 391. Juff. 43. Lamark Illustr. t. 818. Gaertn. t. 14.—Clafs and order, Dioscora Hindiania. Nat. Ord. Surruestae. Linn. Aparagi, Juff.

Female, Cal. Perianth superior, of one leaf, bell-shaped, in fix deep segments, permanent, withering. Cor. none. Sty. Germen inferior, compefted, with a prominent border at one side, three-celled; styles three, the length of the calyx; stigmas obtuse. Petals. Capule membranous, of three cells, without valves, crowned by the calyx; two of the cells barren, almost obliterated, without wings; the third fertile, compefted, extended into a very large, half-ovate, membranous wing. Seed foliary, nearly elliptical, compefted.

Section 1. Leaves simple.

1. R. biffata. Halberd-leaved Raiania. Linn. Sp. Pl. 516. (Jan-Raja ficandens, folio oblongo, angulato et auriculato; Plum. Gen. 33. Bryonia fructu alato, foliis auriculatis; Plum. Amer. 84. t. 98.)—Leaves biffata; somewhat heart-shaped at the base.—Gathered by Plumer, about Port-de-paix in the island of Hispaniola. Root perennial, sometimes large and ovate; sometimes four or five inches long, and two thick, round at each end, like a fudge. Its fruicce resembles that of a radish, without any internal fibres; the bark thin, ash-coloured, a little rugged and warty; the flesh very white, tasting like a bean. This root throws up only one very slender, long, climbing, smooth, knotty stem, thickest at the base, where it is accompanied by several fibrous radicles. We preume it to be annual. Leaves scattered, spreading, on short stalks, smooth and membranous, about three inches long; heart-shaped, dilated, abrupt, and even-ribbed at the base; then suddenly elongated into a nearly linear, entire, central, three-ribbed lobe, bluntish, with a small point; the under side paler, and rather downy. Stipulas in pairs, awl-shaped, minute. Flowers small, white, in simple, axillary, drooping clusters. Bracteas minute, ovate, acute, foliary at the base of each partial leaf. Fruit, as Plumer says, like half that of a maple-tree, of a fivery hue when young, but after wards tawny.

2. R. cordata. Heart-leaved Raiania. Linn. Sp. Pl. 1461. Ait. n. 1. (Jan-Raja ficandens, foliis tami; Plum. 1c. 148. t. 155. f. 1.)—Leaves ovate; somewhat heart-shaped at the base; even-ribbed.—Native of the West Indies, from whence it was sent to Kew garden, in 1786, by Mr. Alexander Anderson. It flowers in the frove in July, and we cannot but with some accurate botanist would publish a good figure and decription of the plant, out of respect to its name. Plumer represents the habit of the roots, stem, &c. much like the foregoing; but the leaves are regularly ovate, pointed, more or less heart-shaped at their base, and furnished with even ribs continued from that part to the point. These ribs are connected by numerous transverse veins. Inflorescences, flowers, and fruicce, much as in R. biffata, but having few no specimena, we can say nothing respecting the stipulas or bracteas, none of which are noticed in the plate.

Subdivided; with flender, smooth, leafy branches. Leaves rather distant, flaked, smooth on both sides, pointed, entire, three-ribbed, veiny; ovate at the base. Footstalks round, smooth, often as long as the leaves. Clusters axillary, numerous, longer than the leaves, flanked, manyflowered, rather zigzag. Flowers diocious; the males in compound clusters; females in simple ones, all flaked, and turned toward one side. Corella very minute, yellowish-green in the male, reddish in the female blossoms. Calyx compressed, with an ovate, falcate, membranous wing. Swartz.

4. *R. angustipetala*. Narrow-leaved Raiania. Swartz Ind. Occ. v. 1. 639. Mart. n. 3.—Leaves lancilanceolate; rounded at the base, three-ribbed.—Native of extremely dry hilly places, in the west part of Hindustan, where it climbs upon high trees, flowering in May. Root annual. Stem thread-shaped, round, twining, flaked, divided, smooth. Leaves nearly as long as the whole, three-ribbed, veiny, smooth. Footstalks smooth, red, twilled according to the direction of the stem. Clusters axillary, in pairs, the length of the leaves, pendulous, flanked, manyflowered; the flowers very minute, nearly fleshy, red, polygamous, five or six on each of the alternate partials, all leaning one way. Bracteas very minute, acute, blood-red under the flowers. On some plants the latter are entirely male, with six nearly fleshy authors; on others all hermaphrodite, with six perfect flowers, a triangular oblique germen, no styles, but three minute stigmas. Cephalas as in the rest of the species. Swartz.

5. *R. quinquefolia*. Five-leaved Clustered Raiania. Lindl. Sp. Pl. 1462. (Jan-Raia scandens quinquefolia; Plum. t. 149. f. 2.)—Leaves five together at each joint, elliptic-oblong. Clusters lateral, between the joints.—Native of the West Indies, but hitherto observed by Plummer only. This seems to have the habit of all the foregoing, except that the stem has tufted joints, at each of which stand five elliptic-oblong, obtuse, entire, three-ribbed leaves, about three inches long, on short footstalks. The clusters are represented not axillary, as in the others, but lateral and alternate, from the spaces of the stem between the joints.

Section 2. Leaves compound.

6. *R. quinata*. Five-leaved Umbellate Raiania. Thunb. Jap. Jap. t. 6.—Leaves five on a common stalk, margined. Umbels axillary.—Observed by Thunberg about Nagasaki and in Kobe, in Japan, flowering in April and May. The Japanese call this plant *Fagi Kadzura*, and *Akiti*. Stem twining, round, smooth, shining, branched. Leaves several together, axillary, flaked, smooth, of five separately flaked, umbellate, ovate, entire leaves, each from three-quarters of an inch to one and a half long, margined with a point. Common footstalks thread-shaped, smooth, two inches or more in length; partial half as long as the finger nail. Flowers in umbels, from the same buds as the leaves, on flender flasks as long as the footstalks; partial flasks capillary, the length of the nail. This species differs from the leaf in having compound leaves, and umbellate flowers. Thunberg.

7. *R. bisphyllyta*. Six-leaved Clustered Raiania. Thunb. Jap. t. 7.—Leaves five on a common stalk, oblong, acute. Flowers racemose.—Native of the country of Fakfakia, in Japan, among bushes, flowering in April. Its vernacular names are *Akiti*, *Mie Kadzura*, and *Tja So*. The stem is round, irriated, smooth, climbing. Leaves alternate, smooth, fix on a stalk, umbellate, on flender partial flasks, oblong, acute, entire, veiny, two inches long; pale at the back. Common footstalks round, bent, three or four inches long, swelling at each extremity. Flowers in axillary clusters, snow-white. Differs from *R. quinata* in having mostly five leaflets on a stalk, which are acute, reticulated with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not umbels.

RAJAPILLA, in Geography, a town of Hindooftan, in Myfor; 16 miles N.N.E. of Anantpour.

RAJAPORUM, a town of Hindooftan, in Burmanaut; 35 miles S. of Dercempour.

RAJAPOUR, a town of Hindooftan, in the circar of Hilar; 48 miles W. of Hilar.—Alfo, a town of Hindooftan, in the circar of Gohud; 10 miles W. of Jamm.—Alfo, a fea-port of Hindooftan, in Concan, where the English and French had formerly factories. The place has a good harbour, but it is not now frequented; 6 miles N. of Geriah.—Alfo, a town of Bengal; 16 miles S. of Silhet.—Alfo, a town of Bengal; 50 miles N.W. of Bundred.—Alfo, a town of Hindooftan, in Bahar; 27 miles W. of Arrah.

RAJARAJESWARI, in Mythology, a name of the Hindoo goddess Parvati. It means, in Sanscrit, comfort of the lord of the king of kings. In the masque it is Rajrajefwara, and is then a name of her lord Siva. See that article.

RAJARSHI, is one description of saint or fage, of whom four forts are comprehended in the more general term of Kifhi. Rajarshi means a royal fage, and is the lowest of the four; the Devarshi, or divine fage, being, as may be supposed, where Brahms are the givers of dignity, the first. See more hereon under MAHARSHI and RISHI.

RAJASEE, in Geography, a town of Hindooftan, in the circar of Gohud; 15 miles S.W. of Darteath.

RAJASERA, a town of Hindooftan, in the circar of Sirhind; 17 miles E.S.E. of Sirhind.

RAIBACH, a town of Bavaria, in the territory of Rothenburg; 7 miles S. of Rothenburg.

RAIBAUG, a town and circar of Hindooftan, in Vifapur; 23 miles S. of Mafiritch. N. lat. 15° 35'. E. long. 7° 52'.

RAIBOLINI, Francesco, in Biography. See FRANCI-CA.

RAJBULHAUT, in Geography, a town of Bengal; 30 miles S. of Bundred. N. lat. 22° 45'. E. long. 88° 7'.

RAICAN, a town of Perfia, in the province of Irak; 15 miles N.E. of Hamadan.

RAICZ, a town of Hungary; 6 miles S.S.E. of Betfico.

RAIDURGAM, a town of Hindooftan, in the Carnatic; 15 miles W. of Tricolore.

RAIDY, a town of Bengal; 25 miles S.W. of Docfa.

RAIE, a town of Asiatic Turkey, in the province of Diarbekir; 118 miles S.W. of Diarbekir.

RAJEEATA, a town of Hindooftan, in Guzerat; 78 miles W. of Gogo.

RAJEE-BEDUROO, a town of Hindooftan, in Laffore; 27 miles E. of Jumnoo.

RAJEGAUT, a town of Bengal; 24 miles S.S.E. of Islamabad.

RAJEGUR, a town of Bengal; 26 miles S. of Burther. —Alfo, a town of Hindooftan, in the circar of Gangpou; 23 miles S.W. of Gangpoure. —Alfo, a town of Hindooftan, in Mewat; 20 miles E. of Cotpurty. —Alfo, a town of Hindooftan, in the circar of Gohud; 27 miles S.W. of Narwa. —Alfo, a town of Hindooftan, in the circar of Bunleund; 22 miles S.E. of Chatterpouer. —Alfo,
A town of Hindoostan; 20 miles S.E. of Allahabad. N. lat. 24° 45'. E. long. 80° 17'.

RAJEGUSDAR, a town of Hindoostan, in Lahore; 33 miles E.N.E. of Behabur.

RAJERHUT, a town of Bengal; 16 miles N.W. of Bhifaripur. N. lat. 23° 15'. E. long. 86° 46'.

RAJEMAL, a circar of Bengal, bounded on the N. by Purnah, on the E. by Purnah, Mauldah, Dinagepour, and Rajecli, on the S. by Sultanabad, and on the W. by Hindoos and Bogilpour. Also, the capital of the above circar, lying on the W. bank of the Ganges, nearly in the parallel of Mauldah, and about 20 miles from it; at the foot of the chain of hills which projects into the river at Sielugully and Terrigully. It is in a ruinous state, although not above 150 years ago the residence of the viceroy; and it has hardly the population of an ordinary market-town at present. Its situation is romantic, but not pleasant; for in Hindoostan, the hills and enclosures being always covered with wood, that beautiful swelling of the ground, which is so justly admired in European landscapes, is lost; and the fancy is presented at first with nothing beyond a wild scene; which can only be relieved by being contrasted with soft and beautiful ones. It is more than thirty miles above the head of the delta of the Ganges, and therefore M. d'Anville placed it erroneously by aligning its situation at this place. N. lat. 23° 26'. E. long. 87° 16'.

RAJEMATCHY, a town of Hindoostan, in Vifapour; 37 miles N.W. of Poonah.

RAJENAGALUM, a town of Hindoostan; 16 miles N. of Thennelly.

RAJETEA, one of the South-sea islands, named also Utetas; which see.

RAJETPOUR, a town of Bengal; 15 miles S. of Rogosopour.

RAJEWICE, a town of Lithuania; 42 miles S.S.E. of Brzece.

RAIGRI, a town of Hindoostan, in Golconda; 10 miles S.E. of Beder.

RAIGUR, a town of Hindoostan, in the circar of Sumbulpour; 15 miles N. of Sumbulpour.

RAIK, a town of Syria, on the Euphrates; 18 miles S. of Bembig.

RAIL, in Architecture, is applied variously; particularly to those pieces of timber which lie horizontally between the pannels of a window, and over and under them. The word is also applied to those pieces of timber which lie over and under balusters in balconies, staircases, &c. Also, to the pieces of timber that lie horizontally from poll to poll in fences, with pales or without. See Fence.

RAILS, in a Ship, are long narrow pieces of fir, or oak, with mouldings of regular members of architecture impressed on them, which are flattened, or sometimes wrought from the solid plank, as ornament to the ship's sides. The former are now discontinued in the navy, as they were found to rot the sides very much; the latter, wrought from the solid plank, are used in merchant ships. The rails of the head and stern are pieces of oak timber handomely wrought with mouldings. The lower rail along the side is named the wind-rail, and the next above it the floor-rail, which are generally placed parallel to the top timber line, the floor-rail with the top of the side amidships, and the wind-rail about twenty inches below it; the rails next above and parallel to the floor-rail are called drift-rails, and the rails above the plank-flare, if any, the flare-rail. The rails of the head are distinguished by the upper or main-rail, the middle and the lower-rail; and the rails of the stern take their names from the parts to which they are fixed, as the trip-rail, lower counter-rail, upper counter-rail, foot space-rail, breast-rail, taffarel-rail, and taffarel flare-rail. (See Plate 1. Ship-building.) To these may be added the thwartship pieces of the framing of the great cabin bulks.

Rails of the head are certain curved pieces of timber, extending from the bows on each side to the continuation of the ship's stem, to support the knee of the head, and the ornamental figure fixed upon it.

Rail, or Water-Rail, in Ornithology, the name of the rallus aquatilis of authors, which is a bird of a long slender body, with short concave wings. The bill is slender, slightly incurvated, and one inch three quarters long; the upper mandible black, edged with red, the lower orange-coloured; the irides red; the head, hind-part of the neck, the back and covert of the wings and tail are black, edged with an olive-brown; the base of the wing is white; the quill-feathers and l-convanties dull; the throat, breast, and upper part of the belly, are ash-coloured; the sides under the wings, as far as the rump, finely variegated with black and white bars; the tail is very short, consisting of twelve black feathers; the ends of the two middle tips with ruff colour; the feathers immediately beneath the tail white; the legs are placed far behind, and are of a dusky flesh colour; the toes very long, and divided to their origin; though the feet are not webbed, it takes the water, will swim on it with much ease, but is often observed to swim along the surface. It delights in flying thus in running, which it does very swiftly along the edges of brooks covered with rushes. When it runs, it every now and then lifts up its tail, and in flying hangs down its legs. Pennant.

This bird, says Mr. Pennant, is properly sui generis, agreeing with no other, but forming a separate tribe; though M. Briffon and Linnaeus place it in the land-rail, and Mr. Ray with the water-birds. It is a well-stayed bird.

RAIL, Land, the rallus cristatus of Linnaeus, is a migratory bird, with a short, strong, thick bill; always found among corn, grass, broom, or furze. It leaves this kingdom before winter. They have long legs, and a singular note, resembling the word crex, often repeated. The feathers on the crown of the head, hind part of the neck, and the back, are black edged with bay colour; the covert of the wings of the same colour, but not spotted; the tail is short and of a deep bay, the belly white, and the legs ash-coloured. They are in great plenty in Anglesea, where they appear about the 25th of April, and seems to pass over from Ireland, where they abound. They are found in most of the Hebrides, and the Orkneys. Pennant.

RAILING, in Rural Economy, a sort of fence constructed with poles and rails. It is often made use of in protecting young hedge fences, from the cropping of cattle or other animals. Any sort of coarse timber does very well for this last purpose, such as outside planks, and the boughs or loppings of timber plantations. See Fence.

RAILERY, as Dr. Johnson hath defined it, denotes flight, fatine, or fatirical meriment; and a beautiful writer compares it to a light which dazzles, and which does not burn. It is sometimes, what it always ought to be, innocent and pleasant, but it is too frequently offensive. Railery is of various kinds; tedious, severe, and good-humoured; there is a kind which perplexes, a kind which offends, and a kind which pleases. It has been justly observed, that in order to rally well, kindnes should prevail in every thing that is said, as the character of a friend should be maintained, to warrant freedom with a person who is addressed, especially in this way. Allusions to past follies, and hints that tend to revive what a person wishes for ever to forget, should never be introduced
as subjects of railery. It is below the character of persons of humanity and good breeding, to indulge mirth, while any one in the company is suffering, as the effect of that mirth, pain and mortification.

RAILWAY, Tram or Dray-road, or Waggon-way, in Rural Economy, a track constructed of iron, stone, timber, or other materials, upon the level surface of an inclined plane, or other situation, for the purpose of diminishing friction, and thus serving for the easy conveyance of heavy loads of any kind of articles. See Plate IV. Canals, figs. 31 to 35. See also Canal.

It has been remarked that railways have hitherto been confined, almost exclusively, to coal-works, and other mines; and that inventions, whose only recommendations are simplicity and cheapness, are often suffered to lie long in a state of public neglect; while others, perhaps, of no real utility, but of more imposing aspect, and being pertinaciously blazoned forth by interested or blinded partisans, are readily adopted; and been, for a while, in the fashionable of public favour. The time has, however, at length arrived, when carriages moving on level surfaces, or on gently inclining planes, with little friction, and without obstructions, are cost, spreading over the face of the country. It has been observed that there may be many lime-works, as well as other forts, from which railways may be laid, in different directions, with great benefit to their proprietors and the surrounding neighbourhoods in general.

With the view of diminishing horse labour, it has been suggested by Dr. Anderson, in his Recreations in Agriculture, that where internal canals cannot be established, this may be effected, and intercourse facilitated, by means of railways, which have not yet been introduced into general practice. It is further stated, that they were first solely employed for transporting coal to a moderate distance from the pits, to the places where they could be shipped, being universally made of wood. And long, says he, had they been applied to this use, without any idea having been entertained that they could be employed for more general purposes. By degrees they were, however, carried to a farther extent; the scarcity of wood, and the expense of their repairs, suggested the idea of employing iron for the purpose of improving these roads. At the first, flat rods of bar-iron were nailed upon the original wooden rails, or as they were technically called, flappers; and this, though an expensive process, was found to be a great improvement. But the wood on which these rested being liable to rot and give way, some imperfect attempts were made to make them of cast iron, but these were found to be liable to many objections, until the busines was taken in hand by Mr. Outram, Engineer, at Butterfly Hall, Derbyshire, who contrived at the same time, so far to diminish the expense, and improve the strength of the road, as to bring them to a degree of perfection, that no one who has not seen them can easily conceive could have been done. And it is added, that this having been carried into execution in a few cases, and found to answer, has been improved upon and simplified by practice, till it is now brought to such a state of perfection as to have given proofs, that it admits of being carried much beyond the limits of what was for many years conceived to be possible, and to afford demonstrative evidence, that it may be in future employed to a wider extent still, to which no limits can be at present assigned or foreseen.

There are a great number of railways in Derbyshire, Shropshire, Lancashire, and many other parts of the country.

In the first of the above counties, there are railways of very different lengths; one of five miles in length, leading from the town of Derby to the collieries in the vicinity; another, from the lime-flone rocks on the Cranford canal, called the Creck railway, which is about one mile and a half in length; a third from the Beggarlee colliery to the same canal, denominated Barber and Walker’s railway, of similar length; a fourth from the lime-works in the neighbourhood of Bolsover, to the canal near Whaley bridge, termed the Peak-forest railway, which is about six miles in length; a fifth called the Maple railway, of about one mile and a half long, on the Peak-forest canal; sixthly, railways over Bilsworth-hill near Nottingham, on the Grand Junction canal, which are three miles and a half in length, and constructed in a double manner; a seventh, which has the name of the Aldby de la Zouch railway, has four miles of double and eight miles of single rails. Some of these railways are formed in a very complete manner, especially those which have been made since the various improvements of them were introduced. They have been of prodigious utility and advantage to the county, both in regard to its agricultural improvements and its manufacturing interests and concerns.

These forts of railway roads have likewise been introduced into many parts of the county of Salop, with vast benefit and success to the different interests of the district. They have here had a new application, in being employed for the purpose of conveying heavy weights from different levels on canals.

Speaking of the great utility of canals in the carriage of various articles in this county, it is observed by Mr. Telford, an able engineer, that another mode of conveyance has frequently been adopted to a considerable extent; which is that of forming roads by means of iron rails laid along them, upon which materials are carried in waggons, which contain from two to thirty hundred weight; experience, he thinks, has now convinced us, that in countries the surfaces of which are rugged, or where it is difficult to obtain water for lockage, where the weight of the articles of the produce is great in comparison with their bulk, and where they are mostly to be conveyed from a higher to a lower level, that in those cases, iron railways are in general preferable to canal navigation.

It is supposed, that on a railway well constructed, and laid with a declivity of fifty-five feet in a mile, one horse will readily take down waggons containing from twelve to fifteen tons, and bring back the same waggons with four tons in them. This declivity, therefore, suits well, when the imports are only one-fourth part of what is to be exported. If the empty waggons only are to be brought back, the declivity may be made greater; or an additional horse applied on the returning journey will balance the increase of declivity. If the length of the railway were to be considered, it may, it is supposed, without much inconvenience, be varied from being level to a declivity of one inch in a yard, and by dividing the whole distance into separate sections, and providing the number of horses suitable for each portion of railway, according to the distance and degree of declivity, the whole operation may be carried on with regularity and dispatch.

It is upon the whole believed, that this useful contrivance may be varied so as to suit the surface of many difficult countries, at a comparatively moderate expense. It may be constructed in a much more expeditious manner than navigable canals; it may be introduced into many districts where canals are wholly unapplicable; and in case of any change in the working of mines, pits, or manufactories, the rails may be taken up and laid down again in new situations, at no very great expense or trouble.

It is also further noticed, that some parts of this and the neighbouring counties, in which canals had once been intended
intended to be formed, have since been looked over and examined with the view of having iron railways instead of navigable cuts; and in many cases this may be the most advisable and proper, particularly in all situations where difficulties arise in the contracting of navigable canals, or other forms of works for water carriage.

The county of Lancashire, too, has a great many of these iron railways for the convenience, accommodation, and advantage of the different collieries, manufactories, and other works, where heavy loads are to be transported. The coal work near St. Helens, in the vicinity of Liverpool, has a double railway some miles in length; and at the iron-works of lord Beccarids, near Wigan, as well as his canal coal pits near the same place, there are double railways of very considerable length. To the south of the town of Prebllon, at a small distance from Bamber bridge, there is likewise one communicating with the Lancaster and Kendal canal, which is also double and of great length; serving to convey the colts from the southern parts of the county to that canal, in order to their distribution in the northern districts.

On the east side of the same county they also prevail in many places, and are found of the greatest use, being the means of dispatching much business in a ready manner and without much expense of labour.

The utility of these railways has been found to be extremely great in other coal-works and canals, where they are at present very extensively employed; and it has been suggested, that they may be applicable in other cases, as for shortening the team labour of a farm so as to bring it within one day's journey, where more than one were formerly necessary, by which a great saving in labour and expence may be made. Also, in rendering the business of time works more easy and expeditious in different instances. It has likewise been hinted by Mr. Batsfou, in the first volume of Communications to the Board of Agriculture, that they might be had recourse to on roads where there are unavoidable rises or falls, for taking up or letting down heavy loaded waggons or other carriages. It is observed, that near Colebrook Dale there is one at a small distance from the iron bridge, upon which loaded boats are drawn up to a canal, two hundred and twenty feet above the level of the river Severn, and let down in a similar manner into it, by which means twenty-two locks are saved, and the work executed in an expeditious manner. It is supposed, that this is the greatest inclined plane in Europe, or perhaps in the world, for though they are much used in China in the place of locks, he has never heard of any of them being equal in height to this. The rails are well made of iron. It is added, that they have been found useful in improving loft, mossy, boggy lands, on which horses cannot travel; a railway of this fort having been formed through a peat moss near Manchester by Mr. Wakefield, while it was under improvement, at the expense only of about three hundred pounds a mile, on which a single horse was capable of drawing with the greatest facility seven waggons at once, each being loaded with about seven hundred weight of marle, bearing in the whole forty-nine hundred weight, and with the weight of the waggons upwards of three tons. This was performed, it is observed, over a place where a few months before a dog could hardly venture without the danger of being swamped. On the Ketley and other canals in the county of Shropshire, vast advantages have been derived from laying railways upon inclined planes, and letting down and drawing up the different articles by means of machinery, as may be seen in the very able Agricultural Report of that district, where excellent representations of them are given.

Besides these different cases of railways, another has been suggested by the writer of the Annals of Agriculture, which is that of having them laid from the back-yards to the threshing machines, by which the grain may be conveyed to them at any time with ease and convenience, as well as any particular flack that may be wanted.

It is further stated by the ingenious Dr. Anderson, that the best idea he can give of the benefit that may result to the community from the use of this kind of railways, will be from stating some facts respecting them, which were lately communicated to the Society of Arts by Mr. Wilkes, of Mechlnian, near Loughborough, in Leicestershire; a spirited and judicious agriculturalist. He had a railway of this form made, which was about five miles in extent, leading from a coal-mine to a market. He found it so fully to answer his expectations after it was finished, that he communicated to the above society an account of some trials he had made of it, requiring that such of the members of that respectable institution as were desirous of information on that head, would do him the honour to witness some experiments that he wished to make upon it, for the information of the public. A committee of the members was accordingly deputed for that purpose, and before them he shewed that a moderate sized horse, of about twenty pounds value, could draw upon it with ease down hill (the deficit being one foot in a hundred) thirty-two tons, and without much difficulty forty-three, and seven tons up hill, independent of the carriages. The doctor concludes from these facts, that upon a perfect level a horse could draw with ease from ten to twenty tons. It is observed, that Mr. Wilkes' railway, on which the experiments were made, was, from local circumstances, laid upon wooden sleepers, and is not so perfect as those done upon stone. But it is added, that twenty tons are the load which such a horse could draw with ease, travelling at the usual waggon rate, in boats upon a canal; so that the number of horses required in this way will not be much, if at all, greater than on a canal. Certain advantages attach to this mode of conveyance, which do not so well apply to a canal, and vice versa; but it is not his intention to draw a parallel between these two modes of conveyance. Nobody can entertain any doubt, it is thought, about the utility of canals where they are easily practicable. He only wishes to point out this as an eligible mode of conveyance where canals cannot be conveniently adopted.

It is further remarked, that it was customary at the first, to put the whole load to be drawn by one horse upon railways into one waggon; but now, when the load is so much augmented, it has been found eligible to divide it into many parts, so that no one waggon shall carry more than one or two tons; by this method the weight is so divided, that the prejudice is never so great upon one point as to be in danger of too much bruising the road; the carriages can be made much more limber and light in all their parts, and they are much more easily moved, and more manageable in all respects than they otherwise would have been. And another advantage of this arrangement, which deferred to be particularly adverted to, is, that it admits of shifting the carriages to as to leave a load, as it were, in parcels at different places where they may be required, without trouble or expense. This, when it comes to be fully understood and carried into practice, will, he thinks, be a convenience of inestimable value, a thing that has been always wanted, and never yet has been found though it has been diligently sought for. The able writer has here endeavoured to illustrate its importance and utility in transporting goods from the wet docks now forming on the Isle of Dogs to London, and in carrying roads to different distant parts of the country; in which cafes,
RAILWAY.

cafes, and in all where there is much business to be done, they would require to be double, one for going, and the other for coming upon, to prevent interruption and interference.

And he afterwards offers a few remarks, tending to shew the practicability of the measure, and to guard against setting out upon a bad plan, which might, he supposes, in time to come, frustrate the good that might have resulted from the undertaking; merely premising, that he proposes these railways solely for the purpose of conveying weighty loads, leaving the roads, as at present, open for coaches and light carriages.

Also with a view to discover how far it may be practicable to introduce these iron railways into general use, he has made some inquiries respecting the expense of making them; and although this must vary according to the abundance and goodness of materials, and other circumstances, the following statement may serve to give some general notions on that head. In the most eligible situation, where materials are abundant and good, and circumstances favourable, the lowest expense at which a single railway of this kind can be made, will be about one thousand pounds a mile. But as a single railway must be liable to great inconveniences, unless under very particular circumstances, double railways ought to be considered as the only useful fort. Thefe, for public as well as private purposes, according to the opinion of the inventor, should be very substantially made. The metal used should be of the stoutest sort, and of sufficient strength, not merely to carry the weights proposed, but to be equal to bear almost any blow or shock that they may be likely to experience; and, thus made, what they will lose by rust or wear, will be long ere it materially weakens them. Made after such a manner, in favourable situations in the country, a double railway may, he thinks, cost about two thousand pounds a mile, but in the neighbourhood of London, where the charge of every thing is high, and where they should be of the strongest fort, we should suppose they might cost nearly three thousand pounds a mile. It is bad economy, he thinks, to fave on articles of this fort at the first; for the little expense thus laid out then will fave much in repairs; how small these repairs are, may be imagined from this circumstance, that when a road is thus made, the undertaker does not scruple to supply all that are broken, free of charge, for the firt three years. Say then that such a road cost three thousand pounds a mile, this would bring a charge upon the turnpike of 156l. 8-year; say 50l. more for annual repairs; this is, in all, 200l. per annum. Compare this with the expense of keeping the prefer roads in repair. It has been fuggled to him, that there is annually laid out in repairs upon the road from Hyde Park Corner to Hounflew, considerably above one thousand pounds a mile; so that the difference of expense is, even at the beginning, very much in favour of railways; and were the money thus at first expended to be gradually paid off, the folls might thus be lowered almost to nothing. And, he thinks, that a turnpike road cannot be made in almost any fitation for fefs, as he is told, than 100l. per mile; but where it is of confiderable width, as near great towns, it will run from 150l. to 200l. per mile; and in annual repairs, including the purchase price of materials, carting them on the road, fprading, raking out, and carting away again, from 100l. to 1000l. a mile. Say 150l. prime cofl, the intereft is 55l, and 150l. for repairs, the annual charge of fuch road will be 225l.

This is an expense of 100l. a-year more than the other. But for the prefent, let us fuppofe that they will be equal, the extra charge for purchasing ground for a new waggon-way, &c. being equal to that surplus; let us now fee what would be the difference of charge to the employers of these waggons in the two cafes. Supposing the road to be so much employed as that 100 waggons (or loaded carriages to the fame amount) pass each day, carrying fix tons each, drawn by eight horses; that, at one shilling each waggon for toll (or two-pence a ton), would produce 5l. a day, or 1825l. a-year; which, at the rate of eight miles for each turnpike, would be 228l. per mile, the surplus being produced by road horses and light carriages. The charge thereto the employer, for this flage, must be 1825l. and the keep of 800 horses, besides servants, incidental charges, and owner's profits for the transporting of 600 tons of goods a day.

Say that the same horses travel two flages a day, the turnpike money would be doubled; that is, 3560l. per annum; the keep of 800 horses, at 2s. each per diem, is 29,420l. These sums added make 32,850l. owner's profit and incidental charges, say 10 per cent., 3285l.; in all 3615l., or, on 219,000 tons (being 600 tons a day), about one-fourth per ton. And supposing the fame quantity of goods carried on the railway, and the fame turnpike money paid, and that each horse drew only fifteen tons, this would require only, he thinks, forty horses; the keep of which, at 2s. a day, would be 140l., add the toll, 1825l. is 3285l. per annum. Owner's profit, &c. upon this sum 10 per cent. as above, 328l.; in all 3615l., or about four-pence a ton, just one-fourth of the charge in the other cafe. He thinks, that when the object comes to be considered in this point of view, few measures that can be proposed will hold forth such an important national improvement as this would be. Considered with regard to the consumption of the produce of the earth (an object at present deferving the fullest attention, as this improvement can be applied to almost every part of the country), it would, he supposes, reduce the number of heavy road horses to one-eight part of what they are at present, and of course augment the number of cattle or other conffnurable provisions in a proportionate degree, so as greatly to lower the price of the necessaries of life. It would, in the next place, lower the price of the carriage of goods of all kinds to an amazing extent; and lastly, as a consequence of that, it would give such encouragement to agriculture, as no other measure that can be contrived could ever effect, and that without coting one shilling expense to any one individual, or to the State. On the contrary, by inducing cheaper of provision, and affording such efficacious encouragement to manufactures and agriculture, it would produce a general prosperity, which, by augmenting the consumption of taxable commodities, would augment the public revenue; while, at the fame time, every individual would feel himself relieved from the preflure of many taxes that prove difreafual to him at prefent. After justly reproving every fort of gambling fpeculations by monopoly men in undertakings of this nature, and shewing the numerous evils that attend them, he advifes it, as highly neceffary to prevent these railways from ever becoming private property, on any account, to keep them open and patent alike, to all who shall choose to employ them as a king's highway, under fuch regulations as it shall be found neceffary to subject them to by law. In short, they should, he thinks, let upon the fame footing, in all respects, as public roads are at prefent, only under the direction of a distinct fett of commissioners, who shoule have the superintendence of every thing that concerns this species of roads only. These commissioners should be vetted with authority under an act of parliament, to erect turnpikes upon them, to levy certain flipulated tolls, and to mortgage the produce of these tolls for the purpose of raising money to be applied in the neceffary purchases of land, and making the roads. In the act it should
should be expressly stipulated, that the produce of these tolls should be applied solely to keeping the road in repair, paying the intereft of sums borrowed, and clearing off the principal as fast as the collections would admit; and when the whole money borrowed was thus paid off, the tolls should be so lowered as only to produce money sufficient to keep the roads in a state of continually good repair. Thus would the expence of transporting goods be annually diminishing, and the prosperity of the country be thereby augmenting from day to day. He adds, that he is particularly inuch in this business, as he has not been an unconcerned observer of the effects that have resulted from the establishment of turnpike roads in Scotland, which were begun within his recollection; and these effects have been such as no man who had not seen it would have believed could ever have taken place. Distance may be said to be thus diminished from place to place; lands that were originally far beyond the influence of the town as a market for any thing else than five-lobe, are thus brought, as it were, close to its gates; and the value of the produce of many articles is thus to them augmented fourfold, while they are at the same time diminished to the public. Not only is the value of produce raised, but the quantity also of that produce is augmented exceedingly by means of manures which become then accessible. Fertile manures, such as chalk, lime, and marle, which were formerly confined to a narrow spot, expanded themselves as if it were by a magical power, and by that expansive influence diffuse around fertility, riches, and plenty. Coals and other weighty articles that may be useful in arts or manufactures of various kinds, which never were, nor ever could have been of any value to the owners of them, so long as the expence of transportation exceeded a certain sum, had a ready market to any extent as soon as the price falls below that rate, thus contributing not only towards the enriching of the owners, but to the furnishing of employment to the various persons who must be engaged in preparing or transporting them to market, and the universal accommodation of the whole. Around every market you may suppose a number of concentric circles drawn, within each of which certain articles become marketable which were not so before, and thus become the source of wealth and prosperity to many individuals. Diminish the expanse of carriage but one farthing, and you widen the circle; you form, as it were, a new creation, not only of stones, and earth, and trees, and plants, but of men also, and what is more, of industry, of happiness, and joy. It is added, that by making these roads the property of the public, and free to every person to bring his own waggons upon them wherever he pleased, farmers, when near them, would make bye roads of the same fort leading into them from their respective premises; the inhabitants of villages and country districts would join together, and at one common expense make roads of the same fort leading to a greater distance inward, as they now make bye roads for themselves. Thus would all be accommodated; those who had business enough to furnish a sufficient load for one horse might go to market with it when they pleased; those who had dealings on a smaller scale could have one, two, or more waggons of their own conjoined with those of others to make up a load for one horse; and those of still smaller means could have one own waggons loaded with the joint articles belonging to two, three, or more. A ton weight might then be pushed before a man to market for many miles, as a wheelbarrow is now. It is fearely possible, he supposes, to contemplate an inftitution from which would result a greater quantum of harmony, peace, and comfort, to persons living in the country, than would naturally result from this arrangement. In fact, he knows, he says, no one
easily, and without much driving; for if too tight fitted it might when wet burrit the stone. These plugs are each to receive an iron spike or large nail, with a flat point and long head, adapted to fit the counter-funk notches in the ends of two rails, and thereby to fall them down in the proper position, or situation in which they are to lie.

With regard to the rails, they should be of the stoutest cast-iron, one yard in length each, formed with a flange on the inner edge, about two inches and a half high at the ends, and three and a half in the centre; and shaped in the best manner to give strength to the rails, and keep the wheels in their track. The foles of the rails, for general purposes, should not, he thinks, be less than four inches broad; and the thickness proportioned to the work they are intended for. On railways for heavy burdens, great use, and long duration, the rails should be very stout, weighing 400 lbs., or, in some cafes, nearly half an hundred weight each. For railways of less consequence, less weight of metal will do; but it will not be prudent to use them of less than 300 lbs. weight each, in any situation exposed to breakage above ground. But it is observed that in mines, and other works underground, where very small carriages only can be employed, very light rails are used, forming what are called train roads, on a system introduced by Mr. Carr; and these kinds of light railways have been much used above ground in Shropshire, and other counties where coals and other minerals are obtained.

It is added, that in fixing the blocks and rails great attention is required to make them firm. No earth or soft materials should be used between the blocks and the bed of small stones or gravel, on which the rails must all be fixed by an iron gage, to keep the fides at a regular distance, or parallel to each other. The weight of road for general purposes is four feet two inches between the flanges of the rails; the wheels of the carriages running in tracks about four feet six inches asunder. Rails of particular forms are necessary where roads branch out from or intersect each other; and where carriage roads cross the railways; and, at turnings of the railways, great care is required to make them perfectly easy. The rails of the fide forming the inner part of the curve should be fixed a little lower than the other; and the rails should be flat a little under the gage, so as to bring the fides nearer together than in the straight parts: the deviation in level and width to be in proportion to the sharpness of the curve. The blocks and rails being fixed and spiked fast, nothing more remains to be done than to fill the horse-path, or space between the blocks, with good gravel, or other proper materials; a little of which must also be put on the outside of the blocks to keep them in their proper places. This gravel should always be kept below the surface of the rails on which the wheels are to run, to keep the tracks of the wheels free from dirt and obstructions. The form of the rails must be such as will free them from dirt if the graveling is kept below their level.

And in the contriving of the carriages great attention to avoid friction is necessary, particularly in the formation of the wheels and axles, which must be adapted to the fort of railways and kind of loading; but for which general directions cannot be given in a narrow compass. It is probable that this valuable invention may also be applicable to many other purposes in agriculture or manufactures, as it becomes more fully understood, and the facilities which it affords are better known. See CANAL.

RAILMPOUR, in Geography, a town of Hindustan, in Rohulmead; 30 miles S. of Bercly.

RAIN, a town of Hindostan, in Guzerat, on the gulf of Cutch; 45 miles W. of Nosangur.—Also, a town of Bavaria; 16 miles N. of Augsburg. N. lat. 48° 37'. E. long. 10° 52'.

RAIN, or Old Rain, a town of Scotland, in Anderdhshire, near which are the remains of a palace of the former bishops of Aber-ni; eight miles S.E. of Inverary.

Rain, the distillation of water which descends from the atmosphere in drops of various sizes. By this circumstance rain is distinguished from dew or fog; in the former of which the drops are so small, that they are quite invisible; and in the latter, though they are of a larger size, they seem to have little more specific gravity than the atmosphere itself, and may therefore be reckoned hollow sphehades rather than drops.

Rain is, apparently, a precipitated cloud; as clouds are nothing but vapours raised from moisture, waters, &c. And vapours are demonstratively nothing else but little bubbles or vehicle detached from the surface of the terraqueous globe by the power of the sular or subterraneous heat, or some other cause. These vehicles, being specificaly lighter than the atmosphere, are buoyed up by it, until they arrive at a region where the air is in a just balance with them; and here they float, till by some new agent they are converted into clouds, and thence either into rain, snow, hail, mist, or the like.

But the agent in this formation of the clouds into rain, and the vapours into clouds, has been much controverted. Some philosophers have supposed that the cold, which constantly occupies the superior regions of the air, chills and condenses the vehicle, at their arrival from a warmer quarter; congregates them together, and occasions several of them to coalesce into little drops; and by these means their quantity of matter increasing in a greater proportion than their surface, they become an overbalance to the thin air, and accordingly descend in rain.

Dr. Derham accounts for the precipitation thus: that the vehicle being full of air, when they meet with a colder air than that they contain, this internal air is contracted into a less space; and consequently the watery vehicle, or cafe, is rendered thicker, so as to become heavier than the air, &c.

It has, however, been objected to this hypothesis, that rain often happens in very warm weather; and though it be allowed, that the condensation may be owing to the cold of the upper regions, yet the drops acquire a considerable increase of size as they descend. E. G. On the summit of a hill they are small and occasion only a drizzling shower; but in descending the hill it becomes more considerable, and at the bottom of the hill the drops are much larger, and the
RAIN.

the rain is impetuous. Hence it appears that the vapours are condensed when the atmosphere is warm as well as when it is cold.

Others only allow the cold a part in the action, and ascribe a share of it to the winds, alleging that a wind blowing against a cloud will drive its vehicle upon one another, by which means several of them, coalescing as before, will be enabled to descend; and the effect will be still more considerable, if two opposite winds blow toward the same place. To which they add, that clouds already formed, happening to be augmented by fresh accretions of vapour, continually ascending, may on this account be enabled to descend.

Against the above stated hypothesis of Derham, it has been objected that the vehicle of vapour, if they be fuch, are filled, not with air, but fire or heat in a latent state, and till they part with this heat, the vapour cannot be condensed. Cold is not always sufficient to produce this effect, for in the most severe frosts the air is fere, and parts with little or none of its vapours, for a considerable time. It is also alleged, that the winds have no considerable agency, since blowing upon vapour is so far from condensing it, that it unites more closely with the air; and wind is known very much to promote evaporation. See Vapour.

Yet the grand cause, according to Rohault, still remains: that author conceives it to be the heat of the air, which after continuing for some time near the earth, is at length carried up by a wind, and there thawing the frozen vills, or flocks of the half-frozen vehicle, reduces them into drops; which coalescing, descend, and having their dilution perfected in their progress through the lower and warmer flages of the atmosphere. Others, as Dr. Clarke, &c. ascribe this defect of the clouds rather to an alteration of the atmosphere than of the vehicle; and suppose it to arise from a diminution of the spring, or elfic force of the air.

This elaficity, which, as they fay, depends chiefly or wholly on the dry terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall, on the common principle of precipitation.

Now, the little vehicle, by air or all these means, being once upon the deficient, will perifh therein, notwithstanding the increaf of refiftance they every moment meet with in their progress through till denier and defier parts of the atmosphere. For, as they all tend toward the fame point, i.e. the centre of the earth, the afar they fall, the more coalitions will they make; and the more coalitions, the more matter will there be under the fame furface; the furface only increasing as the fquares; but the foldity as the cubes; and the more matter under the fame furface, the lefs refiftance or refilience there will be to the fame matter.

Thus if the cold, the wind, &c. happen to act early enough to precipitate the ascending vehicle, before they are arrived at any considerable height, the coalitions being few in fo short a defcent, the drops will be proportionably fmall: and this is formed what we call demo. See Defg.

If the vapours prove more copious, and rife a little higher, we have a fmal or fog; which fcc respectively.

A little higher still, and they produce a small rain, &c. If they neither meet with cold, nor wind enough to condenfe or diflaffate them, they form a heavy, thick, dark fky; which lats sometimes several weeks. This hypothesis of the diminution of the atmosphere's elaficity, requires a more fatisfactory explanation of the caufe of this diminution. By ascribing it to terrene exhalations, we only solve one difficulty by introducing another; for we are totally un-acquainted with the nature and operation of these exhalations.

But let the caufe be what may be supposed, if it act equally, and at once, upon all the vapour in the air, all that vapour must be at once precipitated; and the con-sequences must be, that, instead of gentle showers continuing for a considerable time, we must have copious water-spouts, lasting only for a few minutes or seconds, which, instead of refreshing the earth, would drown and lay it waste.

Those who admit either of the above hypotheses, account for many of the phenomena of the weather; e.g., why a cold is always a wet summer, and a warm a dry one, because the principle of precipitation obtains in the one case, and is wanting in the other. Why have we ordinarily moft rain about the equinoxes? because the vapours arise more plentifully than ordinary in the spring, as the earth becomes loosened from the brumal confipitations; and because, as the fun recedes from us in autumn, the cold increafing, the vapours that had lingered above during the summer heats, are now difpatched down, &c. Why a lighted, thick, clofe fky scarcely ever rains till it has been fiff clear; because the equally diffused vapours must firft be conflafated, and congregated into separate clouds, to lay the foundation of rain, by which means the height of the furface of heaven is left open, and pervers to the rays of the fun, &c.

For other phenomena of rain, as they relate to the weather-gales, see Barometer, and Weather.

It cannot be doubted, that there is a connection between the defcent of the barometer and the fall of rain; but no fatisfactory reason has yet been afligned for the cirfumstance; nor is it poftible to foretell with certainty that rain will follow any changes in the height of the barometer that have been obferved. The immediate dependence of rain, or of any other atmospheric phenomena, on the influence of the moon, appears to be rendered highly improbable, not only by mathematical calculations of the effects of the moon's attraction, but also by the irregularity of the obervations which have been added in favour of a fuch a connection. (See Influence of the Moon.) But however uncertain the ultimate caufes of rain may be in general, their effects in some places are sufficiently confiant, to be attributed to permanent local circumstances, and in particular to the periodical recurrence of fimlar winds.

For a more particular account of other theories, for explaining the acent of vapours, the formation of clouds, and the fall of rain, fee Vapour.

Besides the caufes of rain, mentioned above, Defaguliers thinks it owing to the lofs of electricity in the vapours of which they were formed.

Other writers, in the progres of this part of philosophical science, have confidered rain as an electrical phenomenon; or at leat they have suppofed, that the powers of electricity may concur with other caufes in producing it. Signor Becaria, whole obervations on the general state of electricity in the atmosphere have been more extensive and accurate than thofe of any other perfon, reckons rain, hail, and snow, among the effects of a moderate electricity in the atmosphere. Clouds that bring rain, he thought, were produced in the fame manner as thunder clouds, only by a moderate electricity. He describes them at large, and the refemblance which all their phenomena bear to those of thunder-clouds is very striking. He notes several cirfumstances attending rain without lightning, which render it probable, that it is produced by the fame caufe as when it is accompanied with lightning. Light has been feen among the clouds by night in rainy weather; and even by day, rainy clouds are sometimes seen to have a brightnefs evidently independent of the fun. The uniformity with which
which the clouds are spread, and with which the rain falls, he thought, were evidences of an uniform cause like that of electricity. The intensity also of electricity in his apparatus generally corresponded very nearly to the quantity of rain that fell in the same time. Sometimes all the phenomena of thunder, lightning, hail, rain, snow, and wind have been observed at one time; which shows the connection they all have with some common cause. Signior Beccaria, therefore, supposes, that, previous to rain, a quantity of electric matter escapes out of the earth, in some place where there was a redundancy of it; and in its ascent to the higher regions of the air, collects and conducts into its path a great quantity of vapours. The same cause that collects, will condense them more and more; till, in the places of the nearest intervals, they come into contact, so as to form small drops; which, uniting with others as they fall, come down in rain. The rain will be heavier in proportion as the electricity is more vigorous, and the cloud approaches more nearly to a thunder-cloud. He imitated the appearance of clouds that bring rain, by inflating himself between the rubber and conductor of his electrical machine; and with one hand dropping colophonia into a spoon fastened to the conductor, and holding a burning coal, while his other hand communicated with the rubber. In their circumference, the smoke spread along his arm, and, by degrees, all over his body, till it came to the other hand that communicated with the rubber. The lower surface of this smoke was everywhere parallel to his clothes, and the upper surface was swelled and arched like clouds replete with thunder and rain. In this manner, he supposes, the clouds that bring rain diffuse themselves from those parts of the earth which abound with electric fire, to those parts that are exhausted of it; and by letting fall their rain, restore the equilibrium between them. Signior Beccaria also thought, that the electricity communicated to the air, which both receives and parts with it slowly, would account for the retention of vapours in a clear sky; for small disjointed clouds, not diffused into rain; for the smaller and lighter clouds in the higher regions of the air, which are but little affected by electricity; and also for the darker, heavy, and sluggish clouds in the lower regions, which retain more of it. He even imagined that some alteration in the weight of the air might be made by this electricity of it: the phenomena of rain, he thought, favoured the supposition, that the electric matter in the air did, in some measure, lessen its pressure: for when the electric matter is actually in the air, collecting and condensing the vapours, the barometer is low. When the communication is made between the earth and the clouds by the rain, the quicksilver begins to rise; the electric matter, which supported part of the pressure, being discharged. "Lettere dell Elettricismo," Priestley’s Hist. &c. of Electricity, vol. i. p. 427, &c. 8vo.

Dr. James Hutton’s theory of rain is stated and amply illustrated in the 2d volume of the Edinburgh Transactions, p. 47, &c. It is well known that atmospheric air is capable, with a certain degree of heat, of dissolving a given quantity of water. (See VAPOUR.) Dr. Hutton ascertains the ratio of the dissolving power of air, in relation to water, with different degrees of heat; and thus, by mixing a portion of transparent humid warm air with a portion of cold air, the mixture becomes opaque, and part of the water will be precipitated; or, in other words, the vapour will be condensed into rain. Hence he observes, that since the capacity of air for moisture increases faster than the temperature, there must be a deposition of moisture when two saturated portions of air at different temperatures are mixed. Dr. Hutton supposes that heat and solution do not increase by equal increments; but that, in reality, if heat be supposed to increase by equal increments along a straight line, solution will be expressed by ordinates to a curve, whose convex side is turned towards that line. That the power of solution is not increased in the same ratio as heat is, however, hypothetical, except when we rise pretty high in the scale, when its proportional increase is some what doubtful; nor has our author supported it by experiment. The condensation of the breath in air is not to the purpose, unless we suppose the air to be already saturated with vapour. In any view, it can only amount to this, that to render it visible, the heat must be diminished in a greater proportion than can be compensated by the power of solution in the body of air, in which the portion expired is at first immersed. In order to explain the origin of rain from this cause, we must always suppose a constant diminution of heat to take place at the moment of the condensation of the vapour; but we actually find, that the change from a state of vapour to the fluid state is attended with heat; so that rain must at once oppose its own cause, and continued rains would be impossible without the aid of other causes. Dr. Hutton endeavours, from his own system, to explain the regular and irregular feasons of rain, with regard either to the generality of its appearance, or the regularity of its return. And to obviate the apparent exceptions of the theory, from the generality of rain, he explains the proportion of quantities of rain, and adds a comparative estimate of climates, in relation to rain with the meteorological observations made in our own climate. As our limits will not allow our doing full justice to our author’s reasoning, we must refer to his own paper on the subject.

Mr. Dalton, in his “Meteorological Essays,” (Eff. vi.) expresses his approbation of Dr. Hutton’s theory in general; to this purpose, he says, “the principles of none appear to me to be more plausible and conformable with facts.” Dr. Hutton, as we have above shewn, considers the varieties of heat and cold, affecting the solvent power of the atmosphere, as the sole causes of rain; and Mr. Dalton observes, when we consider that evaporation and the precipitation of vapour are diametrically opposite, it is reasonable to suppose that they should be promoted by opposite causes: and as heat and dry air are favourable to evaporation, so cold, operating upon air replete with vapour, promotes its precipitation. Dr. Hutton, however, seems to consider water as chemically combined with the atmosphere, and that cold produces precipitation in a manner similar to what it does in water saturated with salt, or in other chemical processes; whereas Mr. Dalton supposes, that a portion of the vapour, considered as a distinct and peculiar fluid, is condensed into water by cold; but the effects resulting from the two theories will be the same. See METEOROLOGY, and VAPOUR.

M. de Luc, in the 2d volume of his “Thoughts on Meteorology,” has directed particular attention to the various circumstances that attend rain. He has also examined the several hypotheses of different authors, and concludes, that they are altogether insufficient to account for the formation of it. In this inquiry the grand question under discussion is, what becomes of the water that rises in vapour into the atmosphere? or what is the state in which it subsists there, between the time of its evaporation, and its falling down in rain? If it continues in the state of watery vapour, or such as is the immediate product of evaporation, it must poffefl the distinctive characters essential to that fluid; it must make-
make the hygrometer move towards humidity, in proportion as the vapour is more or less abundant in the air: on a diminution of heat, the humidity, as shewn by the hygrometer, must increase; and on an increase of the heat, the humidity must diminish; and the introduction of other hygroscopic substances, drier than the air, must have the same effect as an augmentation of heat. These are the properties of vapour, on every hypothesis of evaporation; and, therefore, all the water that exists in the atmosphere, without poefling these properties, is no longer vapour, but must have changed its nature. M. de Luc shews, that the water which forms rain, though it has ever been considered and reasoned upon as producing humidity, does not poefls this property, and must, therefore, have passed into another state. As he thinks that the vapour passes into an invisible state in the interval between evaporation and its falling again in rain, and that in this state it is not feftsible to the hygrometer, he considers the laws of hydrology as insufficient for explaining the formation of rain; but he does not pretend to have discovered the immediate cause of the formation of clouds and rain. If it is not in the immediate product of evaporation that rain has its source; if the vapours change their nature in the atmosphere, so as no longer to be feftsible to the hygrometer, or to the eye; if they do not become vapour again till clouds appear; and if, when the clouds are formed, no alteration is perceived in the quality of the air; we must acknowledge it to be very probable, that the intermediate state of vapour is no other than air, and that the clouds do not proceed from any distinct fluid contained in the atmosphere, but from a decomposition of a part of the air itself, perfectly similar to the earth. For other observations on the ascent and nature of vapour, and the subsequent formation of rain, we refer to the articles Meteorology, and Vapour.

As to the general quantity of rain that falls, and its proportion in several places at the same time, and in the same place at several times, we have many observations, journals, &c. in the Memoirs of the French Academy, the Philos. Trans. and many other publications; from which we shall make the following extracts.

Upon measuring the rain falling yearly, its depth, at a medium, is found as in the following table.

Depth of Rain falling yearly, and its Proportion in several Places. Inches.

At Townley, in Lancashire, observed by Mr. Townley 42½
Upminster, in Essex, by Dr. Derham 10½
Zurich, in Swiifferland, by Dr. Schweizer 32½
Piza, in Italy, by Dr. Mich. Ang. Tili 43½
Paris, in France, by M. de la Hire 19
Lille, in Flanders, by M. de Vauban 24

From the Meteorological Journal of the Royal Society, kept by order of the president and council, it appears that

the whole quantity of rain at London, in each of the years specified below, was as follows: viz.

Half Year 36.76 19.24 32.66

As rain-gages have been fixed of late years in almost every part of the kingdom, we are enabled to determine, with considerable exactness, the depth of water which the rain yields in any given place. It may be observed, however, that inland counties have less rain than maritime ones; especially those which border on the western seas. But ifil a greater difference seems to take place between a mountainous country, and a champaign or flat country. In the former there often falls double or triple the quantity of rain in a year that there does in the latter, and never less than an equal quantity. It is also observed, that those winds bring most rain that blow from the quarter in which is the most and nearest sea; as are well and south-west winds. The rain-gage also shews, that more rain is collected in the instrument, as it is placed nearer the ground; without any appearance of a difference, between two places, on account of their difference of level above the sea, provided that the instrument is as far from the ground at the one place, as it is at the other. These effects are noticed in the Phil. Trans. for 1769 and 1771, the former by Dr. Heberden, and the latter by Mr. Daines Barrington. Dr. Heberdeen says, "A comparison having been made between the quantity of rain which fell in two places in London, about a mile distant from one another, it was found that the rain in one of them constantly exceeded that in the other, not only every month, but almost every time that it rained. The apparatus used in each of them was very exact, and both made by the same artist; and upon examining every probable cause, this unexpected variation did not appear to be owing to
to any mistake, but to the constant effect of some circumstance which, not being supposed to be of any moment, had never been attended to. The rain-gage in one of these places was fixed too high, as to rise above all the neighbouring chimneys; the other was considerably below them; and there appeared reason to believe, that the difference in the quantity of rain in these two places was owing to this difference in the placing of the vellum in which it was received.

A funnel was, therefore, placed above the highest chimneys, and another upon the ground of the garden belonging to the same house, and there was found the same difference between these two, though placed so near one another, which had been between them, when placed at similar heights in different parts of the town. After this fact was sufficiently ascertained, it was thought proper to try whether the difference would be greater at a much greater height; and a rain-gage was therefore placed upon the square part of the roof of Westminster Abbey. Here the quantity of rain was observed for a twelvemonth, the rain being measured at the end of every month, and care being taken that none should evaporate by passing a very long tube of the funnel into a bottle through a cork, to which it was exactly fitted. The tube went down very near to the bottom of the bottle, and therefore the rain which fell into it would soon rise above the end of the tube, so that the water was no where open to the air except for the small space of the area of the tube; and by trial it was found that there was no sensible evaporation through the tube thus fitted up.

The following table shews the result of these observations:

From July the 7th, 1766, to July the 7th, 1767, there fell in a Rain-gage, fixed

By this table it appears, that there fell below the top of a house above a fifth part more rain than what fell in the same space above the top of the same house; and that there fell upon Westminster Abbey not much above one-half of what was found to fall in the same space below the tops of the houses. This experiment has been repeated in other cafes with the same result. What may be the cause of this extraordinary difference, has not yet been discovered; but it may be useful to give notice of it, in order to prevent that error, which would frequently be committed in comparing the rain of two places without attending to this circumstance.

Such were the observations of Dr. Heberden on first announcing this circumstance, vis. of different quantities of rain falling at different heights above the ground. Two years afterward, Daines Barrington, esq. made the following experiments and observations, to shew that this effect, with respect to different places, respected only the several heights of the instruments above the ground at those places, without regard to any real difference of level in the ground at those places.

Mr. Barrington caufed two other rain-gages, exactly like those of Dr. Heberden, to be placed, the one upon mount Rennig, in Wales, and the other on the plain below, at about half a mile's distance, the perpendicular height of the mountain being 450 yards, or 1350 feet; each gage being at the same height above the surface of the ground at the two places.

The results of the experiment are as below:

"The inference to be drawn from these experiments, Mr. Barrington observes, seems to be, that the increase of the quantity of rain depends upon its nearer approximation to the earth, and scarcely at all upon the height of places, provided the rain-gages are fixed at about the same distance from the ground.

"Possibly also a much controverted point between the inhabitants of mountains and plains may receive a solution from these experiments; as in an adjacent valley, at least, very nearly the same quantity of rain appears to fall within the same period of time as upon the neighbouring mountains."

Dr. Heberden also adds the following note. "It may not be improper to subjoin to the foregoing account, that, in places where it was first observed, a different quantity of rain would be collected, according as the rain-gages were placed upon or below the tops of the neighbouring buildings; the rain-gage below the top of the house into which the greater quantity of rain had for several years been found to fall, was above fifteen feet above the level of the other rain-gage, which, in another part of London, was placed above the top of the house, and into which the lesser quantity always fell. This difference, therefore, does not, as Mr. Barrington justly remarks, depend upon the greater quantity of atmosphere through which the rain descends; though this has been supposed by some, who have thence concluded that this appearance might readily be solved by the accumulation of more drops, in a descent through a great depth of atmosphere."

In the examination of the results from meteorological tables, it should be observed, that several years' account of the rain at any place is required, before a medium yearly quantity can be obtained with sufficient accuracy. The following table, formed by Mr. Dalton, and published in the first part of the fifth volume of Manchester Memoirs, gives us the largest collection of accounts of rain fallen in different places in England that has to our knowledge hitherto appeared. They are chiefly taken from the Transactions of the Royal Society, and of other societies.
The general mean of 55.2 inches is, as our author apprehends, a little above the medium for England and Wales, as the greater number of places are those where much rain falls. If we take up a mean for each of the above-mentioned counties, (where more than one place in a county is given,) and then a general mean from the counties, the result is a reduced mean of 31.3. Even then it may be objected, that the greater part of the counties are maritime; but it must be observed, that there is no account of rain in Wales; and we may safely conclude, that the rain in Wales would exceed the last-mentioned mean as much as the inland counties of England, not in the above list, would fall short; because Wales is both a mountainous country, and exposed to the sea.

We will, therefore, conclude, that the mean annual depth of rain in England and Wales, deduced from these twenty counties, is 31 inches: a quantity which subsequent observations, our author is confident, will not diminish, and probably not increase much.

The editors of the Encyclopedia, under the article *Weather*, from 16 places of observation, make the annual mean for Great Britain 32.55 inches; and M. Cotte, in the Journal de Physique for 1791, gives a mean derived from 147 places, in different parts of the world, equal to 34.7 inches.

If we take the dew (see *Dew*) at 5 inches annually, we shall have 36 inches of water at a medium annually, on the surface of the earth, in England and Wales, reckoning 31 for rain and 5 for dew. Admitting the computation of Guthrie, the area of England and Wales is 46,450 square miles. This, reduced to square feet, gives 1,378,586,890,000; which, multiplied by 3 feet, the annual depth of rain and dew, gives 4,135,760,690,000 cubic feet of water, = 153,176,320,000 cubic yards, or 28 cubic miles = 115 thousand millions of tons in weight, nearly. This immense mass of water is dispersed partly by the supply of rivulets, and the foaming into the earth a small way, to as to break out again in lower ground in the form of springs, and thence make its way to some river, by which it is conveyed to the sea; and partly by being raised into the atmosphere in the process of evaporation. The decomposition of water by vegetation is not noticed, because it is presumed, that in the course of nature the principles are combined, and water formed again. See *River*, *Spring*, *Evaporation*, and *Vapour*.

As to the use of rain, we may observe that it moistens and softens the earth, and thus fits it for affording nourishment to plants: by falling on high mountains, it carries down with it many particles of loose earth, which serve to fertilize the surrounding valleys, and purifies the air from noxious exhalations, which tend in their return to the earth to make the soil unproductive; it moderates the heat of the air; and is one means of supplying fountains and rivers. However, vehement rains in many countries are found to be attended with barrows of sands and poorefts of the lands, and mischief of the crops in the succeeding year: and the reason is plain; the excessive storms wash away the fine mould into the rivers, which carry it into the sea, and it is a long time before the land recovers itself again. The remedy to the famine, which some countries are subject to from this fort of mischief, is the planting large orchards and groves of such trees as bear excellent fruit; for it is an old observation, that in years, when grain succeeds well, these trees produce most fruit of all. It may partly be owing to the thorough moistening of the earth, as deep as their roots go, by these rains, and partly to their trunks flobbing part of the light mould carried down by the rains, and by this means furnishing themselves with a coat of new earth. Phil. Trans. N° 90.

The water afforded by rain is found highly refreshing to almost all sorts of vegetable crops, and to promote their growth in a rapid manner, when not produced in too great abundance at a time. This effect, which may often be perceived to take place in a sudden manner, after warm showers in the early spring months, is probably caused by the large proportion of oxygen that is contained in rain-water, as well as from the necessary moisture being afforded to the fibres of the roots of the plants. Too much rain may be injurious, however, by leavening the necessary cohesion and compactness of the roots, which they may not afford proper firmness to the roots of growing vegetables. And another injury may be produced by the too frequent occurrence of hasty showers, by which a large proportion of the decompacting vegetable and animal materials of lands, which are soluble or diffusible in water, may be conveyed away into the ditches, rivers, and ultimately into the sea, and of course prove the cause of infertility. In hilly situations, this effect may arise from even light showers; on which account, they have been advised to be ploughed in a planting direction, as by that means the rains may be more perfectly detained in the fields. And it has been suggested by Dr. Darwin, that as the foliage or buds of plants require more moisture for their vigorous growth than their flowers, in this climate, continued rains may be liable not only to wash off the farinaceous
from the hurled anthers, and in that way prevent the impregnation of the pistillum, but also delay the ripening of the seeds or fruit, from the want of a due evaporation of their periplicable matter, as well as from the loss of solar light in cloudy seasons. On this account it is, he supposes, that in the north of Scotland the oats are laid seldom to ripen till the frost commences, with the dry season which accompanies it.

Thus, as the effects of rain are so very considerable on vegetation, it would be highly useful to ascertain the quantity or depth of rain that falls annually in different districts, and the difference in the effects which are produced by it. See Water and Weather.

The vast quantities of rain which fall in some districts, from the peculiar nature of their situations, especially where they are of the grazing or pasture kind, as those of Cheshire, Lancashire, and some others, are often highly beneficial to their general fertility: the natural grafs pastures of which districts, though frequently of inferior qualities to those in many other places, are, in consequence of this circumstance, rendered superior in their abundance of grafs, the strength of its vegetation, and the richness of its quality. The former of the above counties may indeed, without any impropriety, be reckoned one of the most productive grafs-land districts in the kingdom, as is fully evinced by the great abundance and superiority of its dairy products. The grafs lands in this tract of country moislly retain their full verdure during the most sultry and parching seasons, except where they are of a sandy or gravelly nature in their under strata. Where they are near to the sea, however, in this as well as other parts, they are liable to become mofly, or be covered with the mofs plant, either in consequence of so much of the spray from it falling in the manner of light rain, or some other cause of that kind.

The quantity of rain falling upon land has much influence upon its temperature, or state of heat, and, of course, great effect on vegetation in that way; and the nature of its mixture with it, or the manner in which it is distributed through its parts, or combined with its different earthy materials, is another means by which it becomes of great importance, as it relates to the supplying of nourishment and support to vegetables as crops.

Rain falling in large quantities, on particular sorts of retentive soils, is a frequent cause of that kind of injurious wetness, which bands so much in need of surface-draining to remove it. See Surface-Draining.

The nature and causes of showers and rain are extremely curious and interesting in several different points of view, both to the agricultural and the philosophical inquirer.

Rains, Pretumnatural. We have numerous accounts in historians of pretumnatural rains, such as the raining of stones, of dust, of blood, nay, and of living animals, as young frogs, and the like. We are not to doubt the truth of what those who are authors of veracity and credit relate to us of this kind, so far as to suppute that the Falling of Stones (which fee) and dust never happened; the whole mistake (if it be so with regard to the first instance) is the supposing them to have fallen from the clouds; but as to the blood and frogs, it is very certain that they never fall at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine strictly whatever is reported of this kind, and is not to suffer himself to be deceived.

There are two natural methods by which quantities of stones and dust may fall in certain places, without their having been generated in the clouds, or fallen as rain. The one is by means of hurricanes: the wind which we frequently see tearing off the tiles of houses, and carrying them to considerable dilatation, being equally able to take up a quantity of stones, and drop them again at some other place. But the other, which is much the most powerful, and probably the most usual way, is for the eruptions of volcanos, and burning mountains, to toss up, as they frequently do, a vast quantity of stones, ashes, and cinders, to an immense height in the air; and these being hurried away by the hurricanes and tempestuous winds, which usually accompany those eruptions, and being in themselves much lighter than common stones, as being half calcined, may easily be thus carried to vast dilatations, and their falling in places where the inhabitants know nothing of the occasion, they cannot but be supposed by the vulgar to fall on them from the clouds. It is well known, that in the great eruptions of Etna and Vesuvius, showers of ashes, dust, and small cinders, have been seen to obscure the air, and overspread the surface of the sea for a great way, and cover the decks of ships; and this at such a distance, as it should appear scarce conceivable that they should have been carried to; and probably, if the accounts of all the showers of these substances mentioned by authors be collected, they will all be found to have fallen within such dilatations of volcanos; and if compared, as to the time of their falling, will be found to correspond in that also with the eruptions of those mountains.

We have known instances of the ashes from Vesuvius having been carried thirty, nay forty leagues, and peculiar accidents may have carried them yet farther.

The raining of blood has been ever accounted a more terrible sight, and a more fatal omen, than the other pretumnatural rains already mentioned. It is very certain that nature forms blood no where but in the vellums of animals, and therefore flowers of it from the clouds are by no means to be credited. Those who suppose that what has been taken for blood, has been actually seen falling through the air, have had recourse to flying insects for its origin, and suppose it the eggs or dung of certain butterflies discharged from them as they were high up in the air. But this seems a very wild conjecture, as we know of no butterfly whole excrements, or eggs, are of such a colour, or whose abode is so high, or their flocks so numerous, as to be the occasion of this.

It is most probable that these bloody waters were never seen falling, but the people seeing the flading waters blood-coloured, were allured, from their not knowing how it should else happen, that it had rained blood into them. A very memorable instance of this there was at the Hague in the year 1670. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar, on finding their lakes and ditches full of blood, as they thought, and having been certainly full of water the night before, they agreed it must have rained blood in the night; but a certain physician went down to one of the canals, and taking home a quantity of this blood-coloured water, he examined it by the microscope, and found that the water was water still, and had not at all changed its colour, but that it was full of prodigious swarms of small red animals, all alive, and very nimble in their motions, whose colour and prodigious number gave a red tinge to the whole body of the water they lived in, on a less accurate inspection. The certainty that this was the case, did not however persuade the Hollander to part with the miracle; they prudently concluded, that the sudden appearance of such a number of animals was as great a prodigy as the raining of blood would have been; and are allured at this day, that this portent foretold the scene of war and devastation which Lewis XIV. afterwards brought into that country, which had before enjoyed forty years uninterrupted peace.
The animals, which thus color the water of lakes and ponds, are the *polies arborescentes* of Swammerdam, or the water-fleas with branched horns. These creatures are of a reddish-yellow, or flame colour; they live about the sides of ditches, under weeds, and among the mud, and are therefore the least visible, except at a certain time, which is in the end of May or beginning of June; it is at this time that these little animals leave their recellers to float loose about the water, to meet for the propagation of their species, and by that means become visible in the colour they give the water. This is visible, more or less, in either part or other of almost all standing waters at this season; and it is always at this season that the bloody waters have alarming the ignorant.

The raising of frogs is a thing not less wonderful in the accounts of authors who love the marvellous, than those of blood, or of stones; and this is supposed to happen so often, that there are multitudes who pretend to have seen eye-witnesses of it. These rains of frogs always happen after very dry seasons, and are much more frequent in the hotter countries than the cold ones. In Italy they are very frequent; and it is not uncommon to see the streets of Rome swarming both with young frogs and toads in an infant, in a flood of rain; they hopping every where between the people's legs, as they walk, though there was not the least appearance of them before. Nay, they have been seen to fall through the air down upon the pavements. This seems a strong circumstance in favour of their being rained down from the clouds, but when fairly examined, it comes to nothing; for these frogs, that are seen to fall, are always found dead, lamed, or bruised by the fall, and never hop about as the red; and they are never seen to fall, except close under the walls of houses, from the roofs and gutters of which they have accidentally slipped down.

To the raising of frogs we ought to add the raising of grass-hoppers and locusts, which have sometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the least pretence for supposing that these animals descended from the clouds, but that they appeared on a sudden in prodigious numbers. The naturalist, who knows the many accidents attending the eggs of these, and other like animals, cannot but know that some animals will prove particularly favourable to the hatching of them, and the prodigious number of eggs that many insects lay, could not but every year bring us such abundance of the young, were they not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the species by a very numerous flock of seeds, of which perhaps not one in five hundred need take root, in order to continue an equal number of plants.

The raising of fishes has been a prodigy also much talked of in France, where the streets of a town at some distance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houses, &c., were found in a manner covered with fishes of various sizes. Nobody here made any doubt of these having fallen from the clouds; nor did the abounds of fish, of five or six inches long, being generated in the air, at all startle the people, or shake their belief in the miracle, till they found upon enquiry that a very well-stocked fish-pond, which had been blown dry by the hurricane, and only the great fish left, at the bottom of it, all the smaller fry having been tossed into their streets.

Upon the whole, all the supposed marvellous rains have been owing to substances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

Vol. XXIX.
the rain at a little more than one hundred feet above the level of the sea; accounts of which have been regularly kept since the year 1781; but previously to that period the rain was measured by an old rain-gage. It is to be regretted, however, that the exact nature of this invention is not more fully explained; and that other cheap plain inventions of this nature are not better known to the farmer.

Rain. Water. See Water.

Rains, in the Sea Language, denote all that tract of sea to the northward of the equator, between four and ten degrees of latitude; and lying between the meridian of Cape Verde and that of the eastermolt islands of the same name.

It takes its name from the almost continual calms, constant rains, and thunder and lightning, to a great degree, always found there. The winds, when they do blow, are only small uncertain gusts, and shift about all round the compars; so that ships are sometimes detained here a long while, and can make but very little way.

Rainangbong, in Geography, a town of the Birmian empire, situated near a river in which are several wells of petroleum, whence its name signifies a town through which flows a river of earth-oil. N. lat. 20° 26'. E. long. 94° 46'.

Rainbow, Iris, or, usually, the bow, a meteor in form of a parti-coloured arch, or semicircle, exhibited in a rainy sky, opposite to the sun, by the refraction of his rays in the drops of falling rain.

There is also a secondary, or fainter bow, usually seen involving the former at some distance. Among naturalists, we also read of lunar rainbows, marine rainbows, &c.

The rainbow, for Isaac Newton observes, never appears but where it rains in the sun shine; and it may be represented artificially by contriving water to fall in little drops, like rain, through which the sun shining, exhibits a bow to a spectator placed between the sun and the drops; especially if a dark body, e. gr. a black cloth, be disposed beyond the drops.

That the rainbow is opposite to the sun, has always been observed. It was, therefore, natural to imagine, that the colours of it were produced by some kind of reflection of the rays of light from drops of rain or vapour. The regular order of the clouds was another circumstance that could not have escaped the notice of any per son. But though mere reflection had in no other case been observed to produce colours, and it could not but have been observed that refraction is frequently attended with that phenomenon, so that some of the ancients, as we learn from Aristotle's treatise on meteors, knew that the rainbow was caused by the refraction of the sun's light in drops of falling rain; yet no person seems to have thought of having recourse to a proper refraction in this case. Before one Fletcher of Breffaw, who, in a treatise which he published in 1571, endeavoured to account for the colours of the rainbow by means of a double refraction, and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction, both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the spectator. He seems to have overlooked the refraction at the farther side of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature, to bring the ray of the sun to the eye of the spectator. Antonio de Dominis, bishop of Spalato, whole treatise, "De Radiis Visus et Lucis," was published by I. Bartolus, in 1611, was the first person who advanced, that the double refraction of Fletcher, with an intervening reflection, was sufficient to produce the colours of the rainbow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent reflection. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner surface, is from thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent so as to come directly to the eye. To verify this hypothesis, he procured a small globe of solid glass, and viewing it when it was exposed to the rays of the sun, in the same manner in which he had supposed that the drops of rain were situated with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order. The theory of A. de Dominis was adopted, and in some degree improved, by Descartes. Philosophers were, however, for a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed, nothing but the doctrine of the different refrangibility of the rays of light, which was a discovery referred for the great Sir Isaac Newton, could furnish a complete solution of this difficulty.

Dr. Barrow, in his "Lectiones Opticae," (Lect. 12. n. 14.) says, that a friend of his, meaning Mr. Newton, communicated to him a method of determining the angle of the rainbow, which was hinted to Newton by Sluiths, without making a table of the refractions, as Descartes did. The doctor flew the method, with other curious particulars. But the subject was given more perfectly by Newton afterwards, in his "Optics," prop. 9; where he makes the breadth of the interior bow to be nearly 2° 15', that of the exterior 3° 40', their distance 8° 25', the greatest diametre of the interior bow 42° 17', and the lateral of the exterior 50° 42', when their colours appear strong and perfect.

Rainbow, Theory of the. To conceive the origin of the rainbow, let us consider what will befall rays of light coming from a very remote body, e. gr. the sun, and falling on a globe of water, such as we know a drop of rain to be.

Suppose, then, A D K N (Plate XVIII. Optics, fig. 1.) to be a drop of rain, and the lines E F, B A, O N, to be rays of light coming from the centre of the sun; which, on account of the immense distance of the sun, we conceive to be parallel.

Now the ray B A being the only one that falls perpendicularly on the surface of the water, and all the rest obliquely, it is easily inferred, that all the other rays will be refracted towards the perpendicular. (See Refraction.) Thus the ray E F, and others accompanying it, will not go on straight to G; but as they arrive at H I, they will deflect from F to K; where some of them, probably, escaping into the air, the rest are reflected upon the line K N, so as to make the angles of incidence and reflection equal.

Farther, as the ray K N, and those accompanying it, fall obliquely upon the surface of the globule, they cannot pass out into the air, without being refracted, so as to recede from the perpendicular L M; and, therefore, they will not proceed straight to Y, but will deflect to P.

It may be here observed, that some of the rays, arriving at N, do not pass out into the air, but are again reflected to Q; where being refracted, like the rest, they do not proceed right to Z; but, declining from the perpendicular T V, are carried to R; but since we here only regard the rays as they may affect the eye placed a little below the drop, e. gr. at P, those which deflect from N to Q, we set aside, as useless; because they never come to the eye. On the contrary, it is to be observed, that there are other rays,
RAINBOW.

rays, as 2 3, and the like; which, being refracted from 3 to 4, and reflected to 5, and from 5 to 6, may at length, by refraction at 6, arrive at the eye 7 placed beneath the drop.

Thus much is obvious; but to determine precisely the quantities of refraction of each ray, there must be a calculation; by such calculation it appears, that the rays which fall on the quadrant A D, are continued in lines, like those here drawn in the drop A D K N; wherein there are three things very considerable: first, that the two refractions of the rays, in their ingresses and egresses, are both the same way; so that the latter does not depress the effect of the former. Secondly, that of all the rays passing out of A N, N P, and those adjoining to it, are the only ones capable of affecting the sense, as being sufficiently close and contiguous, and because they come out parallel; whereas the rest are diverging, and differed too far to have any sensible effect, at least to produce any thing so vivid as the colours of the bow. Thirdly, that the ray N P has shade or darknes under it; for, since there is no ray comes out of the surface N 4, it is the same thing as if the part were covered with an opaque body. We might add that the same ray N P has darknes above it; since the rays that are above it are inefficacious, and signify no more than if there were none at all.

Add to this, that all the efficacious rays have the fame point of reflection, i. e. the parallel and contiguous rays, which alone are efficacious after refraction, will all meet in the same point of the circumference, and be reflected thence to the eyes.

Farther, it appears, that the angle O N P, included between the ray N P, and the line O N drawn from the centre of the fun, is the angle by which the rainbow is distant from the opposite point of the fun, and which makes the semidiameter of the bow. The method of determining it will be seen in the sequel of the article. But since, besides those rays coming from the centre of the fun to the drop of water, there are many more from the several points of its surface; there are a great many other efficacious rays to be considered, especially that from the uppermost, and that from the lowest part of the sun's body.

Since, then, the apparent semidiameter of the sun is about 16 minutes, it follows, that an efficacious ray from the upper part of the sun will fall higher than the ray E F by 16 minutes: thus does the ray G H (fig. 2.) which, being refracted as much as E F, deflects to 1, thence to L, and at length emerging equally refracted with the ray N P, proceeds to M; and makes an angle O N M with the line O N. In the like manner, the efficacious ray Q R coming from the lowest part of the fun, falls on the point R, 16 minutes lower than the point P on which the ray E F falls; and this, being refracted, declines to S, whence it is reflected to T; where, entering into the air, it proceeds to V; so that the line T V, and the ray O T, contain an angle whose magnitude will be ascertained. Again, upon computing the deflections of the rays, which like that 23 (fig. 1.) coming from the centre of the sun, and being received into the lower part of the drop, we have supposed to be twice refracted, and twice refracted, and to enter the eye by lines like that 67 (fig. 3.) we find that which may be accounted efficacious, as 67 with the line 86 drawn from the centre of the fun, contains an angle 867; whence it follows, that the efficacious ray from the highest part of the sun, with the same line 86, includes an angle lets by 16 minutes; and that from the lowest part of the fun, an angle greater by 16 minutes.

Thus, since A B C D E F is the path of the efficacious ray from the highest part of the fun to the eye in F, the angle 86 F becomes of a certain magnitude ascertained below. In like manner, since G H K L M is the way of an efficacious ray from the lowest part of the sun to the eye, the angle 86 M becomes greater than the former by 16 minutes.

Since, then, we admit several rays to be efficacious, besides those from the centre of the sun, what we have said of the shade will need some alteration; for of the three rays described (figs. 2 and 3.), only the two extreme ones will have a shadow joined to them, and that only on the outer side. Hence it is evident, that these rays are perfectly difposed to exhibit all the colours of the prifm.

For the great quantity of dense or intense light, i. e. the bundle of rays collected together in a certain point, v. gr. in the point of reflection of the efficacious rays, may be accounted as a lucid or radiant body, terminated all around by shade. But the severall rays, thus emitted to the eye, are both of different colours; that is, they are fitted to excite in us the ideas of different colours; and are differently refracted out of the water into the air, notwithstanding their falling alike upon the refracting surface.

Hence it follows, that the different or heterogenous rays will be separated from one another, and will tend separate ways; and the homogeneous rays will be collected, and tend the same way; and, therefore, this lucid point of the drop in which the refraction is efficacious, will appear fringed or bordered with several colours; that is, red, green, and blue colours will arise from the extremes of the red, green, and blue rays of the sun, transmitted to the eye from several drops, one higher than another, after the same manner as is done in viewing lucid or other bodies through a prifm.

Thus, adds sir Ifaac Newton, the rays that differ in refraingibility, will emerge at different angles; and consequently, according to their different degrees of refraingibility, emerging most copiously at different angles, they will exhibit different colours in different places.

A great number, then, of these little globules being difrefed in the air, will fill the whole space with these different colours; provided they be so difposed as that efficacious rays may come from them to the eye; and thus will the rainbow, at length, arife.

Now, to determine what that disposition must be, suppose a right line drawn from the centre of the sun through the eye of the spectator, as the line V X (fig. 2.) called the line of sight, or axis of vision; being drawn from so remote a point, it may be esteemed parallel to all other lines drawn from the same point; but a right line, falling on two parallels, makes the alternate angles equal.

If, then, an indefinite number of lines be imagined drawn from the spectator's eye to a part opposite to the sun where it rains; which lines make different angles with the line of sight, equal to the angles of refraction of the differently refrangible rays, these lines, falling on drops of rain illumined by the sun, will make angles of the same magnitude with rays drawn from the centre of the sun to the same drops. And, therefore, the lines thus drawn from the eye will represent the efficacious rays that occasion the fenstion of any colour.

Now it is known, that the eye, being placed in the vertex of a cone, sees objects upon its surface, as if they were in a circle; and the eye of our spectator is here in the common vertex of several cones, formed by the several kinds of efficacious rays, with the line of sight. Now in the surface of that whole angle at the vertex, or eye, is the greatest, and in which the others are included, are those drops, or parts;
of drops, which appear red; and in the surface of that cone whole angle is least, are the purple drops; and in the intermediate cones, are the green, blue, &c. drops. Hence, then, several kinds of the drops must appear, as if dispersed into so many circular columns, or arches, as we see in the rainbow. (Rohault's System of Nat. Phil. vol. ii. part ii. cap. 17.) This part of the solution for Isaac Newton expresses more precisely, thus: suppose O (fig. 4) the eye, and OP a line parallel to the fun's rays; and let POE, POF, be angles of 45° 17', and 42° 2'. And suppose the angles to turn about their common side OF, with their other sides OE and OF, they will describe the bounds, or verges, of the rainbow.

For if E, F be drops placed anywhere in the conical surface described by OE, OF, and be illuminated by the fun's rays SE, SF; the angle SEO being equal to the angle POE, or 45° 17', shall be the greatest angle in which the most refrangible rays can, after reflection, be refracted to the eye; and, therefore, all the drops in the line OE shall send the most refrangible rays most copiously to the eye, and therefore strike the fenes with the deepest violet colour in that region.

And in like manner the angle SFO being = to the angle POF = 42° 2', shall be the greatest in which the least refrangible rays after one reflection emerge out of the drops; and these rays shall come most copiously to the eye from the drops in the line OF, and strike the fenes with the deepest red colour in that region.

And, by the same argument, the rays which have intermediate degrees of refrangibility, shall come most copiously from drops between E and F, and so strike the fenes with the intermediate colours, in the order which their degrees of refrangibility require; that is, in the progress from E to F, or from the inside of the bow to the outside, in this order: violet, indigo, blue, green, yellow, orange, red; though the violet, by the mixture of the white light of the clouds, will appear faint, and incline to a purple.

Here it may be observed, that all the rays but the violet in the line SE will emerge from E in a greater angle than SEO made by the violet, and consequently will pass below the eye; and all the rays but the red in the line SF will emerge from F in a less angle than SFO made by the red, and consequently will pass above the eye; by which means only red will appear in the line SF, and only violet in the line SE.

And, since the lines OE, OF, may be situated anywhere in the above-mentioned conical surface; what is said of the drops and colours of these lines, is to be understood of the drops and colours throughout the whole superficies. Thus is the primary or inner bow formed.

RAINBOW, Secondary, or Outer. As to the secondary, or fainter bow, usually surrounding the former, in affording what drops would appear coloured, we excluded such as lines drawn from the eye, making angles a little greater than 42° 2', shall fall upon, but not such as should contain angles much greater.

For, if an indefinite number of such lines be drawn from the spectator's eye, some of which make angles of 50° 57', with the line of albedo, EGR; or other angles, of 54° 7', EGR; or other angles, of 50° 57', EGR; those drops on which these lines fall most of necessity exhibit colours; particularly those of 50° 57'.

EGR. The drop D will appear red; the line G O being the fame with an effective ray; which, after two reflections and two refractions, exhibits red colour. Again, those drops which receive lines of 54° 7', EGR, the drop H, will appear purple; the line O H being the same with an effective ray; which, after two reflections and two refractions, exhibits purple.

Now there being a sufficient number of these drops, it is evident there will be a second rainbow, formed after the like manner as the first.

Thus, according to sir Isaac Newton, in the least refrangible rays, the least angle at which a drop can send effective rays after two reflections, is found by computation to be 50° 57'; and in the most refrangible, the least angle is found 54° 7'.

Suppose, then, O the place of the eye, as before, and POG, POH, to be angles of 50° 57', and 54° 7'; and these angles to be turned about their common side OP; with their other sides OG, OH, they will describe the verges, or borders, of the rainbow CHDG.

For, if G, H be drops placed anywhere in the conical superficies described by OG, OH, and be illuminated by the fun's rays, the angle SG O, being equal to the angle POG, or 50° 57', shall be the least angle in which the then least refrangible rays can, after two reflections, emerge out of the drops; and, therefore, the least refrangible rays shall come most copiously to the eye from the drops in the line O G, and strike the fenes with the deepest violet in that region.

And the angle SHO being equal to POH, 54° 7', shall be the least angle in which the most refrangible rays, after two reflections, can emerge out of the drops; and, therefore, these rays shall come most copiously to the eye from the drops in the line O H, and so strike the fenes with the deepest red in that region.

And, by the same argument, the drops in the region, between G and H, shall strike the fenes with the intermediate colours, in the order which their degrees of refrangibility require; that is, in the progress from G to H, or from the inside of the bow to the outer, in this order: red, orange, yellow, green, blue, indigo, violet.

And since the lines OG, OH may be situated anywhere in the conical surface; what is said of the drops and colours in these lines is to be understood of the drops and colours every where in this superficies.

Thus are formed two bows, an interior and stronger, by one reflection; and an exterior and fainter, by two; the light becoming weaker and weaker by every reflection.

Their colours will lie in a contrary order to one another; the first having the red without, and the purple within; and the second, the purple without, and red within; and so of the rest.

RAINBOW, Artificial. This doctrine of the rainbow is confirmed by an easy experiment; for upon hanging up a glass globe, full of water, in the sun-shine, and viewing it in such a posture as that the rays, which come from the globe to the eye, may, with the sun's rays, include an angle either of 42°, or 50°; if, e.g. the angle be about 42°, the spectator, supposing at O, will see a full red colour in that side of the globe opposite to the sun, as at F. And if that angle be made a little less, supposing by depressing the globe to E, the other colours, yellow, green, and blue, will appear successively, in the same side of the globe, also exceedingly bright.

But if the angle be made about 50°, supposing by raising the globe to G, there will appear a red colour in that side of the globe towards the sun, though somewhat faint; and if the angle be made greater, supposing by raising the globe to H, this red will change successively to the other colours, yellow, green, and blue.

The same thing is observed in letting the globe rest, and raising or depressing the eye so as to make the angle of a just magnitude.
RAINFALL.

magnitude. Newton's Optics, part ii. prop. 9. prob. 4. p. 147, ed. 3.

Rainbow, Dimension of the.—Descartes first determined its diameter by a tentative and indirect method; laying it down, that the magnitude of the bow depends on the degree of refraction of the fluid; and allowing the ratio of the sine of incidence to that of refraction to be in water as 250 to 187.

But Dr. Halley has since, in the Philosophical Transactions, No. 530, given us a simple direct method of determining the diameter of the rainbow from the ratio of refraction of the fluid being given; or, vice versa, the diameter of the rainbow being given, to determine the refractive power of the fluid.

The principles of Dr. Halley's construction for this purpose, illustrated and facilitated by Dr. Morgan, bishop of Ely, will be understood from the following view of them. Let $SN$, in (Plate XVIII. Optics, fig. 5.) be two of the efficacious rays incident upon a drop of rain; these, when refracted to the same point $F$, and thence reflected to $G$, will have the parts within the drop on one side NF, $nF$, equal to those on the other side FG, $Fg$, from the nature of the circle, and because the angles of incidence CFN, $CF_n$, are equal to the angles of reflection CFG, $CF_g$. And since the parts within the drop are equal and alike situated, they will be similarly situated with regard to the drop itself; and, consequently, as the incident rays $SN$, $S_n$, are supposed to be parallel, the emergent rays $GR$, $G_n$, will be also parallel. From $C$, the centre, draw the radius $CN$, $C_n$ $CF$, then will $CNS = CFN$ be the angle of refraction, and the small arc $N_n$ the nacent increment of the angle of incidence $BCN$; and as it measures the angle at the centre $NC_n$, it is double of the angle at the circumference upon the same arc, viz. $N_nC_n$, which is the nacent increment of the angle of refraction $NF_C$. Further, let the ray $SN$ (fig. 6) enter the lower part of the drop, and be twice reflected within the drop at $F$ and $G$; then is the ray $N_F$ equal to the ray $F_G$, and the arc $N_F$ the arc $G_F$. Draw $F_G$ parallel to $F_G$, and it will be the reflected part of some ray $i_n$, whose obliquity to the drop makes it cross the ray $N_F$ in its refraction; then will the part $n_f = f_g$, and the arc $n_f = f_g$, and the small arc $F_f = G_g$. Therefore, $2F_f = (F_f + G_g) = (FG + F - F_G)$; and consequently $N_n = 3F_f$, i.e. the nacent increment of the angle of incidence is equal to three times that of the angle of refraction. After a like manner it may be shown, that after three, four, five, &c. reflections, the increment of the angle of incidence will be four, five, six, &c. times greater than that of the angle of refraction. Hence, in order to find the angle of incidence of an efficacious ray, after a given number of reflections, we are to find an angle whose nacent increment has the same ratio to the increment of its corresponding angle of refraction, generated in the same time, as the given number of reflections $(n)$ increased by unity has to unity; i.e. as $n + 1$ to 1. But these increments are as the tangents of the respective angles directly.

For $AC : AB : : 1 : R$; whence $AC = \frac{1}{R} \times AB$; and $CF : BF : = n + 1 : 1$; therefore $CF = \frac{n + 1}{n} \times BF$; or (putting $n + 1 = m$) $CF = \frac{m}{n} \times BF$; and, on account of the right angle at $F$, $AC^2 = CF = AB^2 - BF^2, i.e. \frac{m}{n} = \frac{AB^2 - m^2}{BF^2}$; therefore, $m^2 BF^2 - BF^2 = \frac{m}{n} = \frac{AB^2 - BF^2}{BF^2}$; and, consequently, $BF = \sqrt{\frac{m^2 - R^2}{m^2 - R^2}}$. Hence, because in the first bow, the ray emerges after one reflection, we have $n = 1, m = 2, m^2 = 4$, and $m^2 - 1 = 3$; therefore, $\sqrt{3} RR : \sqrt{11} - 3R : : AB : BF$ : radius: cofine of the angle of incidence. In the second bow, where there are two reflections, $m^2 - 1 = 8$; whence $\sqrt{8} RR : \sqrt{11} - 3R : : AB : BF$. In the third bow, after three reflections, $m^2 - 1 = 15$; and $\sqrt{15} RR : \sqrt{11} - 3R : : AB$.
RAINBOW.

\[ \times A B : B F, \text{ and so on for any given number of reflections.} \]
Wherefore, supposing the ratio of refraction to be, as Sir Isaac Newton has determined it, viz. as 108 to 81 in the red rays, and as 109 to 81 in the violet rays; we shall have I (the least refrangible rays) = 108, II = 11664; and R = 81, and R \( R = 6561 \), and I \( - R = 5103 \).

\[ \sqrt{3} R = 140.3, \text{ and } \sqrt{1 - R^2} = 71.4 \] : therefore,

\[ \text{As } \sqrt{3} R = 140.3, \text{ whose logarithm is } 2.147045 \]
\[ \text{Is to } \sqrt{1 - R^2} = 71.4 \]
\[ \text{So is radius } \]

\[ 9.706868 \]

Hence the angle of incidence A BF is 59° 23' in the red rays.

Secondly, Having given the angle of incidence, and the ratio of I to R, or of refraction; to find the angle which a ray of light emerging out of a refracting sphere, after a given number of reflections, makes with the axis of vision, or an incident ray; and, consequently, to find the diameter of the rainbow.

The angle of incidence, and the ratio of refraction, being given, the angle of refraction is given; which angle being multiplied by double the number of refractions increased by 2, and double the angle of incidence subtracted from the product, the angle remaining is the angle sought.

In order to find the angle of refraction, say

\[ \text{As } I = 109, \text{ whose logarithm is } 2.033424 \]
\[ \text{Is to } R = 81 \]
\[ \text{So is the line of incidence } 59° 23' \]

\[ 9.934798 \]

To the fine of the angle of refraction 40° 12' 9.80985 2.

Then, making the angle CNF (fig. 9.) = 40° 12', N F will be the refracted ray, which at F is reflected into F G, and at G emerges in G R. Produce the incident and emergent rays S N and R G, till they intersect each other at X, and as C F bisects the angle N F G, it will, if produced, bisect the angle S X R. Then C F N = C X N + F N X; but F N X = C N X - C N F, or C F N; therefore C F N = C X N + C N X - C F N = 2 C N X - C X N; or 80° 24' - 59° 23' = 21° 4' = C X N; therefore 2 C X N = S X R = 42° 2', which is the measure of the angle that the incident and emerging rays, which are the least refrangible, contain with each other. If instead of the ratio 108 to 81, we take that of 109 to 81, we shall find the values of \( \sqrt{3} R R \) and \( \sqrt{1 - R^2} \), such as will give the angle of incidence B C N.

And the arc B N = 58° 40', and the angle S X R = 40° 17', for the most refrangible, or extreme violet rays.

If the ray be twice reflected, viz. at F and G, as in the production of the extreme bow, and emerges at H in the direction H A, intersecting the incident ray S N in V, we may find the angle A Y S thus: produce A H till it meets G X, produced in R; then in the triangle H G R, the external angle H G X = H R G + G H R. But because of equal angles of reflection at F and G, G H R = F G X, therefore H G X = F G X = H R G + G H R = 2 C G F, or C N F. But S X R = 4 C N F = 2 C N X; therefore in the triangle X Y R we have the two internal angles R + X = 6 C N F - 2 C N X = the external angle at Y, viz. A Y N. In this case, to find the angles of incidence and refraction, we have \( \sqrt{8} R R : \sqrt{1 - R^2} : \text{ radius : cosine of the angle of incidence; whence the said angle will be found } 71° 50' = C N X \). And as 108 = 81 : five of 71° 50' : fine of 45° 27' = C N F, the angle of refraction; therefore \( 6 \times 45° 27' - 2 \times 71° 50' = 15° 3' = A Y N \); and, therefore, its complement A Y S = 50° 57'; the angle required for the least refrangible rays.

But for the most refrangible rays, where I : R : 109 : 81, we have the angle of incidence 71° 26', and the angle of refraction 44° 47'; and, therefore, the angle A Y S = 54° 7'. In the same manner the same angles are calculated after three or four reflections.

From the preceding problems we obtain the following results, viz.

I. Rainbow, \{ Red \ 42° 2' \} The spectator's back being turned to the fun.
II. Rainbow, \{ Red \ 50° 57' \} the fun.

If the angle made by a ray, after three or four reflections, were required, and therefore the diameters of the third and fourth rainbow (which are scarcely ever seen, on account of the great diminution of the rays, by so many repeated reflections) they will be found,

III. Rainbow, \{ Red \ 41° 37' \} The spectator's back being turned towards the fun.
IV. Rainbow, \{ Red \ 43° 52' \} the fun.

Dr. Morgan's Diffiliation upon the Rainbow, among the notes upon Rohault's Syntax of Philosophy, part iii. chap. xvii.

Hence, the breadth of the rainbows is easily found: for the greatest demi-diameter of the first bow, i.e. from red to red, being 42° 2', and the leaf, viz. from violet to violet, 40° 17', the breadth of the facia or bow, measured across from red to violet, will be 1° 45'; and the greatest diameter of the second bow being 54° 7', and the leaf 50° 57', the breadth of the facia will be 3° 17'. And hence the distance between the two will be found 8° 55'.

In these measures the fun is only esteemed a point; wherefore, as his diameter is really about 30', or 32', so much must be added to the breadth of each facia or bow, from red to violet, and so much must be subtracted from the distance between them.

This will leave the breadth of the primary bow, 2° 15'; that of the secondary bow, 3° 40'; and the interval between the bows, 6° 25'; which dimensions, deduced by calculation, Sir Isaac Newton affirms us from his own observations, agree very exactly with those found by actual observation in the heavens. Optics, p. 153. ed. 3.

RAINBOW, Particular Phenomena of the. From this theory of the rainbow, all the particular phenomena of it are easily deduced: hence we see why the iris is always of the same breadth; because the intermediate degrees of refrangibility of the rays between red and violet, which are its extreme colours, are always the same. See Apparent Magnitude.

Secondly, Why it is more distinctly terminated on the side of the red than on that of the violet? there being no efficacious rays in the space adjoining to the red drops, i.e. to the space between the bows, whence it terminates abruptly; whereas, in the space on the side of the violet ones, there are some rays emitted to the eye, which, though too feeble to affect it strongly, yet have this effect, that they soften the violet edge insensibly, so that it is difficult to determine precisely where it terminates.

Thirdly, Why the bow shifts its situation as the eye does, and, as the popular phrase has it, 'flies from those who follow it and follows those that fly from it'? the coloured drops being disposed under a certain angle about the axis of vision, which
RAINBOW.

is different in different places: whence also it follows, that every different spectator sees a different bow.

Fourthly, Why the bow is sometimes a larger portion of a circle, sometimes a less: its magnitude depending on the greater or less part of the surface of the cone, above the surface of the earth, at the time of its appearance; and that part being greater or less, as the line of ascent, or axis of vision, is more inclined or oblique to the surface of the earth; which inclination, or obliquity, is greater as the sun is higher: whence also, the higher the sun, always the less the rainbow.

Fifthly, Why the bow never appears when the sun is above a certain altitude: the surface of the cone, in which it should be seen, being lost in the ground, at a little distance from the eye, when the sun is above 42° high.

Sixthly, Why the bow never appears greater than a semi-circle, on a plane? since the bow ever so low, and even in the horizon, the centre of the bow is still in the line of ascent; which, in this case, runs along the earth, and is not at all raised above the surface.

Indeed, if the spectator be placed on a very considerable eminence, and the sun in the horizon, the line of ascent, wherein the centre of the bow is, will be notably raised above the horizon (considering the magnitude of the circle, whereof the bow uses to be a part). Nay, if the eminence be very high, and the rain near, it is possible the bow may be an entire circle.

Seventhly, How the bow may chance to appear inverted, i.e. the concave side be turned upwards? viz. a cloud happening to intercept the rays, and prevent their shining on the upper part of the arch: in which case, only the lower part appearing, the bow will seem as if turned upside down; which, probably, has been the case in several prodigies of this kind, related by authors.

Indeed the bow may appear inverted from another cause: for, if when the sun is 41° 46′ high, his rays fall upon the smooth surface of some spacious lake, in the middle of which a spectator is placed; and if, at the same time, there be rain falling, to which the rays may be reflected from the lake, it will be the same as if the sun shou'd shine below the horizon, and the line of view be extended upwards: thus the surface of the cone, wherein the coloured drops are to be placed, will be wholly above the surface of the earth.

But since the upper part will fall among the unbroken clouds, and only the lower part be found among the drops of rain, the arch will be inverted.

Eighthly, Why the bow sometimes appears inclined? the accurate roundness of the bow depending on its great distance, which prevents us from judging of it exactly; if the sun, which exhibits it, chance to be much nearer, we shall see its irregularities; and if the wind, in that case, drive the rain so that the higher part be farther from the eye than the lower, the bow will appear inclined.

Ninthly, Why the legs of the rainbow sometimes appear unequally distant? if the rain terminate on the side of the spectator, in a plane so inclined to the line of ascent as to make an acute angle on the left hand, and an obtuse angle on the right, the surface of the cone, which determines what drops will appear, will fall upon them in such manner as that those on the left hand will appear farther from the eye than those on the right. For the line of ascent being perpendicular to the plane of the bow, if you suppose two rectangular triangles, a right and left, the cathetus of each to be the line of view, and the base of the semi-diameter of the bow, inclined as above; it is evident, since those angles of the triangles, next the eye, must always be the same (viz. 43° in the inner bow), the basis of the right-hand triangle will, in this case, appear much longer than that of the left.

Dr. Langwith, in the Phil. Tran. N. 375, describes a remarkable rainbow, in which he observed several serics of colours, which increased the bow to a breadth far exceeding what had been determined by calculation. The colours of the primary rainbow, he says, were as usual: under this was an arch of green, and then alternately two arches of reddish-purple, and two of green, and under all a faint appearance of another arch of purple. The order of the colours was, 1. Red, orange, yellow, green, light blue, deep blue, and purple. 2. Light green, dark green, and purple. 3. Green and purple. 4. Green, and faint vanishing purple.

M. Bouguer frequently saw a phenomenon of this kind, when he was upon the mountains of Peru, where the sky is often extremely serene. Similar appearances have been also observed by others. Dr. Pemberton has attempted to explain them by means of the Newtonian doctrine of its easy reflection and refraction; but he goes upon the supposition that the differently-coloured rays have their separate fits, on their arrival at the surface of any medium, without any regard to the thickness of it; whereas it is plain, that, in such a case, all kinds of rays are reflected or transmitted promiscuously. It is most probable that these colours are formed in very minute drops of water or vapour, intermixed with the larger drops, that their formation depends upon the same principle with the colours of thin plates, and that they are similar to those of several kinds of halos. Dr. Pemberton himself observes, that it is most likely that these additional rings of colours are formed in the vapour of the cloud, which the air, being put in motion by the fall of the rain, may carry down along with the large drops. This, he says, may be the reason why these colours appear under the upper part of the bow only, this vapour not descending very low. As a farther confirmation of this, these colours, he observes, are seen strongest when the rain falls from very black clouds, which cause the fiercest rains; by the fall of which the air will be most agitated. Phil. Tran. abr. vol. vi. p. 140. Prieditly on Light and Colours, p. 593.

It has been a subject of controversy among biblical critics, whether the antediluvian atmosphere presented any such phenomenon as a rainbow. The occasion of this debate is a passage in Genesis, ch. ix. 12—17. Mr. Whitehurst, in his "Inquiry into the original State and Formation of the Earth, &c." attempts to establish the probability that the antediluvian atmosphere was so uniformly temperate, as to be subject to no storms, tempests, or rain. The opinion is by no means probable, nor does the above-cited passage warrant any such conclusion. The rainbow was then made the sign or token of God's covenant with Noah, that no such calamity should again take place. 7N denotes a sign or token, and in this sense it is used in the case of Cain, Gen. iv. 15. The mark set upon Cain was, as Shuckford conceives, a sign or token (7N) given to him, that he should be preferred from the evil which he deprecated.

RAINBOW, Lunar. The moon sometimes also exhibits the phenomenon of an iris, or bow, by the refraction of her rays in the drops of rain in the night-time.

Aristotle says, he was the first that ever observed it; and adds, that it never happens, i.e. is never visible, but at the time of the full moon; her light, at other times, being too faint to affect the eye after two refractions, and one reflection.

The lunar iris has all the colours of the solar, very distinct and pleasant; only faint, in comparison of the other; both
both from the different intensity of the rays, and the different disposition of the medium.

In that mentioned, Philosophical Transactions, No. 331, Mr. Thoresby observes, the largets of the arch was not so much less than that of the fun, as the different dimensions of their bodies, and their distances from the earth, should seem to require; but as to its entirenes, and the beauty of its colour, it was admirable. This continued about ten minutes before the interposition of a cloud hindered its observation.

RAINBOW, Marine. The marine or sea-bow is a phenomenon sometimes observed in a much agitated sea; when the wind, sweeping part of the tops of the waves, carries them aloft; so that the fun's rays, falling upon them, are refracted, &c. as in a common shower, and paint the colours of the bow.

F. Bourzes, in the Philosophical Transactions, observes, that the colours of the marine rainbow are less lively, less distinct, and of less duration, than those of the common bow; that there are scarce above two colours distinguishable, a dark yellow on the side next the sun, and a pale green on the opposite side.

But these bows exceed as to number, twenty or thirty being sometimes seen together: they appear at noon-day, and in a position opposite to that of the common bow, i.e. the concave side is turned upwards, as indeed is necessary it should be, from what we have shewn in accounting for the phenomena of the polar bow. A coloured bow is always to be seen in the scattered water of a jet, a broken cascade, and the like, when the fun and the spectator are in proper situations.

To this class of bows may be referred a kind of white or colourless rainbows, which Montezibus, and others, affirm to have been seen at noon-day. M. Mariotte, in his fourth Essay de Phyfiique, says, these bows are formed in mists, as the others are in showers; andadds, that he has seen several, both after fun-rising, and in the night.

The want of colours he attributes to the smallness of the vapours which compose the mift; but we should rather account for it from the exceeding tenacity of the little vehicle of the vapour; which being, in effect, only little watery pellicles floated with air, the rays of light undergo but little refraction in passing out of air into them; too little to separate the differently-coloured rays, &c.

Hence, the rays are reflected from them, compounded as they came, that is, white.

Rohault mentions coloured rainbows on the graves, formed by the refractions of the sun's rays in the morning dew. Trait. de Phyf.

Rainbows have been also produced by the reflection of the sun from a river; and in the Philosophical Transactions, vol. 1. p. 294. we have an account of a rainbow, which must have been formed by the exhalations from the city of London, when the sun had been yet twenty minutes, and consequently the centre of the bow was above the horizon. The colours were the same as in the common rainbow, but fainter.

The best way of forming a resemblance of a rainbow is to gather a number of small solid glass balls, or a number of small glass bubbles full of water, upon a dark board, and to present the board thus furnished to the sun at proper inclination, which experience easily finds, whilst you turn your back to the sun, and look at the board.

RAINFELDEN, in Geography, a town of Austria; 2 miles N. of Hainfelden.

RAINHAM, a township of Norfolk county, in Upper Canada; being the first township fronting on lake Erie, west of the grand river. Lands.

RAINSBRIA, a town of Germany, in the margraviate of Anspach; 3 miles N. of Creglingen.

RAINY LAKE. See Le Plue.

RAJDE, a town of Hindooftan, in Malwa; 30 miles E. of Tanjila.

RAJORA, a town of Hindooftan, in Dowlatabad; 18 miles W. N.W. of Kondur.—Alfo, a town of Bengal; 65 miles N. of Dacca.

RAIPOUR, a town of Hindooftan, in ladybore; 35 miles N.W. of Jumlaoo.

RAJOWLY, a town of Hindooftan, in Bahar; 30 miles S. of Bahar.

RAJPOOTANA, a country of the Rajpoots, generally denoting Agimere (which fea), and the original country of the founder of the Mahatta state, whose rulers, about half a century ago, aspired at universal empire in Hindooftan; but they have been reduced to their present low state, by the depredations of Mahatta detachments, which, being composed of light horfe, and accustomed to separate into small parties, have, by their defolatory movements, at once spread defolation, and eluded the attacks of the inhabitants. This is the fact with regard to the open parts of Rajpootana; the mountainous parts remaining free from their incursions.

Rajpootana was divided into three great principalities, under the names of Oudipour, Joodpur, and Amber (or Amere), now better known by that of Jefingpur, or Jyeneagur. (See each respectively.) In Aedar's division of the empire, these principalities were classed as belonging to the fouban of Agimere, sometimes called Marwar. It is not easy to assign the precise limits and dimensions of these principalities, which occupy the space between the western confines of Agra and the north-east part of Guzerat, and during the fandy defert (or Regifhan) and Malwa; that is, an extent of 350 British miles from N.E. to S.W., and 200 broad in the widely part. Jyeneagur or Jyeepour lies to the N.E., Oudipour to the S.W., and Joodpur to the N.W., bordering angularly on the other two. Pere Wendell's MS. cited by Rennell, fates the revenues of Oudipour at 10 lacks of rupees, Marwar at 45, and Jyeneagur at 40, per annum, in the year 1779. The whole income of the fouban of Agimere, in the time of Aedar, appears to have been only about 75 lacks. Aaurungzebe is faid to have doubled the land-tax on the Rajpoots, and accordingly in Mr. Fraher's account, Agimere is fated at 163 lacks of rupees. The two former, &c. Oudipour and Marwar, are very mountainous, with a fandy foil in the vallies; the latter is the moft fertile, and was, about the middle of the latter century, in a high state of improvement, under the government of the celebrated rajah Jyefing, or Jeffing, who founded the new capital of Jyeepour, whence the name of the province was changed to that of the capital. Jyeepour was a place of great wealth and commerce in 1779, being the entrepot of the principal part of the goods that are brought from every quarter of India. The rajah built an observatory in his capital; but the confusions that have fo long prevailed in this province, must have greatly reduced the wealth and importance of the capital. Sindia, as Rennell informs us, received the tribute of all the three Rajpoot provinces, and converted it to his use; and he also made considerable conquests in them, particularly in Jyeneagur. In early times the whole Rajpootana probably constituted one entire kingdom, or empire, under the rana or prince of Oudipour, the head of the Rajpootflate; the antiquity of whose house may be inferred from the name
RAI

RAJPAOTS, the inhabitants of Rajpoutana, which see. They were not confined entirely to the foubah of Agimere; as some inferior tribes of them are settled in Bundelcund, and in Garry-Mandella. Others, according to Thevenot, are settled in Moultan; and indeed he represents Moultan as the original country of the Kuttries, from whom the Rajpouts sprung.

The Kuttries or Catries, who formed a particular sect of Hindoos at Moultan, were the Catheri of Diodorus, and the Cathel of Arrian, with whom Alexander carried on war, on the borders of the Mallis. The Rajpouts are ordinarily divided into two tribes or classes, viz. those of Rathore, and Chohra or Sealodya. Marwar, or the N.W. division of Agimere, is the proper country of the former; and Meywar, or Oudipour, of the latter. The Rathore tribe were originally the most numerous of the two; and it has been said by colonel Dow, among others, that the Maharatta chiefs had their origin from the Rathore tribe: and in proof of this he has been alleged, that the etymology of the name Maharatta has been deduced from Rathore, prefixing to it "maha," or great. (See MAHARATTA.) The Rajpouts are represented by Thevenot as having spread from Moultan, their proper country, over all the Indies. Diodorus Siculus distinguishes them by the custom of their women burning themselves alive, on the funeral piles of their husbands: which is indeed a custom among them, as well as some other Hindoos, at this day. Remiell.

RAJOUR, a town of Bengal, on the bank of the Ganges; 10 miles N.N.E. of Currauckdeagh. RAISE, in the Tagore, is used for working. See RAISING.

RAISE is likewise used for placing a horse's head right, and making him carry well, and hindering him to carry low, or to arm himself.

RAISE Tacks and Shovels, in Sea Language, the order to let them go in the article of tacking, that the falls may be fet on the contrary tack they were on before.

RAISEN, in Geography, a town of Hindooistan, in Malwa; 15 miles S. of Biffin. N. lat. 23° 16'. E. long. 77° 49'.

RAISER, in Building, a board set on edge under the forfide of a step, a flaire, &c. See STAIR, &c.

RAISIN, in Geography, a river of America, which runs into lake Michigan, N. lat. 43° 12'. W. long. 85° 42'.—Also, a river of America, which runs into lake Erie, N. lat. 43° 20'. W. long. 82° 55'.

RAISEN Island, a small island in lake St. Francis. N. lat. 43° 6'. W. long. 74° 57'.

RAISES, or RAIFEN, Market, a small market-town in the eall division of the wapentake of Walshcroft, parts of Lindley, and county of Lincoln, England, is situated on the banks of the river Raizen, whence it derives its name, at the distance of 15 miles N.E. from Lincoln, and 140 miles N.W. from London. According to the population returns of 1811, it contains 164 houses, and 964 inhabitants. Here is a weekly market on Thursday, and there are fairs every alternate Tuesday, after Palm Sunday, and on the 25th of September. The church is an ancient structure, and is remarkable for the peculiar form of the upper windows in its embattled tower. These have a pointed arch, divided into two pointed lights, and a quatrefoil head. Up the centre runs a strong mullion, crossed by a transom, terminating at the imposts, as happens in the church of Yarborough, near Louth, which renders it probable that both edifices were erected by the same architect. The living is a vicarage in the gift of the crown; and by the endowment the vicar is entitled to the mutual tythe of ale. Besides the church, there are in Raizen a Roman Catholic chapel, and a Methodists' meeting-house; also a free-school, and an hospital for poor old men.

At a short distance from Market-Raizen, are the villages of Middle and West Raizen. Middle Raizen was formerly divided into two parishes, called Drax and Topholm, but these are now united. At Topholm stood an abbey of Premonstratensian canons, which was founded in the reign of Henry II., by Alan de Neville, and his brother Gilbert. Previous to the dissolution, it was inhabited by nine monks, whose annual income, according to Speed, amounted to 119l. 2s. 8d. The church is a small, but ancient building, consisting of a nave and chancel, which are separated by elegant screen work, beneath a pointed arch, supported by circular columns. The nave appears to have had side-aisles, as the pillars and pointed arches stand in relief from the present wall.

The principal seats in this vicinity are Willingham-houfe, a seat of the Boucherett family; and Thurgundy, the property of lord Middleton. The latter anciently belonged to the Willoughbys. The house is situated on an eminence, commanding an extensive view over the vale to Swinhope, and is surrounded by pleasure-grounds, finely varied by wood and lawn. Beauties of England and Wales, vol. ix. by John Brin, 1807.

RAISING, in the Mange, one of the three actions of a horse's legs; the other two being the flay, and the tread. The raising or lifting up of his legs in capricious curves, &c. is esteemed good, if he perform it hardly, and with safety, not crossing his legs, nor carrying his feet too much out or in; yet bending his knees as much as is needful.

RAISING the Land, in Sea Language. See Laying the Land.

RAISING a Purchafe, denotes the act of disposing of certain instruments or machines in such a manner, as that, by their mutual efforts, they may produce a mechanical force suffिient
RAI

RAISINS, grapes prepared by drying them in the sun, or in the air; to fit them for keeping, and for some medicinal purposes.

Of these there are various kinds: as, raisins of Damascus, thus called from the capital city of Syria, in the neighbourhood of which they are cultivated. They are much used in the composition of pithains, together with jujubes and dates; they are brought flat, and seeded, of the size of the thumb; whence it is easy judging of the extraordinary bulk of the grape, when fresh. Travellers tell us of bunches weighing twenty-five pounds. Their taste is faintish and disagreeable.

Raisins of the fun are a kind of raisins brought from Spain, of a reddish or blueish colour, seeded, and very agreeable to eat.

There are various other sorts, denominated either from the place where they grow, or the kind of grape, &c. as raisins of Calabria, Muscadine raisins, &c.

The finest and best raisins are those called in some places Damacus and jube raisins. These are the fruit of the vitis Damascena, and are distinguishable from the others by their larger size and figure; they are flat, and wrinkled on the surface; soft and juicy within, near an inch long, and semipellucid, when held against a good light; they have a sweet, agreeable, and vinous taste; and when fresh, and growing on the bunch, are of the size and shape of the large olive.

The common raisins are the fruit of several species of grape, which are better or worse, according as they have been more or less carefully cured. The raisins of the fun, or jar-raisins, so called, because they are imported in jars, are all dried by the heat of the sun; and these are the sorts used in medicine.

The common way for drying grapes for raisins is to tie two or three bunches of them firmly together, while yet on the vine, and dip them into a hot laxative of wood-ashes, with a little olive oil in it. This dispels them to shrink and wrinkle; and after this they are left on the vine three or four days, separated on sticks in an horizontal situation, and then dried in the sun at leisure, after being cut from the tree. Some raisins are dried by the heat of an oven; and the difference between these and such as are dried in the sun, is obvious; the latter are sweet and pleasant, but the former have a latent acidity with the sweetness, that renders them much less agreeable. See Currants.

All the kinds of raisins have much the same virtues; they are nutritive and balsamic, but they are very subject to fermentation with juices of any kind; and hence, when eaten immoderately, they often bring on colics. They are allowed to be antiseptic, and are given in cafes where the humours are too thick and viscid, and they are said to be very good in nephritic complaints; they are, however, too familiar in our foods, to be much regarded at present as a medicine. They are an ingredient, indeed, in our phlegmatic decoctions, and in some other medicines of that intention; in which cases, as also in others where aromaticity is not required of them, they should have the bones carefully taken out. The are used in some compositions rather with an intent of taking off the nauseous taste of other ingredients, and for obtunding their acrimony, than of doing any extraordinary service themselves.

RAISIN-Brandy, a name given by our distillers to a very clean and pure spirit, procured from raisins fermented only with water. Thus treated, they yield a spirit, scarce at all distinguishable from some of the wine-spirits; for there are as many kinds of wine-spirits as there are of grapes. The sooner the operation of distilling is performed in this case, the nearer will be the resemblance of the wine-spirit; that is, there will be most of this flavour in the spirit, when as much as can be of the oil is thrown up with a galloping heat.

The distillers are very fond of the wine-spirit, with which they hide and disguise the taste of their nauseous malt, and other spirits; and in defect of that spirit, this of raisins, made in this coarse manner, will go almost as far. It is indeed surprising how extensive the use of these flavouring spirits is, ten gallons of raisin-spirit, or somewhat less of the wine-spirit, being often sufficient for a whole pipe of malt-spirit, to take off its native flavour, and give it an agreeable visonity. It is no wonder, therefore, that the distillers, and ordinary rectifiers, are so fond of this, as it is a good cloak for their defects, and the imperfections of their processes.

When raisin-brandy is intended for common use, the fire should be kept lower and more regular in the distillation; and the spirit, though it hath less of the high flavour of the grape, will be more pleasant and more pure.

RAISIN-Wine. See Wine.

RAIT, in Rural Economy, a term used to signify the process or operation of dissipated the tap of vegetables, by exposure to moisture, or the influence of the atmosphere. It is mostly applied to hemp, flax, or other similar substances, and sometimes to hay, when it has been much exposed to alternations of wet and dry weather.

When the process is performed by means of water, as is mostly the case with hemp, frequently but not always with flax, and occasionally with other articles of the same nature, it is usually denominated water-rating, and the article is said to be water-rated; but where it is effected by exposure to the air, upon the ground, when spread out, it is generally called ground-rating, and the substance is said to be ground-rated. In the performance of these operations or processes with hemp, flax, and such like substances, there is great nicety and attention required to see that they are carried to a sufficient length, without going too far, to as to injure the textures of the substances in their cortical parts. This may probably be accomplished with the greatest certainty by the frequent examination of the materials themselves; keeping them perfectly under the water in the former case, and frequently turned with new surfaces to the atmosphere in the latter, never having the grasy surface on which they are spread out of too great a length. The effects of heavy rains, when long continued, melt likewise be carefully attended to in latter instance. See Flax, Hemp, and Water-rating.

RAITAPOUR, in Geography, a town of Hindoostan, in the circuit of Rajamundry; 12 miles N. of Rajamundry.

RAITCH, in Rural Economy, a term signifying a line or lift of white, down the face of a horse. It is a very common mark in the faces of horses.

RAITENBACH, in Geography, a town of Germany, in the principality of Cumbach; 8 miles E. N. E. of Wosfield. Also, a town of Bavaria, in the bishopric of Aichstadt; 8 miles N. of Aichstadt.

RAITENBURG, a town of the duchy of Carniola; 3 miles N. of Rudolfsleworth.

RATING, GROUND, in Rural Economy, that method of rating or accomplishing the separation of the barks or coverings of the stems of flax, hemp, and other similar plants, by
RAK

by means of spreading them out in a thin manner upon clove grassy surfaces, instead of putting them into ponds or pools of stagnant water, in order that they may be exposed to the atmosphere. It is occasionally employed for flax and other small flaked plants, but seldom or never for hemp and those which have large ones. It is a practice which stands in need of considerable attention and management. See Rait.

RAJUAPUR, in Geography, a town of Mocam-pour; 18 miles S. of Bergao.

RAJASTHAN, in Hindoo Mythological History, one of the saints or sages included in the denomination of Menus. Rajasthana is said to have been the son of Agni, the regent of fire, also called Pavana, (which see), and Menu.

RAJYA, in Geography, a town of Hindooistan, in Bahar; 20 miles E.S.E. of Bahar.

RAKAPORAH, a town of Hindooistan, in the circar of Jufpourt; 10 miles N.E. of Odeypour.

RAKAS, a town of Transylvania, on the Altar; 16 miles N.W. of Crenstad.

RAK, in Agriculture, a tool of the toothed kind, made use of for many purposes of husbandry, as for collecting together hay, corn, flubble, roots, leaves, and other similar sorts of materials. It is a very useful and convenient kind of tool in all such intentions. There are many descriptions of this sort of implement.

RAKE, Bean-Stubble, a tool of the rake kind, constructed for the purpose of clearing bean-stubbles. It is employed on some farms in Essex, as by Mr. Ketcher, at Burnham, where it is found to be well adapted to this use, and to do its work in a perfect manner. The head, which is seven feet eight inches in length, is formed with a very slight curve, having teeth set in it in rather a close manner, which are one foot and a half in length, bending or curving a little forwards at the points. It is attached by a frame to the axle of the wheels, which is three feet two inches long; and the wheels are two feet six inches in their diameter. The hooks and shafts for the horse are four feet in length. This is a very simple construction of this nature, and one which is capable of easy application. The teeth should be made strong, whether they are of wood or iron. This is an implement which wants to be better known in other districts.

RAKE, Corn, a large strong rake, made use of in different districts for bringing together the mown grain crops. It is sometimes constructed with wooden teeth, but a better mode is to have them of iron, being a little bent forward, having the length of seven or eight inches. As it requires much exertion to perform the work with them, they should always be made as light as possible, to fo as to have sufficient power to perform the work. It has been rated by Mr. Somerville, in his Agricultural Survey of the District of Eskit Lothian, that though the common hay-rake is mostly used there, a different kind for grain has been partially tried, and found to answer the purpose much better. In this, the length of the head is from ten to fifteen feet, the handle about seven feet, with a piece of wood across the end of it, by which it is drawn by two men. The teeth are of wood or iron; the lat is the belt, as well as the moat durable, and are a little bent forward at the point, which gives them the power of retaining and carrying the ears along with them, much better than they would otherwise do. To make clean work, especially if the ridges are gathered, the field is raked across; in that way, everything is taken up. But when it is preferred to draw the rake in the direction of the ridges, it may be considerably improved, by cutting the head into two or three lengths, and joining them with hinges, which will allow it to bend and accommodate itself to the curvature of the ridges. The advantage of this kind of rake has been found considerable, even in cases where every possible attention has been paid to the cutting of the crop; but it frequently happens, that, owing to the dampness, greenness of the straw, or a foul grassy bottom, it is necessary to leave the crop unbound for a day or two, during which, if it be overtaken by a high wind, much of it will be scattered and lost, unless considerable pains are taken to gather it by hand-raking, or otherwise. Where the long rake is used for that purpose, the expense will in no instance, he thinks, exceed four-pence sterling per acre. An experiment made on a field of 30 acres, will convey some idea of the benefit that may be derived from the use of that instrument. The field was in barley, and the rakings, when threshed, yielded

Which deducted from 14l. 5s., leaves a profit of 13l. 3s. 2d. sterlilng. It is necessary to observe, that about ten acres of the field were left unbound, and a good deal disordered by a high wind; but as considerable pains were taken in the binding, the proportion obtained from these ten acres did not greatly exceed what was got from the rest of the field, the whole of which was cut with a great deal of care.

But though this mode of working the rake affords considerable profit and advantage, they would be a great deal more, by having recourse to horses in the draught of them. One horse in each would do as much labour as several men, in a given time; and by having shafts and low wheels fixed to the tool, it could be readily adapted to this method of being wrought.

RAKE, Couching, a large fort of strong horse-rake, with long round tines or teeth, crooked or bent forward in a gentle manner, and placed about two inches distant from each other; and a small beam in the middle, with side pieces, and an apparatus for attaching the horse to it. It is found very useful in bringing together the roots of couch, and other weeds, in order to their being burnt, or carried off the land, and in other ways destroyed. See Couching-Rake, Quitch-Rake, and Rake-Twedid.

RAKE, Dew, a fort of large rake, or hand drag, so named from being used before the dew is off the ground, or other fort of harvest work can be begun. It is a powerful convenient fort of implement for harvest work.

RAKE, Garden, a well-known fort of tool for raking the ground, as well as for putting in feeds, &c. In order to suit every kind of gardening work with rakes, there should be three or four different sizes, from about six to eighteen inches long in the head, having handles from six to eight feet in length, and the heads toothed with iron teeth two or three inches long, being placed from one to two inches asunder, according to their respective sizes. The first or largest rake should have the head about fifteen to eighteen inches long, the teeth three inches, and placed two inches asunder, which is proper for raking stubborn or rough dug ground, and for putting in large kinds of feeds, raking off large weeds after hoeing, and many other purposes.
It may be noticed, that all these sorts of rakes are constructed both with wooden heads and iron teeth, and with the heads and teeth wholly of iron in both; of which the teeth are generally flattened, the back edge rounded off, and narrowing gradually to the point; the other upright, and placed on the heads edgewise acroos, with the back edge outward, and with the points all inclining very moderately inward, in a regular manner: the wooden-headed rakes having each end of the head hooped with a thin flat iron ring, to secure it from splitting. It is very seldom that wooden teeth are employed in this way, or for these uses.

Those of the first fort are generally the lightest and cheapest, being proper for any kind of garden raking; but the latter, or iron-headed rakes, when made neat and as light as possible, with the teeth well set, in a proper position, and firmly fastened, are equally proper, and in some cases preferable, as in some wettish or moist soils, as not being liable to clog so much as wooden rakes, and at the same time more durable. They are, however, more proper for middling and small rakes than for large ones; as, in strong raking, the teeth are more liable to get loose than in the wooden-headed rakes. Both the forms, in their different sizes, are sold at the principal ironmongers' shops, both with and without handles.

And rakes having the heads, teeth, and handles, wholly of wood, may sometimes be used for particular purposes; such as raking in light kinds of kitchen-garden seeds in light ground, and taking off large hock-up weeds in wide clear spaces, raking up swaths of mowed short grass before the sweepers, also fallen leaves of trees in autumn, and clippings of hedges, &c. as well as several other uses about the pleasure-garden.

Rake, Hay, a well-known tool, with short teeth and a long handle, made use of in making hay. It is usually made of willow, or some other similar wood, in order that it may be light and handy. The teeth should not be too long, as, when that is the case, they are apt to hang and pull among the flubs of the grass in raking with them, and thereby retard the operation, as well as cause much fatigue to the labourer.

Different improvements have been made on this implement. A late useful alteration is the making the teeth to screw into the head, and fasten with screw nuts, by which the inconvenience of their dropping out in dry seasons is obviated. It has been observed, that with the spring-toothed rake, the operator is capable of performing much more work than by the common one. They are likewise capable of being conveniently made use of for both hay and corn. They were originally made and sold by Mr. Cort, of Lice-eller.

Another improvement is mentioned in Young's Agricultural Report of Norfolk, which is the addition of wheels. It is stated, that the "hand wheel-rake" of Fig. is an excellent implement for both hay and corn: it is to answer the purpose of the common hay-rake, and is about four feet long in the rake; and the two wheels, of nine inches diameter, so fixed, that the teeth are kept in any posture, at the will of the holder.

In some parts of Lancashire, they make use of a large horse-rake for collecting the hay together, and raking it up from the ground, which is found to be highly convenient and beneficial; as one horse, in one of these rakes, will perform as much labour as a great number of men, in a certain space of time; and besides the expedition, the work is considerably better done, in consequence of the greater weight of the implement.

The head of the rake has something of a large easy half circular form, into which two strong pieces of wood are fastened, which constitute the shafts for the horse. There are two low wheels behind, and the head has long teeth, curving a little forward, fixed into it at two or three inches from one another. The teeth may be made either of wood or iron, and should have considerable strength. The whole has no very great weight, though it must obviously be considerably heavier than the common rake; which is found of much advantage in its working, as has been hinted at above.

Rake, Horse, an implement used in Norfolk and Suffolk, on the large and middling-sized farms, and, from its great utility, extending itself into other districts. It is employed for barley and oat crops, being drawn by a horse. And it has been stated by Mr. Young, that one man and a horse, driven by means of a line or rein, are capable of clearing from twenty to thirty acres, in a moderate day's work; the grain being deposited in regular rows or lines across the field, by simply lifting up the tool, and dropping it from the teeth, without the horse being flopped. It cult from four to five pounds.

Figures of it may be seen in the above Agricultural Reports. Horses have now been employed for working other forms of rakes, and found of great advantage, as has been already seen.

Rake, Horse Stubble, a large heavy kind of horse-rake, having strong iron teeth, fourteen or fifteen inches in length, placed at five or six inches from each other, and a beam four inches square, and eight or ten feet in length. To draw it, two horses are mately made use of, by which it is capable of clearing a considerable quantity of stubble in a short time. Tools of this fort are highly useful on corn farms, for collecting this useful material, and should be much more frequently employed than they are at present.

Rake, Twitch, a large horse-rake, employed in certain cases for clearing lands from the roots of couch, twitch, or quitch-gras, as well as those of other sorts. It is constructed in different ways, as with one or two rows of teeth; but the latter is probably the best method, as by placing one row opposite the intervals of the other, it must be rendered a very effective tool.

Rake of a Ship, is so much over her hull as overhangs at both ends of her keel.

That part of it which was before, is called the rake forward-on; and that part which is at the setting on of the stern-poll, is called her rake-ofs, or afterward-on.

When a ship hath but a small rake forward-on, but is built with her stern too straight up, she is called bluff-headed.

Rake of the Rudder, is the hindmost part of it.

Rake, among Hunters. See Rag.

Rake, in the Manege. A horse rakes, when being shoulder-splaid, or having brained his fore-quarter, he goes so lame, that he drags one of his fore-legs in a semi-cirle; which
which is more apparent when he trots, than when he paces.

RAKE, or Vein, in Geology, the most common repository of metallic ores. These veins intersect mountains nearly vertically, or more or less inclined from the perpendicular. They are filled with ores, intermixed with the peculiar minerals accompanying each kind of metal. They vary from a few inches to some feet or yards in width, and extend to a very considerable depth and distance. The upper side of the vein is provincially called the banger, and the lower side the ledger; and the inclination from the perpendicular is called the back of the vein. For a particular account of the structure and formation of veins, see Veins, Metallic.

RAKEL, in Geography, a town of Dobruzii Tartary, on the Danube, 15 miles W. of Haski.

RAKESBURG, or Rakelburg, a town of the duchy of Sturia, situated on an island in the Muehr; the inhabitants of which carry on a considerable trade with Hungary and Croatia; 36 miles S.E. of Gratz. N. lat. 46° 45'. E. long. 15° 37'.

Raking signifies sloping or winding, as when a wall is not built up right or straight.

Raking, in Agriculture, the operation of performing work with a rake. It is a sort of work that requires little art or trouble in its execution; but whether performed with the common or horse-rakes, it should always be done in an effectual manner. In the buskins of haymaking, raking clean raking not only affords a seat for the appearance, but, over the greatest extent of surface, a considerable saving of hay. See Hay-Making.

In raking hay lands, where horses are employed, some degree of care is necessary in directing the work, and driving the animals, in order that no inconvenience of delay may be experienced, and that every part of the land may be gone over in the most regular manner. Small boys may serve to direct the horses by riding upon them, and have faving made in that way.

In raking cut corn crops with horse-rakes, especially those of oats and barley, it is sometimes the best method to proceed in a cross direction of the ridges, drawing up the produce into long rows at suitable distances; the horses being driven by the men, who know the management of the handles of the rake, by means of whip reins brought from the horses to the flits of the implements. It seldom happens that so good work can be made in going the length ways of the lands, particularly where they are much rounded, and of a small size in breadth, as the tools will not fit well to their rounded form, unless they are constructed in separate parts in their heads, so as to admit of motion by means of joints. In this mode of raking, the corn may sometimes be readily tied up into sheaves.

But in the raking of stubbles, it is more usual to pass in the direction of the ridges, though the contrary method is not unfrequently had recourse to. In these cases, as well as in the others, the fluffy grains or stubbles are always brought together into lines or rows, in order to be more readily taken up by the carts either bound or unbound.

In the raking of the roots of weeds together upon lands, it is commonly the best practice to perform the work in both directions; as, by such means, the whole of them may be laid hold of in a more complete and effectual manner than could otherwise be done. See Rake.

Raking, in Gardening, a necessary operation in the garden, to break the surface of the soil small, and render it fine for the reception of particular sorts of small seeds and plants, previous to sowing and planting, as well as to render it neat and even to the eye. It is also employed in raking in feeds, as being an expeditious mode of covering them in. In all kinds of small feeds, or hardy plants, the ground being dry, &c. and the surface remaining rough after the spade, the feed is sown, and then raked in with an even hand, once or twice in a place, as a back and a fore stroke; or more as may be necessary.

And this operation is useful also among growing plants, that land difficult enough to admit the rake, particularly where the surface is inclined to bind, or where numerous small feed-weeds appear, as it loosens the soil, and retards the growth of the weeds, and promotes the growth of the young plants. It is also good culture at particular feasons, to annoy flugs, especially in kitchens-gardens, to rake between the rows of small plants in autumn and winter, &c. The raking of the beds, borders, and other compartments of pleasure-grounds, now and then, smooth and even, like-wise gives an air of culture and neatness to the whole.

It may be observed, that this sort of work should generally be performed in dry weather, and when the ground is also moderately dry; as when done in rainy weather, or when the ground is very moist and cloggy, the surface is apt to cake and bind hard. This should be well attended to in fowing feeds. Rough dung ground does not rake well, when it is become very dry at top, especially if it was dug wet, and suffered to lie till the clods have become very dry and hard; in which case it will not rake well, until mollowed or pulverized by a shower of rain. But common light garden ground generally rakes well when fresh dung, perhaps the same day, or day after at the first thin, before it is dried too much by the sun and wind, or rendered wet by rain, &c. The operation should, however, be performed when the ground is in such order as the clods will readily break and fall to pieces under the rake, without clogging much to it, or the mould become even without running into lumps.

Raking of a Horse, is the drawing his ordure with the hand out of the fundament, when he is collitve, and cannot dung. In order to do this, the hand must be moistened with stall-lad-oil, or butter.

Raking a Ship, is the act of cannonading a ship on the stern or head, so that the balls shall fire the whole length of her decks, which is one of the most dangerous incidents that can happen in a naval action, so much so, that the men are ordered to lie down at their quarters. This is frequently called raking fore and aft, being the same with what is called enfilading by engineers. See Entrance.

Raking-Keel. See Keel.

Raking-Table, or Raked Table, among Architects, a member hollowed in the figure of a pedestal, or elsewise. See CAVETTO, and SCOTIA.

RAKIEL, in Geography. See RAICH-KORI.

RAKONITZ, or RAKONITZ, a town of Bohemia, and capital of a circle of the same name, which is mountainous and covered with forests, but fertile in corn, and affording some excellent horses. It was made a royal town in 1558. It is celebrated for its beer, which is the principal article of its commerce; 22 miles W. of Prague. N. lat. 50° 5'. E. long. 13° 37'.

RAKORA, a town of European Turkey, in Bulgaria; 40 miles S.S.E. of Viddin.

RAKOW, or RACOW, a town of Austrian Poland, in the palatinate of Sandomirz, formerly populous; the Societians had a college and printing-house here, but were expelled in 1643; 40 miles W. of Sandomirz. See RACOW.

RAKOWENA, a harbour on the coast of Kamptchatka, in Awakla bay; three miles long, and one and a half
h alf broad, with water from thirteen to three fathoms, and a bar at its entrance; it runs at first in a south-ea~ and afterwards in an easterly direction; three miles S. of St. Peter and St. Paul.

RAKSHA, in Hindoo Mythology, a species of malignant demon, of whom great ufe is made in their epic machinery and popular tales. They are of various shapes and colours, and Suppoed to be animated by the fouls of bad men of earlier existence, receiving punishment in these forms as enemies to the gods, and obstructors of their beneficent intentions towards mankind. Another class of these evil genii comprehends thofe called Yaksha. Rakshasa and Yakshas are the plurals, and Rakshini and Yakshini the feminine; for these evil doings are not confined to fex. Ravana, the giant king of Lanka, or Ceylon, who oppofed Rama, aided by the gods in the invasion of his kingdom, is fometimes called the lord of Rakshasas. See RAVENA.

RAKULSKOI, in Geography, a town of Russia, in the province of Ulting, on the Dvina; 20 miles N. of Krafno-bork.

RALEGH, Sir Walter, in Biography, a dillignified character in the reigns of queen Elizabeth and James I., was fecond fon of a fome gentleman of an ancient family in Devonshire. Few names, fays Sir Walter's biographer, Mr. Cayley, vary fo much in the manner of writing it. By Sir Robert Naunton and lord Bacon it is written Ralegh; in fome old deeds the orthography is Rale or Ralga; while king James, Hooker, and other respectable writers, adopt the mode of spelling which is still common in this country, viz. Raleigh; but the original letters of Sir Walter himfelf, wherever the signature is preferred, have Raleigh, and on that account we choose to adopt it in this work. Sir Walter, of whom we are treating, was born at a farm called Hayes, in that part of Devonshire that borders on the sea, in the year 1552. By his mother he was related to thofe famous knights, Sir John, Sir Humphrey, and Sir Adrian Gilbert.

After he had received the uffual education, he was fent to Oriel college, Oxford, where he dillignified himfelf by a proficiency in learning far beyond his age; but the active disposition and martial ardour with which he was endow'd, foon put an end to his learned career. About the year 1569, he, in company with many young gentlemen of the beft families in the country, went into France, as well to instruf theiufelves in the art of warfare, as to affift the Protestant in that kingdom, who were then grievously oppreffed. In this school he was employed five or fix years, but by what means he efcape the horrible machinery of Paris, and the provinces, on the famous St. Bartholomew's day, we have no knowledge. He returned to England in 1575, and it fhould feem he immediately became a resident in the Middle Temple, whence a commendatory poem of his, prefixed to a work of George Gafcoigne's, is dated in 1576. That he was not a fludent in the law, at this time, he has himfelf declared, and he shortly after pafled into the Netherlands, where he ferved fome time againft the Spaniards. In this, and other transafions of the fame kind, he followed the fashion of the times. France and the Netherlands were in thofe days the fchool of Mars; to which all were obliged to refer who meant to purfue the fortune of arms. Many young men returned to their native country ruined in their fortunes, their conftitution, and morals; but Raleigh had made a good ufe of his time, gained a large fock of ufeful knowledge, and was fo completely polish'd in his manner of address, that he was now confidered as one of the beft bred and moft accomplished gentlemen in England.

On his return in 1578, he found his half-brother, Sir Humphrey Gilbert, engaged in a defign of making dico-
Richard Greenville, Raleigh's relation. During this voyage they took possession of that tract of country which has been so famous, by the name bestowed upon it by Queen Elizabeth, and not given, as it has been generally supposed, by Raleigh, of Virginia. After expending a large sum in repeated attempts to repair the misfortunes that had happened to the newly established colony, he affixed over his patent to a company, referring to himself only a portion of the expected gold and silver ore. This enterprise probably made England first acquainted with tobacco, and also conferred upon it the much greater benefit of introducing the culture of the potato, first practiced on Raleigh's estate in Ireland.

About this time he was chosen knight of the hire for the county of Devon, and very soon after the queen conferred upon him the honour of knighthood, an honour which he did not render cheap by prostituting it. In the year 1589 he fitted out another fleet for Virginia, in which he had good success, his ships, in their return, taking a prize worth 50,000l. He was likewise concerned in captain Davis's undertaking for the discovery of the north-west passage, on which account a prominence in Davis's criticisms was called Mount Raleigh. For these public-spirited and expensive projects, the queen was pleased to make him some profitable grants; particularly two, the first giving him authority to licence the retailers of wine throughout the kingdom, and the other of a fegnity in Ireland, consisting of twelve thousand acres, which he planted at his own expense, and many years after sold to Richard Boyle, the first earl of Cork. In 1586 he was appointed rear-admiral of the duchies of Cornwall and Exeter, and lord-warden of the Flannaries; and so high did he seem rising in the queen's favour, that the favourite minifter, the earl of Leicester, took the alarm, and brought forward the earl of Essex as his competitor. But her majesty's partiality was fully justified; it was, in this instance, extended to a man, who at all times purposed whatever appeared to him conducive to the public good, how little soever it turned to his private advantage. "With justice, therefore," says Campbell, "was the wife queen Elizabeth liberal to such a man, who, whatever he received from her bounty with one hand, bestowed it immediately in acts glorious to the nation with the other." In the year preceding the attempt of the famous Spanish armada, sir Walter was captain in the queen's guard, and her lieutenant-general for Cornwall. In the latter capacity he was active in disciplining the militia of the country; and he was one of the council of war to whom the consideration of the whole means of opposing the dangers of that momentous period was committed. When the armada appeared in the Channel, he was one of the gallant volunteers who nobly joined the English fleet with ships of their own, and had a share in the defeat of the enemy. In 1589 he was among those who accompanied the expelled king of Portugal in his attempt to reunite himself. The queen showed her continued approbation of his services, by making him gentleman of her privy-chamber, and augmenting the profits of his other places. This last was no small favour in Raleigh's estimation, for though in many respects of an elevated mind, fond of glory, splendid and liberal, he was likewise intent upon gain, and neglected no source of emolument which his court interest placed within his reach. He did not scruple, we are told by some of his biographers, though the fact is not noticed by Campbell and others, to take direct bribes for the exertion of his influence; and he is said to have received no less than ten thousand pounds for procuring a pardon for Mr. Littleton. See Biog. Brit. article Littleton.

On his return from his Portugal voyage he visited his Irish estates, and there either formed or renewed his acquaintance with the poet Spencer, who celebrates him under the title of the "Shepherd of the Ocean," and acknowledges the obligation of having first made him known to the queen. To his Fairy Queen he likewise prefixed a letter to Raleigh, explanatory of its plan and design. The patronage of literature was one of the best traits in the public character of an age, in which men were singularly mixed with heroism. The naval enterprises of the reign of Elizabeth were for the most part predatory expeditions, set on foot by individuals for their private benefit, and encouraged, though but feebly, by the crown. In 1592 sir Walter Raleigh engaged in a considerable undertaking of this kind, with a view of attacking Panama, and intercepting the Spanish Plate fleet. He fitted out thirteen ships, by himself and his associates, which were joined by two of the queen's men of war, and he was appointed general of the whole fleet. Scarcely had he set sail when he was recalled by his sovereign; proceeding, however, to Cape Finisterre, he divided his fleet into two squadrons, with cruising orders, and then returned. One of the squadrons fell in with a rich carrack, the capture of which was the only instance of success which attended the expedition. His ardour for war was shown by his support in parliament of a motion, that certain subsidies granted to the crown should be for the express purpose of carrying on a war offensive and defensive against Spain. To undermine his credit with the queen, Parfins, a Jesuit, published a libel against him, charging him with Atheism; the queen is said to have imbibed some prejudice against him on this account, but he incurred her heavy displeasure by an intrigue with one of her maids of honour, the daughter of sir Nicholas Throgmorton. The confessions of this amour brought a scandal upon the court of the virgin queen; and though he made the best reparation in his power, by marrying the lady, his offence was punished by an imprisonment in the Tower of some months, and a subsequent banishment from the queen's presence.

During his imprisonment he projected an expedition for the discovery of the empire of Guiana, which had already been visited by the Spaniards, and the extent and opulence of which had been the subject of many marvellous tales. Having obtained some preliminary information, from an old navigator whom he dispatched for the purpose, he embarked in person, in the month of February 1595, with a squadron of ships fitted out at a great expense, and failed in the island of Trinidad, where he made himself master of the town of St. Joseph; he then proceeded up the great river Oroonoko, but was obliged by the heat of the weather, and the difficulties of the navigation, to return, with doing nothing more than merely taking possession of the country in her majesty's name. Unwilling to return without appearing to have done something, he published a work, entitled "Discovery of the large, rich, and beautiful Empire of Guiana," which was evidently the refutation of a fertile imagination rather than of real observation, and which Hume dignifies as a production "full of the grossest and most palpable lies that were attempted to be imposed on the credulity of mankind."

Sir Walter had so far regained the good opinion of the queen, that he had a naval command in the expedition against Cadiz, in 1596, under the earl of Essex and lord Elingsham. In the attack he was one of the leaders of the van; and by his courage and prudence contributed a full share to the success of the glorious action. In the following year he failed as rear-admiral in the expedition of which Essex was commander-in-chief, and the purpose of which was to intercept the Spanish West India fleet. Arriving first with his
his squadron at Fayal, after waiting some time for Essex, he thought it expedient to make an attack on the place by himself, which proved successful. The commander-in-chief was mortified with this action, thinking it was designed to rob him of the glory due to him, and would have called forth Ralegh, if lord Thomas Howard had not interposed his services to effect an apparent reconciliation. "On their return Lord Essex published some remarks upon what had happened in the course of the voyage, in which he questioned every body's conduct but his own. "The queen, however," says Campbell, "taking time to inform herself, made a right judgment of the whole affair; in consequence of which she paid a due respect to every man's merit, and greater to none than to that of sir Walter Ralegh."

During the remainder of this reign Ralegh chiefly appears as a member of parliament, and as an affecter of the privileges and interests of the people in the west, over whom his authority extended. That he was completely restored to the favour of his royal mistress is evident from the circumstance, that in 1661 he attended her in a progress through part of the kingdom. He was likewise appointed by her to receive the duke of Biron on his arrival as ambassador from France, and conferred with him on the subject of his mission. In the queen's last parliament sir Walter was a very active member, and distinguished himself upon all occasions, by opposing such bills as, under colour of deep policy, were contrived for the oppression of the middle and lower ranks of society. He witnessed the ruin of his great antagonist the earl of Essex, whose execution he indecently urged upon the minister Cecil; and he was even an eye-witness of the deed. Campbell, endeavouring to justify him in every thing, is evidently, in some infinances, a pamphlet rather than a faithful historian. The decease of the queen, which soon followed the execution of her former favourite lord Essex, and which was probably hastened by it, gave a final, and to Ralegh a very unexpected, blow to his own prosperity.

When James came to the crown it was a sort of contest between sir Walter Ralegh and sir Robert Cecil, who should obtain the confidence of his majesty; the latter, however, was admitted to the royal councils, to the exclusion of sir Walter Ralegh. In truth, James had a prepossession against Ralegh, as having been the enemy of Essex, and still more, as having, with some others, entertained a design of forcing the king to agree to certain limitations with respect to the number of his countrymen whom he was to bring with him. Sir Walter's martial and enterprising spirit was also obnoxious to a prince of a pacific disposition. He was, therefore, received, barely with civility, a circumstance which preyed upon his high spirit, and was probably the means of throwing him into the party of the discontented. A conspiracy, for the purpose of placing upon the throne lady Arabella Stuart, was at this time formed, in which Ralegh in some measure participated. He was apprehended, and brought to trial on a charge of high treason; but, says the historian, his condemnation, upon the evidence produced, was one of the most disgraceful infinances on record, of the base subversion of an English jury to the vindictive wishes of a court. His only accuser was lord Cobham, a man of bad character, and one who was deeply implicated in the plot, to whose proposals he had given ear, but probably without entering into, or even approving them. In his defence he displayed so much eloquence, temper, and force of argument, that some, who had been highly prejudiced against him, were brought to regard him as an innocent victim, and, it should seem, from the testimony of contemporary historians, that all parties were ashamed of the injustice of his condemnation.

It is said that even Coke, the attorney-general, who treated Ralegh on his trial with all the abuse that belonged to his character, and was thought authorized by his office, expressed surprize at the sentence, and declared that he had charged him with no more than misprision of treason. Three were executed for this plot, two were pardoned, and Ralegh was only reprieved and committed to the Tower. His wife, at her own earnest solicitation, was permitted to become his fellow-prisoner, and his youngest son was born in the Tower.

In Mr. Cayley's life of sir Walter Ralegh, published in London in 1806, we have a curious letter of lord Cecil, then secretary of state, to sir Thomas Parry, the English ambassador in France, in which he gives an account of the conspiracy just referred to, and of the motives which led the different persons to take a part in it. Sir Walter was indicted for conspiring to deprive the king of his government, to raise up a sedition within the realm, to alter the religion and bring in the Roman superstition, and to procure foreign enemies to invade the kingdom. The principal overt act laid in the indictment was, that sir Walter had a conference with lord Cobham, as to the best means of advancing Arabella Stuart to the crown and throne of this kingdom, and that they should apply to the king of Spain to procure his assistance in this cause. Sir Walter made an able stand in his trial against the legality of conviction upon the evidence of a single witness, but the judge, rendered infamous by his conduct on the trial, over-ruled the objections.

The active mind of sir Walter Ralegh was now left to exert itself within the walls of a prison, and its employment conduced more to his honour than his liberty perhaps would have done. Here he composed the greater part of his works, especially his "History of the World." Prince Henry, a youth of most amiable qualities, and as unlike his father as possible, contracted a generous admiration for the splendid talents of Ralegh, and cheered him in his solitary confinement by his friendship and correspondence. "No king," said the royal youth, "but my father would keep such a bird in a cage." Henry, however, died, and with him the hopes of deliverance vanished from the mind of the state prisoner. At length, however, after twelve years' confinement, sir Walter obtained his liberation, but probably not without the use of bribes, applied to the new favourite Villiers. For the purpose of repairing his fortunes, he planned a new expedition to Guiana, and his report of a rich gold mine existing in that country was a sufficient inducement for a number of adventurers to engage in the scheme. He obtained a patent under the great seal from the king, for making a settlement in Guiana. James, however, in order to retain his hold upon him, did not grant him a pardon of the treasons of which he had been convicted. There is no doubt but sir Walter might have purchased a pardon, and, at one time, had thoughts of doing so. He even consulted sir Francis Bacon, whether it would not be advisable for him to give a round sum of money for a pardon in common form; to which the learned lawyer answered, "Sir, the knee timber of your voyage is money; spare your purse in this particular, for, upon my life, you have sufficient pardon for all that is past already, the king having under his broad seal made you admiral of your fleet, and given you power of the martial law over your officers and soldiery." Ralegh having employed all his resources in fitting out the expedition, failed for Guiana with twelve armed vessels in July 1617. He had not been long before he was obliged to put into the harbour of Cork, by flaws of weather, where he remained till the 15th of August. In November he arrived at Guiana,
Guiana, where he was received with the utmost joy by the Indians, who not only rendered him all the service in their power, but endeavoured to persuade him to end all his labours there, and take upon himself the sovereignty of the country, which, however, he readily refused. A violent and long continued sickness prevented him from undertaking the discovery of the mine in person. This important affair he entrusted to one of his captains, Keymis: the scheme, however, proved abortive; the Spaniards having been before hand with him in the search of gold. Hume, for the purpose of excusing James, endeavours to shew that the real intention of Sir Walter Raleigh was to plunder the Spanish settlements, and neither to colonize, nor to work the mines. He assumes that Raleigh was a wilful deceiver in the expeditions he had raised of vast subterfuanee: riches: but considering his character, it is fairely more reasonable to believe that he was carried away by some vague ideas of this kind, and Hume admits that the Spaniards were at the very time working some mines. It will be readily admitted, that James did not imagine he was giving Raleigh a commission of hollow promises against Spain, yet he must have known that the exclusive claims of that crown in South America rendered every interference with its dominion hostile in its eyes. The fact seems to be, that the expedition was undertaken with an intention to make the most of it, by any means within the power of the armament, and that the commander trusted to its success for justification before a court where bribery to favourites was omnipotent.

In this expedition Raleigh's eldest son lost his life, of which, and of the unfortunate issue of Keymis's undertaking, he reproached his captain very severely, who, without hesitation, put an end to his own life. Raleigh, with a heavy heart, receded homewards. In July 1618 he arrived at Plymouth, and in his journey to London he was arrested, and carried back to Plymouth. Twice he attempted to escape, but was secured and committed a prisoner to the Tower. James was exasperated at the injury which had been inflicted on Spain, a power then in amity with England, and which had been complimented of by the Spanish court in very strong terms. He was, moreover, about to enter into a more intimate connection with that court, and therefore, without hesitation, determined to sacrifice Raleigh to its resentment. Though his death had been determined on, it was difficult to take away his life. His conduct in the late expedition, though the want of success had rendered it criminal in the eyes of the court, was far from being so in the light of the nation; and though judges might have been found who would pronounce it treason, yet even in those days it was not easy to find a jury who would, without evidence, have found him guilty. The commissioners therefore, who had been appointed to inquire into the matter, and who had frequently examined him, finally reported, that no ground of legal judgment could be drawn from what had passed in the expedition. Upon this, it was resolved to call him down to judgment upon his former sentence, which, says Campbell, was done, with all the circumstances of iniquity and brutality that can well be conceived. Being brought before the court of king's bench, his plea of an implied pardon, by his having acted under the king's commission since sentence had been pronounced, was overruled, and he was not permitted to enter into a vindication of his conduct in the late voyage. Execution was accordingly awarded, and the king's warrant for it produced, which had been signed and sealed before-hand.

"That this judgment was illegal," observes Dr. Campbell, "and that Sir Walter was really murdered, has often been said, and, I believe, seldom doubted; but I think it has not been made so plain as it might be; and, therefore, in respect to his memory, I will attempt it, by shewing that the judgment was absolutely illegal, as well as manifestly iniquitous.

"It is a maxim in our law that the king can do no wrong; and most certainly it is, that no king can do legal wrong, that is to say, can employ the law to unjust purposes. Sir Walter Raleigh, after his conviction, was dead in law, and, therefore, if king James's commission to him had not the virtue of a pardon, what was it? Did it empower a dead man to act, and not only to act, but to have a power over the lives and estates of the living? It either conveyed authority, or it did not. If it did convey authority, then Sir Walter was capable of receiving it; that is, he was no longer dead in law: or, in other words, he was pardoned. If it conveyed no authority, then this was an act of legal wrong. I cannot help the blunder; the absurdity is in the thing, and not in my expression. A commission under the privy seal, if not under the great seal, granted by the king, with the advice of his council, to a dead man, or to put it otherwise, a lawful commission given to a man dead in law, is null and not to be endured; and, therefore, to avoid this, we must conceive, as Mr. Francis Bacon, and every other lawyer did, that the commission included, or rather conveyed, a pardon. Indeed, the same thing may be made out in much fewer words. Grace is not so strong a mark of royal favour as truth; and, therefore, where the latter appears, the law ought, and, indeed, does, presume the former. This judgment, therefore, did not only murder Sir Walter Raleigh, but, in this instance, subverted the constitution, and ought to be looked upon, not only as an act of the baflfest prostitution, but as the most flagrant violation of justice that ever was committed."

The sentence of death was pronounced on him one day, and put in execution on the following, Oct. 29, 1618, in Old Palace Yard. His behaviour on the scaffold was calm and manly. He addressed the people of some length: he said he never feared death, and much less at that time; that as to the manner of it, though to others it might seem grievous, yet for himself, he had rather die in this way than in a burning fever. He desired to see the axe, and feeling the edge of it, said to the sheriff, "this is a sharp medicine, but a sure remedy for all evils." Being asked which way he chose to place himself on the block, he replied, "let the heart be right, it is no matter which way the head lies," and giving the signal, he received the stroke with the most perfect composure. Such was the end of the illustrious Sir Walter Raleigh, in the 66th year of his age, by a sentence which was regarded as one of the most dishonourable measures of an odious administration. The panegyric upon his character by Dr. Campbell is much too highly coloured: Sir Walter Raleigh was not faultless, though in extent of capacity and vigour of mind he had few equals in an age that abounded with great men. His imprisonment was the occasion of his obtaining a high reputation as an author. His writings were on various topics, and are classed as poetical, geographical, political, philosophical, and historical. They are now but little known. His "History of the World," though not much read, is regarded with respect, as one of the best specimens of the English language of that time; the style is pure, nervous, and without pedantry. It is the style of a man of business as well as of a scholar. It has been many times reprinted, but the best edition is that of Oldys, in 1735. He brought down his history no farther than the overthrow of the Macedonian empire. Of his miscellaneous works, a collection in two volumes 8vo, was printed in 1748. Bio. Brit. Hume. Campbell. Caxley.

RALEIGH, or RAYLEIGH, in Geography, a market-town and
and parish in the hundred of Rochford, and county of Essex, England, is situated at the distance of 14 miles S.E. by S. from Chelmsford, and 34 miles E. by N. from London. This place appears to have been anciently of considerable note. It was the head of the barony of Swayne, and had a castle adjoining to it, of which some fragments and earthworks still remain. This confit of a mount, with an oval-shaped base, surrounded by a double ditch and rampart, and several outworks, particularly on the east side. The summit of the mount is divided; the western division being of a circular form, and 100 feet high; and the eastern one of an oval form, and lower: the principal ditch varies in width from 30 to 50 feet, and the interior vallum is 50 feet high. The church here is an ancient edifice, and contains an old tomb, greatly mutilated, but displaying the remains of very beautiful workmanship in the pointed style. The perfen whose memory it was intended to preserve is now unknown; the upper part, to which the inscription was probably affixed, being totally destroyed. The market at Raleigh is held on Saturday, weekly; and there is an annual fair on Trinity Monday. Hearne, in his edition of Leland's Itinerary (vol. iii. p. 8), informs us that a custom-court is kept here, yearly, the Wednesday next after Michaelmas's day. "The court," says that author, "is kept in the night, and without light, but as the sky gives, att a little hill without the town, called the King's hill, where the steward writes only with coals, and not with incke; and many men and women of great worth hold of the same; and do sitt on this strange court, where the steward calls them with as low a voice as possible he may; giving no notice when he goes to the hill to keepe the same court; and he that attends not is deeply amerced, if the steward will. 'Tis commonly called Leadeh-Court." Weever, in his "Funeral Monuments," adds, respecting this custom, that he was informed, "that this vile attendance was imposed at the first upon certain tenants of divers manors hereabouts, for conspiring in this place, at such an unreasonable time, to raise a commotion." According to the parliamentary returns of 1811, Raleigh parish contains 162 houses, and 1,131 inhabitants.

RALEIGH, a township of Essex county, in Upper Canada, W. of Harwich, bounded on the N. by the Thames, and S. by lake Erie.

RALEIGH, a town of America, in Wake county, North Carolina, the present seat of government, about ten miles from Wake court-house. The general assembly of the state in December 1791, appropriated 10,000l. towards erecting public buildings, and named it after the celebrated Sir Walter Raleigh, under whose direction the first settlement in North America was made at Roanoke Island; and in Albemarle Sound, the first-house a large handsome building, and cost 6000l. The plan of the town is regular; the streets intersecting each other at right angles. It is, however, subject to the disadvantage of being remote from navigation; 61 miles N.E. of Fayetteville, 147 from Petersburg in Virginia, and 448 S.W. of Philadelphia.

RALEMO, a river of Chili, which runs into the Pacific ocean, S. lat. 3° 55'.

RALENDOFF, a town of the duchy of Carinthia; 12 miles S. of Saxenburg.

RALESTEDES, a town of the duchy of Holstein; 8 miles E. of Hamburg.

RALICOTTA, a town of Hindoostan, in Naini-pour; 31 miles N. of Anamabar.

RALLENTANDO, Ital., a musical term of late invention, for relaxing the measure at particular parts of a composition, which, when done by a great master, manifests feeling and intelligence; but when attempted by mean performers, it has no other effect upon an audience than that of breaking time; and we think that this refinement is often abused. It has been chiefly practiced in France, and of such effectuation, and that overcharged tendermeds which render the national airs tendres too disagreeable, or too ridiculous, to the natives of all other countries.

RALLUS, the Rail, in Ornithology, a genus of birds of the order Grallae; the generic character is, that the bill is thickish at the base, attenuated on the back towards the tip, compressed, a little incurved, pointed; the tongue is rough at the tip; the body is compressed; the tail is short; the feet have four cleft toes. There are fourteen species.

1. Ccrex: land rail, crake, corn crake, daker hen, &c. Of this species the wings are of a ruddy red; the bill and legs of a brownish-Ah; the irides are of a Hazel colour; the feathers of the body are of a reddish-brown; the upper ones are black in the middle; the chin is very pale, and the belly is of a whitish-yellow. It is about nine or ten inches long, and inhabits the fegdy parts of Europe and Asia. From the circumference of its appearing at the same time with the quail, and frequenting the same places, it has been denominated the king of the quails. Its well-known cry is flit heard as soon as the grasa becomes long enough to shelter it, and continues till the grass is cut. The bird, however, is seldom seen, as it flits in the thickest parts of the herbage, and runs so nimbly through it, winding and doubled in every direction, that it is difficult to come near it. When it is hard pressed by the dogs, it sometimes hops short and snails down, by which means its too eager pursuer overtops the spot and looses the trace. It seldom springs but when driven to extremities, and generally flies with its legs hanging down, but never to a great distance. As soon as it alights, it runs off, and before the fowler has reached the spot, the bird is at a considerable distance.

It emigrates, appearing with us about the latter end of April, and departing in October. On its first appearance, and till the female begins to sit, the male is frequently heard to make a singular kind of noise, much resembling that of a comb when the finger is drawn along the teeth of it, and which has been used as a decoy. When they first arrive, they are very lean, but before their departure, they become excessively fat, and are much sought after for the delicacy of their flesh. They lay from twelve to sixteen eggs in the grass, of a dirty whitish colour, with a few yellow spots; the flesh is excellent. There are two varieties, thus described: 1. Rufous brown, beneath paler; wings and tail deeper; the chin and vent are white; the legs are dusky red. This is found in the island of Jamaica. The bill is larger and black. 2. Reddish-grey beneath, and wing-coverts ruddy brown. This species inhabits China; the legs are of a dusky colour.

AQUATICUS: Water Rail. Wings grey spotted with brown; flanks spotted with white; bill orange beneath, but black and reddish at the base; the irides are red; the feathers of the upper part of the body are of an olive-brown, and black in the middle; the lower ones are cinereous; those of the lower part of the belly and vent are edged with rufous; quill-feathers dusky; the lower tail-coverts are white; the tail-feathers are shorter and black; the two middle ones at the tip, and the others, are edged with ferruginous; the legs are of a dusky red. It is about twelve inches long, but does not weigh more than four ounces. It is found in the watery places in Europe and Asia. It is sometimes, but not in any
any great numbers, met with in various parts of Great Britain, in low situations, about water couries and rivulets, where it seeks shelter among fedges, rushes, and reeds, and is seldom put to flight, depending on its legs for safety. When routed it flies only to small distances, and is a heavy and very awkward manner, with its legs hanging down. It runs nimble, and frequently fits up its tail. Its neck is made of fedge and coarse gral, among the thickets aquatic plants, or in willows beds. The female lays fix or more eggs, rather larger than those of a blackbird, of a pure white colour. This bird continues with us all the year, and by many it is erroneously believed to be the land rail metamorphosed in the autumn; but the different bills which the two birds have constitute an effential distinction.

*PORZANA;* spotted gallinule, or spotted water hen. This species has the two middle tail-feathers edged with white; the bill and legs are of a pale olive. It inhabits Europe and North America, and is generally found on the sides of small streams, hiding itself among the bushes; it is nine inches long. This bird is described as having a greenish-yellow bill; its irides are hazel, and head brown, spotted with black. The line over the eyes is of a pale grey; the neck above and flanks are of a brown ash, with small white spots; the back and wing-coverts are olive, with black stripes, and near the edges of the feathers with white spots; the greater with white stripes and lines; the cheeks, chin, and throat, are of a pale grey, with brown spots; the breast is brown with white spots; the belly is varied with cinereous and white; the vent is of an ochre-yellow. This bird is extremely timid and fpeded, and is but seldom seen in Great Britain, eluding observation by its perpetual vigilance and lurking habits. Its neck is formed, withingular care, of feathered sheaths, and materials which will float on the water, on which it remains tied, by some filaments, to the stalks of reeds, by which it is prevented from being carried away by the tide or current. The bird is in great esteem for the table.

*CREFITANS;* Clapper Rallus. Bill and legs brown; body above olive, the feathers ash at the edges; chin white, throat and breast yellowish-brown. This species inhabits New York, and is from fourteen to fifteen inches long.

*FUSCUS;* Brown Rallus. This is brown, as its specific name imports; its vent is waved with white; the legs are yellow. It inhabits the Philippine isles, and is seven inches long. The body beneath is light chestnut, on the belly it is inclining to grey; the tail is barred with white and black.

*STRIATUS;* Streaked Rallus. Blackish, waved with white; chin reddish. The bill of this species is of a horn colour; the crown is varied with dusky and bay; the neck is bay; neck, back, shoulders, and rump, brown, with whitish spots; the wing-coverts are marked with a jet transverse white streaks; the chin is of a reddish-white; the cheeks, throat, breast, and upper part of the belly, cinereous, with a tinge of olive; the lower part is barred with dusky and white; quill-feathers brown, the outer bands reddish-white; the inner are white; the tail is brown with white lines; the legs are of a greyish-brown. It inhabits the Philippine islands, is eight inches long, and is probably a variety of the philippensis.

*TORQUATUS;* Banded Rallus. Brown, beneath waved with white; it has a white line below the eyes. This also is found in the Philippine isles, and is twelve inches long. The bill and legs are grey-brown; cheeks and chin black. The body beneath is transversely streaked with black and white; the collar is of a bay colour; the quill-feathers on the outer edge paler; bands within on the first three white, the fix next reddish-bay.

*PHILIPPENSI;* Philippine Rallus. The specific character of this bird is brown, but beneath it is barred with grey; the eye-brows are white, and the neck beneath has a reddish cast. There are three other varieties, thus described: 1. Red-brown, spotted and streaked with black and white; head chestnut; body beneath and eye-brows cinereous; this, notwithstanding its name, is found at Otaheite. 2. Brown, spotted and streaked with white, beneath white; eye-brows grey; the tail is barred with brown and white: this inhabits Tongataboo. 3. Above brown, beneath ash; back and wings lined with white spots; the belly beneath is white, with blackish bars. This is about eleven inches long, and is found in the Philippine islands.

*ECAUDATUS;* Tailless Rallus. Olive; beneath blueish; body transversely waved with black; eye-brows white. It inhabits Otaheite. The bill is blackish, and the upper part of the head is of a pale brown; the orbits are black; over the eyes, on each side the head, it has a broad white line; the body above is of a deep-glossy olive, with a tinge of olive on the shoulders; the vent is of a pale yellow; the tail is so short as to be scarcely perceptible; the coverts are of a pale blue.

CAROLINUS; Sorex. This bird is brown; the frontal is black; the breast is of a lead colour; the bill is yellow; the legs are greenish. It inhabits Virginia, and is from seven to eight inches long; this is a capital bird for the table. The irides of this bird are red; the crown and body above are brown, marked with black spots; the face and chin are black; but the red of the neck, temples, and breast, are of a blueish-slate; the belly and outer edge of the wings are white; the wings and tail are brown.

PHINICULUS; Red-tailed Rallus. This species is black but beneath it is white; the bill and legs are greenish; the front is naked, and of a flesh colour; the vent and tail of a rilly red. It is found in the island of Ceylon, and is about nine inches long. The bill and legs are tinged with red; the crown and cheeks are pure white; the quill-feathers are spotted with blue. There are two varieties, 1. Above cinereous, beneath white; the belly and vent are red. This is an inhabitant of China, and is fifteen inches long. 2. The front of this is white; the vent is red, and the legs are yellow. It is found in Madagascar, and is longer than the last.

VIRGINIANUS; Virginian Rallus. Brown, without spots; the bill and legs are brown. It inhabits Virginia, and is probably a variety of the R. aquatics.

FERRUCINES; Red-breasted Rallus. This bird is dusky above, and cinereous beneath; the neck and breast are ferruginous; the bill is pale, and the legs yellow. It is nine inches long; the eye-brows are pale, and the flanks are marked with transverse narrow, white lines.

CAPENSIS; Cape Rallus. This species is of a ferruginous colour but the lower part of the breast, belly, vent, wings, and tail, are waved with black and white; the bill is black, and the legs are of a blood-red. It inhabits the Cape of Good Hope and Ceylon, and is of the size of the R. crex. The two middle tail-feathers are ferruginous.

CERULEUS; Blue-necked Rallus. This is of a bay colour above, but blueish beneath; the bill and legs are red; the vent is white, and the belly is marked with transverse black streaks. It inhabits the Cape of Good Hope; it is seven and a half inches long.

ZEYLANICUS; Ceylon Rallus. The head of this bird is dusky; the body above is ferruginous, beneath it is reddish, waved with brown; the first quill-feathers are black; the
bill and legs are red. It is found, as its name imports, at Ceylon; it is larger than the R. aquaticus, and has a long tail.

AUSTRALIS; Trogodytus Rallus. Rufous ash; wings and tail deep brown; the feathers are barred with black. It inhabits New Zealand, and is seventeen inches long. The bill and legs are yellowish; the body above is of a rufous brown, beneath rufous ash; quill and tail-feathers are waved with black.

PACIFICUS; Pacificus Rallus. Black, speckled with white; wings barred; body beneath whitish; the head is brown, the breast is of a blueish-brown. It is found in Otaheite, and the neighbouring isles. Bill red, the legs are of a flesh colour; the chin and eye-brows are white; the nape of the neck is rufous.

TABBUSIS; Tabanus Rallus. Brownish-black; beneath it is of a dusky colour; the bill is black, and the legs are bay. A variety has its vent streaked with black and white; the legs are red. It inhabits the South-sea islands, and is fix inches and a half long. The eye-lids and irides are red.

NIGER; Black Rallus. Black; bill red at the base, brown at the tip; the legs are brown or red. This is an African bird, and is nine inches long.

SANDICENIS; Sandwich Rallus. This is of a pale ferruginous colour; but the bill is of a dusky ash; the legs are of a dull flesh colour. A variety has a yellowish bill and legs. It inhabits the Sandwich islands, and another variety is very small, and found in the Tanna isles.

TAITHELENIS; Otahite Rallus. Cinereous; body above red-brown; the bill, rounded tail, and claws, are black. This inhabits Otahite and the Friendly isles, and is about fix inches long. The quill-feathers are dusky and edged with white; the legs are yellow.

OBSCURUS; Dulky Rallus. This is brown streaked with black, beneath it is of a rufous brown; the bill is black, and the legs are of a red-brown. It inhabits the Sandwich islands, and is six inches long; the edge of the mandibles is yellowish.

LONGOSTRIS; Long-billed Rallus. The upper part of this species is cinereous, spotted with brown, beneath it is rufous white; the flanks are transversely waved with white, the bill is long and of a ferruginous colour. It inhabits Cayenne, and is from nine to twelve inches long. The bill is tipt with brown; the legs are yellowish, and the chin whithis.

VARIEGATUS; Variegated Rallus. This bird is streaked and spotted with white and black; the hind-head is dusky; the bill is yellowish; the chin is white; and the legs are yellow. It inhabits Cayenne, and is eleven inches long. The wings are brown, the covert are spotted with white; some of the middle tail-feathers are edged with white.

CAYENNENIS; Cayenne Rallus. The crown of this bird is rufous; the body above is of an olive-brown; beneath it is rufous; the ocular band is blackish; the quill-feathers are black; the bill is brown, and the legs bay. There is a variety having its crown bay; chin and vent reddish-white. It inhabits Cayenne and Guiana; it is eight inches long; in the evening it is noisy and gregarious, by day it is solitary; it builds in the forked branch of a shrub, near the ground. The vent is pale.

JAMAICENIS; Jamaica Rallus. Above reddish-brown with black streaks; the bill and chin are black; the throat and breast are of a blueish-ash; the belly is marked with white and brown lines. It, as its name imports, inhabits Jamaica, and is fix inches long. The bill is reddish at the base; wing-coverts brown, spotted with white; the quill-feathers are of a reddish-brown, with black lines, the secondaries and tail-feathers are spotted with white, and the legs brown.

MINUTUS; the Little Rallus. This is brown, but beneath it is yellowish; eye-brows, streaks on the back, and spots on the wing-coverts, white; tail barred black and white. A variety has the middle of the neck above rufous; the belly and vent are waved with black and white. It inhabits Cayenne and Jamaica, and is five inches long. The bill is brown; the wing-coverts are black; the chin is white, and the legs are yellow.

PUSILLUS; Dwarf Rallus. Striped with ferruginous and black; the body beneath is blackish, with narrow white bands; the throat and breast are blueish. This is found near salt lakes of Dauria, and is of the size of a lark. The face, neck beneath, and middle of the breast longitudinally, are blueish; the middle of the chin is white; the longitudinal band through the eyes of a pale rufous colour; the back is scattered with white longitudinal lines; the legs are greenish.

BARRAHICUS; Barbary Rallus. This is of a ferruginous colour; the bill is black; the wings are spotted with white; the rump is streaked above with white and black, and beneath with white; the legs are of a dusky brown. This, as its name imports, is an inhabitant of Barbary, and is the size of a plover.

DUBLUS; Doubtful Rallus. Striped with brown and ferruginous; the belly is white; the flanks are barred with brown and rufous ash; the first quill-feathers without are longitudinally white. It is the size of the common gallinule. The face is of a pale rufous colour; the chin is of a dirty white, surrounded with a brown crown; the sides are brown; the bill and legs greenish-black.

RALLYING, in War, the reassembling, or calling together of troops, broken, routed, and put to flight.

RALPH, JAMES, in Biography, a miscellaneous writer, defended probably from mean parentage, was the intimate friend of Dr. Franklin, who speaks of him as ingenious and shrewd, genteel in his address, and extremely eloquent. Franklin knew him in America, and though he does not mention what Ralph's situation then was, yet as he wrote a fine hand, and was well veried in accounts, it is imagined he was a schoolmaster. In 1725 Ralph accompanied Franklin to England, with a resolution of not returning to America, where he left his wife, with whom, and with whole family, he had lived on ill terms. In London he was, for a considerable time, supported by his friend Franklin, till their intimacy was dissolved, when Ralph considered the quarrel as a complete discharge of the debt which he owed his benefactor. Ralph changed his name to that of Franklin, which he thought necessary, having formed a new female connection, and settled as a schoolmaster in a village in Berkshire. From this time there is no regular narrative of his life, which was probably passed as a hired party writer. He is spoken of with much contempt in the Dunciad, as the author of a poem called Night:

"Silence, ye wolves! while Ralph to Cynthia bows,
And makes night hideous—And war, ye owls!"

In a note, it is said he wrote a swearing piece, entitled "Sawney," very abusive of Swift, Gay, and Pope; that he panegyrised his own works in the journals, was wholly illiterate, wrote plays, and was employed in a political newspaper. The satire of Pope must be taken with much limitation, it being inspired by party motives: Ralph having recommended himself to perfons in power at the beginning of George II.'s reign, would for that reason be obnoxious to Pope and his friends. He became an able writer.
R A M

writer in prose, and was author of many political pamphlets, which were much applauded in their time; but his chief work was "The History of England during the Reigns of William, Anne, and George I., with an introductory Review of the Reigns of the Brothers Charles II. and James II., in which are to be found the Seeds of the Revolution. By a Lover of Truth and Liberty," 2 vols. fol. 1774-6. This work obtained the plaudits of Mr. Fox, who, in his posthumous historical fragment, speaks of the author as an historian of great acuteness as well as diligence. The last publication of this author was entitled "The Cafe of Authors by Profession or Trade, lated with regard to Book-sellers, the Stage, and the Public," which is laid to contain much good sense and lively satire. Mr. Ralph died at Chiswick, in the year 1762. Gen. Biog.

R.A.M., in Geography, a town of European Turkey, in Servia, on the S. side of the Danube; 10 miles E. of Paffarovitz.

R.A.M. in Agriculture, the male of the sheep kind. It may be observed, that the rams of different breeds of sheep vary greatly in their forms, wools, fleeces, and other properties; but the following description by that excellent flock-farmer, Mr. Culley, deserves the attention of the breeder and grazer. According to him, his head should be fine and small, his nostrils wide and expanded, his eyes prominent, and rather bold or glaring, ears thin, his collar full from his breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very fine and graceful, being perfectly free from any coarce leather hanging down; the shoulders broad and full, which must at the same time join so easy to the collar forward, and chine backward, as to leave not the least hollow in either place; the mutton upon his arm or fore-thigh must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluous skin and coarse hairy wool from the knee and hough downwards; the breast broad and well forward, which will keep his fore-legs at a proper width; his girth or chest full and deep, and instead of a hollow behind the shoulder, that part by some called the fore-flank should be quite full; the back and loins broad, flat, and straight, from which the ribs must pierce with a fine circular arch; his belly straight; the quarters long and full, with the mutton quite down to the hough, which should neither stand in nor out; his twist, or junction of the inside of the thighs, deep, wide, and full, which, with the broad breast, will keep his fore-legs open and upright; the whole body covered with a thin pelt, and that fine, bright, soft wool. It is observed, that the nearer any breed of sheep comes up to the above description, the nearer they approach towards excellence of form.

But though this is a very correct, appropriate, and admirable description of a finely-formed ram, objections have been made by some to a few of the properties which are laid down. Width and expansion of the nostrils in sheep, it is supponed, are liable to cause the lower parts of the noses to be too thick and large; while in naturally good and improved forms, the lower parts of the noses and mouths are for the most part small. Nor is the prominent and bold daring eye held in more estimation, as it is thought not to shew a good disposition; but, on the contrary, to displaey too much quickness and acitivity, or wildness of nature in the animal. Opinions, however, differ much on this point among sheep-farmers; and a lively quick eye is almost always considered as favourable to a good disposition.

Rams naturally pollies more boldness and courage than either wethers or ewes; and they are very apt, unless great care is taken, to acquire mischievous habits of attacking perfons or animals that may by accident approach them.

In some sheep-districts the breeders are greatly in favour of large rams, but in others those of a smaller size are preferred; the choice of the size of the rams should, however, in every instance, be regulated by the nature and abundance of the keep, or the quality of the lands, as it is utterly impossible that the inferior sorts of pastures can keep sheep-flock of the large size, as in those of the better kinds; and it would be highly disadvantageous in the best rich sorts to have a small-sized flock when they could support a large one in an equally perfect manner. Middle-sized rams are, upon the whole, the most suitable and proper for lands in general, and for all the purposes of the breeder.

The growth and constitutions of young rams should never be suffered to be endangered by their having too great a number of ewes, as is too frequently the practice with sheep-breeders.

It is a very improper culm, but one which prevails with the graziers in some sheep-districts, to keep all their rams, perhaps to the amount of from twenty to fifty or more of all kinds, in one field or pasture; as their contents are often so violent, especially about the riding time, as to cause the los of one or two rams to each in all such fitches. This practice is the most common in the sheep-districts towards the eastern part of the isle, being seldom met with in those of the midland or more northern parts. It ought to be every where done away with.

The old rams are now almost always got quit of by being fattened as rams, and fold at the neighbouring markets, or to butchers, at a very inferior price, there being often much competition for this sort of low-priced meat in some situations. It was formerly, however, the custom in some places to knip them before they were fattened and fold to the butchers or otherways, but much injury and los being found to be suffered by that method, it has been left off; it being now concluded, on the whole, that the los of knitting the rams is greater than that which is suffered in the reduction of the price of ram mutton.

The practice of letting out rams in the midland districts for the purpose of improving the breeds of sheep, having produced such beneficial effects, the rife, nature, and progress of it may deserve the attention of the flock-farmer. It has been ably and accurately delineated, in the following manner, by Mr. Marshall, in his Rural Economy of that part of the kingdom.

It is stated, that in this district, in general, the management respecting rams is similar to that of other parts of the island; the breeders rearing or purchasing them. But that it is observably, however, that the advocates of the old breeds, though they will not adopt the modern flock, have fallen, in some degree, into the modern practice of letting by the feafon. But that the rams of the modern breed are never fold, but are palled from breeder to breeder, by the feafon only. And that for the purpose of promoting this inter-course, each principal breeder has his blow of rams; commencing, by common consent, the 8th of June, and lasting until Michaelmas, or until the feafon of letting be past. That during a few weeks after the shows commence, every ram-breeder may be paid to keep open house. Breeders and others, from all quarters of the kingdom, as well as the promoters of the breed who reside in the neighbourhood, attend these shows; going, in parties, from one to another: Code to take, others to see and pass their judgment. And that these private exhibitions close with a public blow, at Leicester, the 10th of October; when rams of every description, but mostly an inferior sort of the improved
being

proved breed, are collected; being brought in waggons; many of them from a considerable distance; come to be
folded, but chiefly to be let for the feason. That this shew
has been held, be believes, time immemorial; not, however,
for the purpose of letting, but for that of sale. But the let-
ting of rams by the feason has long, he understands, been a
practice in Lincolnshire. However, the origia, in the mid-
land districts, may be traced—to a ram let by Mr. Bakewell,
at Leicetser fair, about forty years ago, at the low price
of sixteen thillings. But humble, however, as was this
beginning, it proved, Mr. Marshall says, to be the first
stone of the foundation of a department of rural busineses,
that has already risen to an astonishing height, and may,
for some length of time, continue to bring in a copious
source of wealth to the country. In the management of
this busines, the principal ram-breeder, fay, annually,
twenty, thirty, or perhaps forty ram-lambs; cataration
being seldom applied, in the firft infance, to the produce
of a valuable ram. For, in the choice of these lambs, they
are led more by blood, or parentage, than by form; on
which, at an early age, little dependence can be placed.
He adds, that their treatment, from the time they are
weaned, in July or August, until the time of shearing, the
firft week in June, confists in giving them every indulgence
of keep; in order to push them forward for the shew: it being
the common practice to let such as are fit to be let the firft
feason; while they are yet yearlings—provincially shorhogs.
Their firft pastire, after weaning, is pretty generally, he be-
lieves, clover that has been mown early, and has got a second
time into head: the heads of clover being confidered as a
moit forcing food for sheep. After this goes off, turnips,
cabbages, coleswort, with hay, and report fans, with corp.
But the use of this the breeders severally deny, though,
collectively, they may be liable to the charge. However
this may be, something confiderable depends on the art
of making up,—not lambs only, but rams of all ages. Fat,
like charity, covers a multitude of faults; and, besides, is the
best evidence their owners can produce, of their fattening
quality,—their natural propensity to a state of fattens; while
in the fattens of the shorhogs is teen their degree of inclination
to fat at an early age. And that the fattening quality being
the one thing needful in grazing fock: and being found, in
some confiderable degree at leaft, to be hereditary,—the
fattens rams are of coufre the leaft; though other attachments,
well or ill placed, as to form, or fashionable points, will per-
haps have equal or greater weight in the minds of some
men, even in this enlightened age and district. And the shor-
hogs, which will not make up sufficiently, as to form and
fattens, are either kept on to another year, to give them a
fair chance, or are caltrated, or butchered, while shorhogs.

With regard to the shewing, it is remarked, that the
shews of the principal breeders confift, by common consent,
of forty rams each, mostly from one to five years old,
they being seldom found efficient after that age; some,
however, will continue in vigour to the sixth or seventh
year. And that, during the shew, they are mostly kept in
small inclosures, of two, three, or four acres; with three,
four, or more rams in each, according to their ages, and
the advancement of the feason. And in a corner, or other
convenient part of each paddock, a small pen, made with
hurdles, is placed; for the purpose of handling them. Into
these pens they go, through custom, as tractably as worked
oxen to their stalls. Indeed, the old rams, from the unin-
wieldiness of their frame, and the load of fat they have to
carry at this season, as well as from habit, will suffer them-
selves to be handled abroad; and even appear to take plea-
fure in the requisite which they have thrwn them. But it is
observed, that of late a new mode of shewing has been
struck out by the leading breeder, and adopted by one
at least of his followers. Instead of shewing them abroad,
and driving three or four of them up together in a pen, they
are shut up in houses, and brought out separately, being never
seen together. He thinks, that among accurate judges, this
mode of shewing may be well enough; but to those who
have had less experience it gives offence, as it depraves
them of their bel bel bel, comparison; and he can see no fair ad-

It is observed, that though the desirable points of a ram
are such as have been noticed, the choice of the hirer
is determined, in some measure, by the intention for which
he is about to hire: as whether it be that of getting
weddens, or mere grazing fock; or rams for the purpose
of letting. Hence the grazier and the ram-breeder choose
different sheep, so as to suit their different purposes. He
adds, that the characteristic difference between what is
termed a ram-getter and a wedder-getter, or a good grazier's
sheep, is that of the former being even where cleaner and
finer, the head small, the bone and offal light, the flesh
good, and the form beautiful. The mere grazier likes a
ram no worse for having a strength of frame, and is less
scrupulous about his form than the ram-breeder, whose
animalcy is fineness: his eyes, and the natural tenden-
cy of the breed, serve to give his offspring size and
sublimity when it is wanted.

In respect to the practice of letting, it is observed, that
a novel circumstance has likewise taken place lately in the
busines of letting. The long stablished custom of letting
a price was exploded, at leaft by the late Mr. Bakewell,
and one of his disciples; whole customers were left to make
their own valuations, and bid what they pleased. But this,
as well as shewing them separately, it is observed, gives
more advantage, especially to strangers, who cannot brook
the idea of being both buyers and sellers. The latter, how-
ever, has more than one advantage in referring the price,
provided he do not thereby drive away his customers: he is,
in effect, letting to the best bidder. Besides, he is, through
this mean, enabled to regulate his prices to his customers,
without giving any of them pointed offence: for as the
principal breeders are, in the nature of their busineses,
competitors, it is no more than common good policy, in the
leader at leaft, to advance himself, and keep back those
who prefer upon him closed. It is, therefore, good man-
gagement, Mr. Marshall thinks, in him to let a superior
ram to an inferior breeder, whose ewes are yet of base
blood, at a lower price than to one who is farther advanced,
and whose ewes are nearly equal to his own: for if the
hirer may not thereby be able to get the lead from him,
he may run away with part of the bell prices; and the only
line the leader has to tread is, either to refuse him, or to
make him pay in the first instance. And again: sometimes
or three capital breeders will join in the hiring of one
superior ram; and, in this case, the blood being more widely
diffused, the price ought to be, and always is advanced, in
proportion to the number of partners there may be in the
busines. Hence, in the leader, a reservation of price may
be allowable, especially in the letting of first-rate rams.

He observes, in regard to the conditions of letting, that
notwithstanding the number of years the letting of rams
has now been in use, and the extraordinary height to which
the prices have risen, the transaction does not appear to have
yet received any settled form; nor to have been rendered
legally binding, by any written articles, or conditions of
letting; much being still left to the honneur of the parties.
It is, however, generally understood, that the price agreed
upon
upon shall not be paid, unless the ram in contract, or another as good, impregnate the filipulated number of ewes. If, through accident or inability, part only be impregnated, a proportional part of the price is abated. If he die while at ride, the los falls on the letter, whether his death happens through accident or neglect; no cafe, he understands, having yet been otherwise determined. It is likewise under-
flood, that the hirer shall not suffer him to serve any other than his own ewes; and, if he, no more than a filipulated number, which is proportioned to the age or ability of the ram, and the mode of using him. And further, that if a grazer hire a valuable ram, at a wadder-getter's price, (which is not unusual at the wane of a feason, when valuable rams happen to be unlet,) it is understood, or rather agreed, that he shall not rear rams from him; a condition which may frequently be advantageous to both parties. The letter pockets five or ten guineas, which otherwise he might not have had; and the hirer, by sufficing himself to be "tied down," as it is termed, gets a greater improvement in his flock than otherwise he could have got for the same money. He adds, that the time of paying the money is, he understands, unfixed; seldom, he believes, until after the ewes have brought proofs of the ram's efficiency, or after the lambing feast.

It is observed, that with regard to the prices for letting rams by the feason, that from the first letting to the year 1780, the prices kept gradually rising from sixteen shillings to a guinea, and from one guinea to ten. In 1780, Mr. Bakewell let several at ten guineas each; and what is rather inexplicable, Mr. Parkinon of Quarendon let one, the same year, for twenty-five guineas, a price which then amonihed the whole country. That from that time to 1786, Mr. Bakewell's flock rofe rapidly, from ten to a hundred guineas; and that year he let two-thirds of one ram (refering one-third of the usual number of ewes to himself) to two principal breeders, for an hundred guineas each; the entire services of the ram being rated at three hundred guineas. This excellent breeder making that year, by letting twenty rams only, more than a thousand pounds! and that, since that time, the prices have been still rising. Four hundred guineas have been repeatedly given. The above breeder, this year (1789), makes, he understands, twelve hundred guineas by three rams, (brothers he believes,) two thou-
sand of seven, and of his whole letting full three thousand guineas! And that he now lets nothing under twenty guineas; a well-judged regulation, which Mr. Marshall thinks will probably be beneficial both to himself and his cutomers. It is added, that, beside this extraordinary sum made by Mr. Bakewell, there are six or seven other breeders who make from five hundred to a thousand guineas each. The whole amount of monies produced this year, in the midland counties, by letting rams of the modern breed for one feason only, is estimated, by those who are adequate to the busi-
ject, Mr. Marshall says, at the almost incredible sum of ten thousand pounds. He knows that it is a popular idea, espe-
cially of those who, living at a distance, have only heard of these extraordinary things, without having an opportunity of coming at facts, that the extravagant prices which are talked of are merely nominal; the principal part of the money being returned, the actual prices given being small, in proportion to those held out. This, however, is, he be-
lieves, and on the best authority, an erroneous idea. At the first setting out of the high prices, there might be some tranfactions of that nature; but if ever they existed, they have ceased long ago. Mr. Bakewell at prezent has the same, at least, of being parsimonious, even to the shepherds of the flocks on which his rams are employed. His highest prezent, he understands, is five shillings; if the price be under fifty guineas, only half-a-crown. But the enormou-
sness of these prices may be explained, he thinks, on other grounds. The high prices are not given, he says, by graziers, for the purpose of getting wadders, as grazing flock; but by ram-breeders, for the purpose of getting rams, to be let to graziers: the highest being given by the principal breeders only, not for the purpose of getting rams to let to graziers as wadder-getters, but for that of getting rams, to be let out again to inferior tup-men, as ram-
getters.

It is further stated, that the graziers' prices run, even now, from one to ten guineas. He has not heard of more than ten guineas being given, by a mere grazer, for a ram, for the sole purpose of getting grazing flock: five or fix guineas is the common price. And supposing he gives the highest price, ten guineas, and that the ram serves a hundred ewes, (some single, some double,) the expense of getting amounts to no more than two shillings a head; which is in-
considerable, compared with the difference between a well and an ill grazing flock, between a sheep that will get as fat at two years old as another will at three; or, in other words, which will, at two years and a half old, fetch ten or fifteen shillings more than his comrades of another breed, but of the same natural fize, and going in the same pature, or feeding on the same fort of food: In respect to the middle prices, as those from twenty to fifty guineas, they are, under the present circumstances, equally reconcileable, he thinks, to common sense. If a breeder, who gives fifty guineas, rar ten tolerable rams fit for the grazer's use, and let them at five guineas each, he brings himself home, even the first season of letting, beside having the rams for another and another feason, and beside a general improvement in his flock for the future. And those who give the higher prices, as one to two hundred guineas, have, or ought to have, proper bakes to build upon, sufficient flocks of well-
bred ewes; in which case, they have a fair chance of pro-
ducing ram-getters, worth, while the prezent spirit of improvement lasts, twenty to fifty guineas a feason. And that with respect to the very high prices, they are given by a few first-rate breeders, who are playing a high game, run-
ning a hard race, for the pride and profit of being a leader, when Mr. Bakewell is not; a contention which may laft as long as Mr. Bakewell, and be at once an honour to his genius, and a reward of his services.

In respect to the treatment of rams after letting, it is remarked that the breeders of rams, as well as of bulls, find it expedient to reduce them from the cumbrous rate in which they are shewn, previously to the season of employ-
ment; the old rams, in particular, being frequently returned upon their hand, not-efficient. Hence, as they are let, they are transferred to private patures, and moderate keep; it being a pretty general rule not to flew a ram after he is let, or contracted for to a perfon.

In the sending out let rams, the usual time of beginning is the middle of September: the means of conveyance, car-
rriages of two wheels with springs, or hung in flings; some of them being large enough to hold four rams. In these they travel from twenty to thirty miles a day; being some-
times fent, in this way, two or three hundred miles, and sometimes more.

It has been observed by the same writer, that the manner of using these rams has lately received a very great improve-
ment. Instead of turning them loose among the ewes at large, as heretofore, and agreeably to the universal practiee of the island, they are kept apart, in a separate paddock or small
final inclosure, with a couple of ewes only each, to make
them rest quietly; having the ewes of the flock brought to
them daily, and leaping each only once. He thinks, by
this judicious and accurate regulation, a ram is enabled to
impregnate near twice the number of ewes he would do, if
turned loose among them, especially a young ram. And
he adds, that, in the old practice, fifty or sixty ewes were
effected the full number for a ram; in the new, from a
hundred to a hundred and twenty are allowed. Seven score
have been ferried by one ram in a season: this, however,
much too great a number.

And while at ride, the treatment of the ram is merely that
of keeping him well, and free from disorders; suffering him
to serve no other than the hireer's own ewes, and of these
the limited number only; and to return him safe when he has
done; generally the beginning of December: or, if the hireer
has met him on the road, (which is customary,) the latter,
in return, meets him on his journey home. And the after
treatment confines in friving, by every devoirable means, to
load his carcass, and make him fat and handsome for the
enfuing show, in order that he may be let again with advan-
tage.

This is the whole of the plan that was pursued in that
district, which has led the way to so much improvement in
the breeding of sheep flock; and from which the country
has derived such vast benefits, and such a number of advan-
tages. But though the above practices have not been lately
carried on to their former extent, they are still very con-
iderable. See Sheep.

It is remarked, that the practice of hiring rams in
Romney Marsh is not carried on with the same degree of
spirit as it is in Leicestershire, and that rams were of more
value for the hiring season some time ago than they are at
present, especially when the crops of the above county took
place, as then from twenty to one hundred guineas were fre-
fently given. One graizer some time since let rams to the
amount of twelve hundred guineas; but the rage is now
over, the people not being so foolish as to be duped out of
their money, without the prospect of being repaid. It is
here the practice with some to ride their ram lambs; but
they are paid always to be injured in their growth, if not in
their constitutions and dispositions, by it. When a ram
dies while at ride, the losbs falls on the owner, and, besides,
his is not paid for the riding. The time of paying is when
the rams are removed from the eves. This is done by car-
rying them away in carts, or leading them by ropes. The
ram lambs are here now mostly selected and faved, in such
numbers as are proper for the hire.

Some time before the riding season, the graziers call and
agree for the hiring or purchasing of rams, the general price
usually from three to five guineas; but a superior one will
bring ten in particular cases, though many good useful ones
let at three guineas. Some purchase them to ride, and im-
mEDIATELY afterwards sell them in the markets. The rams,
which are to be hired, are here flown all together in pasture
fields, which is a disadvantageous method.

In Suffolk, until lately, ten guineas were the highest price
that was heard of for the sale of any ram. Now some let
many of their three-years old rams for fifty; and inferior ones
let at three guineas. Some have even been let for as high as one hundred guineas.

RAM is also a term used to signify any thing which has
a strong smell or taint.

RAM, in Astronomy. See Aries.

RAM of M. Montgolfier, Hydraulie, in Mechanics, a ma-
chine for raising water to any given height, which has lately
attracted much attention in France. The first person who
employed this method was Mr. Whitehurst, and it was
afterwards improved by Mr. Boulton. Its contraction and
use may be sufficiently understood by the following state-
ment. It serves to raise water by means of the momentum of
a stream of water flowing through a long pipe. The
passage of the pipe being flopped by a valve, which is ra-
ised by the stream, as soon as its motion becomes sufficiently
rapid, the whole column of fluid must necessarily con-
centrate its action almost instantaneously on the valve, and in
this manner it loses the characteristic property of hydraulic
pressure, and acts as if it were a single fluid; so that, sup-
powering the pipe to be perfectly elastic and inextensible,
the impulse must overcome any pressure, however great,
that might be opposed to it; and if the valve open into a pipe
leading to an air-veil, a certain quantity of the water will
be forced in, so as to condense the air, more or less rapidly,
to the degree that may be required, for raising a portion of
the water contained in it to any given height. Young's
Course of Lectures on Nat. Philos. vol. i.

RAM, in Mythology, the name of the highest god among
the Gentoos. When a widow offered herself to be burnt on
the funeral pile of her husband, she was encouraged by the
presence of a number of attendants, who formed a circle
around her, and offered her fresh betel, intriguing that, as
she would in a short time appear with her husband in the
presence of Ram, or their highest god, she would supplicate
for various favours for them; and above all, that she would
salute their deceased friends, whom she might meet in the
cedal abodes, in their names.

RAM, Battering. See Aries.

RAM's-Horns, in Fortification, a name given by M. Beli-
dor to the tennailles.

RAM-Head, on board a Ship, the name of a great block
belonging to the fore and main halliards. It hath in it three
thieves, into which the halliards are put, and at its head
the eyes are reeved into a hole made there for that purpo-
se.

RAM-Head, in Geography, a cape on the S. coast of Ire-
land, and county of Waterford; four miles E. of Youghal
bay. N. lat. 51° 56'. W. long. 7° 44'. — Alio, a cape on
the S.E. coast of New Holland. S. lat. 36° 56'. E. long.
149° 35'. — Alio, a cape of England, on the S. coast of
Cornwall, in the English Channel, between Whiteband and
Plymouth Sound. N. lat. 52° 19'. W. long. 4° 12'.

RAM-Hornus, a town of Persia, in Chufiian; 65 miles
S.E. of Susit or Shimeh. — Alio, one of the most roman-
tic valleys in Persia, which has been lately placed under
the beglerbeg of Beshian. It is fifteen furlongs in length
(the furlong being estimated at 35 English miles), and from
fix to eight miles in breadth. The river Jeriski, entering at
the eastern extremity, flows through the centre of it, when
meeting the Koorokkanckend, which descends from the
mountains six miles E. of the town of Ram-Hornuz, they
gether force a passage through a low ridge of hills, which
skirt the valley to the south. This fertile spot is, at pres-
cent, in the hands of five hostile chiefs, the head of whom
is an Arab, who refides in a mean village, situated at the
W. end of the valley, and built amid the ruins of the an-
cient city of Ram-Hornuz. The remaining four are Per-
fians, and brothers, who have each a castle, or fortified vil-
lage; from which they make frequent forays, and carry off
the corn and cattle of their rivals. A great battle was
fought in this valley, between Artaraxers Babegan, and
Artabans, in which the former was victorious, and first
affixed the title of "Shah en Shah," or king of kings.
Kimier's Perf. Emp. 1813.

RAM's Islandt, an island in lough Neagh, Ireland,
about two miles from the shore, and containing about six
acres.
acres. It is in the western part of the lough, in what is called Sandy bay, and is the only island. One of the round towers, so frequent in Ireland, is found here, and renders it an interesting object from the neighbouring grounds.

Dubourdieu's Antrim.

RAMA, or Rama, a town of Palatine, which was formerly large, and defended with strong walls; celebrated as the place where St. Paul cured Aeneas. The Muffulmen reverence here the tomb of Lucian, the wife, and the sepulchres of seventy prophets, said to have been buried here. The church of St. George is the only object now worthy of notice. The place has a kind of market for gall-nuts, fans, and gun-arabic, which the Arabs bring thither for sale; 20 miles N.W. of Jerusalem.

RAMA, a town of Dalmatia; 20 miles S.W. of Molitar.

RAMA, or Ramah, signifying an eminence, in Scripture Geography, a town of Judea, in the tribe of Benjamin, according to the book of Joshua, ch. xviii. v. 20. It was situated towards the mountain of Ephraim, between Gaba and Bahel, about seven miles from Jerusalem, according to St. Jerom. This city lay on the road from Samaria to Jerusalem; for which reason Baasha, king of Israel, caused it to be fortified, to obstruct the passage from the land of Judah into that of Israel. This is the Ramatha, or Ramathaim-Zophim, the country of the prophet Samuel. (1 Sam. i. 1—19, and ii. 11, &c.) It was on the frontiers of Ephraim and Benjamin; and frontier cities were inhabited by both tribes. Jeremiah probably speaks of this Ramah. Jer. xl. 1, 2, 3. See also ch. xxxix. 15, 16, 17.

RAMA, a city of Naphtali (Joth. xix. 36.), on the frontier of Apher (Joth. xix. 29.).

RAMA, in Hindoo Mythology, is the name of a distinguished mortal, in whom their deity Vishnu was incarnated for the purpose of relieving mankind from the tyranny and oppression of Ravana, the malignant king of Lanka, or Ceylon. This incarnation is one of the ten avatars, or defects of Vishnu, and is, in its supposed importance, second only to that of Krishna. It is similarly a popular history, and allusions to it perpetually occur in the writings and conversations of the Hindoos. The invasion and conquest of Lanka is the subject of one of its finest poems, entitled the Ramayana; it furnished subjects for the drama, for itinerant bards, and for every purpose of poetry, being replete with magnificent imagery, and abounding in striking incidents. (See RAMAYANA.) The mortal parents of this divine hero were Raja Dafaratha, king of Ayodhia (Oude), and his first wife Kalumila. Hence Rama is sometimes called Dafat Rama, to distinguish him from other heroic Ramas; and sometimes Rama Chandra, meaning of lunar descent.

There are three persons of the name of Rama, recorded as incarnations of Vishnu. One is Bala Rama, the elder brother, by the same parents, of Krishna; the second, Parasu Rama; and the third, Rama Chandra, the subject more immediately of this article. But it has been made a question, whether they be not three representations of one person, or three different ways of relating the same history; and whether any or all of them mean Rama the son of Cuth, for W. Jones (Af. Ref. vol. i.) says he leaves others to determine. He deems Rama to be the same as the Grecian Dionysos, who is said to have conquered India with an army of satyrs, commanded by Pan; and Rama was also a mighty conqueror, and had an army of large monkeys or satyrs, commanded by Marut, son of Pavan. (See MARUTY.) Rama is also found, in other points, to resemble the Indian Bacchus: he is, notwithstanding his lunar appellation above noticed, fabled to be a descendant of the sun, his wife's name is Sita; and it is very remarkable that the Peruvians, whose Incas boasted of the same descent, fabled their great festival Ramafton.

In a charge delivered by Dr. Watson, afterwards bishop of Landaff, to the clergy of the archdeaconry of Ely in May 1780, are many curious and fresh observations on oriental usages. He notices a "firing of custom wholly the same amongst people far removed from each other as the Egyptians and Peruvians. The Egyptian women, he says, made sacred cakes of flour, which they offered to the queen of heaven, at their principal sular festivals called Raymi and Citua: the Peruvian women did the same." Almost all the customs described as common to these distant people, the Egyptians and Peruvians, as well as their, noted same Hindoo customs, ancient and existing.

All the Ramas are famed as great warriors and as youths of perfect beauty. In the Gita, an episode of the Mahabarat, Krishna, describing himself to Arjun as pre-eminent among all things and personages, says, "Among those who carry arms, I am Rama." It is Rama Chandra, however, and his lovely Sita, who are the favourite subjects of heroic and amatory poetry: he is described in the Ramayana as "of ample shoulders; brawny arms, extending to the knee; neck shelled-formed; chest circular and full, with auspicious marks; body hyacinthine; with eyes and lips of sanguine hue; the lord of the world; a moisture of Vishnu himself; the source of joy to Ikshwak's race." He is suitably mated in his faithful Sita, one of the most interesting females in Hindoo poetry. (See under her name for some account of her, and a description of her person.) Rama is also called Raghuna, or son of Raughu, (see these articles,) like Ikshwaku, one of his mortal ancestry. Kaka-pakshadara, or crow-winged, is an epithet given to the Ramas, and to other warriors, from a certain mode of shaving the head, leaving the hair over the ears only, resembling crow's wings, as is fancied. Sayamala, or blue-bodied, is an appellation of Rama, as well as of Krishna, and of their common prototype, Vishnu; all being represented of hyacinthine hue. It may be here remarked, that several incidents in the Sri-Bhagavat, (a history of Krishna,) and in the Ramayana, told similarly of their several heroes, seem to mix or approximate, though perhaps scarcely to identify, the characters of Krishna and Rama. Each won a wife by bending an unyielding bow, not very unlike the story of Ulysses. Each is described as overcoming the demon Kumbakarna, and others. Krishna descended into hell; so did Sita, the facti, or energy of Rama. Both have adventures with the bear Jambu. See JAMEA, &c.

All fefts and tribes, who, under the denomination of Vaishnavas (which see), worship Vishnu, (bating such delitical philosophers as sceptically deny the personal existence of inferior deities, attributes, or avatars, of whom (fee under JAINI,) agree in stating, that, with the exception of Krishna, the potentiality of the preferring power was never exhibited in such plenitude as in the avatar of Rama. In popularity, and in dramatic, historic, and poetic shapes, it rivals that of Krishna. And as one or more sects adore Krishna as the deity himself, and draw rules for their religious and moral conduct from the Sri-Bhagavat, so the sect called Ramuji similarly clothe Ram in allmighty attributes, and deem the Ramayana a complete body of ethics and morality. See RAMANJ.

In the series of incarnations of Vishnu, called das-avatara, or the ten defects, to distinguish them from others of less importance, the avatars of Parasu Rama and Rama Chandra are usually placed sixth and seventh, as given under VISNU. Sometimes Krishna is altogether omitted; in which case,
Bala Rama ranks as the eighth. *Majali is a name of the third Rama, under which word some notice is taken of him. And of *Parvga or *Parvga Rama, see under that article. The name of Rama, or perhaps more correctly of Ram, is one of the many names of *Parvga, comfort of *Siva. The name is also used, beyond the pale of his own sectaries, in supplication and praise. Ram-Ram is a usual salutation, like our good morrow, between friends at meeting or parting, and is used by both Vainhnavas and Saivas; and it is reverently reiterated in times, and in aid of abridgment (see *Jap); and under the operation of feelings of enthuilasm or dilett."

**RAMADA,** or *Nemi Salamanus, in Geography, a town of South America, in the province of St. Martha; 90 miles E. of St. Martha. N. lat. 17° 16'. W. long. 73° 20'.

**RAMADAN,** a fort of bent obtained by the Mahometans, in obedience to the express command of the Koran, during which they fast the whole day, from the time the new moon first appears, till the appearance of the next new moon, with such extreme flipperity, that they not only abstain from eating, drinking, and women, but dare not wash their mouth, nor even swallow their spittle, from daybreak till night, or fun-fet.

The men, indeed, are allowed to bathe themselves; but it is on condition they do not plunge the head under water, let alone drops enter by the mouth or ears, &c. But as for the women they are strictly forbidden bathing. Some are so cautious, that they will not open their mouth, to speak, lest they should breathe the air too freely. The fall is also deemed void if they kiss or touch a woman. To make amends, they fast all night till day-break; though the more rigid begin the fast again at midnight; and usually spend more in this month than in six others.

The Ramadan happens at different feasons of the year; and when it is in the summer it is very hard on the labourers. This month once in thirty-three years is in every season of the year, the Turkish month being *Humra, and they beginning at the day they can see the moon; whereas the Jews begin their account from the day the moon makes, which is a day before the Turks.

The reason given why the month of Ramadan was fixed upon for this purpose is, that on this month the Koran was sent down from heaven. From this fall of Ramadan none are excused, except travellers and sick persons, under which latter denomination are included all those whole health would be manifestly injured by keeping the fast; but then they are obliged, so soon as the impediment is removed, to fast an equal number of other days; and breaking of the fast is ordered to be expiated by giving alms to the poor.

**RAGILLE,** a term used by some of the chemical writers to express acids.

**RAGMIL,** a term used for the boughs or branches of trees. Hence, **Ragumile-Hawk, or Falcon,** one that is wild and coy, as having been long among the boughs, preying for itself. All falcons retain this name till they have lost the aery; being so called in May, June, July, and August. They are very rarely reclaimed. See *Branchier, Falcon,* and *Hawking.*

**RAGME** *Velvet.* See *Velvet.*

**RAMAGURKY,** in Geography, a town of Hindoostan, in the Carnatic; 30 miles W. of Trichinopoly.

**RAMAH,** a town of Arabia, in the province of Nedjed; 120 miles N.W. of Jammah.

**RAMAH, or Ramala, Rambla, Ramula, Ramba, Ruma, or Remarbi,** a city W. of Jerufalem, between Lydia and Joppa, according to St. Jerome; or between Joppa and Jerufalem, as modern travellers describe it. This is the place which Ezechias and St. Jerome took for Arimatheia, the country of Joseph. Matt. xxvii. 57.

**RAMAI,** in Natural History, a name given by many old writers to hole armecic.

**RAMAK,** in Ichthyology, a name given by some anatomical authors to the vent porte.

**RAMANU** the name of a religious sect of Hindoos, of the great subdivision of Vainhnavus, who worship *Vishnu,* the personification of the preserving power of the deity, in his incarnation of Rama. Of this sect some worship Rama only, some his spouse Sita, and some both Rama and Sita conjointly. (See *Rama.* Among the Ramanus none are addicted to the indecent, or left-handed, mode of worship noticed under the article *Raga* as disgracing her votaries. (See farther under *Sakti,* and *Sekts of Hindos.* The different sects of Hindoos are distinguishable by a variety of marks on their foreheads; of which a great many are represented in the second plate, with copious explanations in page 404, of the Hindu Pantheon. The sect of Ramanus are known by a double upright white line on the forehead, with a red line between, or sometimes a circle or dot. Sometimes the lines are red and the circlet black.

**RAMAS, Cape,** in Geography, a cape on the W. coast of Hindoostan; 21 miles S. of Goa.

**RAMASSERAM,** a town of Hindoostan, in the cir- car of Rajamundry; 33 miles S.S.E. of Rajamundry.

**RAMAYANA,** the title of a poem in the Sanscrit language, of great celebrity in India, and regarded as facred by some sects of Hindoos, and greatly venerated by all. Its subject is the exploits of three princes named Rama; but more especially the wars conducted by one of them, named Rama Chandra, for the conquest of Lanka or Ceylon, from its powerful sovereign Ravana, or rather, indeed, for the rescue of his wife from the hands of that tyrant. It is comprised in seven kandas, or books, containing 24,000 sthikas, or metrical stanzas; named thus: 1. Adi-kanda, containing 64 stanzas, and 2950 stanzas; 2. Ayodyiyaka, 80 stanzas, and 4750 stanzas; 3. Aranyakaka, 114 stanzas, and 4150 stanzas; 4. Kisikinda-kanda, 64 stanzas, 2925 stanzas; 5. Sundaraka-kanda, 43 stanzas, 2045 stanzas; 6. Yuddha-kanda, 105 stanzas, 4350 stanzas; 7. Uttara-kanda, 90 stanzas, 3350 stanzas. The Ramayana may be called an epic poem, as it is on one continued, interesting, and heroic action. It is second in celebrity only to the Mahabarat, and perhaps superior to it in reputation for holiness. (See Mahabarat.) We have the authority of Sir William Jones for saying, that this great epic poem, in unity of action, magnificence of imagery, and elegance of diction, far surpasses the elaborate work of Nonnus, in forty-eight books, entitled Dionysiacs; and for believing that the heroes of the poems Rama (patronimically distin- guished by the name of Dafarat Rama) and Dionysos are the same.
A curious parallel might be drawn between the manners and customs described in these two works, the Dionysiana and Ramayana. The proceedings and rites detailed in the former seem descriptively, with a little licence for poetical embellishment, of those in vogue to this day in India. Some of these Bacchic orgies are noticed under our articles Dionysus and Noxnea; which see. A keen etymologist would find innumerable linguistic coincidences; and, in truth, many of the names of persons, Bacchus and Dionysos, and of places, as well as original persons, seem soberly traceable to the sacred language and rites of the Brahmins.

So highly is the Ramayana venerated, that the fourth class of Hindoos, the Sudra, is not permitted to read it. At the end of the first book, a promise is made of great benefit to any individual of the three first classes or castes, who shall duly read it. “A Brahman, reading it, acquires learning and eloquence; a Khatriya will become a monarch; and a Vaisy will obtain vast commercial profits; and a Sudra, hearing it, will become great.” Of these distinctions of tribes or classes, the reader will find due notice under Strees of Hindus.

Under Rama we have stated that his name reiterated is used by several sects as a sort of salutation, or benediction. The author of the Ramayana, in the vanity of playful egotism, which, from its frequency with oriental poets, has ceased to seem amusing, calls on his readers to “salute Valmiki, the kukiia (cuckoo), who, mounted on the branch of peepal, founds the delightful note of Ram-Ram.”

It has been surmised that the Ramayana, like the Mahabharat, is allegorical, so far as relates to personal adventures; which, in both cases, are mere machinery for the introduction of a concealed system of philosophy and ethics: in the first instance the allegory is physical, in the latter moral. Under the article MAHABHARAT the allegorical nature of that extraordinary poem is sufficiently shewn. The Kurus and Pandus, the heroes of that poem (see KURU AND PANDU), are personifications of virtues and vices. The Ramayana and the Dionysiana relate how their respective Indian conquerors led armies of fayts. (See hereunder MARUTY AND RAMA.) These fayts, or monstae, we apprehend to be personifications of winds, or gaseous metaphors. In the Ramayana we find the machinery to confit of the sun and planets, fire, the firmament, wind, water, &c. personified in the gods or regents of those bodies, elements, &c. It has been farther surmised, that whenever these two extraordinary poems, the Mahabharat and Ramayana, shall appear in English, and their allegories be more fully examined, it may possibly be found, that not only the three Ramas will melt into one, but that all will amalgamate with Krishna. Some objections to the identity of the Rama and Krishna, have been offered of a chronological nature. Paracur Rama, it is contended, reigned or flourished eight generations before Rama Chandra. Their poetical identity, however, is sufficiently established; and one can scarcely bring a tiffle of allegory, incarnations, and whimsical adventures, to the text of sober historical and chronological accuracy. The names of these two Rama have been so mingled, so amalgamated, at all given periods, for they have always been so commonly used, as to be full.

The Ramayana is so replete with incident, that it is carelessly possible to give any analysis of its subject with sufficient brevity for this work. Unity of action is, however, its characteristic, namely, the recovery of Sita from the hands of her ravisher Ravana, the gigantic tyrant of Ceylon. It may be noticed in passing, that the Ramayana, like the Iliad, is founded on a rape, and that Sita is the Helen of the Hindoo epic. (See SITA.) So inextricably intermixed are the varied subjects of the Hindoo mythological history, that the diffusion of one necessarily brings another under notice. This is the cause of such frequent references to and from the articles under which we have endeavoured to give a succinct account of such a number of subjects of that description, distinct apparently, but in reality connected, and often confounded with each other. On the subject of this article, the Ramayana, or for quotations from it, we may therefore refer to the following, among others: CEYLON, LAKSIMI, LANKA, MANTRA, PARASU RAMA, MENAKA, RAVENA, and THEMBA, in addition to those pointed to in earlier paragraphs of this article, and those articles just named.

What precedes, referring to the poem bearing the title of this article, is offered respecting the Ramayana of Valmiki. There are many other poems of the same name in Sanskrit, Prakrit, Hindi, and many other Hindoo dialects, as well as in Arabic, Persian, Malayen, and others derived from the like source. These are of course of unequal celebrity and merit; and acknowledged to be greatly distant from Valmiki’s divine poem. Even of this it may be said, that the style is frequently flat and diffuse, the deficient in ornament, and abundant in repetitions. As well as Valmiki’s work, several others, under the same title, are usually confounded with more respect than more profane poems. Some is ascribed to Vyasa, the reputed author or compiler of the Vedas and Puranas. (See those articles.) A considerable portion of several of the latter mythological romances is occupied by the same subject, to wit, the adventures of Rama; but in the Vedas no mention is made of this person, except, indeed, in some detached parts, reasonably suspected to have been interpolated by zealous sectaries. The titles even of the philosophical and profane poems, commentaries, &c. that in divers languages owe their origin to the Ramayana, would require a catalogue of no inconsiderable extent to contain them. Among these are included many dramatic works. The quotations from, and allusions to its mythological personages and fables, in the works of the minor poets, are incessant; and upon the whole, there is no subject, perhaps, in the whole range of Hindoo mythology, or history, so often in the minds and mouths of that race of all ranks and sects, as the story of the Ramayana in some of its bearings. That of Krishna rivals it in popularity. Both are chanted by itinerant bards, who illustrate their subjects by exhibiting a series of pictures from the Ramayana and Mahabharat. Women flogers frequently accompany these eastern troubadours, who are commonly met with in every city, camp, and town of India.

RAMAZZINI, BERNARDIN, in Biography, an Italian physician of distinction, was born at Carpi, near Modena, in 1639, where his father was a respectable citizen. Having received a classical education from the Jesuits at his native town, he went to Parma for the study of philosophy at the age of 19, undecided what profession to adopt: at the end of three years he selected that of physic, and received the degree of doctor at Parma in the beginning of 1659. He then repaired to Rome for the completion of his studies, and settled in practice in the duchy of Caffero. He was soon obliged by ill health, however, to return to his native air; and, on his recovery, he married, and pursued his profession at Carpi. Finding his reputation increasing, he removed to Modena, at the solicitation of some friends, in 1671, where he met with merited success, and excited the jealousies of his brethren. In 1682 he was appointed professor of the theory of medicine in the university, which had been recently established at Modena, by Duke Francis II.; and he continued to fill this office for eighteen years, attending at the same time to practice, and not neglecting the cultivation of polite literature, to which he was particularly partial. The
elegance of his Latin style in his writings, evinces the suc-
cess with which he pursued the study of the classics. In
1700 he was invited to a professorship at the more distin-
guished university of Padua, and removed thither. Though
somewhat advanced in age, he fulfilled the duties of his
chair with an ardour, not to be surpassed by his junior col-
leagues, for the space of three years, when he was attacked
with a disease of the eyes, which threatened to destroy his
vision, and which, in fact, did ultimately deprive him of
that faculty. Having lost the pleasure of reading, which
was the only source of his regret, he supplicated that annul-
ment by the assent of his grand-children, who read to
him, and acted as his amanuenses. In 1708, however,
the senate of Venice appointed him president of the college
of physicians of that capital, and in the following year raised
him to the first professorship of the practice of medicine.
He continued to perform the duties of these honourable
posts, at the earnest solicitations of his constituents and
pupils, with great diligence, to the end of his life, and died
on his birth-day, November 5th, 1714, in consequence of
an attack of apoplexy, which feized him while he was
preparing for his lectures, at the age of 81.

Ramazzini was a member of several of the academies
of science established in Germany, Berlin, &c., and left several
works; the principal of which, and one which will ever
be held in estimation, is his treatise on the diseases of artifists
and manufacturers, entitled "De Morbis Artificum Dia-
trib," first published in 1700, and frequently reprinted.
He also published some tracts relative to certain epidemics,
both among men and cattle; some "Epilomerides Barome-
trices;" a work on the abuse of Peruvian bark; and several
orations delivered in his professorial capacity. All his
works have been collected and published together at Padua,
Geneva, London, and Naples; the edition of London is
the most correct. Eloy Diet. Hist. de la Med. Hutchin-
fon's Biog. Med.

RAMBANG, in Geography. See Rembang.

RAMBERVERVILLE, or Remberville, a town of
France, in the department of the Vosges, and chief place
of a canton, in the district of Epinal; 19 miles E. of Mere-
court. The place contains 4926, and the canton 14,014
inhabitants, on a territory of 317½ square kilometres, in 28
communes. N. lat. 43° 21'; E. long. 6° 43'.

RABIN, a town of Anterior Pomerania; 10 miles
W.S.W. of Bergen.

RAMBÉ, a town of Spain, in the province of Cor-
dova; seven miles N.W. of Montella.—Alfo, a town on the
W. coast of the island of Teneriffie; three miles W. of La-
guna.

RAMEBOULLET, a town of France, in the depart-
ment of the Seine and Oise, and chief place of a canton, in
the district of Verailles, the seat of a tribunal, and of a na-

dional, farm, where the sheep are much celebrated for the
fineness of their wool; 27 miles S.W. of Paris. The

place contains 2586, and the canton 9652 inhabitants, on
a territory of 305 square kilometres, in 17 communes. N. lat.
48° 30'. E. long. 1° 54'.

RABREURE, a town of France, in the department
of the Somme; 3 miles W. of Oiffemont.

RAMBURELLES, a town of France, in the depart-
ment of the Somme; 9 miles S. of Abbeville.

RAMCIUND-POUR, a town of Bengal; 30 miles
N.E. of Calcutta.

RACHUNDA, a town of Hindoostan, in the cir-
cus of Mohurunge; 23 miles S.S.E. of Harripour.

RAMICHUNP, a town of Bengal; 60 miles N.
of Dhecca.

RAMCOTT, a town of Thibet; 13 miles S.W. of
Simangur.

RAMCOUTY, a town of Hindoostan, in Bahar; 28
miles N.E. of Goorackpore. N. lat. 26° 51'; E. long.
8° 8'.

RAMDILLY, a town of Hindoostan, in the Nayrs;
25 miles N.N.W. of Tellicherry.

RAMEAU, John Philip, in Biography, chevalier de
St. Michael, compofer to the king of France, and to the
Academy Royale de la Musique, or leen operas at Paris, was
born at Dijon in 1683. He went early in his life to Italy,
and at his return was appointed organist at Clermont en
Auvergne, where his "Traité de la Musique" was written,
in 1722. He was afterwards elected organist of St. Croix
de la Bretomnerie at Paris. Here his time was chiefly em-
ployed in teaching; however, he published harpsichord lec-
tions, and several other theoretical works, without distin-
guishing himself much as a vocal compofer, till the year
1733, when, at fifty years of age, he produced his firt
opera of "Hippolitc et Aricie." The music of this drama excited profefsional envy and national difcord. Part
rage was now as violent between the admirers of Lulli and
Rameau, as in England between the friends of Bononcini
and Handel, or, in modern times, at Paris, between the
Gluckists and the Piccinistis.

When the French, during the last century, were so con-
tented with the music of Lulli, it was nearly as good as
that of other countries, and better patronized and supported
by the most splendid prince in Europe. But this nation, so
frequently accused of more volatility and caprice than their
neighbours, have manifestly a steady perfevering ftanchy
in their music, which the strongest ridicule and contempt of
other nations could never vanquish.

Rameau only answered his antagonists by new productions,
which were still more successful; and, at length, he was ac-
nowledged by his countrymen to be not only superior to
all competition at Paris, but sole monarch of the musical
world. From 1733 to 1760 he compos'd twenty-one operas,
of which the names and dates are annually published in the
"Speciales de Paris," and in many other periodical works.
Rameau's style of compofition, which continued in favour
almost unmolested for upwards of forty years, though formed
upon that of Lulli, is more rich in harmony, and varied in
melody. The generos, however displeasing to all ears but
those of France, which had been nuri'd in it, was carried
by the learning and genius of Rameau to its acme of per-
fection; and when that is achieved in any fyle, it becom-
es the business of subsequent compofer's to invent or adopt
another, in which something is still left to be done, besides
fervile imitation.

The opera of "Callor and Pollux" having been long re-
garded in France as the matter-piece of this compofer, we
shall here insert a few remarks upon it, that have been made
on a recent examination.
The overture is the beft of this author, upon Lulli's plan.
The opening symphony is beautiful; but why the fame me-
loidy was not applied, in the fame meafure, to the poetry,
we know not, unlefs the verification required a change of
time; but, in that cafe, why write the symphony on a sub-
ject that would not suit the words? But tho' eternal
changes in the meafure, which teaze and difappoint the ear
of all that are nuf'd to other music, is general in feroius
French operas, and seems as much the fault of the poet as mu-
ician. It is, however, wonderful, that this defect was not
sooner discovered. The over-charged tendernefs of Ra-
meau's music appears in all his flow movements, which are in
one fyle, and generally in triple time. This matter perpe-

11
RAMEDEGA, in Geography, a town of Hindooftan, in the cir- 
car of Gungour; 15 miles S.W. of Pada.
RAMEL, a town of Bengal; 50 miles S. of Isla-
mabad.
RAMEEPATAM, a town of Hindooftan, in the Carnatic; 30 miles S. of Onogo.
RAMEEPOUR, a town of Hindooftan, in Allaba-
dad; 35 miles E.N.E. of Gazyprop.
RAMELLI, Agostino, in Biography, a celebrated 
Italian mechanic and engineer, was born, in 1520, at Ma-
fasanana, in the diocese of Milan. Having entered the 
army, he served a considerable time under the marquis de 
Mariagnato, a general of Charles V. After this, he served 
under the duke of Anjou as captain, or engineer, at the 
flege of Rochelle, in 1573, where he was dangerously 
wounded, and taken prisoner. When that prince, afterwards 
Henry III., was called to the crown of Poland, he was the 
friend of Ramelli, and he nominated him his engineer when 
on the throne of France. In 1588 he published a work in 
Italian and French, entitled "Le Diverse et Artificiale Ma-
chine del Capitano Agollo Ramelli," &c. with nearly 
200 figures, describing a great number of machines for vo-
rious purpofes, most of his own invention, and which exhi-
bibit much ingenious contrivance. The work is very scar-
er, and is much prized by the curious.
RAMELSBACH, in Geography, a town of Ausfria; 
5 miles S.E. of Meiflai.
RAMELTON, or Rathmeltou, a small poft-town 
of the county of Donegal, Ireland, situated on a bay at the 
bottom of lough Swiilly. It is 117 miles N.W. by N. from 
Dublin.
RAMENAPILLY, a town of Hindooftan, in the cir-
car of Rajamundry; 42 miles E. of Rajamundry.
RAMENTUM, in Botany, a form of pubefcence in 
plants, which, as the name signifies, has the appearance of a 
shaving, being flat, membranous, mostly irregular in figure 
and shape, quite unlike the uniform hairs or bristles of which 
the clothing of molt plants confifts. (See PUBECE.
ENCE.) The above term was first used, if we recollect rightly, by l'He-
ritier, and occurs in some species of Begonia. The scabieus 
of Ferns is of a fimilar nature.
RAMERUP, in Geography, a town of France, in the 
deartment of the Aube, and chief place of a can-ton, in the 
district of Arcis-fur-Aube; 6 miles E. of Arcis-fur-Aube.
The place contains 403, and the can-ton 8870 inhabitants, on a 
territory of 440 kilometres, in 29 communes.
RAMESAN, an oriental term for a month of fasting, 
very religioufly observed among the Turks, and otherwife 
called Ramadan; which fea.
RAMESERAM, in Geography, a town of Hindooftan, in 
the cir-car of Cuddapa; 6 miles E. of Gandicotta.
RAMETTA, a town of Sicily, in the valley of De-
omana; 6 miles W. of Messina.

RAMEX,
RAMEX, (ramus, a branch,) in Surgery, a rupture, or hernia. See HERNIA.
RAMEX Varicosus. See CHRISOCELE.
RAMGAD, in Geography, a town of Hindooftan, in Bahar; 10 miles W. of Bahar.
RAMGARY, a town of Hindooftan, in the country of the Narys; 19 miles W.N.W. of Palancheonry.
RAMGAUT, a town of Hindooftan, in the subah of Delhi; 37 miles S.E. of Secundara.
RAM-GETTER, in Rural Economy, a term applied by the midland breeders to such rams as are proper for getting ram-flock, in contradiftribution to fuch as are fit only for getting wedder-flock. See Ram.
RAMGONGA, in Geography, a river of Asia, which rises in Tibet, and runs into the Ganges, 10 miles N. of Canoge.
RAMGOT, a town of Hindooftan, in Cooncan; 25 miles N. of Goa.
RAMGUR, a circur of Bengal, bounded on the N. by Bahar, on the N.E. by Curruckdeagh, on the S.E. by Pachete, on the S. by Nagpur, and on the W. by Koonda and Toree; about 90 miles long, and 60 broad.—Alfo, the capital of this circur; 175 miles W.N.W. of Calcutta. N. lat. 23° 40'. E. long. 83° 42'.—Alfo, a town of Hindooftan, in Dowlatabad; 33 miles S. of Neermoil. N. lat. 18° 30'. E. long. 79° 11'.—Alfo, a town of Hindooftan, in Malva; 8 miles S. of Ragooopour.—Alfo, a town of Hindooftan, in the subah of Delhi; 5 miles N. of Coel.—Alfo, a town of Hindooftan, in Guzerat; 50 miles E.S.E. of Surat.—Alfo, a town of Bengal; 13 miles N.W. of Midnapour.
RAMGUR. See SESVAM.
RAMGURRA, a town of Hindooftan, in the Myfore, captured by the English in 1791; 42 miles N.E. of Seringapatam.
RAMHYTTE, a town of Sweden, in Gotlandland; 36 miles from Stromfohn.
RAMI, in Hindoo Mythology, one of the many names of the goddef Parvati; which fec. Under this name the fie is faid to be worthifhipped at the fpringid temple on the ifland called Ramiferam, between Ceylon and the cape named barnes Comorin, but which fhould be called cape Kaumari, or Kumari, another of the names of this goddef, and meaning the virgin. (On this point fee LANKA and PARVATI.) Sami is the name of a tree or woof freighted with Parvati, and she is sometimes called Sami Ram; and it has been ufhed that this is the origin of the Semiramis of the Greeks, (See hereon A¥. Ref. vol. iv. p. 382. vol. viii. p. 256. Svo. ed.) A description of the celebrated temple of Ramiferam will be found under that article. See also SAMI.
RAMI-AVENPOUR, in Geography, a fort of Bengal; 27 miles S.S.W. of Bardwan.
RAMIFICATION, the production of boughs or branches, or of fpecies reharlling branches.
RAMIFICATIONS, in Anatomy, are the divisions of the arteries, veins, and nerves, arifing from some common trunk.
RAMIGNI, a word ufed by fome writers as a name for colophony.
RAMILLIES, in Geography, a village of France, in the department of the Sambre and Meufe, at the forace of the river Geete; worthy of being recorded on account of a battle fought here in the year 1706, between the allies commanded by the duke of Marlborough, and the French under marshal Villery. The confederates took the whole of the enemy's baggage and artillery, and about 120 standards, 600 officers, and 6000 private feldiers: about 8000 were killed or wounded. The lofs of the allies did not exceed 3000 men; 13 miles N. of Namur.
RAMING, a town of Aufrria; 11 miles S. of Steyr.—Also, a town of Persia, in the province of Irak; 40 miles E. of Cofar.
RAMINGHAM, a town of Hindooftan, in Dowlatabad; 10 miles N. of Oudigher.
RAMINGSDORF, a town of Aufrria; two miles E. of Steyr.
RAMINGUE, in the Manche. A horse gets this name that is relive, and refifts or cleaves to the purs; that is, defends himfelf with malice againft the purs; fometimes doubles the runs, and frequently yeiks to favour his difobe- dience. See TIECHIF and DOUBLE.
RAMIS, BARTOLOMEO, in Biography, a Spaniard, the firft modern who inflaniffed the neceffity of a temperament in musical instruments, of which the tones are fixed. He was contemporary with Franchinus, and in 1482 published a work, entitled "De Musica, Tractatus, five Musica practica."
He feems to have converted Petro Auran to his opinion; as that theorift manfully exalts the character of Ramis on all occasions at the expence of Franchinus.
The Spaniard was attacked in a rough manner by Nicholas Bur'tius, for differing from Guido in his division of the monochord, in a tract entitled "Musices Opus- lum cum Defenf. Guidonis Aretrini adversus quendam Hilpamian veritatis praecipitator." Benon. 1487. This tract, printed in black letter, is in the Afolm Collec- tion among the books of Ant. Wood.
Burtius imagined the honour of Guido to be injured by the Spaniard, as Guido ufed the Pythagorean proportions, and had never thought of a temperament. Burtius, in his turn, was handled very roughly by Spataro, the disciple of Ramis (Ioannes Spadarius Bononiensis, Musices ac Bartolomii Rami Paulo ejsus praecipuis honenti Defenfio in Nicol. Burtij Paraff. Opus. Bologna, 1491.) and the venerable Franchinus, finding himfelf very rudely handled in the dis- pute by the favourers of temperament, in 1522, when he was upwards of seventy years of age, took up the defence of Pythago-ras, as Fontenelle, at near a hundred, did of Des Cartes. After this, the war became general, and continued to rage with great violence for more than a century, between the friends of tempered scales, and the adher- ents to ancient proportions and equal harmony.
RAMISERAM, in Geography, an ifland in the Indian fea, between the ifland of Ceylon and the coast of Coromandel; to which there is a passage of about 12 or 14 leagues from the ifland of Manaar, on the coast of Ceylon. But the advantages that might be derived from this fpedy communication are in a great measure prevented by the numberof shallow fea and bank-banks, which every where interrupt the passage, and which are fo high, that many of them are dry except during the monfoons. There is in particular a line of bank-banks, which runs quite across from Manaar to Ramiferam, denomi- nated Adam's bridge, and also Rama's bridge, becaufe God is faid to have come by this way into Ceylon. (See Adam's Bridge and Manaar.) From Rama, Ramiferam takes its name, and it has a large temple dedicated to him. The fortrefs of the passage from Ramiferam to Manaar is particularly useful on account of the fpedy conveyance it affords to people on bufnics, and the communication of intelligence. The mealfongers who usually go from Columbo to Manaar, a diftance of 160 miles, in three days, take boat here, and crofs over by Adam's bridge to Ramiferam, and then proceed along the Coromandel coast to Madras. An
express in favourable weather will run from Columbo to Madras in eight days, and the journey has been accomplished once in seven days. (See MANAR.) The site of Ramisieram, which is the limit of the Hindu religion in more modern times, and of the conquests of the Mughulman princes, is, as we have said, separated from Ceylon by Adam's bridge. The island is low, sandy, and uncultivated, except with a few scattered Palmyra and cocoa-trees. The pagodas, for which it is so famous, lie on the Ceylon side, near the sea, and are the refection of innumerable multitudes of different sects of religion in India, during the season of certain festivals. The numerous pagodas are constructed in the same style with those on the Coromandel coast; and they are surrounded with the houses of the brahmins, priests, and other religious persons, whose zeal leads them to attend on their temples; among whom, in particular, may be seen the descendants of the Tamuls, Telingas, Canarions, Mahbrattas, and Oria, who compose a great body of the original inhabitants of the southern peninsula. Their houses are built of the cocoa-tree, in small squares and streets, where their families are seen reclining on the little mud terraces, and under the 'payals or virandals. They do not allow Europeans to enter these temples; but they are known to resemble those of the coast in their crowded ornaments, spires of brickwork, long porches in front, and viutas, at the extreme end of which are placed the deities, in an obscure situation, surrounded by lamps burning day and night. It seems strange to think of so many temples on the coast of Ceylon. The Brahmins allow no labour or cultivation to be carried on in the island of Ramisieram, considering it altogether as fared. The contributions of these who visit it are sufficient for the support of the temples. Several of the neighbouring Poligar chiefs contribute largely, and some of these rajahs have statues erected to them for their gifts. The chief pagoda has several of these statues in its different squares. Low as the land lies in this island, good water is easily procured; for on scooping it up, the water collects immediately in the holes; but this is not the case in Manar and the west coast of Ceylon.

The guardianship of this sacred temple belongs to a family of devotees, called "Byrgees," the chief of whom is always doomed to celibacy: the succession being carried on by the litter or the collateral branch, who only are permitted to marry. This institution is similar to that of the sovereignty of the Travancorians and Nairs of the Malabar coast. The clothes and turbans of the devotees are of a tawny red colour, decorated with large black beads, of a particular kind of wood. From the pagodas just mentioned there runs out a long narrow piece of land, terminating in a point, within a mile of which is a choultry at Tone Goody. This is a square of houses with a court inclosed for the accommodation of pilgrims, who come to the farthest point of the island to perform their ablutions in the sea, the most sacred and the purest of their ceremonies. A brahmin takes care of this choultry, and a pole with a light is fixed at the end of the point to direct the pilgrim. N. lat. 9° 18'. E. long. 76° 22'. Percival's Ceylon.

Of the temple in this island we shall give some account, extracted from a publication of Mr. Cordiner, who visited it. The external appearance is not remarkably grand, and at a distance, no idea is excited of the minute ornaments and laboured workmanship which strike the eye on a nearer inspection. All the architecture seen without doors is insignificant, compared with the magnificence of the interior. After an examination of the whole structure, which is entirely of hewn stone, Mr. C. deemed the extent of masonic labour in its execution, must have been equal to that of any of the most splendid cathedrals of Europe. "On entering it we were," he says, "completely astonished at the grandeur of the workmanship, and extent of the dimensions, which far surpassed any idea that we had formed of Indian magnificence." From the west gate a low gallery, 144 feet in length, with three rows of pillars on each side, leads down to the centre of the building; where it branches off, in galleries similarly constructed, to the right and left, each extending 150 feet, then running from west to call 500 feet, and enclosing an oblong rectangular space. The galleries run also along the centre of the temple 788 feet, and a similar gallery runs across from north to south, where are the entrance, interjecting the former in the centre of the rectangular space. All the galleries have on each side three rows of lofty stone pillars, of highly laboured workmanship. Those in the front line are the largest and most superb, having a huge lion, with the mouth wide open, sculptured in bas relief, above three distinct capitals, over which is a scroll, and a richly ornamented cornice. Statues of the size of life are attached to many of the pillars, representing gods and deified persons. The pillars stand on a continued basement, forming the floor of the galleries, raised three feet, with steps to ascend by, all of stone. The roofs of all the galleries are flat, formed of slates reaching across, from the projection of one cornice to that of the other. The galleries are eighteen feet wide, and in the centre thirty feet high from the floor. The number of pillars within the temple amounts to 2525. The edifice is inclosed by a heavy stone wall, 20 feet high, 830 feet from call to call, and 625 from north to south. Large as these dimensions may appear, they are rated to be but small compared with those of temples on the continent of India, one of which covers a square mile of ground. The covered gallery, fronting the south gate, which seems unfinished, strikingly resembles the entrance of the Elephants' cave, near Bombay. Solid pyramidal crenations surmount the western and eastern entrances, composed externally of a great number of small pillars, two and two, in the form of window frames or gateways, rising one above another, in seven different stories. That over the western, which is the principal entrance, appears to be 150 feet high; the eastern seems lower, and unfinished. The north and south gates are less majestic than the others; but their completion is said to be intended, when they will be similarly surmounted and ornamented as the western portal. Privileged persons, among whom were women carrying water-pitchers, appeared constantly passing and re-passing about the interior of the temple.

Two hundred Brahmins are attached to this temple, and supported in ease and luxury by its endowments. It is dedicated to Siva, the destroying power, called by the vulgar Rama Lingam. It contains likewise, Mr. Cordiner says, images of Vishnu the preserver, and of all the subordinate divinities. Of Brahma, the creator, he states, the Hinduos never dare to form any likenesses. This is a common error, that is explained and corrected in the article POLATRY of this work.

A broad street runs parallel to each side of the temple, composed of comfortable houses, and large choultries for the accommodation of pilgrims and travellers, of stone, with flat roofs supported in front by pillars; the fronts being open. In one of these Mr. Cordiner observed two ivory palankeens inlaid with gold, the property of officers belonging to the sanctuary. In others he noticed five carriages, called by the English Swamy coaches, used for the purposes of carrying the idols in procession: the upe to which the ivory palankeens are, we apprehend, also applied. These
These carriages are described as solid masses of wood, of a pyramidal shape, intended to symbolize the Linga. (See Linga.) The exterior of these coaches are covered with grotesque obscene carving.

At the external corners of the temple, and in the streets of the town, there are smaller temples in honour of different deities, and containing images. In some of the streets spreading trees, among them the ficus religiosa and tamarind, are surrounded with square stone terraces, on which are placed little images of Pollear or Ganefa, (see Pollear,) the Linga, two serpents entwined, and other emblems of Hindoo mythology. These terraces are used for contemplation, or more active religious duties, as noticed under the article Pradaekhina. Rows of fruit-trees, among them the cocoa-nut, plantain, and pomegranate, frond in gardens beyond the north and south walls of the temple.

On the opposite side of the island, near the sea, distant about eight miles from the temple, is the ancient fort and choultry of Pombom. The road between is very pleasantly paved with smooth stones, each six feet by four; and the greater part of the road is nobly shaded by the most beautiful and majestic trees. The larger trees of this superb avenue are surrounded by smooth raised terraces of mossy on which travellers rest in comfort, completely shaded. About half way between the great temple and Pombom is a very elegant small temple, built on the same general plan with the larger, having two lofty towers raised in the centre of the oblong area, and a covered walk, with three rows of pillars on each side, all round. The outside of the towers is completely covered with statues in miniature, representing all the variety of their mythological divinities. The choultry, for the accommodation of pilgrims and travellers at Pombom, has two fronts, and three inclosed squares; and is surrounded by piazzas raised several feet, with square pillars and terraced roofs. Contiguous is a small temple, the door of which was open, displaying an image of Ganefa or Pollear, in the usual form, elephant-headed and pot-bellied, ornamented with necklaces of flowers.

There are several other elegant temples on this interesting island, which is entirely dedicated to the purposes of religion. No plough is allowed to break the soil, and no animal, wild or tame, is ever killed on it.

Dancing girls, mountebanks, and beggars, abound here, as in other resorts of the idle and wealthy.

The small remains of antiquity still extant on Ceylon, sufficiently prove that similar religious institutions did once exist there, and that choultries and temples were erected at the different stages, all the way from Manar through the island, 200 miles, to Dondra, its southern extremity, and the ultimate extent of Hindoo pilgrimage. At the latter place, the ruins of a temple dedicated to Siva are still to be recognized; but only some rows of scattered pillars, and a few remnants of broken images, have survived the fanatic fury of the early European invaders. Ramz's peaceful island falling under the protectorate of a more liberal and enlightened government, fortunately escaped those religious tempests, which spread destruction round the coasts of Ceylon.

Lord Valentia has more recently visited this interesting scene, and Mr. Salt, who accompanied his lordship, has published a very elegant view of the temple. The entrance is described to be through a gateway, about 100 feet high, covered with carved work to the summit. The door is 40 feet high, composed of single stones placed perpendicularly, with others crossing. This massive workmanship reminded Lord Valentia of the ruins of Egyptian architecture. He describes the quadrangle to be about 600 feet each side, and fays that, on the whole, this temple is the finest piece of architecture that he had seen in the east. Words, he says, cannot describe its magnificence. The concourse of pilgrims is very great, and brings in a large sum; each paying according to his rank. The raja of Tanjore had been expected the year before, but could not afford it; as in previous and various expences, it was estimated that his hignefs could not have performed this act of devotion under 60,000 pagodas, about 25,000/ sterling. His whole family would of course have expected to participate in the happiness and benefits of the pilgrimage. The idol ufed no water but what is brought from the Ganges by fakirs; with this it is bathed every morning; and this holy water, thus acquiring additional sanctity, is bought and purchased by the devotee for expiatory purposes.

RAMISTS, in the History of Learning, the disciples of Peter Ramus, who was born in a small village in Picardy, in 1515, and from being a ser vant in the college of Navarre at Paris, became, by his talents, industry, and perseverance, one of the most famous professors of the sixteenth century. By attacking the authority of Aristotle, and attempting to sublimate in the place of his logic a method of reasoning better adapted to the use of rhetoric and improvement of eloquence, he excited a terrible uproar in the Gallic schools; so that the two first books he published, viz., his "Institutiones Dialecticae," and "Aristotelice Animadversiones," were prohibited through the kingdom of France, and the author prohibited from any more teaching philosophy. His enemies perverted him with lampoons and fatares, and even held him up to public ridicule on the stage. However, Ramus afterwards recovered his credit, so that he obtained the royal professorship of philosophy and eloquence, and afterwards of mathematics, at Paris, in 1547. But his enemies were inveterate in their persecution of him, and as soon as it was known that he favoured the party of the Hugonots, he was obliged once again to withdraw himself from the effects of their resentment. In the interval of peace, he returned to his isolation; but in 1568, when the civil war was a third time renewed, he resolved to leave France, and make a tour through Germany. After spending three years in visiting the principal German universities, and receiving many tokens of respect, he resolved, fatally for himself, in 1571, to return to his own country. Accordingly he settled at Paris, where he perished in the massacre on St. Bartholomew's day. On the tumult of this execrable day, Charpentaire, professor of mathematics, who had been eclipsed by the superior talents of Ramus, seized the opportunity of being revenged on his rival, and, under the pretence of religion, employed assassins to murder him. His body was afterwards thrown into the Seine to the enraged pupils of Charpentaire, who dragged it ignominiously along the streets, and then cast it into the Seine.

The disciples of Ramus, such as was the astonifbing influence of their master's learning and character, prevailed so far as to banish the Peripatetic philosophy from several universities of learning, and to substitute in its place the fyltem of their master, which was of a more practical kind, and better adapted to the purposes of life.

Although he had considerable merit in expounding the defects and inconsistencies of the Aristotelian philosophy, he does not seem to have been equally successful in his attempt to establish a new logical institute. The general outline of his plan is as follows. Considering dialectics as the art of deducing conclusions from premises, he endeavours to improve this art, by uniting it with that of rhetoric. Of the several branches of rhetoric he considers invention and disposition
position as belonging equally to logic. Following chiefly the example of Cicero, he divides his treatise on Dialectics into two parts; the first of which treats of the invention of arguments, the second of judgments. Arguments he derives not only from what the Aristotelians call middle terms, but from any kind of propositions, which, connected with another, may serve to prove any altercation. Of these he enumerates various kinds. Judgments he divides into axioms, or self-evident propositions, and "dianoëa," or deductions by means of a series of arguments. Both these he divides into various classes; and illustrates the whole by examples from the ancient orators and poets.

In the logic of Ramus, many things are borrowed from Aristotle, and only appear under new names; and many others are derived from other Greek sources, and particularly from the dialogues of Plato, and the logic of the Stoics. Whilst the author has the merit of turning the art of reasoning from the futile speculations of the schools to forensic and common use, his plan is defective in confining the whole dialectic art to the single object of disputation, and in omitting many things which respect the general culture of the understanding, and the investigation of truth. Defective as the systém of Ramus is, lord Bacon (Augm. Sc. i. vi. c. 2.) has praised too severely a cenotaph upon him, and others have concurred in it: for he is unquestionably entitled to great commendation for having, at the period in which he lived and wrote, with so much firmness and perseverance, asserted the natural freedom of the human understanding.

The logic of Ramus obtained great authority in the schools of Germany, Great Britain, Holland, and France; and science derived ultimate advantages from the contetns which were maintained between the followers of Ramus and those of the Stagyrite. But the name of Ramus vanished before that of Des Cartes. Brucker's Phil. by Enheld, vol. ii.

RAMLA, in Geography, the original Arimathea, a town of Palestine, distant one-third of a league from the village of Loudd, or the ancient Lydda and Diospolis. This town is almost in as ruinous a state as Loudd itself. Within its boundaries nothing is found but rubbish; nevertheless, the aga of Gaza resides here in a ferai, the floors and walls of which are tumbling down. He maintains about 100 horsemen, and as many Barbary folders, who are lodged in an old Christian church, the nave of which is used as a stable, and in an ancient kan, which is disported with them by the sepoys. The adjacent country is planted with lofty olive trees, disported in quinquences. Amidst these plantations, which are decaying, are found dry wells, cisterns fallen in, and vaulted referrrors, which prove that, in ancient times, this town must have been upwards of 18 league in circumference. At present it scarcely contains 200 families. The little land, which is cultivated by a few of them, belongs to the mutfi, and two or three of his relations. The rest content themselves with spinning cotton, which is chiefly purchased by two French houses established there. At Ramla there is also a soap manufactory, the produce of which is almost wholly sent to Egypt. In 1784 the aga built here a wind-mill, which, says Volney, is the only one I have seen in Syria or Egypt, though they are said to have been invented in these countries. The only remarkable antiquity at Ramla is the minaret of a ruined mosque on the road to Yafa. By an Arabic inscription, it appears to have been built by Sai-el-din, sultan of Egypt. From the summit, for it is very lofty, the eye discerns the whole chain of mountains, which begins at Nablous, and skirting the plain, loses itself toward the south. Volney's Travels in Egypt and Syria, vol. ii.

RAMLEAH, a mountain of Arabia, in the province of Nedsjed, extending from S.W. to N.E. about 250 miles; the S.W. extremity bearing 80 miles E. of Kalat el Mollah.

RAMLER, Charles-William, in Biography, a celebrated German poet and professor of belles lettres at Berlin, was born at Colberg in the year 1725. He was distinguished at a very early period by his poetical genius; and in 1754 published a poem, entitled "The Game of Chefs," which displayed a considerable share of genius. In 1758 he translated the Abbé Batteux's Treatise on the Belles Lettres, which he adapted to the genius of his native language, and added some dissertations on the German style and verification. In the following year he published, in conjunction with Letting, the epigrams of Logan, an author who, notwithstanding his great merit, had been suffered to remain in obscurity. In 1760 he published "Sacred Cantatas," which were followed, during the next 20 years, by a great number of other publications, chiefly poetical, of which a list is given in the General Biography. In the year 1780 Ramler turned his attention to several of the old German poets, and published at Leipzic the Epigrams of Wernike, Opitz, Tichemning, Andrew Gryphus, and Adam Olearius. He was so successful in polishing the works of others, and gave such proofs of his taste and critical talents, that Göze, one of the most distinguished German amatory poets, allowed him full liberty in his last will to retain or reject such parts of his poems as he might think proper. In 1782 he published at Berlin a translation of the poetical pieces in the different volumes of the Spectator, which he followed, in the subsequent ten years, by a variety of other works on different subjects; among which may be mentioned "A Short Introduction to Mythology, in two Parts." Ramler has been styled the German Horace; and his biographer says, that though his verses display perhaps less boldness and simplicity than those of the Roman, they equal them in sublimity, and surpass them in harmony. It has been remarked to the honour of Ramler, that he attached to him his Frederic the Great, and his successor, by his poetical talents: from the latter he had a considerable pension paid him during the closing years of his life. Ramler was one of the directors of the national theatre at Berlin, and professor of the belles lettres in the school of the corps of cadets; but the latter office he resigned in 1790. Gen. Biog.

RAMME, in Geography, a river of the district of Drenmen, which joins the Orfe, near its source.

RAMMED Earth Buildings, in Rural Economy, are such as are raised with some form of earthy material. This mode of building with earthy materials is suppos'd fome to have been known at a very early period, and has been long practised with success in the northern parts of France, especially about Lyons, though but little understood in any other part of Europe until lately. This method has, however, appeared to have so many advantages, that it was made trial of in different places in this country; and the result has been so favourable, that the practice seems to deserve the attention of the proprietors of land, in all situations where buildings are to be erected on a cheap and economical plan. In order to facilitate the knowledge of the art, Mr. Holland has presented the public with the method of performing the busines, in a paper, translated from a French work on the subject, inserted in the first volume of Communications to the Board of Agriculture, in which he says that the French writer, M. Francois Coin- teraux, remarks, that the possibility of raising the walls of houses two or even three stories high, with earth only, which
which will sustain floors loaded with the heaviest weights, and of building the largest manufactories in this manner, may astonish every one who has not become an eye-witness of such things. It is a method, which in the above district of France is known by the term rif; but as it is accomplished by the ramming or compreling earth, or earthy substances, in moulds or cafes, the above term has also been applied to it. See Pits, Building in.

**RAMMEKENS**, in Geography, a sea-port town of Holland, in the isle of Walcheren, formerly one of the chief harbours in Zealand. This town, which was constructed as a fortress in the year 1547, and called "Zeeburg," was one of the towns pledged to Queen Elizabeth by the states general for the succours the lent them against Spain in the year 1585; three miles E. of Flushing.

**Rammel**, in Agriculture, a term applied to a substance which forms a part of the subfoil or subplate of particular districts. It is usually covered with a thin weak earth or mould in some places. It is penetrable by the roots of some plants, but notwithstanding that, is very unfriendly to the vegetation of plants in general. It is frequently met with in Cheshire and some other counties. See Soil.

The term signifies a composition of various kinds of clay, white sand, and gravel, which is intimately intermixed with a small portion of oxyd of iron. It is for the most part found under a weak brown or grey earth which is rarely more than four or five inches in depth in the above district, lying in itrata of from eighteen to thirty inches in thickness, upon a white or red sand or chalyce marble, the latter often partaking of its nature for the depth of some feet. Rammel or rammelly soils are therefore constantly of a barren and unproductive nature.

**Rammelberg**, in Geography, a large and lofty mountain in Westphalia, celebrated for its mines. These mine-works yield lead, copper, silver, fome gold, borax, lapis calaminaris, zinc, sulphur, jet, vitriol, and yellow ochre. It lies near Goslar. — Allo, a town of Westphalia, in the county of Mansfeld; three miles S.E. of Wippra.

**Ramelly**, in Agriculture, a word used to signify such crops as are tall or rank, as beans, &c.

**Rammer**, a well-known implement formed of wood in different ways, according to the purpose for which it is to be used. These implements are very necessary in putting posts into the ground, in inclosing land, in order to close the earth firmly about them, as well as for laying down turf or ivy, in order to render it smooth and even. See Beetle.

**Ram of a Gun**, the gun-stick; a rod or staff used in charging a gun, to drive home the powder to the breech, as also the shot, and the wad, which keeps the shot from rolling out.

The rammer of a great gun is a cylinder of wood, whose diameter and length are each equal to the diameter of the shot, with a handle fixed to it. See Spunge.

**Ramna**, in Geography, a mountain of Bosnia; 16 miles N. of Orach.

**Ramonchamp**, a town of France, in the department of the Volges, and chief place of a canton, in the district of Remiremont. The place contains 3785, and the canton 11,325 inhabitants, on a territory of 245 square kilometres, in 6 communes.

**Ramondon**, Lewis, in Biography, an English singer, who first appeared on the stage of Drury-lane in 1706. But
The rampart is sometimes lined, i.e. fortified with a stone wall within, otherwise it hath a berm.

It is encompassed also with a moat or ditch, out of which the earth that forms the rampart is dug.

The height of the rampart should not exceed three fathoms, this being sufficient to cover the houses from the battery of the cannon; neither ought its thickness to be above ten or twelve, unless more earth be taken out of the ditch than can be otherwise bestowed. See Construction, according to M. Vauban's first Method.

The ramparts of half-moons are the better for being low, that the small fire of the defenders may the better reach the bottom of the ditch; but yet they must be so high as not to be commanded by the covert-way.

RAMPART is also used, in Civil Architecture, for the space left void between the wall of a city and the next houses. This is what the Romans call pomerium, in which it was forbid to build, and where they planted rows of trees, for the people to walk and amuse themselves under.

RAMPARTS, in Geography, a town of Bengal; 8 miles S.E. of Rungpore.

RAMPERING, or Sonning, denotes the process of building sodd or turf walls, or banks.

RAMPERSGRUBE, in Geography, a town of Germany, in the county of Henneberg; six miles W. of Mainz.

RAMPHASTOS, the Toucan, in Ornithology, a genus of birds of the order Picea, of which the generic character is as follows: Bill very large, light, hollow, convex, ferrate at the edges; each mandible incurvate at the tip; nostrils behind the base of the bill, long, narrow; the tongue is feathered at the edges, the feet mostly clambering.

The birds of this genus first became known to naturalists on the discovery of South America, and to the warmer regions they appear, in general, to be confined. Like the hornbills, they are distinguished by the size of their beaks, which, in some species, is nearly equal to that of the whole body. It is, however, of a very light subtile and, in the living bird, it is compribible between the fingers. Both mandibles are ferrated in an outward direction; the tongue is of a highly singular form, representing the appearance of a very narrow lanceolate feather, being of a somewhat horny or cartilaginous nature, and divided on each side into innumerable short and close-set fibres; in confluence of which structure it was described by some early writers on natural history as a real feather, supplying the place of a tongue. The orbits of the eyes are generally bare. These toucans are supposed to feed on fruits, but in a state of captivity they will eat animal food. They deposit their eggs, which are usually two in number, in the hollows of trees, on the surface of the decayed wood. These birds have been as yet met with only in South America, and there merely between the tropics, being totally incapable of standing the cold. They are easily tamed and familiarized, and several species have been brought to England, where fruits, fish, and flesh have been promiscuously devoured by them with considerable voracity. Whatever was received by the bill was thrown into the air, and on its return caught, and, without the slightest malacation, instantly devoured. There are seven species enumerated by Gmelin, though Mr. Latham mentions only fifteen.

Species.

VIRIDIS; Green Toucan. Green, with a yellow belly, and red rump. This species is found in Cayenne, and is about fourteen inches long. The upper mandible is yellow, with red sides, and a black line in the middle; the lower one is black, the base and round the nostrils are red; the teeth in both are white; the irides and naked orbits are yellow; the legs are of a lead colour; the claws are black; the tail is wedged, beneath inclining to ash; head, chin, and throat, in the male black, in the female bay, terminated by a black narrow transverse band.

ENTULTUS; Toothless Toucan. In this the bill is not ferrate at the edges. It inhabits Cayenne, and is twelve inches long. The upper part of the body is green, but beneath it is more of a yellowish colour; the head and neck are chefnut; the rump is red; the upper mandible is brown, the lower black; the thighs green, and it is thought to be a variety of the viridis.

PAVONICUS; Pavonine Toucan. The general colour of this is green; but the feathers are sprinkled with red spots. It is also known by a mixture of red and changeable or peacock-coloured feathers interperped. The bill is variegated yellow and black; the legs and claws are black.

Piperivorus; Pipcrine Toucan. Green; the fore parts are black; the vent and thighs red. This species has been described by Edwards under the name of the green toucan. Its length is about seventeen inches, and its general colour is of a dull green; the head, neck, and breast, are of a deep black; behind each ear is a somewhat lengthened orangecoloured spot, and immediately behind the lower part of the neck is an orange-coloured bar or collar; the belly is pale and yellowish-green; the thighs are purple; the vent is red, and the tail, which is cuneated, slightly tipped with dull red; the bill is about three inches long, and of a black colour, but towards the base it is variegated with red, whitish, and orange-yellow. In the female the head, neck, and breast, are brown instead of black, and the lower part of the belly is grey. It is a native of Cayenne, and fed to feed on the pepper of the country. The female of this species has been known to vary in having the bill of a horn colour, with a black bar near the end, and two others near the edge; the ridge also being black, and the yellow crest on the neck is wanting.

ARACARI. This species is green, but the abdominal band, vent, and rump, are red; the belly and breast are yellow. It is a native of Brazil, Surinam, and Cayenne, and is full sixteen inches long. The upper mandible is black on the back and tip, but the sides are whitish. The base is three-lobe at the nostrils, with a white arch at the root, lower black; the head, the wings, and tail, are black; the breast and body are yellow and scarlet, with a black roundish spot in the middle of the breast, and a similar transverse one on the beginning of the belly; the thighs are tawny.

TORQUATUS; Collared Toucan. This bird is black above, and beneath it is whitish; the belly is green, the hind part is red, and the collar red. It inhabits the coasts of New Spain, is about eighteen inches long, and feeds on fish. The upper mandible is blackish, and the lower black; the irides are of a reddish-yellow; the head and neck are black; the lower tail-covers are red; the thighs purple; the legs are of a greenish-ash colour; the claws are black.

PACIVORUS; Brazil Toucan. This is blackish, but the abdominal band and vent are red; the rump is white. It inhabits South America, and is twenty-one inches long. The bill is yellow, with a scarlet spot on the tip; the lower mandible is blue; the cap, back, wings, tail, belly, and thighs, are black; the temples, chin, breast, and rump, are white.

ERYTHROPYCHOS; Red-breasted Toucan. Blackish; cheeks, chin, and throat, white; upper tail-coverts sulphur, but the lower and crescent on the breast are red. This is found...
found in various parts of South America. The bafe and back of the bill are yellow; tip of the upper mandible, and hollow of the lower, red; the noftrils are edged with black; the orbits are blue; the legs are plumbeous, and the claws are black.

TUCANUS; Yellow-breathed Toucan. This is also black-iff; the abdominal band, vent, and rump, yellow. It measures about nineteen inches in length, and has been defcribed by Mr. Edwards from a living fpecimen brought into England. According to this gentleman, the bill of this species is large in proportion to the fize of the bird; it is comprefled fideways, having a fharp ridge along its upper part, and toothed on its edges; the upper mandible is green, with a long triangular spot of orange colour on each fide, and the ridge on the upper part yellow; the lower mandible is blue, with a fhad of green in the middle; the point is red; it has about five tranverfe faint dusky bars, which crofs the joinings of the two mandibles; the noftrils are invisible in the black line that surrounds the bill; the iris of the eye is of a fair green colour; round the eye is a broad fpae of naked skin, of a violet colour; the skin beneath the feathers is of a violet colour, below which is a bar of fcarlet feathers, which parts the yellow on the freat from the black on the belly; the covert-feathers of the tail are white above, and thoie beneath are of a fine red; the crown of the head, upper part of the neck, the back, wings, belly, and tail, wholly black, though on the upper fide of the wings and tail it has a changeable glos of blueifh-purple; the legs and feet are all of a blue or violet colour. The fpecimen from which this defcription was made, was brought from Jamaica, but the bird is a native of the hotter parts of South America.

PICATUS; Preacher Toucan. Blackif; breast yellow, vent and tips of the tail-feathers red, rump black. It inhabits Guinea and Brazil, and is more than twenty inches long. The bill is yellowifh-green, fipt with reddifh; the belly is red; the tail is dotted with red at the tip. This bird is faid to have a frequent habit of moving its head from fide to fide, while uttering its notes; hence it has obtained the name of preacher.

DICOLORUS; Yellow-throated Toucan. Blackif; breast, belly, vent, and rump, red; the chin is yellow. It inhabits Cayenne, and is leventeen inches long. The bill is olive, with a black bafe; the mandibles are edged with red; the cheeks are of a sulphur colour; the throat is orange, but edged with sulphur.

TOCO; White-throated Toucan. Blackif; chin, throat, and rump, white; orbits, circle on the breaft, and vent, red. It inhabits Cayenne, and is about nine or ten inches long. The bill is of a reddifh-yellow, the bafe is black; the upper mandible is black at the tip.

INDICUS; Indian Toucan. The throat, quil-feathers, and tail, black; the cheeks and breaft are white; belly and thighs are yellow; the crown is of a reddifh-orange; rump crimson. It is found in divers parts of India. The bill is hardly ferrate, and not fo large as in the others.

LUTEUS; Yellow Toucan. This is of a yellowifh-white; the neck is marked with two black lateral fripes; the tail and wings are variegated with black and white; the lefier wing-coverts are yellow. It inhabits New Spain, and is about the fize of a pigeon. The bill is black; the irides are yellow; the legs are brown; the claws are yellowifh.

CERULEUS; Blue Toucan. Blue mixed with cinerous. It inhabits the coasts of New Spain. The bill is longer than the body; the eyes are black and the irides are tawny.

DUBUS. This is the blue-throated toucan of Mr. La- than, defcribed from a catalogue of the museum of baron Fangers of Montpellier, where it is announced as an undec- scribed species.

ALBUS; White Toucan. This is entirely white.

RAMPS, in Fortification, are gentle flopes made for the cannon to be drawn up and down by, and alfo for the easy communication of the troops poled in a battery that is raised above the level of the ground on which it is built. The rife of these flopes is about two inches, on twelve of bafe, or the length of the ramp's bafe is fix times the height, and this is general for the draught of carriages; but footways need not be of fo gentle a flope, as a rife in one foot in three may anwer the purpofe; or, instead of ramps, fairs may be, and commonly are, used for the paflage of the foot. The breadth of a carriage ramp is ufually about nine or ten feet, that breadth being sufficient both for the carriage and footway; but those for foot- paflage only need not be above three or four feet wide. Ramps may either rife on the fide of an elevated work, or againft a fahant angle of that work, or on each fide of an entering angle.

RAMQUILLA, in Geography, a town of Sweden, in the province of Smaland; 5 miles N.W. of Calmar.

RAMSAY, ALLEN, in Biography, a poet of considerable celebrity, who wrote in the Scottifh dialect, was born in the year 1686, in the parish of Crawford, Lanerkshire. He received no other education than that of the parish school, and was apprenticed to a barber in Edinburgh. He has not been aecertained when he first began to make verses; but about the year 1715, several of his poems had been publifhed. Soon after this he laid afide the trade to which he had been brought up, and adopted the more congeal one of a bookfeller. In 1721 his detached poems were publifhed, by fubfcription, in a quarto volume. In 1724 he began to pubflish his collection of fongs, entitled "The Tea-table Mufeum," which at length extended to four volumes. This work was followed by one, entitled "The Evergreen," being a collection of fongs written by the ingenious before the year 1600. These publications were well received; but his fame was greatly extended by his
"Gentle Shepherd," which was afterwards enlarged from two pastoral poems, in the form of a regular drama. He now held a correspondence with several poets and other ingenious persons of the time, and his shop in Edinburgh was the resort of the men of letters who then flourished in the capital of Scotland. He is supposed to have opened the first circulating library in that city, and in 1736 he built a play-house, which was the first ever known at Edinburgh; but the act prohibiting the exhibition of plays in unlicensed buildings, caused it to be shut up. Ramsay, towards the middle of his life, withdrew from the field of authorship, and attended to the more profitable business of selling, rather than writing of books. He died in 1738, at the age of 71. The poems of Allan Ramsay, say an eminent critic, "display none of the fire of the genius so conspicuous in those of Burns, but have occasionally an agreeable pastoral simplicity, and are often marked with a vein of humour, natural, though coarse. The Gentle Shepherd is, perhaps, one of the best pastorals with respect to the pictures of real life, which are drawn with great propriety, and generally present pleasing images."

RAMSAY, ALLAN, son of the preceding, was born at Edinburgh about 1709, and having devoted himself to painting, went at an early period of his life to study in Italy, and there received instructions from Solimene and Imperiale.

After his return, he practised in Edinburgh for some time, but afterwards removed to London, and by the influence of his countryman, the earl of Bute, was introduced into the vortex of the court, painted the prince of Wales, and on the death of Shakspeare in 1767, was appointed principal painter to the crown; although Reynolds was then in possession of the highest reputation.

Ramsay never ventured to attempt the higher walks of the art, but confined himself solely to portraits, which he painted agreeably. Not possessed of brilliancy of genius sufficient to attempt strong character, with striking effects in his pictures, he contented himself with that portion of art which meets the expectations of common observers; never offending with affectation or neglect, he finished his pictures with care and neatness, and retained his friends and reputation till he ceased to practise. He was far attached to his art, that he visited Italy four times; to what purpose does not appear, unless it was to derive benefit from the portraits of Pompeo Battoni; for no traces of higher character are observable in his productions. Yet he was a man of found sense and strong understanding; possessed of literary acquisitions, and devoted to study. Though he understood the Latin, French, and Italian languages, he was not satisfied till he added a knowledge of the Greek, acquired when he was advanced in life. Thus endowed, he was emulous of literary fame, and published, under the title of "The Investigator," Essays on Ridicule, as the tale of truth, on the Naturalization of Foreigners, on Taste, &c.; and, as occasion prompted, the town was favoured by him with some fugitive pieces on the politics of the day. He was always held to be highly efficient as a man, and enjoyed his fame and good fortune to about the advanced age of 75.

RAMSAY, ANDREW MICHAEL, called the chevalier Ramsay, was born at Ayre, in Scotland. He received a good education at Edinburgh, where he distinguished himself so much, that he was chosen to attend the son of the earl of Wemyss at St. Andrew's. After this he went to Leyden, with the view to farther improvement, where he became acquainted with Poiret, one of the leaders of the Quattrelle, some of whose doctrines he imbibed. He next went on a visit to the celebrated Fenelon, archbishop of Cambray, who converted him to the Roman Catholic religion, and Ramsay ever after this considered himself as the disciple of that excellent prelate. Upon his works he formed his literary taste, and he even adopted France for his country, and made use of its language in his writings. Here he obtained four poils of honour and emolument, and was made knight of the order of St. Lazarus, whence he had the title of chevalier. His reputation caused him to be invited to Rome by the Pretender, in order that he might undertake the care and education of his children. This he accepted; but having found that little court so divided by faction, he quickly resigned his office, and returned to Paris. In the next year, 1725, he revisited his native country, and refided some years with the duke of Argyle, employing himself in the composition of several works. After his return to France, he entered into the service of the prince of Turenne, duke of Bouillon. He died in 1743, at St. Germain-en-Laye, the retreat of the exiled Stuart family, at the age of 57. His principal writings were, "L'Histoire de la Vie et des Ouvrages de M. de Fenelon;" "Essai sur le Gouvernement Civil;" "Difcours sur le Poème Epic;" "Le Psychomètre," being remarks on lord Shaftesbury's Characteristic; "L'Histoire du Marechal de Turenne;" and "Les Voyages de Cyrus." The last is that which is by much the best known, and it has been frequently printed in the French and English languages. Voltaire has styled it a valuable imitation of Tele- machus; it is, however, written with elegance, but is tedious. Another of the chevalier's works was "A Dissertation on Free-Masonry," of which he was grand chancellor in France. In this he traces the origin of the institution to Palestine, in the time of the Crusaders; and having found a great declension of the mystical ceremonies formerly practised, he strongly urged their renewal, and proposed a general assembly of the brotherhood of all nations to be held at Paris. Biog. Brit.

RAMSAY, in Geography. See RAMSEY.

RAMSAY POINT, a bay on the E. coast of the island of Lewis, N. lat. 57° 43', W. long. 6° 39'.

RAMSBURY, a village and parish in the hundred of Rambury, and county of Wilts, England, is situated about six miles to the eastward of the town of Marlborough, and 70 miles west by south from London. In the time of the Saxons it was a place of so much importance, as to be constituted the seat of the see, when Wilts was made a distinct bishopric by Pegmound, archbishop of Canterbury, in the year 699. Rambury church was then the cathedral church of the diocese, and continued to be till bishop Herman prevailed upon king William the Conqueror to unite the bishoprics of Wilts and Sherborne, and fixed his episcopal seat at Old Sarum. The church, an ancient building, is divided into a nave, two aisles, and a chancel, with a massive square tower at its western extremity. In the chancel is a long stone, which tradition affirms to be the grave-stone of a giant; also an old altar tomb of Purbeck marble, without any inscription, and several monuments commemorative of the Joneses of Rambury manor, or park. This seat is now the property of Sir Francis Burrett, bart., in right of his mother, second daughter of the late William Jones, esq. The house was designed in the Grecian style, by John Webb, nephew to Inigo Jones. The inclosures are extensive and well wooded, and are intersected by a branch of the river Kennet, which spreads itself out in the form of a lake, from the sides of which the grounds rise in easy, sloping lawns. Littlecote park, the seat of major-general Edward Leybourne
bourn Popham, is situated partly in the parish of Ramf
bury, and partly in that of Chilton-Foliot. The house is a
large ancient structure, built by one of the Darells, the
former possessors of this domain, about the middle of its
time. Architectural and decorative features were no longer
in evidence in the country mansion. Notwithstanding many late altera-
tions, the interior still preserves many of its original features.
The great hall is very spacious, floored with tiles, and
lighted by large and very lofty windows. In it flanks a
large oaken table, at which the vassals of the domain were
wont to feast at the expense of their lord. The remainder of
the furniture is in a suitable style, particularly an arm-chair,
which is said to have been used by Sir John Popham, chief
justice of the court of king's bench in the reigns of queen
Elizabeth and king James I., who purchased the house and
manor from the Earl of Pembroke. There is also a curious
instrument for the punishment and confinement of servants;
by fastening their thumbs between two boards. The walls
of the hall are decorated by numerous guns, carvings, pittats,
doublets, &c. and here are also two very fine candleabras,
designed and executed by Mr. George Bullock of London,
in an admirable style, as adapted to the age and character
of the mansion. One of the bed-rooms is said to have been
the scene of a singular and mysterious murder, the incident
attaching which are recorded in a note to Scott's poem of
Rokeby. In the gallery, which is about 100 feet in length,
are portraits of judge Popham and Nell Gwyn; also a
curious piece of needle-work, representing a large Roman
teffellated pavement, which was discovered in the adjoining
park in 1728, by Mr. George (reward to Edward Popham,
Cf.), who made a coloured drawing of it, and communicated
the fame to the Society of Antiquaries. This pavement
consisted of two divisions, which appear to have formed the
floor of a temple. The interior division was ornamented with the figure of Apollo playing on a harp; and
in four surrounding compartments were four female figures
riding on different animals, and designed to represent the
Horse, or Sirens. Exterior to the circle inclosing them
were three other compartments, each displaying a face of the
sun. From these circumstances the temple is supposed to
have been dedicated to Apollo; but some emblems on its
exterior division referring to Ceres and Neptune, it may,
perhaps, be more properly esteemed a port of Pantheon.
Another smaller Roman pavement, and a curious cup or
patera of brass, were likewise discovered by Mr. George
on Rudge-farm, adjoining the northern boundary of Little-
cot park. The cup was adorned with foliage, and was
inscribed with the names of five Roman flates. It was
conjectured by Gale to have been a libation cup used at
an annual feast instituted by the inhabitants of these towns.

Pickford, in this vicinity, is a government depot for the
interior merchandise, established in 1805. It includes about forty acres of
ground, on which are erected three magazines for powder,
barracks for the detachment of the military, and various
necessary houses and offices. Beauties of England and
Wales, vol. xv. by John Britton, F.S.A.

RAMSDAL. See REMSDAL.

RAMSDEN, Jesse, in Biography, an eminent English
mathematical and altronomical instrument-maker, the son of
an inn-keeper at Salterhebble, near Halifax, in Yorkshire,
where he was born in the year 1735. At nine years of age he
was admitted into the Halifax free-school, where he acquired,
during three years, the elements of classical learning;
and after which he was removed to the care of an uncle at Craven,
by whom he was sent to a clergyman of the name of Hall,
who had acquired much reputation by teaching at his school
the mathematical sciences. Under this gentleman's instruc-
tions, young Ramden became a proficient in geometry and
algebra, and was advancing rapidly in these and other col-
lateral branches of study when his father sent him home,
to apprentice him out with a clothier at Halifax. At the
age of twenty he went to London, where he became clerk
in a wholesale cloth warehouse. This situation he retained
about two years and a half, when, his inclination for the
sciences revived so strongly, that he resolved to qualify him-
self for some business which should prove suitable to the
 bent of his mind. With this view he bound himself
apprentice for four years to Mr. Burton in the Strand, who
was elctected one of the best workmen of his time in
making thermometers and barometers, and in engraving and
dividing mathematical instruments. After the expiration of
his apprenticeship, he worked as journeyman with a person
of the name of Cole, with whom he afterwards associated
himself as partner. This connection did not last long,
when Mr. Ramden opened a workshop on his own ac-
count, in which he soon recommended himself to the em-
ployment of the principal mathematical instrument-makers
in London. In the course of his business his repeated exa-
nination of the instruments which were sent him to be
engraved or divided, led him to discover their defects, and his
inventiveness suggested to him the means of removing them, or of
constructing better instruments. In order to put his plan
into execution, he made himself master of the prac-
tical operations of the trade, and formed the design of
examining every astronomical instrument in use, with the
view of correcting those which, being founded on good
principles, were faulty only in the construction, and of
proscribing those which were defective in both these
respects. About this time, by his marriage with Mrs. Dolid
and, he became possessed of a part of Mr. Dollond's patent
for achromatic telescopes. In the year 1766, Mr. Ramden
opened a shop in the Haymarket, where he continued till
1774, when he removed to Piccadilly, where he remained
till the time of his death. Before his settlement in the
Haymarket, he had improved the sextant, and he had in-
vented his celebrated dividing machine. (See the art. En-
gine.) Having spent ten years in bringing this machine
to perfection, he obtained from the Board of Longitude
a premium of 1000l. Mr. Ramden constructed an instru-
ment for dividing straight lines, which has been described
in a former volume of the New Cyclopædia, and while he
was employed on his dividing-machine he made great im-
provements in several other instruments. The Theodolite
(see the article), before his time, consisted merely of a
telecope, turning on a circle, divided at every three minutes,
by means of a Vernier, which fee; but in the hands of
Mr. Ramden it became a new and perfect instrument,
serving for measuring heights and distances, as well as taking
angles. The largest and most perfect theodolite ever con-
structed was made by him for general Roy, for the purpose
of measuring the series of triangles in England. Though
this instrument is only of eighteen inches radius, its accuracy
is so great as not to admit of an error of a fingle second.
With this instrument general Roy measured the angle be-
tween the polar star and the sides of his triangles, in order
to have the exact difference between the observations
of Paris and Greenwich, which he found to be 9'20'. Mr.
Ramden was a great improver of the barometer for
measuring the height of mountains, which he could ob-
tain to a degree of accuracy that was very surprising,
and he caused to be engraved a table to accompany his
barometers, which, without the trouble of calculation,
gives the heights of places, according to the heights of
the mercury, and even at different temperatures. He also
pointed
pointed out a new method and apparatus adapted to the conveynance and support of the portable barometer. Mr. Ramfden made improvements on the electrical machine; and on manometers for measuring the density of the air: he invented an instrument for measuring inaccessible distances: affaying balances which turn with less than a thousandth part of the weight used: levels and a variety of other instruments. The pyrometer also exercised his talents, and on this occasion, as on all others, Mr. Ramfden shewed a fort of natural and almost intuitive faculty in recovering the essential faults of an instrument, and in inventing the most simple and exact methods of correcting them. With respect to optics, he discovered a method of correcting, in a new and perfect manner, the aberration of sphericity and refrangibility in compound eye-glasses applied to all astronomical instruments. Opticians had imagined that the purpose might be accomplished by making the image of the object-glasses fall between the two eye-glasses, which was attended with this great inconvenience, that the eye-glasses could not be touched without deranging the line of collimation, and the value of the parts of the micrometer. To remedy this inconvenience, he fet out from a simple experiment, viz. that the edges of an image observed through a prism are less coloured, according as the image is nearer the prism. This led him to attempt placing the two eye-glasses between the image of the object-glasses and the eye, without failing to correct the two aberrations; which he did by changing the radii of the curves, and placing the glasses in a manner very different from that commonly employed. In the Philosophical Transactions for the year 1779, Mr. Ramfden has described a new reflecting object-glass micrometer; to the paper on this subject we refer our readers, and also to the article Micrometer in this Dictionary. With this micrometer the diameters of the planets may be measured; it may be adapted to all kinds of achromatic telescopcs; it may be brought near to, or removed from, the object-glasses at pleasure, to render vision distinct; and it may be removed from the telescope, if the observer will to use the latter without a micrometer. The high degree of merit to which Mr. Ramfden's many and important inventions were intitled, led his friends to propose him as a member of the Royal Society, and he was elected in the year 1786.

The Equatorial or Transit instrument (see the articles) received great improvements in the hands of Mr. Ramfden, who rejected the endless screw, which by prefling on the centre destroyed its precision; he placed the centre of gravity on the centre of the base, and caused all the movements to take place in every direction; he pointed out the means of rectifying the instrument in all its parts, and he applied it to a very ingenious small machine, for measuring or correcting the effect of refraction. The greatest equatorial instrument ever attempted, is that which he constructed for Sir George Snuckburg, on which he employed several years, and of which we have given a description and figure. Mr. Ramfden's meridian telescopcs which he made for Blenheim, Manheim, Dublin, Paris, and Gotha, are also remarkable for the excellence of their object-glasses. With that of Dublin, Mr. Upher observed stars of the fourth magnitude in the open day, and those of the third very near their conjunction with the moon. These telescopes are eight feet in length. There is a five-feet one at the observatory at Palermo. Mr. Ramfden made great improvements in the mural quadrant, of which a full account will be found in the article Circle, to which we refer our readers for much valuable information on the subject of astronomical instruments. Having in various parts of our work entered into the nature of Mr. Ramfden's improvements and inventions, it is unnecessary to repeat here what has already been fully explained.

The field in which the inventive genius and superior talents of Mr. Ramfden were exercised, was, as we have seen, very extensive. In order that every part of his instruments might be fabricated under his own inspection, he collected in his workshops men of every branch of trade necessary for their construction. So important did he consider the principle of division of labour, that he always confined the same workmen to the same branch, and by that means arrived at the greatest correctness and nicety in executing it. Notwithstanding the great perfection of his instruments, which ought to have secured to Mr. Ramfden a large fortune, he sold them cheaper than any other artifl in London, sometimes even one-third below the usual price. Such was the demand for them, from almost all parts of the world, that though he employed sixty men, he was unable to execute all the orders which he received. His great attention to business injured his health, and hastened his death. He died at Brighton, where he had been for the benefit of the sea-air, November 5, 1800, in the sixty-sixth year of his age. He had been elected a member of the Imperial Academy of Sciences at Petersburg in 1794, and in the following year he was presented with the gold medal, adjudged by the Royal Society to persons distinguished for their scientific talents.

Mr. Ramfden was by nature endowed with uncommonly strong reasoning powers, and a most accurate and retentive memory, but, at the same time, with such a quickness of penetration, that he could, as it were, with a single glance, view in every light the subject on which he thought, and adopt the most advantageous mode of considering it. He possessed, in an exquisite degree, that quality of mind which is emphatically styled elegance, which in the abstract sciences leads to clearness, simplicity, and precision, as in the fine arts and literature, it gives the half polish to genius, and is more generally known by the appellation of taste. In his habits he was temperate to abstinence, satisfied with small quantities of food, and a small portion of sleep. Unacquainted with dissipation or amusement, and giving but little time even to the society of his friends, the whole of those hours which he could spare from the duties of his profession, he devoted either to further improvements in his instruments, or to the perusal of books of science, particularly those mathematical works of the sublime writers which had any connection with the subject of his own pursuits. Mr. Ramfden's only relaxation from almost constant and severe studies, was the occasional perusal of the belles lettres, which was the occasional perusal of the belles lettres, particularly of the French language as to read with peculiar pleasure the works of Boileau and Molière, one can believe that he mis-spent his hours of amusement. Short and temperate as were his repasts, a book or a pen was the constant companion of his meals; and when illas broke his sleep, a lamp and a book were ever in readiness to beguile the fife of pain, and make bodilyicknesses minister to the progress of his mind. He was well skilled in the abstruser parts of mathematics, and conversant with the belles lettres on the sciences; and such was his manual dexterity, that there was not one tool in any of the numerous branches of his profession which he could not use with a degree of perfection equal to that of the very best workman in that particular branch, and he could have been and finished every single part of his most complicated instruments. For this article we are chiefly indebted to a very elaborate and excellent original memoir in the 8th vol. of the Gen. Biog.
RAMSDORF, in Geography, a town of Saxony, in the bishopric of Naumburg; three miles N.E. of Zeitz.

RAMSEA, or RAMSEY, a market and sea-port town in the parish of Kirk-Maughold, Isle of Man, Great Britain, is situated at a distance of fourteen miles north-east from Douglas, the chief town in the island. Anciently this place was of considerable note, but it is now comparatively decayed. The bay upon which it is built might be rendered capable of affording anchorage and security to very large vessels, but it is much choked up with sand at the entrance to the harbour, and is therefore little frequented, though protected by a fort, mounted with several pieces of cannon. The chief article of export from Ramsea is grain, the produce of the vicinity which is among the best cultivated districts in the British islands. Several boats, with good accommodation for passengers, sail weekly from hence to Liverpool, and to Whitehaven; but what gives most importance to the town at present is, the circumstance of its being the seat of the courts of justice for the northern district. According to the population returns of 1792, (the last returns made for the island,) Ramsea contained 1010 inhabitants, but their number is now probably increased to 1400.

In the parish of Kirk-Andreas, to the north of Ramdea, are several curiosities, particularly an ancient intrenchment at Ballacharry, which occupies a small isolated eminence, in a very level tract of country. This earthen work is of a square form, and is surrounded by a wide and deep fosse and rampart, flanked at each angle by a very noble bastion. The area within is much funk below the level of the works, which are in a state of excellent preservation, and might easily be rendered effectual for the purposes of modern warfare. This intrenchment abounds with sepulchral tumuli; some of them environed by large upright stones. Several of these barrows were opened, about twenty years ago, by Mr. Chaloner, and found to contain simple urn interments. In the church-yard here stands a square pillar of stone, bearing a Runic inscription, which is thus translated by Mr. Beauford of Athy, in Ireland. "The son of Ulfd of the Swedrs (Swedes) erected this croun to the warrior Anarins, the son of Cunnru." Another inscription on a similar monument is to be seen in the neighbouring church-yard of Kirk-Michael, which is an extensive village, pleasantly situated near the sea. In this parish is a monument of the cairn description, composed of small stones heaped together. It is called Cairn Viad, but nothing is known respecting its origin, and peculiar appropriation. About a mile from hence is Bishop's Court, the usual residence of the bishops of Man. The palace was nearly rebuilt about twenty years ago. It is an elegant and convenient mansion, surrounded by agreeable gardens and pleasure grounds. Beauties of England and Wales, vol. iii. By John Britton and E. W. Brayley, 1802. Carlyle's Topographical Dictionary of Scotland, 2 vols. 4to. 1813.

RAMSEIL, a town of Hindooshan, in Baglana; ten miles N. of Nalsee.

RAMSELE, a town of Sweden, in Augermanland; 70 miles N.W. of Hernand.

RAMSENTHAL, a town of Germany, in the principality of Culmbach; four miles N. of Bayreuth.

RAMSEY, a market-town in the hundred of Huntingdon, and county of Huntingdon, England, is situated on the banks of a small river, to which it gives name, at the distance of ten miles N.N.E. from the town of Huntingdon, and sixty-eight miles N.W. from London. It is particularly celebrated in history for its abbey, which was founded by the renowned duke Alwin, at the perambulation of Olwald, bishop of Worcester, in the year 969. The buildings were completed in the course of five years, at the expiation of which, the monastery was dedicated to the Holy Virgin and St. Benedict, and filled with monks of the Benedictine order. Alwin gave considerable privileges to his new establishment, and procured for it many valuable privileges from king Edgar. This monastery continued to the monks all their lands, and gave them the right of impressing the image of his royal person upon their seals. Several succeeding princes, and many private persons of rank and opulence, contributed to enrich the abbey, which afterwards became one of those distinguished by the title of "mitred." Its abbots were consequently privileged to sit in parliament among the peers, and enjoyed all the other accustomed rights of mitred abbots. Many of the monks were men of pre-eminent genius and learning, and were especially noted for their proficiency in the Hebrew language. The library belonging to the monastery was extensive, and contained many books written in that tongue by its inmates. At the era of the dissolution, its annual revenues were estimated, according to Dugdale, at 176l. 12s. 4d.; but Speed, on the authority of Sir Robert Cotton, states their amount at 1937l. 15s. 3d. Some years after that event, the demesnes and lands of the abbey, with several lakes belonging to it within this parish, were granted to Sir Richard Cromwell, ancestor to the Protector.

Ramsey consists chiefly of one long street, with another branching off from it, in a northern direction. The abbey stood at the upper end of the town, towards the south, near the manor-house, a large and elegant mansion, built out of its ruins. The only portion of the old buildings standing is a gateway, which appears, from the style of its architecture, to have been erected about the reign of Henry VI. Since the destruction of the abbey, it was for some time used as a prison. At a short distance from this relic stands the present church of Ramsey, a spacious and handsome edifice, consisting of a nave, chancel, and aisles, with an embattled tower at the west end. The nave is separated from the aisles by seven large and well-proportioned arches on each side, springing from clustered columns; and from the chancel by a still larger arch, with a screen richly carved in wood crossing the lower part. The windows are large, and, as is apparent from many fragments remaining, have once been filled with stained glass, exhibiting figures of angels, crowned heads, &c. Several branches of the Cromwell family were buried in this church, but there are no monuments to their memory. In this town is a free-school, founded and endowed in 1663, under a decree of chancery, but the establishment has been much neglected; also a charity-school for girls, instituted about a century ago by John Dryden, esq. who bequeathed 16,000l. for various charitable purposes. The market day here is Wednesday, weekly, and there is an annual fair on the 22d of July. Ramsey suffered greatly from the plague in the year 1665-6, that dreadful distemper having been introduced by the accident of major William Cromwell wearing a coat, the cloth of which had been brought from the metropolis. The number of deaths amounted to 400 within one month. This town likewise sustained much injury from fire in 1731; but the damage was soon repaired. According to the population returns of 1811, the parish contains 484 houses, and 2390 inhabitants.

The country around Ramsey is extremely marshy, and hence is intersected by numerous ditches, or drains to carry off the water. To the north-west about two miles, is a lake
lake called Ugg-Mere, and at the distance of a mile further northwards, is a still larger collection of water, named Whittlesea-Mere; and there is a third to the north-east of the town, styled Ramfey-Mere. All these lakes abound with fish of various kinds. Running northwards from that hall mentioned, is a high causeway, called King's- deutsch or dyke, which is mentioned in record as early as the reign of King Edgar. It is commonly confounded with Cantis-deutsch, or Sverdes-deutsch, called also Steeds-deutsch, which forms the boundary of this county with Cambridgeshire. Beauties of England and Wales, vol. vii. by E. W. Brayley, 1808.

RAMSEY, Isle of, an island in the county of Mynyw, centre of Pydiag, (now called the hundred of Dewi-lan,) and county of Pembroke, South Wales, is situated in the Irish sea, opposite to the promontory called St. David's Head, from which it is about three miles distant. This island is nearly four miles in length, and exceeds one mile in breadth. Throughout its whole extent the surface is lofty, and at each extremity a mountain floats to a great height above the general level, giving the island a very romantic appearance. From the shore the aspect is bold and precipitous on all sides, and at one spot, called the Choir, the rocks assume an amphitheatre form, and rise perpendicularly to a tremendous elevation. Ramsey was formerly cultivated, but is now chiefly appropriated as pasturage for sheep and horses. It is abundantly supplied with fresh water, for which benefit tradition records that the island is indebted to Julianin, a devotee from Brittany, who settled here in the fifty century. Here were anciently two chapels, one faced to Devus, or Devynoy, and the other to Julianin above-mentioned, who was murdered by his servants, and buried on the spot where the chapel was raised to his memory. Ramsey belongs to the bishop of St. David's, as do likewise several smaller islands in its vicinity, of which seven are distinguished by the appellation of the Bishop and his Clerks. Immemorial flocks of birds frequent and breed on these islands, and, among other kinds, the celebrated hunting falcon is frequently seen. An Historical Tour through Pembroke Shire, by Richard Fenston, F. S. A. Cardiffe's Topographical Dictionary of Wales, 4to. 1813.

RAMSGATE, a member of the town and port of Sandwich, in the upper half hundred of Ringlow, Isle of Thanet, late of St. Auguflin, and county of Kent, England, is situated on the shore of the German ocean, at the distance of 72 miles S.E. from London. Like Margate, it was formerly only a small fishing hamlet, confiding of a few mean, and indifferently built, houses. In the reign of queen Elizabeth, indeed, it was returned in the maritime survey as having no more than seventy sailors belonging to it, and these chiefly fishermen. What first gave it importance was the extension of the Russian trade after the revolution in 1688; but it is chiefly indebted for its present consequence to the improvements made in the harbour since the middle of the last century; for although a pier for shipping existed here, at least from the time of Henry VIII., yet it was altogether inadequate to afford security to the numerous ships driven on the coast in tempestuous weather. Parliament was therefore induced, at the petition of the merchants and shipowners who were interested, to pass an act, ordering a proper harbour to be formed for the reception of ships of, and under, 300 tons burthen. Under this act the trustees were, as usual, appointed; and in the year 1740-50, the work was begun, according to designs by William Ockenden, c, and captain Robert Brooke. So many difficulties, however, occurred in carrying it into execution, that the harbour was not completed till the year 1791. The sum which the whole cost exceeded 600,000l.; but that amount is trivial compared to the great benefit derived from it to our shipping interest. The area of the harbour is nearly circular, and comprehends about forty-six acres. The piers, basins, &c. are constructed of Purbeck and Portland stone, principally the latter. The entire length of the east pier, including its flexures, or angles, amounts to nearly 2000 feet; that of the west pier is about 1500 feet; the width of the entrance is 240 feet. The general breadth of the piers is twenty-six feet, including a strong parapet, which defends the outer sides next the sea. What is called the East Channel, is formed by the passage between the east pier and a large bank of land which nearly covers the harbour as far as the basin, and is of considerable use for ships to bring up upon, in heavy gales, when driven into the harbour without anchors or cables. Near the north end of the west pier is a massive frame work of timber, and a stair-case, called Jacob's ladder, forming a communication from the top of the wall to the bottom of the cliff. The east pier is a favourite promenade in summer, and is much admired for the peculiarly fine sea-views which it commands.

In judicial proceedings, Ramsgate is technically denoted the slip of Ramsgate. It is in the parish of St. Lawrence, and is affixed to that church, but it maintains its own poor separately; and the inhabitants have the right of choosing one churchwarden from among themselves. As an ancient member of the town of Sandwich, it is in subjection to the justices of that place. The mayor of Sandwich appoints a deputy, or constable, here, and the inhabitants are allotted by the commissioners of that borough, what proportion of land tax they shall pay. A small annual sum is also paid out of the duties collected at Ramsgate harbour towards the support of Sandwich haven. The influx of visitors to this town of late years has greatly increased, and has consequently occasioned a considerable extension of its buildings. A market has been established for several years; and the streets are paved, lighted, and watched, under the authority of an act of parliament passed in 1785. Here is a spacious chapel of ease, and several meeting-houses for dissenters of different denominations. The accommodation for the summer residents is similar to those at Margate, though perhaps less numerous, and far less splendid. The assembly room and tavern is a spacious building adjoining the harbour. It is elegantly fitted up, and contains convenient tea and card-rooms, a billiard-room, and a coffee-room. Here are likewise several good inns, with bathing-rooms, libraries, boarding-houses, &c. The bathing-place is a fine sandy shore, beneath the cliffs to the south of the pier: the machines are similar to those at Margate, viz. a long port of close caravan, having a door and small flight of steps behind, by which the bathers descend to the water, and are concealed from view by a pendant covering of canvas. Within the last forty years the population of Ramsgate has increased almost in the ratio of three to one. In 1801, according to the parliamentary returns, it contained 275 houses, and 3115 inhabitants; but, in 1811, the former were returned as amounting to 319, and the latter to 4221.

Half a mile westward from Ramsgate is Ellington, an ancient seat of a family of the name of the same, who, towards the end of the reign of Edward IV., were succeeded by the Thatchers, another ancient Kentish family, from whom it passed to the Sparklings. St. Lawrence is a large village, situated on the brow of the hill overlooking Ramsgate; the houses forming a long winding street along the high road to London. The church here is a spacious edifice, confiding of a nave, aisles, and three chancels, with a square tower, supported upon four massive columns, between the nave and principal chancel. The tower, and part of the body, are of Norman architecture, and on the outside of the former, by way of decoration,
The compiling monkey Lanka, the man Venice the fubstitiute Geography, length that 670, is much milder and also de 5 learned much springing house. name offered the Augufine, fled with and dred, as The the fubfequently who Ihe of Wales, fiort feald.

The wild colour North, and geographical range of the lake gradually narrows, and from its northern edge a small brook flows, and at the other extremity it discharges itself into a much larger lake. This lake, it is said, is held in high respect by the inhabitants of Boatan, whose superstition leads them to consider the increase or decrease of its waters as portentous of good or evil to their nation. They fancy it to be a favourite haunt of their chief deities. Turner's Thibet, p. 212, &c.

RAMTEAK, or Ramteen, a town of Hindoofian, in the circuit of Greatvandia, held sacred by the Hindoos, who pretend that Ram collected his army here, prior to his expedition against Rawun at Lanka, or Ceylon. The Hindoos believe all the Europeans to have descended from Rawun, and Ceylon to be an immense mountain of gold invisible to them. Near the town is a temple, in which they offer up their sacrifices and devotions; 15 miles N.E. of Naepour. N. lat. 21° 25'. L. long. 79° 57'.

RAMTRUT, in Mythology, the name of a deity worshipped by the Kamzsins, a people of Hindoo-land, where he has a celebrated temple at Onor. The characters under which it is represented more resemble those of a monkey than of a man.

RAMULOSE LEAF, in Botany. See LEAF.

RAMUNDA, or Ronila Boda, in Geography, a town of Sweden, in Nerica.

RAMUHAR. See RAGOUR.

RAMUS, Peter, in Biography. See RAMISTS.

RAMUS, in Anatomy. This word, signifying branch, and the term ramification, are used in describing the arteries, veins, and nerves, the divisions and subdivisions of which bear some analogy to the branching of a tree. In the same way we speak of trunks of arteries, &c. and describe them as branching out.

RAMUS, in the Anatomy of Plants, a name given to the fork or lateral branches, which go off from the petiole, or middle rib of a leaf. The subdivisions of these are called fursculi; and the final divisions of these into the most minute of all, are by some called capillaments; but in general, both these kinds are comprehended under the name of furcula.

RAMUSIO, or Rannusio, Giambatista, in Biography, an early collector of voyages and travels, the son of Paolo, an eminent lawyer, defended from a learned and distinguished family of Venetian citizens, was born at Venice in 1458. He was in early life deputed by the State upon public business to Switzerland, Rome, and France; and in the latter country he so much ingratiated himself with Lewis XII., that he was by him caufed to travel through almost the whole of his kingdom. As a reward for his services, he was made secretary of the council of ten at Venice, which post he at length resigned; and returning to Padua, employed himself in compiling his great work, "Recolta delle Navigazioni e de Viaggi," which was published at different periods between the years 1554 and 1559, in three volumes folio. He had prepared a fourth volume, which was burnt at the printer's. Ramusio died at Padua in 1557; of course, a part of his work was given to the world after his decease. Ramusio was author of a treatise "De Nili Incremento." He was a man of great learning, and was extremely conversant in history, geography, and the ancient languages: he had some knowledge in astronomy, and held a correspondence with many learned men and well informed persons, both in Italy and Spain. It was by their influence, and at the desire of Trachtoro, that he compiled the
the work already mentioned. This was a collection of all the voyages and travels that had hitherto been published; in which he gave translations of those in foreign languages; and he prefixed dissertations, in which he diligently examined the pretensions of different authors, comparing them with one another.

RAN, in our Old Writers, is used for open and public robbery, so manifest that it cannot be denied. "Ran dictur aperta rapina que negari non potest." Lamb. 125. Leg. Canut. cap. 58. Hence it is to this day vulgarly said of one who takes the goods of another injuriously and violently, that he has taken or snatched all he could rap and ran.

Ran, twenty cords of twine, wound on a reel; and every cord so parted by a knot, as to be easily separated.

RANA, in Geography, a town of Austria; 12 miles S. of Aigen.—Alo, a town of Austria; 13 miles S.S.W. of Zwettl.

RANA, or Orana, one of the Sandwich islands, in the North Pacific ocean, situated about three leagues from Mowree and Morotoi, and lying to the S.W. of the passage between these islands. The country to the south is high and craggy; but the other parts of the island had a better aspect, and appeared to be well inhabited. It produces very few plantains, and bread-fruit trees; but abounds in roots, such as yams, sweet potatoes, and taro. The number of inhabitants is estimated at 26,400. Its S. point is in lat. 20° 46'. E. long. 203° 3'. Cook’s Third Voyage, vol. iii.

RANA, in Surgery. See RANULA.

RANA, in Zoology, the frog, a genus of the class Amphibia, of the division Reptiles, of which the generic character is: Body four-footed, naked; it generally has no tail, the hind legs are longer than the fore. This genus differs from the Laterta (see the art. Lizard), in having a shorter body, broader, thicker head, and in general no tail. The animals of it feed on insects; they are full grown about the fourth year, and seldom live beyond the twelfth. Their fore-feet are moitly cleft, having four toes; their hind-feet are palmate and five-toed; they are extremely prolific, flocking to the female for days and weeks; the tadpole is excluded from the egg without feet, but with a tail resembling a fish’s, which drops off as the legs are produced; in this state they have like wise a sort of gills and lungs, and many have a small tube on the lower lip, by which they can affix themselves to other bodies; near the left eye is a vehicle, from which they discharge water: in breeding time, the fore-thump of the male is watery: toads, as we all know, are filthy in their aspect, and live in damp, obscure, dark places, and crawl out by night; their eggs are in a long chain: frogs are more active, and more about by day; these lay their eggs in a confused mass.

Dr. Shaw, in his entertaining and instructive Zoology, says this genus may be divided into three sections; viz. 1. Frogs, commonly called Rana, with light active bodies, and which leap when disturbed. 2. Slider-limbed frogs, Hyla, Calamita, or Rana arborea, viz. such as have light bodies, very slender limbs, and toes terminating in flat, circularly expanded tips, enabling the animal to adhere at pleasure to the surface even of the smoothest bodies. Several of this division actually reside on trees, adhering by their toes to the lower surfaces of the leaves and branches. The work continues on folio pages.
gradually becomes obliterated, and the animals leave the water, and betake themselves to the surface of the ground. This generally happens early in the autumn, at which period it is not uncommon to find such numbers of the young animals in some particular places, that their appearance has frequently given rise to the vulgar idea of their having been flowered from the clouds.

The toad is an animal too well known to require any particular description of its form. It may be necessary to observe, that it is always covered by tubercles, or elevations on the skin, of larger or smaller size in different individuals, and that the general colour of the animal is an obscurere brown above, much paler and irregularly spotted beneath. The toad, however, is occasionally found of an olive cast, with darker variegations; and in some specimens, more especially in the earliest part of summer, the shoulders and limbs are marked with reddish spots, while a tinge of yellow often pervades the under parts both of the limbs and body.

The toad arrives at a considerable age; its general term of life being supposed to extend to fifteen, or even twenty years; and Mr. Pennant, in his British Zoology, gives us a curious account, communicated by Mr. Arfott, of Teholt, in Devonshire, of a toad's having lived, in a kind of domestic state, for the space of more than forty years, and of having been, in a great degree, tamed, or reconciled from its natural habits or desire of concealment; since it would always regularly come out of its hole at the approach of its master, &c. in order to be fed. It grew to a very large size, and was considered as soingular a curiosity, that even ladies, laying aside their usual aversion and prejudices, requested to see the favourite toad. It was, therefore, often brought to table, and fed with various insects, which it feized with great avidity, and without seeming to be embarrassed by the presence of company. This extraordinary animal generally reposed in a hole beneath the steps of the house door, fronting the garden; and might probably have survived many years longer, had it not been severally wounded by a raven, which feized it before it could take refuge in its hole, and notwithstanding it was liberated from its captor, it never again enjoyed its usual health, though it continued to live above a year after the accident happened.

The toad is looked upon with great aversion by the maj or part of mankind, and it must be confessed, that its appearance is disgusting, yet the eyes are remarkably beautiful, being surrounded by a reddish gold-coloured iris, the pupil, when in a state of contraction, appearing transverse.

We shall conclude the history of this animal, with mentioning the very extraordinary circumstance of its having been occasionally discovered inclosed, or imbedded, without any visible outlet, or even any visible air, in the substance of wood, and even in that of bone or blocks of marble. "For my own part," says Dr. Shaw, "I have no hesitation in avowing a very high degree of scepticism as to these suppo sed facts, and in expressing my suspicions that proper attention, in such cases, was not paid to the real situation of the animal. That a toad may have occasionally been inclosed in some part of a tree, and have been in some degree preserved or inclosed by the growth of the wood, so as to be obliged to continue in such situation, without being able to effect its escape, may perhaps be granted; but it would probably continue to live for a long time as there remained a passage for air, and for the ingress of insects, &c. on which it might occasionally feed; but that it should be completely blocked up in any kind of bone or marble, without either food or air, appears entirely incredible, and the general run of such accounts must be received with a great many grains of allowance for the natural love of the marvelous, the spurze often enjoyed by the fuddens appearance of the animal in an unsuspected place, and the consequent neglect of minute attention at the moment, to the surrounding parts of the spot where it was discovered." *

* *

**RUBETA ; the Natter Jack.** Of this the vent is obtuse; and it has a yellow line on the back; the body beneath is spotted with black, but above it is of a dirty yellow, clouded with brown, and covered with porous pimpls of unequal sizes. This species frequents dry and sandy places, and is found on Putney Common, and near Reveyh-Abbey in Lincolnshire, where it derives its trivial name. It never leaps, neither does it crawl, with the flow pace of a toad, but its motion is more like running. Several are frequently found together, and like others of the genus they appear in the evening.

**GIBBOSA ; Gibbons Toad.** Body oval, convex, with a longitudinal cimereous dentate band. A variety has its back marbled with red and yellowish-ah; the belly is yellow, spotted with black. The fr is found in divers parts of India, the second at Surinam.

**BOZENA ; Laughing Toad.** Belly orange, spotted with sky-blue; the pupil is triangular. Gmelin gives three varieties of this species; viz. 1. That which is distingunished with a black belly, marked with clear white spots and points. 2. One which is brown with white spots; the sides and round the joints are red. 3. One which is distinguished for its loud resonant voice. It is found in the rainy parts of Germany and Helveta; leaps like a frog; emits a clear sound like a man laughing; it a good deal resembles the common toad, but is small, black, and everywhere rough, with dots on the upper part, and variegated beneath, with transverse wrinkles under the neck.

**SALSA ; Salt Toad.** Above of a dirty olive colour, but beneath it is white, spotted with black. This species is found in the stagnant waters of Berchtelfag, and is less than the R. arboea, hereafter to be noticed; it avoids the light, is inodorous, and emits no liquid from its minute perforated warts; the legs are marked with brown bands, beneath it is yellow.

**VENTICOSA ; Tumid Toad.** The month of this is semi oval, and the throat ovate. A variety is marked with pale white pustules. It is found in South America, and in some parts of India. The body is brown and orbicular; the tubercles on the top of the neck longitudinally disposed; the back has three longitudinal wrinkles; the flanks are tumid and dilated.

**MARINA ; Marine Toad.** Shoulders tumid; eye-lids watery, couched; the hind feet are subpalmate; there is a variety, which is spotted with brown; beneath it is shaded with livid, the neck and shoulders are spotted with gray. This is found in various parts of America, and is more than six inches long. Its body is yellowish-grey, with a few rather tawny spots; the warts are distingue with an elevated bay spot in the middle; the protuberances of the shoulders are oval, smooth, and porous; the vent is surrounded with wrinkled radii; the hind toes are connected only as far as the first joint, the last joint is fringed with a bar membrane.

**BRASILIENSIS ; Brafil Toad.** Yellowish-ah; with red waved spots, beneath smooth.

**ANTICO ; Chili Toad.** All the feet of this species are palmate. It inhabits, as its name imports, the waters of Chili; in its size it resembles the R. temporaria described below; on the hind toes there is a slight appearance of claws.

**LUTEA ;**
**RANA.**

**Lutea;** Yellow Toad. The body of this is yellow; all the feet are subpalmate. This is also found in Chili, and much resembles, in its habits, the R. ecdeluta, but is much less; the last joints of the toes are not connected.

**Margaritifera;** Pearl Toad. Body brown-red, sprinkled with pale red spots.

**Cornuta;** the Horned Toad. This takes its specific name from the circumstance of having its eye-lids horned. It inhabits Virginia and Surinam, and of the whole tribe it is the most deformed. It is said, indeed, to surpaso all animals in ugliness. It is thus described: the head is large, and rounded behind; the mouth is exceedingly large; the eye-lids are soft, munterate, trifid at the point; the eyes are seated in the middle; the body is of a greenish-brown, with broad longitudinal whitish stripes on the back; the legs are transversely fuscate with brown; when full grown, the back, the thighs, and vent, are sphyi.

**Sitkaunda;** Dorsal Toad. The specific character is, that above it is ashly-glauces, varied with blackish-green spots, beneath of a dirty white; the hind feet are semi-palmate, with the appearance of seven toes. It inhabits the dry deserts near the Ural, sometimes hides itself in holes, and crawls out in the evening; it resembles the common toad, but is somewhat larger.

**Vespetina;** Siberian Toad. This has a transverse spot between the eyes, forked behind, and other spots running obliquely from the eyes to the nose; the body above is cincerea, with longitudinal subconfluent brown spots, variegated with different shades of green; beneath it is dailed with a whitish-ash. As its trivial name imports, it inhabits Siberia, and is about the size of a common toad; it leaps slowly; the head is short; the body above is sprinkled with subvarvart papillae.

**Riderbunda;** Jocular Toad. Body brown, spotted above with cincerea; the dorsal line is yellow, or greenish; beneath it is smooth, whitish; seams brown, spotted with milk-white. The head of this species is broad; the upper eye-rid is convex, sprinkled with pores; the apertures of the ears are flat; the back is porous; the sides are marked with obsolete warts; the fore thumb is divericate, thick at the base; the next toe shorter than the rest; the hind limb subfuscate; the hind feet have a callos within, resembing a fifth toe; the toes have a wart beneath, near the joints.

This species is found in great numbers near the rivers which empty themselves into the Tapian sea; it never ventures on the dry land; it is very large, and frequently weighs more than half a pound; it resembles the R. temporaria, but is broader and shorter; its voice in the evening is like that of a man laughing.

**Variabilis;** Changeable Toad. Colour variable; back and sides gibbous; warts yellowish in the centre; it is very small on the middle of the back, and larger on the most prominent part of the flanks. It inhabits the shady places in Germany, and is only about two inches long; in its habits, it holds an intermediate place between the toad and frog; when full awake its body is white, with green spots; in the heat of the sun it is entirely cincerea; when asleep, the spots are only cincerea, and when torpid the body has a flesh-coloured call.

The head is rounded, and the mouth without teeth; the margin of the upper jaw is doubled; the tongue is fleshy, thick, placed far back, the base obscurely bilai, very entire at the tip; it has hardly any upper eye-rid, the lower one is folding; cavities of the ears white; the warts resemble teats, very numerous on the groin; the chin is marked with prominent dots; the colour, when preferred in spirits, is yellowish, and above it is of a pale olive; the fore feet are three-toed, beneath they are emarginate, the thumb is larger; the second toe of the hind feet is very long.

**Section B.—Body more oblong, smooth; Legs longer. Frogs.**

**Typhosia;** Hurricane Frog. Of this species, the distinguishing characteristic is, that the holes of the ears are oval. It inhabits America, and is said to make a noisy croaking before hurricanes and whirlwinds. The back is marked with four longitudinal wrinkles, elevated points, and black spots; the hind toes are narrow, without claws, the second is very long.

**Pentadactyla;** Mackarel Frog. All the legs are fuscate, five-toed; body veined, the dorsal streaks transverse, the lateral ones are osculate. There is a variety which is brown; the fore feet have four toes, with the rudiment of a fifth; the hind feet have five toes, with the rudiment of a sixth.

**Ocellata;** Oscillate Frog. The ears are marked with an osculate spot; feet with claws, the hind ones subpalmate. It inhabits America.

**Pipiens;** Physorous Frog. This is green, with numerous osculate spots, surounded with a yellowish ring. This species is smaller than the green frog, but, in its general habits, it bears a considerable resemblance to that animal. It is a native of North America, and frequents rivulets and ditches of water, and is so strong and vigorous, that it can leap to the distance of five or six yards. In the spring and beginning of summer, it is said to indicate the approach of rain by the peculiar sound which it emits. In the living animal the ears are of a shining golden colour; the region of the anus is very much wrinkled; the third fore toe from the thumb longer than the rest; the body resembles that of the eculent, or green frog, but the hind thighs are longer; the flanks are longer still, and hind feet are longer than those, marginate on each side; the toes are connected nearly to the tip, the fourth is longer than the rest.

**Bicolor;** Blue and Yellow Frog. Colour blue, ochreous beneath, feet unwebbed; toes flattened and orbicular. This elegant species is of a moderate size; it measures more than four inches in length. The whole of the upper surface is of a beautiful blue, while the under parts are of a pale orange, or ochre colour. The head is large, the mouth wide, and the tip of the nose truncated. All the toes are furnished with a large orbicular tip, and beneath each of the joints there is a process or tubercle. The upper parts of the female have a deeper shade of violet than those of the male. It is supposed to be native of Surinam.

**Maxima;** the Great Frog. All the feet are palmate, as well as the toes, fuscate; body veined and variegated; the top of the back obliquely spotted. Bands of the legs in pairs, approximate, above confluent.

**Alpina;** Alpine Frog. This is entirely black, and inhabits the declivities of the mountains in Austria.

**Vavulosa;** Veined Frog. Feet cleft; the body veined with confluent spots. It inhabits India and South America.

**Virginia;** Virginian Frog. Cincerea, spotted with red, beneath it is yellowish; the back is five-angled, with as many stripes. It is found in Virginia.

*Temporaria;* or Common Frog. The back of this is flattish and sub-angular. There is a variety, which is of a dirty olive colour, with large warty spots, the head above plain, beneath whitish; twice the size of the common frog. Both are found in this country, and the latter also in Persia; it lives, during the spring, in water, among toads, and in the summer...
tum"er on land, at which time it is silent; it feeds on various
insects, and is the prey of ducks and cranes, croaks very
much when in muddy ditches; the variety makes, by night,
a noise like that of an angry man.

Of all the European species this is the most common.
The general colour is of an olive-brown, variegated on the
upper parts of the body with irregular blackish spots. The
patch beneath each eye, which reaches to the setting on of
the fore-legs, seems to constitute one of the principal specific
distinctions. The under part of the body is of a pale
greenish colour, and obscurely spotted. But it ought to be
observed, that the colour of the frog varies at different fea-
sons of the year, and perhaps in different places. Towards
the end of summer, for instance, the colours are much
brighter; and as this species frequently calls its skin, the
cuticle falling off irregularly from different parts of the
body, produces considerable variations in the intensity of the
colours.

The frog has a light elegant form and a lively appear-
ance; the limbs are well calculated for its peculiar motions,
and the hind feet being strongly webbed, enable it to swim
well. The frog, it is said, does not reach its full size till it is
five years old, and it lives from twelve to fifteen years.
It retires during the heat of summer to the water, and in winter
it becomes torpid, and is generally found in the soft mud at
the bottom of stagnant waters, or in the cavities beneath
their banks, where it remains till the return of spring.

The frog, as well as many other of the reptile tribe, is ex-
tremely tenacious of life. It survives, for a considerable
time, the loss even of some of its essential organs, and it has
been found to exist for several days when entirely confined
under water.

The frog deposits its spawn in the month of March.
This is composed of a gelatinous transparent mass, including
the ova or eggs, in each of which is imbedded the embryo
or tadpole, which has then the appearance of a round black
globule. The period of hatching varies according to the
temperature of the season, but it is commonly in about a
month or five weeks. In its progress the egg becomes gra-
dually larger, and before the tadpole is excluded, it is seen
in motion within the surrounding gelatin. When they are
first hatched, their only food is the remains of the gelatin
in which they were included. A few days afterwards, if they
are minutely examined, a pair of ramified branches, or tem-
porary organs, may be observed on each side of the head,
which after a short time disappear. The tadpole, which is
so completely unlike the animal in its perfect state, seems
to confit only of a head and tail. The head is large, black,
and roundish; the tail is slender, and marked with a
broad transparent fin. The motions of the tadpole are very
lively. Its food consists of duck-weed and other small wa-
ter plants, with different kinds of animalcula. The mouth
is furnished with very minute teeth, and when the tadpole
has reached a certain size, it may sometimes be heard gnaw-
ing the edges of the leaves on which it feeds. By means of
a sucker placed between the lower jaw, with which the ani-
mal in this state is furnished, it can attach itself at pleasure
to the under surface of aquatic plants. When it is very
young, it sometimes hangs from this part by means of a
glutinous thread, similar to some small flugs.

The internal structure of the organs of the tadpole is
very different from that of the future animal. In so resepct
is this difference greater than in the disposition of the inter-
tines, which are coiled in the form of a flat spiral, like a ca-
ble. The first change which appears on the tadpole is at
the end of five or six weeks after it is hatched. It is about
this time that the hind legs first appear; and gradually in-
creasing in length and size, they are succeeded about two
weeks afterwards by the fore legs. These latter, indeed, are
formed at an earlier period beneath the skin, and are some-
times protruded, and again drawn back by the animal,
through a small hole on each side of the breast, before their
complete evolution. The tail now gradually decreases, and
afterwards more rapidly, so that in the space of a day or
two, it is quite obliterated. After this change, the animal
leaves the water, and covers the banks in myriads. The
sudden appearance of such multitudes of young frogs, has
probably induced the ground-bats to popular belief, of their
having fallen from the clouds in showers. The frog having
now arrived at its perfect form, it changes entirely the na-
te of its food. It lived formerly on vegetables, now it
depends solely for its existence on animal food. It lives
chiefly on small snails, worms, and insects. To seize
its prey, the structure and position of the tongue are re-
markably well fitted. It is of considerable length, and
is attached to the fore part of the mouth; and when at
rest it lies backwards. The extremity is bifid, and
secretes a glutinous matter, so that in this way it can se-
cure its prey, by darting out its tongue with great celerity,
and to some distance from the mouth. This it does with so
instantaneous a motion, that it is scarcely perceptible to the
eye.

**MARGINATA;** Borderd Frog. The sides of this are
marginate, and the feet cleft. It inhabits India and South
America.

*ESCULENTA;* Esulent, or Edible, or Green Frog.
Of this species the distinguishing characteristics are, that
it is of an olive colour, spotted with black, with three
yellowish lines on the back; the abdomen is whitish.

Of all the European frogs this is the largest species.
The general appearance is very like that of the R. tempo-
raria, but it is larger in size, and of an olive-green colour,
strongly marked on the upper part of the body with roundish
black spots. The limbs are elegantly marked with trans-
verse bands of the same colour. "Three distinct pale yellow
stripes run from the tip of the nose down the whole length
of the back; the middle one being slightly depressed, but
the two lateral ones are considerably elevated. The head is
proportionably larger than that of the common frog.

The green frog is rare in England, but is very common
in France, Italy, and Germany, where it is employed as an
article of food.

This species, it is observed by naturalists, does not leave
its winter retirement till a much later period than the com-
mon frog; and in those countries where it is used as food, it
is worth while to attend to this fact: for if they are pre-
tended to be brought to market at an earlier period, the
common frog, and sometimes even toads, must be subti-
tuted. During the breeding season, the croaking of the
male is so loud, that it may be heard at a great distance;
and in those places where they are numerous, it becomes so
intolerable to those who are unaccustomed to hear them,
that they are often deprived of sleep. At this time, too, a
large inflated globular bladder is protruded from each side
of the head of the male. The globules of spawn in the
green frog are proportionally smaller than in the former
species: they have somewhat of a yellowish cast. The pro-
gress of the tadpole, towards the evolution of the perfect
animal, is considerably flower in this species. The fore
legs do not appear before October, and the animal does not af-
fume its perfect shape till the beginning of November. The
tail at this time begins to decrease, and in the space of four
days entirely disappears.

This species is extremely voracious, seizing it is said, on
young
young birds of different kinds, mice, and even ducklings, and, as it does with the rest of its prey, swallowing them whole. At the end of four years it has reached its full growth. It begins to breed the year following, and the period of its life is sometimes extended to sixteen years.

Australis; Australian Frog. The body of this is brown above, beneath blueish; the flanes are speckled with ochre colour; the toes of the fore feet are supine. It inhabits New Holland. The second toe of the hind foot is very long; the claws are red.

Paradoxa; Paradoxical Frog. This is of a yellowish and olive colour, variegated with rufous bands; the hind legs or thighs are obliquely streaked.

In its general form this station resembles the R. temporaria. The oblique longitudinal stripes on the hind legs constitute the principal mark of distinction. There are four toes on the fore feet, and they are unwebbed; the hind feet have five toes, and are deeply palmated to the very ends of the toes. Near the short toes there is an oblong callus, forming a tuberous one. The upper jaw is bifurct with a row of small denticleations. This station is a native of South America, and is more common in Surinam than in other places.

Naturalists, says Dr. Shaw, have been extremely puzzled with regard to the real nature of what has been taken for the tadpole of this frog. At one time it was confidered by Linnaeus as a species of lizard, and therefore arranged by him under the genus lacerta. At another time he has placed it under the present genus, with the specific name paradoxus. It was described by Edwards under the denomination of the frog-fish of Surinam. The structure of the animal, which has been the subject of so much disputation, shews clearly that it is the larva or tadpole of a frog; and it is supposct, with no small degree of probability, that the differences in the accounts given of this animal by naturalists have arisen from the different stages of its progres, in which it has been found. But as this tadpole is so much larger in size, in proportion to the perfect animal, than any other species yet known, it may be the larva or tadpole of some of the larger species, and not that of the R. paradoxa, which is but a small frog.

C. Hind Feet very long; the Claws lenticulate.

Arbores; Tree-Frog. The body of this is green, beneath granulate; feet cleft. Gmelin enumerates five varieties of this species. 1. Thofe which have four toes to their fore feet, and five to those that are behind; the knees are warty beneath. 2. Thofe that are of a green colour, with a straight yellow line on each side. 3. The body of this variety is reddish. 4. Of this it is brownish-green. 5. The flenerons of the body marks this variety.

"In the beauty of its colours," says Dr. Shaw, "as well as in the elegance of its form, and agility of its movements, the tree-frog excels every other European species. It is a native of France, Germany, Italy, and many other European regions, but is not found in the British islands. Its principal residence, during the summer months, is on the upper parts of trees, where it wanders among the foliage in quest of insects, which it catches with extreme celerity; feeding softly towards its prey, in the manner of a cat towards a mouse, and, when at the proper distance, seizing it with a sudden spring, frequently of more than a foot in height. It oftenfulps itself by its feet, or abdomen, to the under parts of the leaves; thus continuing concealed beneath their shade. Its size is smaller than any European frog, except the R. bombina. Its colour, on the upper parts, is more or less bright in different individuals; the abdomen is whitish, and marked by numerous granules; the under surface of the limbs is reddish; and the body is marked on each side by a longitudinal blackish or violet coloured stripe, separating the green of the upper parts from the white colour of the lower; the lower edge of this dark lateral stripe is tinged with yellow. The body is smooth above, and moderately short or plump; the hind legs are very long and slender; the fore feet have four, and the hind feet five toes, all of which terminate in rounded, flat, and dilated tips, the under surface of which, being soft and glutinous, enables the animal to hang with perfect security from the leaves of trees, &c. The skin of the abdomen is also admirably calcified by nature for this peculiar power of adhesion, being covered with small glandular granules, in such a manner as to clasp firmly even to the most polished surface; and the animal can adhere at pleasure to that of galls, in whatever position or inclination it is placed, by merely prelling itself against it.

Though the tree-frog inhabits the woods during the summer months, yet, on the approach of winter, it retires to the waters, and from submerging itself in the soft mud, or concealing itself beneath the banks, remains in a state of torpidity; and again emerges in the spring, at which period it deposits its spawn in the waters, like the rest of this genus. The male at this period inflates its throat in a furruzine manner, and exerts a very loud and harsh croak, which may be heard to a vart distance. The spawn is deposited about the end of April, in small clustered masses; the incrucible globules or embryos being of a pale yellowish-brown colour. The tadpoles become perfect frogs, by the total decay of the tail, about the beginning of August; and soon begin to ascend the neighbouring trees, where they continue to reside during the remainder of the warm season: as do likewise the parent animals, after the breeding season is past. During their residence among the trees, they are observed to be particularly noisy on the approach of rain; so that they may be considered, in some measure, as a kind of living barometers; more especially the males, which, if kept in chambers, and supplied with proper food, will afford an infallible preage of the changes of weather.

Leucophyla; White-spotted Frog. Body smooth, hoary, with oblong milk-white spots; the fore feet are lobate, the hind feet palmate. It inhabits America, and weighs only about forty-fix grains. Eyes of a fine golden colour, and between these, on the sides and middle of the back, there are oblong white spots; the haunches are flender.

Squlimgera; Scaly Frog. In this a scaly band reaches half-way round the back; the fides and throat have folds; the fore feet are semi-palmate, the hind feet are palmate. This is about two inches long, and is supposct to be an inhabitant of America. The body is varied with grey and brown in thick aggregate specks, and a few spots down the hind part of the back, in a serpentine direction; the band confists of minute, sub-pellucid, rhomboid, imbricate scales; the hind limbs are twice as long as the fore.

Boans; Croaking Frog. Body smooth, with continuous dots beneath; feet palmate. There are two varieties. 1. The body above is of a blueish lead-colour. 2. The body of this is inclining to orange. It is found in America, and differs only from the tree-frog in having the feet webbed, and the body marked with white spots.

Rana Arborea, the Tree-Frog. See Ranunculus Vitis-idaea, and the preceding article.

Rana Pipatrix. See Lophius Pipatrix, and Sea-Dog.
RANARIDII, in Geography, a town of Austria; 11 miles S. of Aigen.

RANASAGUR, a town of Hindooistan, in Bahar; 18 miles W. of Arrah. N. lat. 25° 37'. E. long. 84° 31'.

RANCAGUA, a jurisdiction of South America, in Chili. It derives its name from the inhabitants living in single houses, without the appearance of a village; every family lodging in their lonely cottage, four, six, or more leagues from each other. It is not, however, without a capital, consisting of about 50 houses, and between 50 and 60 families, most of them being Meztizos, though their east is not perceivable by their complexion. The whole jurisdiction may contain about 1000 families, Spaniards, Meztizos, and Indians. Ullao's Voyage, vol. ii.

RANCE, Armand-John-le Bouthillier de, in Biography, the initiator of the order of La Trappe, was of noble descent, and born at Paris in the year 1626. At a very early period he exhibited an extraordinary genius for classical and polite learning; and at the age of 10 he had read many classical works, in the Greek as well as the Latin languages, and is said at that early period to have understood Homer. When he was only 13 years of age, he prepared for the prefs a new edition of Anacreon, with notes, that displayed considerable talent and research. This was published in 1639. Four years previously to this, he had received the clerical tonsure, and had been nominated a canon of Notre Dame at Paris. He was promoted by the king to the sinecure priory of Boulogne, near Chambor; and he was subsequently promoted to three different abbeys, among which was that of La Trappe, and to other places of honour and trust in the church. He studied divinity at the Sorbonne, and in 1651 he was ordained priest; and in less than three years, the degree of doctor of divinity was conferred upon him by the faculty of the Sorbonne. Having thus completed his studies, he entered into the world, and, like one broken from his shackles, he devoted himself eagerly to its honours, pleasures, and gains. He soon became a favourite at court, and was appointed almoner to the duke of Orleans, and one of the deputies of the second order in the assembly of the clergy in 1655. On a sudden, and for a cause that never was well understood, he became disaffected with the world, and resolved to renounce for ever its pleasures, enjoyments, and vanities. No sooner had the abbe de Rance formed the resolution than he withdrew to his estate in the country, to deliberate concerning the mode of life which he should pursue. Having made up his mind to embrace the monastic life, he sold his estate, and bestowed the money which it produced on the Hôtel-de-Dieu at Paris. He also resigned all his benefices and dignities, excepting his priory of Boulogne, and the abbey of La Trappe; the latter of which he retained by a special permission of the king, in order to introduce into it a reformation of the statues and discipline. He took the habit, and made his profession in the year 1664, and set about establishing the gloomy and austere discipline of monastic in its full perfection. The place itself seemed peculiarly adapted to the horrid folly which he established, being the most gloomy, barren, and desolate spot in the whole kingdom of France. Here the days of the monks were constantly spent in prayers, tears, contemplation, silence, the perusal of holy books, the hardships of bodily labour, and the practice of the most rigid austerities. All other delights and occupations, however laudable and excellent in themselves, they were to regard as vain and sinful to persons of their order. The least relaxation, or amusement of the most innocent nature, they were not allowed; and they were prohibited from engaging at all in literary studies. Strange! that a mind stored with liberal knowledge, and distinguished by good taste, should have been so far perverted by superstition and fanaticism, as to devise or sanction such regulations.

That the world might be acquainted with the discipline of his community, he published "A Treatise on the Sanctity and Duties of the Monastic State." As de Rance advanced in years, the severe discipline to which he strictly conformed, rendered him so infirm, that, finding himself unequal to the duties of his post, he resigned it into the king's hands, but was permitted to appoint his successor. At length, worn out with infirmities and mortifications, and lying on a bed of ashes and straw, he died in 1700, in the 74th year of his age. He was author of a great number of theological and other pieces, among which may be mentioned "Moral Reflections on the Four Evangelists;" "The Constitution and Rules of the Abbey of La Trappe," in 2 vols.; and "A Discourse on Purity of Intention." Moreri.

RANCÉ, in Geography, a river of France, which runs into the sea near St. Malo.

RANCHANO, a small island near the coast of Darien, in the Pacific ocean.

RANCHERIA, a town of South America, in the vice-royalty of Granada, and province of St. Martha; 20 miles N.E. of Hacha. N. lat. 11°. W. long. 72° 36'.—Alfo, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 50'. W. long. 82° 16'.

RANCHERIAS, a name given, in the province of Panama, to assemblages of Indian huts under the jurisdic- tion of a village. These rancherias are situated to the southward, in the small chains or breaches of the mountains.

RANCID, in Rural Economy, from the Latin ranctus, of ranco, to be rank, a term applied to substances, which have contracted a strong offensive smell and taste by keeping, as bacon, butter, and all fat substances are apt to do. It would be a very useful discovery, to find out any easy simple method of preventing this effect from taking place.

RANCÓN, in Geography, a river of France, in the department of the Lower Seine, which runs into the Seine, at Caudanee. —Alfo, a town of France, in the department of the Upper Vienni; 8 miles E. of Bellac.

RANCONET, Aimar de, in Biography, a learned and worthy magistrate, who flourished in the 16th century, was born at Bordeaux, in which city his father was an advocate of parliament. Having received the advantages of a good education, he became deeply skilled in the Roman law, to the study of which he joined that of philosophy, mathematics, and antiquities. Having been some time a counsellor in the parliament of Bordeaux, he was raised to the post of president of the fourth chamber of inquests in that of Paris. The religious contentions of the time were fatal to him. When the cardinal of Louvain assembled the parliament of Paris, to procure its opinion concerning the punishment of heretics, Ranconet brought the works of Sulpicius Severus, and read aloud the passage in which that writer censures the execution of Priscillian; upon this the prelate caused him to be imprisoned in the Baillfe, where he died of grief in 1559, at the age of 60. His latter days had been singularly unfortunate. He was reduced by want to be a corrector of the presses to the Stephens; he gave his daughter die on a dunghill, and his son executed, and his wife was killed by lightning. This learned man published scarcely any thing in his own name, but contributed much to the labours of others. He is said to have had the chief part in the valuable treatise, "De Verborum Significatione," and in the "Formula" of Briion; and Pithou affirms,
affords, that he compiled the Dictionary that bears the name of Charles Stephens. He wrote "Le Treoir de la Langue Françoise, tant ancienne que moderne." Moreri.

RANCONNIERES, in Geography, a town of France, in the department of the Upper Marne; 9 miles W. of Bourbonne.

RANDEL, Dr. John, in Biography, organist, doctor in music, and music professor in the university of Cambridge. He was brought up in the king's chapel, was one of the children of that choir who first performed in Handel's oratorio of Ephraim, at the house of Bernard Gates, master of the boys in James-street, Westminster, on Wednesday, February 23, 1731, when it was performed in action, previous to its having been heard in public, or anywhere but at Cannons, the magnificent seat of the duke of Chandos, for whose chapel it was composed in 1726.

Randal was never rated very high in his profession; he was regarded as a flight organ-player, and had never distinguished himself as a composer. He obtained his degree at the installation of the duke of Grafton in the university of Cambridge, for which he composed the ode written by Mr. Gray, to the solemnization of all the musical professions, by undertaking to have it performed by the musiciens refident in the university, without putting his grace to the expense of additional hands and voices from London, as Drs. Greens and Boyce had thought necessary on former occasions at Cambridge, and Dr. William Hayes at Oxford.

As Dr. Randal's professional life was unmarked by talents, his death, which happened in 1799, was hardly noticed, except by the candidates for the professorship, and his organist's places.

RANDELSTOWN, in Geography, a port-town of Ireland, in the county of Antrim, in the neighbourhood of which is Shane's castle, the seat of lord O'Neill. It is situated on the river Léin, near the northward of Lough Neagh. Randelstown is 4 miles N.W. from Antrim, and 88 N. by W; from Dublin. Before the union, it was represented in parliament. Carlisle, &c.

RANDS, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the district of Riom; 12 miles N.E. of Riom. The place contains 1,047, and the canton 7,956 inhabitants, on a territory of 130,000, in 11 communes.

RANDASALMI, a town of Sweden, in the government of Kuopio, 52 miles S. of Kuopio.

RANDAZZO, a town of Sicily, in the valley of De- noma; 25 miles W. of Taormina. N. lat. 37° 57'. E. long. 15° 4'.

RADEER, a town of Hindoostan, in Guzerat, on the Tapté, opposite to Surat.

RADEGG, a town of Austria; 8 miles N.N.E. of Bavarian Waldovien.

RANGERADT, a town of France, in the department of the Depart; 10 miles N.W. of Julliers. N. lat. 50° 59'. E. long. 6° 8'.

RANDERS, a town of Denmark, in North Jutland, on the Gulden. This town is reduced, and has now only one parish church, a grammar-school, an hospital, and a chapel near the town. The chief articles of trade consist of leather gloves, salmon, earthen-ware, and strong beer. It was formerly well fortified; 20 miles E. of Viborg. N. lat. 56° 28'. E. long. 10° 5'.

RANDERSACKER, a town of the duchy of Wurzburg, on the Maine; 2 miles S. of Wurzburg.

RANDEA, in Botany, was so named by Houblon and Linneus, in honour of Mr. Isaac Rand, F.R.S., an apothecary in London, who filled the place of lecùter and de-

Vol. XXIX.
viously to this he had been appointed prel&-ctor of poetry, proctor, and in 1782 Regius professor of Greek. In this same year he was made prebendary of Salisbury, canon of Christ-church, and Regius professor of divinity; and in 1783 rector of Ewelme. In 1799 he was elevated to the bishopric of Oxford, from which he was translated to that of Bangor in 1807, and then to the metropolitan see of London in the year 1809. Notwithstanding these high preferments he passed a great part of his life in the university of Oxford, and it was generally believed that when he was elevated to the see of Oxford, the university was complimented with the nomination by the crown. His lordship was author of many sive fomorous, and charges delivered on different occasions; also of "De Greece Linguo Studio Preleclito habita in Schola Linguarum," 1783, and "Conic ad Clerum in Synodo Provincialis Cantuariensis Provinciae ad D. Pauli," 1790. His lordship was a zealous promoter of the National schools in opposition to those founded by Lancaster, and he was understood to be a violent opponent to the bible society, and to the spread of what has been termed Sectarism. One of his last works was a Report of the Progrees made by the National Society, to which the general committee referred in terms of gratitude, at their first meeting after his lordship's decease, in the following terms: "whose zealous employment had been to flate, for the information of the public, the progrees of a work to which he had contributed his time, his labour, and his counsels, the committee could not fail to entertain a common sentiment of profound regret for the loss which they have sustained, and to cherish in their minds the lively recollection of the service which has been so successfully fulfilled by him in this second report. They wish, therefore, to add to this document, designed for general circulation, the senfe of what is due from the public, and themselves, to the memory of one who was a constant and afficious promoter of this salutariffinstitution, from its first establishment to the last hour of his life.—The committee trust, that this testimony, though limited to a single object in the large field of pastoral duty in which he was incessantly engaged, may serve to denote the benefits which have resulted from his prompt, unwearyed, and effectual exertions."

The following is the character drawn of him by Mr. archdeacon Jeffron, and which alludes to his zeal for the church of which he was an active member. "Fearles now of being cenfurcd for mercenary adulation, or reproved by unconfeious merit, a just tribute may be paid to the charader of that departed and exalted prelate, who is, and will be, most lamented where he was left and most entirely known. This opportunity, therefore, is willingly embraced of offering a heart-felt condence to the ministry of the diocese on the affecting and important loss, which, in these perilous times of contending sects and unfounded opinion, has arisen to them, and to the church:—To them, in the premature privation of a diocesan, firm in his support of eccleciastical authority, but considerate in its application; eminently verified in the letter of ecclesiastical law, but liberal in its practical construction, reluctant in interference, but determined in duty, flow in the profession of service, but prompt in its execution; disinterested in patronage, unwavering in meafures, correct in judgment, attentive in counsel, and kind and compassionate to diftreces:—To the church, in the premature privation of a father, diligent in her rites and services, but unobtientious in piety and devotion; found and unrelaxing in her doctrines and faith, but different in zeal, and comprehensive in charity; ever vigilant in defending her interests, ever forward in asserting her privileges, and ever able in the affliction and the defence."

The bishop died suddenly on the 28th of July 1813. He was one of the governors of the Charter-house; trustee of the British Museum; dean of the Chapel royal; visitor of Sion college; and provincial dean of Canterbury. Gent. Mag.

RANDOLPH, in Geography, a poll-town of America, in Massachusetts, formed of the S. precinct of Brantree, in Norfolk county, in the year 1783; 15 miles S.E. of Bolton. The inhabitants are mostly farmers, but manufacture large quantities of flours for market.

RANDOLPH, a county of Hillborough district, in North Carolina, bounded N.E. by Orange, and N.W. by Guildford. The number of inhabitants is 10,112, and they are mostly Quakers; the other denominations are Presbyterians, Baptists, Methodists, and Universalists. Their good land produces 40 or 50 bushels of Indian corn, or 20 of wheat, per acre. The chief town is Hillsborough.

RANDOLPH, a county of Virginia, bounded N. by Monroe, and S. by Pendleton. The number of inhabitants is 2854.

RANDOLPH, a poll-town in Orange county, Vermont, being the 4th town W. of Thetford, on Connecticut river. The number of inhabitants is 2255. White river, by its two branches, waters the E. and W. side of the town. It has a large bed of iron ore, two forges, and a slitting mill. The congregational meeting-house has a steepel, and is large; 47 miles from Rutland.

RANDOLPH, a county of the Indiana territory.

RANDOLPH, a town of Morris county, in New Jersey, containing 1271 inhabitants. RANDOM, a township of Essex county, in Vermont, W. of Brunswick. RANDOM Island, a small island in Trinity bay, near the E. coast of Newfoundland. N. lat. 48° 15'. W. long. 53° 40'.

RANDOM Shot, a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly, or point-blank.

The utmost random of any piece is about ten times as far as the bullet will go point-blank; and the bullet will go farthest when the piece is mounted to about forty-five degrees above the level range.

The space or distance of the random is reckoned from the platform to the place where the ball first grazes. RANDOM, in Geography, a river of Brandenburg, which runs into the Ucker; three miles S. of Uckermund.

RANDS, a lake of Norway, in the province of Aggerhuus, 35 miles long, and two broad; 20 miles N. of Christiana.

RANDSBORG, a town of Sweden, in Welf Gathland; 76 miles E. of Uddavalla.

RANDYCHOAR, a town of Bootan; 18 miles N. of Beyhar.

RANEA, a town of Welf Bothnia; 60 miles W. of Tornea.

RANELAGH, Rotunda and Gardens, built and opened for musical performances and public amusements in 1742. The building was erected in the spacious garden belonging to the residence, at Chelsea, of lord Ranelagh, one of the ministers of Charles II., when paymaster of the army. It was planned by the late Mr. Lacey, afterwards joint-tenant of Drury-lane theatre with the great actor Garrick.

At the first opening of this stupendous building, several experiments were made in placing the orchestra, in filling it, and in the time of performance, before it was settled as an evening promenade. The orchestra was at first placed in the middle of the rotunda. The performance was in a morning; and oratorio chorusses chiefly furnished the bill of fare. Sir John Barnard complaining to the magistrates, that
that the young merchants and city apprentices were frequently seduced from their counting-houses and shops by these morning amusements, they were prohibited, and the doors opened at six o'clock in the evening. The performance, however, did not begin till eight o'clock, but was ended at ten.

It was intended to rival Vauxhall, and was little injured by bad weather; as the company, at such times, had a safe and pleasant retreat into the rotunda, and as few went thither but in carriages.

Its success as an evening's amusement remained undiminished more than 40 years. It was ruined by the late hours to which it was gradually brought by fine folks, who, at length, never came thither till past ten o'clock, when the musical performances were over, and sober people used to return home before eleven o'clock to their supper, which enabled them and their servants to go to bed, and rise, at their accustomed time.

But, at length, perfons of rank and fashion made a de-bauch of this innocent amusement, and went to it and departed from it as late as at a maquerade. This precluded all that had any thing to do themselves, or any employment for their servants in the morning, and so much refined the company, that at midnight there had been seldom sufficient money received at the entrance, to cover the expenses of the lamps, the terms of admission being only 3s., for which, besides a good concert by the bell performers in London, the company was furnished with excellent rolls, butter, and tea.

In the year 1803 it was shut up, and only used occasionally for a maquerade, a festival, or an exhibition of fire-works. But since the period just-mentioned, the building has been pulled down, and the materials sold piecemeal, as was the cafe at Cannons, the splendid mansion of the duke of Chandos, (or Palazzo, as it would have been called in Italy,) and the ground is now (1809) of no other utility than occa-sonally to drill and excercise the Chelsea volunteers.

RANES, in Geography, a town of France, in the department of the Orne; 10 miles S.W. of Argentan.

RAHESTAD, a town of Sweden, in Angermanland; 50 miles N.N.E. of Hernofand.

RANFORCE Ring. See Reinforced Ring.

RANG, in Geography, a town of Sweden, in the province of Skonen; 11 miles S.S.W. of Lund.

RANGA, in Hindoostan, one of the many names of Siva, the personification, according to the Hindoo mythologists, of the destructive or changing form of the deity. (See Siva.) The epithet Sri, meaning holy, or divine, or blessed, prefixed, has given this name to the capital of My- fore; Sri Ranga-pattan being the city of the blessed Ranga, altered by Europeans to Seringapatam. See Sri.

RANGALORE, in Geography, a town and Port of Hindoostan, in the cir-cre of Cicacole; 38 miles W. of Cicacole.

RANGAMATTY, a cingal of Bengal, bounded on the N. by Bootan and Almora, on the E. and S. by Almora, and on the W. by Baharbord, Bettebord, and Goollah; about 40 miles long, and from 10 to 40 broad. Rangamatty, the capital, is 128 miles N.N.E. of Moorshedabad, and has a celebrated pagoda. N. lat. 26° 8'. E. long. 90° 0'.

RANGANJA, a town of Bengal; 15 miles N.E. of Chattigong.

RANGAPALEAM, a town of Hindoostan, in Coim- betore; eight miles N.N.E. of Darapurum.

RANGAPILLA, a town of Hindoostan, in the Carnatic; six miles N.E. of Pondicherry.

RANGASUNDRUM, a town of Hindoostan; 15 miles W. of Thuellavell.

RANGE, in Gunnery, the path of the ball, or the line it describes from the mouth of the piece to the point where it lodges. The flight of a shot is distinguished, by artillerymen, into three different ranges, of which the first is called the point-blank, the second the random-shot, and the third the ricochet, or rolling and bounding shot. The first, or point- blank, is to suppose a piece fixed upon a level plain, and laid level, then the distance between the piece and the point where the shot touches the ground first, is called the point- blank range of that piece; but as the same piece ranges more or less, according to a greater or less charge, the point-blank range is to be understood to be that, when the piece is loaded with that charge which is commonly used in action.

This range is much less than the greatest range, or ran- dom-shot, but the piece cannot be levelled, or, as it is generally expreased, pointed at an object intended to be bat- tered, if that object is not within the distance of the point- blank range; for beyond that the shot is very uncertain, therefore rarely used in the sea-service, and on land only when the shot cannot fail of doing great execution in the place on which it falls.

In ricochet firing, the piece is only elevated from three to six degrees, and loaded with a small charge, in order that the ball may be bounded, and roll along the inside of the pa- rapet. The shot, thus discharged, goes rolling and bound- ing, killing and maiming, or destroying all it meets in its course, and creates much more disorder by going thus low- ly, than if thrown from the piece with greater violence. See Cannon, Gun, and Projectile.

Range of a Projectile. See Amplitude.

Range, Point-blank. See Point-blank.

Range, in a Ship, denotes a sufficient length of the cable, drawn up on the deck, before the anchor is cast loose from the bow, to let it sink to the bottom, without being inter- rupted, that the flukes may be forced the deeper into the ground, by the additional weight which the anchor acquires in sinking. For this reason, the range, which is drawn up out of the tire, ought to be equal in length to the depth of the water, where the ship anchors.

RANGER, a sworn officer of the forest, whose business is to walk daily through his charge, to drive back the deer out of the purifies or defafored places into the forest lands; and to prevent all trepailles done in his baili- wick at the next court held for the forest.

The ranger is made by the king's letters, and has a fee paid yearly out of the exchequer, and certain fee-deer. In the Charta de Foretia mention is made of twelve kinds of rangers. It is now principally a honorary and finecur- employment; but the holders sometimes likewise receive pay.

RANGES, in Ship Building, horned pieces of oak, like belaying cleats, but much larger, bolted to the midle of a ship, in the way for belaying the tacks and sheets. Also those pieces of plank fixed between the ports, with semi- circular holes in them for keeping shot in.

RANGIFER, in Zoology, a variety of the Cervus Taurus; which bee.

RANGING, in War, the disposing of troops in a condition proper for engagement, or for marching.

In Building, the side of a work that runs straight, without breaking into angles, is said to range, or run range.

Ranging out a canal, denotes determining or letting out on the ground the lines which are to be occupied by its middle and fides.

RANGE, in Falconry, is when gravel is given a hawk to bring her to her roman.

RANGOON, in Geography, a sea-port town of the
Birman empire, situated on a branch of the Irrawaddy, called the Rangoon river, which forms the only communication that the Pegue river has with the sea. The town, in its present state, has been extended by increasing trade and confluence population far beyond the limits which formerly comprehended Rangoon, as it was originally founded, in 1755, by Alompra, the sovereign of the Birman empire. Rangoon, or Dangoun, which signifies victory achieved, was denominated Dagon, before Alompra took it, and laid the foundation of the present town. Here stood, in former days, a large and populous city, called in the Pali, or sacred language, Singouterra; the site of which Alompra diligently explored, and raised on its ruins the present flowerishing sea-port of the Pegue dominions. Dagon, often called Shohe-Dagon, or the golden Dagon, is a name peculiar to the temple; a noble edifice, three miles distant from the banks of the river. (See Dangoun.) Rangoon stretches along the bank of the river about a mile, and is not more than a third of a mile in breadth. The city, or mious, (mious being a term applied either to a city or a district,) is a square surrounded by a high foackle, in the manner of the country, and on the North side it is further strengthened by an indifferently well built row of houses, from which a wooden bridge is thrown; in this face there are two gates, in each of the others only one. Wooden slates are erected in several places within the foackle, for marqueeters to stand upon in case of an attack. On the South side, towards the river, which is about 20 or 30 yards from the palaifade, there are several huts, and three wharves, with cranes for landing goods. A battery, of twelve cannon, fixed and nine-pounders, raised on the bank, commands the river; but the guns and carriages are in such a wretched condition, that they could do little execution. Close to the principal wharf are two commodious wooden houses, used by the merchants as an exchange, where they usually meet in the cool of the morning and evening, to converse, and transact business. The streets of the town are narrow, and much inferior to those of Pegue, but clean and well paved; there are numerous channels to carry off the rain, over which strong planks are laid, to prevent an interruption of intercourse. The improvement of the town has been very much owing to the activity of the descendant of a Portuguese family, named Jamsee, of low origin, but advanced to length at the important office of Shabhunder, or intendent of the port, and receiver of the port-customs. Under his direction and influence, the streets were paved, several well built wooden bridges were constructed, and also a wharf, which, extending into the river, and raised on posts, enables the ships to deliver and receive cargoes without the assistance of rivercraft; under his direction also a spacious custom-house has been erected. This is the only lay building in Rangoon that is not constructed of wood, it is composed of brick and mortar, and the roof covered with tiles; within, there is a number of wooden slates for the reception of bale goods. The houses, in general, are raised on posts from the ground: the smaller supported by bamboos, the larger by strong timbers. All the officers of government, the most opulent merchants, and persons of consideration, live within the fort; shipwrights, and people of inferior rank, inhabit the suburbs; and one entire street, called Tackally, is exclusively allowed to common prostitutes, who are not permitted to dwell within the precincts of the fortification. Swine are suffered to roam about the town at large; they do not belong to any particular owners, but are regarded as servants of the public, or common scavengers; as they go under the houses and destroy the filth. The Birman are also fond of dogs, numbers of which infest the streets; the breed is small, and very noisy. The borders of the terrace on which the temple of Dagon is raised, are planted with shady trees in regular rows; and from this eminence there is a beautiful and extensive prospect; the Pegue and Rangoon rivers are seen winding through a level woody country, and the temple of Syriam, little inferior to others at Pegue and Rangoon, stands near the junction of the streams. The road leading from the city to the temple is formed with earth, a wide causeway in the centre throwing off the rain to the sides; and numberless little spates are ranged along the edge of the road, in which are niches to receive small images of their divinity Guadma. Several kiosons or monasteries lie in this direction, generally removed at a short distance from the public way, under the shade of pipal or tamarind trees. The Birmans being, like other inhabitants of the east, fond of processions, scarcely a week passes in which there is not a religious display at Rangoon; either a funeral of some person who leaves sufficient to defray the expense of a pompous public burning, or the ceremony of admitting youths into the convents of the Rhaahas, on which occasion parents and friends spare no expense in entertainments and presents to the Rhaahas. See RHAHAANS.

The population of Rangoon is considerable; there are 5000 registered taxable houses in the city and suburbs; so that if each house be supposed to contain six people, the estimate will amount to 30,000. Having long been the asylum of insolvent debtors from the different settlements of India, it is crowded with foreigners of desperate fortunes, who find from the Birman a friendly reception, and generally support themselves by carrying on a small trade. The exchange, if it may be so called, exhibits a motley assemblage of merchants, such as few towns of much greater magnitude can produce; Malabars, Moguls, Periads, Parfees, Armenians, Portuguese, French, and English. The members of this discordant multitude, engaged in various branches of commerce, are not only permitted to reside under the protection of government, but likewise enjoy the most liberal toleration in matters of religion. They celebrate their several rites and festivals, totally disregarded by the Birman, who have no inclination to make proselyte. In the same street may be heard the solemn voice of the Muezim, calling pious Muslims to early prayers, and the bell of the Portuguese chapel tinkling a fanmonous to Romish Christians. Processions meet and pass each other without giving or receiving cause of offence. The Birmans never trouble themselves about the religious opinions of any sect, nor disturb their ritual ceremonies, provided they do not break the peace, or meddle with their own divinity Guadma; but if any person commit an outrage, which the Muffulmen, in their zeal for the true faith will sometimes do, the offender is sure to be put into the flocks; and if that does not calm his turbulent enthusiasm, he is baffled into tranquillity.

The Parfees, the Armenians, and a small proportion of Muffulmen, engage the largest share of the trade of Rangoon; and individuals from their number were frequently selected by government to occupy employments of trust, that related to trade and transactions with foreigners, the duties of which the Birman conceive that such persons could perform better than themselves. These people, particularly the Armenians, naturally behold with a jealous eye any ordinance of a commercial nature, that may tend to diminish their influence, and deprive them of that dictatorial power, which they assume and exercise over all merchants and mariners that resort to Rangoon; but of none are they so apprehensive as of the English; a connection with whom might teach the Birmans to transact foreign business without their assistance, and give them a more adequate sense of their own interest.
The French have long maintained an agent at Rangoon, and are thoroughly acquainted with the advantages which the country of Pegue affords. The imports into Rangoon from the British settlements in the years 1794-5, amounted, according to Mr. Symes, to more than twelve thousands of rupees, about 135,000l., being chiefly of coarse piece goods, glass, hardware, and broad cloth, the demand for the last article being considerable; and returns were almost wholly made in timber. Teak, the most durable wood that is known, and best adapted for the construction of ships, is produced in the Birman and Pegue empire in inexhaustible abundance. The river of Rangoon is equally commodious for the construction of ships; the spring tides rise 20 feet in perpendicular height; the banks are soft, and so flat, that little labour is necessary for the formation of docks; vessels of any burden may be built. Nature, says Symes, has liberally done her part to render Rangoon the most flourishing sea-port of the eastern world. The entrance of the river, about twelve miles below Rangoon, and the banks on each side, bear a near resemblance to those of the Ganges; but the navigation is much more commodious. The channel is bold and deep, from six and a half to eight fathoms, uninterrupted by shoals or inequalities of soundings. At this place the breadth of the river is diminished to be from three quarters to one mile. On the bank of the river, opposite to Rangoon, is a considerable town, called Maindu, the residence of the governor of the province of Dalla. This government is entirely distinct from Rangoon, on the east side. The city of Dalla, from which the province takes its name, is said to be on the west side of the China Buckier river, and was formerly a place of considerable importance. The town of Maindu is composed of one long street; at the east end is a creek, which goes all the way to Bassein, and has twelve feet depth of water, at high tide; on the west side is a smaller creek, on the bank of which stands a village called Mima-Shunos, or the village of proficients, being wholly inhabited by women of that description. Rangoon lies in N. lat. 16° 47', E. long. 96° 9'. Symes's Embassy to Ava, in 3 vols. 8vo. See Burman Empire.

RANGANUA, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 16° 25'. W. long. 88° 52'.

RANHADOS, a town of Portugal, in the province of Beira; 18 miles N.W. of Caftel Rodrigo.

RANINA, Artexia et Veris, in Anatomy, the artery and vein situated on the inferior surface of the tongue. See Artexia and Vein.

RANIVALE, BLEEDING FROM. See FRANUM.

RANIVAL, VESSELS, BLEEDING FROM. See FRANUM.

RANISH, in Geography, a small island near the W. coast of Scotland. N. lat. 57° 55'. W. long. 5° 5'.

RANK, a due order, or a place allotted to a thing suitably to its nature, quality, or merit.

Kings are personages of the first rank on earth. In cavalcades, processions, &c. every person is to observe his rank.

RANK, in Military Discipline, denotes a feries, or row of soldiery, placed side by side; a number of which ranks form the depth of the squadron or battalion, as a number of files does the width.

When infantry is drawn up three deep, the first rank is called the front rank; the second, the centre rank; and the third, the rear rank.

To close the rank, is to bring the men nearer; to open it, is to let them farther apart. To double the ranks, is to throw two into the space of one, by which the files are thinned. See Doubling.

RANK, in the Army and Navy, is used for the order of precedence; which see.

In the army the officers in the life-guards are entitled to the rank of lieutenant-colonel, when they obtain or purchase a majorship, provided they are of seven years standing. Their commissions in this case run major and lieutenant-colonel. But if an officer should not have completed either of those periods, he obtains the rank of major only until its completion.

A lieutenant-colonel attains to the rank of full colonel if he has been seven years major, or twenty-one years in the British service. Cornets in the life-guards rank as sub-lieutenants in their own corps, and as first lieutenants in the army. The English fuzileers enjoy the same privilege. Sub-lieutenants in the Welsh fuzileers, rank only as second lieutenants in the army. Marines do the same.

Officers of the regular forces command the officers of equal degree belonging to the other services. Officers of the militia, fencibles, yeomanry cavalry, and volunteer corps, rank together, according to the dates of their respective commissions. These regulations are subject to some exceptions, specified in the articles of war. Officers of the militia rank generally with the regular forces as junior of their respective commissions. An ensign in the guards ranks no higher than an ensign in the regulars. The chief of the engineers ranks as colonel; director, as lieutenant-colonel; sub-director, as major; engineer in ordinary, as captain; engineer extraordinary, as captain-lieutenant; sub-engineer, as lieutenant; practitioner-engineer, as ensign.

In the navy the admiral or commander-in-chief of his majesty's fleet has the rank of a field-marshial; admirals, with the flags on the top-mast-head, rank with generals of horse and foot; vice-admirals, with lieutenant-generals; rear-admirals, as major-generals; commodores, with broad pennons, as brigadier-generals; captains of pilot-ships, after three years from the date of their first commission, as colonels; other captains, commanding pilot-ships, as lieutenant-colonels; captains, not taking pilot, as majors; and lieutenants, as captains.

RANK, Brevet, rank without pay, nominal distinction, which sometimes entitles the holder of it to command in mixed service. The brevet rank in the militia is confined to the colonels and adjutants of the several corps in that establishment. The former receive the brevet rank of colonel in the army whilst actually employed for service, and command all lieutenant-colonels in the line when they do duty together. Adjutants in the militia may have the brevet rank of captain, provided they have served five years as lieutenants in the militia, or in other forces on the British establishment. In the line, an adjutant who has the rank of captain, may command as such when there is no superior officer on the parade, or for duties. This is not the case in the militia. No adjutant, let his brevet rank of captain be ever so ancient, can command the youngest captain of a company. The same difference prevails with respect to the captain-lieutenany; which is literally brevet rank.

In the regulars, a captain-lieutenant, the inattendant he is attached to a company, takes rank according to the date of his first commission; and, as we have observed, may be major brevet; but no captain-lieutenant can ever avail himself of that seniority to the prejudice of a captain of a company in the militia; nor can an officer in the latter establishment take advantage of his standing, when he quits one regiment to serve in another, even in time of war, although he may have the requisite qualifications in both counties.

Brigade majors rank with captains, provided they have the
that rank in the army, independent of their staff appointment. But aids-de-camp do not possess any rank in that capacity with regard to the army. The latter constitute a part of the general's family, and are paid out of his allowance; they are in fact the mere carriers of his orders in the field, and his domestic inmates at home, &c. The former belong to the brigade, and are a necessary part of its effective force. It has been judicially ordained, that both the one and the other should be regular officers.

There is likewise a fort of brevet rank which exists in the several regiments belonging to the British service, and is confined to the rank and file, or corporals and private soldiers. Thus a lance-serjeant is a corporal who does the duty of serjeant without the pay or emoluments of the latter; and a lance-corporal is a private soldier who does the duty of corporal. So that lance, which comes from lance-potent, is not the invention of the German, and when put before serjeant or corporal, points out, that a private soldier has the brevet rank of one of those situations. Captains of companies appoint or reduce lance-serjeants or corporals, according to their judgment.

**Rank**, in respect of ships. See Rate.

**Rank and File**, denote men carrying the fire-lock and standing in the ranks. Thus corporals are included in the return which is made under that head.

**Rank and Files**, are the horizontal and vertical lines of soldiers, when drawn up for service.

**Rank Keel**, in Ships. See Keel.

**Rank Modus, in Law**, See Modus.

**Rank** is also a term provincially applied to signify any fort of crop of large growth, standing thick or close on the ground, as corn, peas, beans, &c. and even trees in woods. The term is often used to denote corn or grain crops, which are of such strong growths as to be laid down or lodged.

**Rankah**, in Geography, a town of Bengal; 25 miles W.N.W. of Calcutta.

**Rankness** in Cheese, in Rural Economy, a term signifying its strong pungent quality arising from the impurity of the rennet or leaf, either in consequence of neglect of the vessels holding it, the want of, or the imperfect separation of the curdy matter from the whey, by which fermentation and part-puerefaction occur and produce this taste. See Cheese and Dairying.

**Rankpole**, in Geography, a town of Hindoostan, in Guzerat; 45 miles E. of Calcutta.

**Ranni**, a town of Hindoostan, in Orissa; 30 miles S.S.W. of Balasore.

**Rannel-Bauk**, in Rural Economy, a word provincially used to signify the wooden bar or hook laid across the cottage chimney, for hanging the pot-hooks on, &c.

**Rannungan**, in Geography, a town of Bengal; 76 miles N.E. of Dacca.

**Ranno**, a town of the duchy of Wurzburg; five miles N. of Schweiningt.

**Rannutsch**, a town of Thibet; 36 miles E. of Jemlah. N. lat. 50° 42'. E. long. 82° 15'.

**Ranny**, in Rural Economy, a provincial word, applied to the small field-mouse.

**Ranny Bidaree**, in Geography, a town of Hindoostan, in the circar of Sanore; 20 miles W. of Bifnagar. N. lat. 15° 18'. E. long. 75° 37'.

**Rannycotta**, a town of Thibet; 35 miles S. of Gangotrib.

**Rannydee**, a town of Bengal; 11 miles S. of Curacoe-daag.

**Rannygong**, a town of Hindoostan, in Dowlatabad; 15 miles S.S.W. of Ameenpur.

**Rannygunge**, a town of Bengal; 35 miles N. of Dinagepur.

**Rannypookra**, a town of Bengal; 30 miles W.N.W. of Rognatpore.

**Rano**, a small island in the N. part of the gulf of Bothnia. N. lat. 65° 43'. E. long. 22° 52'.

**Ranran**, a town of Greenwich, and the capital of a province. N. lat. 12° 30'. E. long. 108° 56'.

**Ransacken**, a town of the duchy of Wurzburg; 3 miles S. of Wurzburg.

**Ransom**, a sum of money paid for the redemption of a person out of slavery, or for the liberty of a prisoner of war.

With regard to prisoners of war, it is allowed that there is no obligation of releasing those who are detained as such, till after satisfaction has been obtained. Whoever makes a just war has a right, if he thinks proper, to detain his prisoners till the end of the war; and then, in releasing them, he may justly require a ransom, either as a compensation at a peace, or, if the war continue, for diminishing his enemy's prisoners, at the same time, that he strengthen his with the return of soldiers. Prisoners of war, among European nations, are exchanged or ransomed during the war; and this is generally stipulated in a previous cartel. If sovereigns at war have agreed on a cartel for the exchange or ransoming of prisoners, they are faithfully to observe it no less than every other convention; but if, as was formerly the general practice, the state leaves to every prisoner, at least during the war, the care of redeeming himself, such particular conventions offer many questions, of which some of the principal are the following. He who has acquired a lawful right of demanding a ransom from his prisoner, may transfer his right to a third person. This was practiced in the last ages. But as the person taking a prisoner is obliged, for the sake of his reputation, to treat him with justice and humanity, he is not to transfer his right, in an unlimited manner, to one who might probably abuse it. When he has agreed with his prisoner, concerning the price of the ransom, he may transfer the right to whom he pleases. On the conclusion of an agreement made with a prisoner for the price of his ransom, it becomes a perfect contract, and cannot be rescinded, under a pretense that the prisoner is discovered to be richer than was imagined; for there is no manner of necessity that he should be rated according to the wealth of a prisoner, because that is not the scale for measuring the right of detaining a prisoner of war. But it is natural to proportion the price of the ransom to the prisoner's rank and character; the liberty of an officer of distinction being of greater consequence than that of a private man, or inferior officer. If the prisoner has not only concealed, but dig buzzing his rank, it is a forfiet fraud, and gives a right for annulling the agreement. If a prisoner, having agreed on the price of his ransom, dies before payment, it has been queried whether this price be due, and whether the heirs are obliged to discharge it? Unquestionably, says Vattel, they are obliged to it, if the prisoner died in possession of his liberty; and, from the moment of his release, in consideration of which he had promised a sum, this sum becomes due, and does not at all belong to his heirs; but if he had not
not obtained his liberty at the time of his death, it can be no debt to him, or to his heirs, unless the agreement was otherwise; and he is not reputed to have received his liberty, till he is absolutely permitted to depart free; when neither he whole prisoner he was, nor the sovereign, opposed his release and departure. If indeed he has only been permitted to take a journey for applying to his friends, or his sovereign, in order to obtain the means of ransoming himself; and he dies before he is polled of his full liberty, before his final discharge from his parole, nothing is due for his ransom. If, after agreeing on the price, he is detained in prison till the time of payment, and he dies before the debt is paid by his death, and does not affect his heirs; such an agreement on the part of him, who detains his prisoner, being no more than a promise of giving him his liberty for a certain sum paid down. A promise of buying and selling does not supposes the purchaser to pay the price of a thing, if it happen to perish before the bargain is concluded. But if the contract of sale be perfect, the purchaser shall pay the price of the thing sold, though it should happen to perish before the delivery of it, provided there was no fault or delay in the seller. For this reason, if the seller has absolutely concluded the agreement of the ransom, and from that time owns himself a debtor for the ransomed sum, remaining no longer as a prisoner, but for the security of the payment, his intervening death does not extinguish the debt: the ransom agreed on remains still due. If the agreement says, that the ransom shall be paid on a certain day, and the prisoner happens to die before that day, then the heirs are bound to deliver it; for the ransom was due, and the day was assigned, only as the term for payment. Upon the same principles, strictly speaking, it follows, that a prisoner, released by agreement of procuring the release or discharge of another, should return to prison, in case the latter happens to die before who would procure him his liberty. Such an unfortunate case, however, is entitled to regard, and equity seems to require that this prisoner should continue in the enjoyment of liberty, provided he pays a just equivalent; it being now out of his power to purchase it precisely at the price agreed on. If a prisoner fully set at liberty, after having been ransomed and paid, his ransom, happens to be taken a second time, it is evident that, without being exempt from paying his first ransom, if he is willing to be set at liberty, he must pay a second ransom. On the contrary, though the prisoner has agreed for the price of his ransom, if before the execution of the compact, before he is set at liberty in virtue of it, he be taken by his party, he owes nothing. It is here evidently supposed, that the finishing hand was not put to the compact, and that the prisoner had not acknowledged himself debtor for the rate of his ransom. He who prisoner he was, had, as of were, only made him a promise of delivering him, and he had promised to purchase; but the purchase and the debt had not actually passed into effect; the property was not actually transferred. The property belonging to a person does not pass to him who takes his prisoner, unless at the same time he seizes on such things. Of this there is no doubt, especially in our times of moderation, when prisoners of war do not fall into slavery. And even by the law of nature, the property of a slave's goods does not, without some other reason, pass to the master of a slave. There is nothing in slavery of which this can itself be the natural effect. If a man obtain a power over the liberty of another, does it follow that he has likewise a right over his property? Therefore, if an enemy has maimed his prisoner, or the latter has found means to conceal something from his search, what he has preferred should belong to him, or he may employ it towards the payment of his ransom. At present even prisoners are not always stripped. The death of a prisoner puts a period to the right of him who had taken him; therefore an hostage, given for the procuring of a person's liberty, is to be released the moment the prisoner expires; and if the hostage dies, the prisoner is not released by such death. The verdict of this is true, if one, instead of being an hostage for the other, had been substituted in his stead. Vattel's Law of Nations, b. iii. ch. 17.

Formerly it was a common practice to ransom British ships, when captured by an enemy, by delivering to the enemy what was called a ransom-bill, which decreed to the captor the price agreed upon, and operated as a bill of sale of the ship and cargo to the original owners, and as a protection to the ship against other cruisers of the enemy during the remainder of the voyage. A hostage was delivered to the captor, for securing to him the punctual payment of the ransomed sum. This ransom-bill, independent of the hostage, was considered as a contract of the law of nations, and obligatory upon the owners, as well as upon the captain and hostage who signed it; and actions have been often brought upon them in course of common law. And where the ship or goods were injured, the demand of the ransom was usually taken to be the measure of the demand of the injured upon the underwriters, in respect of the capture. But this practice of ransoming ships captured by the enemy being found to operate more to the disadvantage than for the benefit of this country, it was thought proper at length to prohibit it altogether. And therefore by Stat. 22 Geo. III. c. 25. § 1. it is enacted, that it shall not be lawful for any of his majesty's subjects to ransom, or to enter into any contract or agreement for ransoming, any ship or vessel belonging to any of his majesty's subjects, or any merchandise or goods on board the same, which shall be captured by the subjects of any state at war with his majesty, or by any person committing hostilities against his majesty's subjects. By § 2. all contracts and agreements which shall be entered into, and all bills, notes, and other securities, which shall be given by any person or persons for ransoming of any such ship or vessel, or of any merchandise or goods on board the same, shall be absolutely void in law, and of no effect whatever. And by § 3. a penalty of five thousand pounds is given to the informer, for every offence against the act. This statute has put an end to all questions on the law of ransoms. Marshall's Treatise on the Law of Insurance, vol. ii.

In our Lower Books, ransom is also used for a sum paid for the pardoning of some notorious crime.

Horn makes this difference between _ransom_ and _amerciation_, that ransom is the redemption of a corporeal punishment due to any crime.

It is never usual to affect a larger fine than a man is able to pay, without touching the implements of his livelihood, but to inflict corporeal punishment, or a limited imprisonment, instead of such fine as might amount to imprisonment for life. And this is the reason why fines in the king's court are frequently denominated _ransoms_, because the penalty must otherwise fall upon a man's person, unless it be redeemed or ransomed by a pecuniary fine (Mrr. c. 5. § 3. Lamb. Eirenaech. 57.); according to an ancient maxim, "qui non habet in crumena latr. in corpore." Yet, when any statute speaks both of fine and ransom, it is holde, that the ransom shall be treble to the fine at least. Dyer. 232.

**RANSTADT**, in Geography, a town of Germany, in the principality of Stolberg; 17 miles N.E. of Frankfort on the Maine.

**RANSTADT**, or **Mark Ranstadt**, a town of Saxony, in the
the territory of Merseburg; 10 miles S.S.E. of Merseburg. N. lat. 51° 18'. E. long. 12° 14'.

RANT, in the Drama, an extravagant flight of passion, overlooking nature and probability.

La's tragedies abound with rants; yet the wilder of them, it is observed, have frequently met with applause on the stage.

We find instances of rants, even in our severest poets. Such, e. g. is that in the beginning of Ben Johnson's

Catailine, where the parricide, in speaking to Rome, says, "I'd plow up rocks, steep as the Alps in dust; and have the Tyrrhenian waters into clouds, but I would reach thy head!"

RANTAMPUR, in Geography, a circar of Hindoostan, in the country of Angamere, bounded on the N. by Jeynagar, on the E. by Agra, on the S. by Kottah, and on the W. by Oudipour and Siroyo.—Allo, a town and fortress, being the capital of the above named circar; 86 miles E. of Angamere. N. lat. 28° 35'; E. long. 76° 58'.

RANTZAU, JOHN, in Biography, a general in the Danish service, was born in 1492, and at the age of 13 he entered into the army. In 1515 he began to travel into foreign countries, visiting in succession England, Spain, Germany, Italy, Greece, Syria, Palæstine, and other parts of the East. In 1517 he was knighted at Jerusalem; and upon his return to Denmark, was appointed to accompany Duke Christian, afterwards Christian III., on his tour to Brandenburg, and other towns of Germany. When Frederic I. accepted the crown of Denmark, he was promoted to be a general in 1553, and entrusted with the command of the troops in Holstein. He became greatly distinguished in his military character, and on various diplomatic concerns, and died in 1565. As an author he is known by the following works: "A true and brief Account of the Wars carried on in 1559, by Frederic king of Denmark, and Adolphus duke of Holstein," &c.; "Descripizio Cimbrica," printed in Welfphalen's Monumenta inedita, tom. i. Gen. Biog.

RANTZAU, in Geography, a county of Germany, in the duchy of Holstein, about ten miles long and six broad. It takes its name from a feat seven miles N. of Eutyn.

RANTZEN, a town of the duchy of Siciaria; 6 miles N.W. of Muckrau.

RANTZENBACH, a town of Austria; 6 miles S.S.W. of St. Polten.

RANVILLE, a town of France, in the department of the Calvados; 5 miles N.E. of Caen.

RANULA, dim. of rana, a frog. This term is, in Surgery, applied to a swelling of the salivary ducts under the tongue. Whether the tumour is so named from a whimsical supposition that it bears a resemblance to a frog, or from its being fancied to oblige the patient to make a croaking noize, in attempting to articulate, is a point which surgical writers leave undetermined. The swelling is round, of a greyish colour like a kydatid, soft, compreaffible, indolent, and, in the early stage, almost transparent. At first, it is of about the same size as a nut, or cherry; but, by degrees, its volume becomes much more considerable. It is very frequently met with in young children; its occurrence in adults is more uncommon. It consists of a succifive dilatation of the excretory tube of the submaxillary, or else of the sublingual gland, the orifice of which duct is by some cause or another flapped up, or obliterated; so that the confined saliva accumulates, becomes viscid, and ceases to flow in the usual manner. In proportion as the ranula increases, the incipient flat of it having been neglected, its enlarged size raises up the tongue, and forces it backward; and the consequence of which is, that mastication, deglutition, and respiration, are obstructed. The voice becomes indistinct, and hoarse; the motion of the tongue is restrained; this organ cannot be put out of the mouth. By degrees, the incisor and canine teeth of the lower jaw are loosened; the layer of muscles, composing the lower pairites of the mouth, is depressed; and the swelling, having attained a considerable size, makes a very manifest prominence beneath the chin. In this advanced stage, that is to say, when the ranula has existed ten or twelve years, as practitioners occasionally see instances of, the appearance of the swelling is quite altered from what it originally was. The tumour is now hard, elastic, painful, ulcerated, and, as it were, farcomatous: it is as large as a turkey's egg, and not situated at the side of the frenum, but anteriorly under the tongue, to which it is closely adherent. The mouth emits a very fetid smell; and the breathing is so much obstructed, that the patient, through fear of suffocating, is obliged to lie with his mouth wide open, when he goes to sleep.

While a ranula is recent, the fluid which it contains is a viscid saliva, resembling the white of egg, and sometimes of rather a yellow colour. In time it is gradually changed, becoming turbid and puriform; and, in certain instances, soft, friable, greyish concrections, from the size of a pea to that of an almond, commonly called salivary calculi, are found in the kind of cyst, which is produced by the dilatation of the salivary duct. These calculi essentially consist of a large proportion of the phosphate of lime, united with a mucilaginous substance; and concretions of the same kind frequently occur in the tonsils, and in the salivary glands themselves, as well as their excretory ducts. Forellus, lib. xiv. cbb. 26. p. 112. Blegney, Nouvelles Découvertes, &c. tome i. ann. 1679, p. 230. Mém. de l'Acad. de Chirurgie, tom. v. p. 464. Petit, OEuvres Pothumiennes, &c. tome i. p. 188. Blaïeis, Obf. 14. p. 81.

A ranula, whether recent or inveterate, cannot be cured except by a surgical operation. The curative indication, in the first of these states, is to make an outlet for the fluid accumulated in the tumour, and to make an opening sufficiently capacious to let the saliva readily pass into the mouth. Merely making an incision into the swelling, or opening it with a trocar, or a poniion drawn through it, are flated to be ineffectual methods. The tumour does indeed subside as soon as the aperture is made; but the edges of the wound grow together again, and the disease recurs. There is an absolute necessity for first making an incision the whole length of the swelling, and then removing, with the aid of forceps and a pair of dissecting forceps, a portion of the edges of the recent wound. This flight leaves of substance prevents the return of the complaint, and always injures a free passage for the saliva; an advantage of which there is no certainty in any other mode of proceeding. By this flight operation, ranula in children may be cured in the course of a few days, without the least occasion for the application of any dressings whatsoever. It has been proposed to dilate the contracted orifice of the salivary duct with a probe. (Mém. de l'Acad. de Chirurgie, tom. iii. p. 460.) But this orifice is difficult of detection, and the swelling cannot be in this manner easily emptied. M. Laffos seems to entreat doubts whether Warton's canal can ever be made to resume its original flat, after once being closed. Pathologie Chirurgie, tom. i. p. 405.

When a ranula has existed a long while, is attended with considerables hardnefs, and is of large size, it is a tumour which requires to be completely extirpated. A transverse incision, parallel to the opening of the mouth, is to be made in it through its whole extent. The surgeon is then to cut out...
out the upper portion of the swelling, situated in front of the
mouth of the tongue, to which it is also adherent, and
next the inferior portion, which sometimes extends into the
interface between the genio-hyoidei and genio-glophi muscles,
with which it becomes confounded. A pair of forceps, a
hook, scissors, and a straight bistoury, are the instruments
necessary for this operation. A degree of hemorrhage al-
ways ensues. The use of a detergent gargle, made of
barley-water and honey of roses, will serve to finish the cure
in a very moderate space of time.

In confirmation of the latter observation, Lallius ad faced
the following case. A young man, aged 22, had a ranula,
which had continued ever since he was born, and was equal
in size to a turkey's egg. The incisor teeth of the lower
jaw were loosened, and forced forward by the sucesfive
increase of the swelling. A fenton had been passed quite
through it, without any useful effect. The breath of the
patient and his saliva were intolerably fetid. The tumour
was closely adherent to the lower and anterior part of the
tongue; and extending laterally, confused itself with this
organ, of which it impeded the motion. A straight, nar-
row bistoury was introduced into one of the openings at the
side of the tumour, and carried completely across to the op-
posite aperture. Thus a transverse incision was made into
the cavity of the diseaee. By means of the same instrument
and a hook, the lateral portions of the swelling were re-
moved. A profuse hemorrhage ensued, caused by the total
division of the frenum, the raninal veins, and one of the
cancial arteries. It was flapped by putting under the
tongue a large quantity of dry lint, and by compressing the
dorsum of the tongue several hours with the fingers, while
the thumb was employed in compressing the parts behind the
chin from below upwards. This double fort of preasure
answered the purpose. No cautery was found necessary,
and, by the use of detergent gargles, the patient was cured
in about a fortnight.

When a ranula of long duration, situated at the side of the
tongue, and of considerable size, forms a tumour, that
makes its appearance outwardly towards the base of the
jaw, Lallius seems to disapprove of making a free incision
through the skin, for the purpose of extirpating that part
of the swelling which cannot be removed through the mouth;
a plan which was, in one instance, practised by Marchetti. Obf. Med. Chirurg. obf. 31. p. 48. See Lallius' Pathologic Chirurgicam, tom. 1. chap. 61.

RANULARES, in Anatomy. See RANNA.

RANUNCULACEAE, in Botany, the 61th natural order in Jullieu's Sytem, or the first of his 13th clas, for
whose character see GEANIA. The Ranunculaceae are
defined as follows.

Calyx of many leaves, sometimes wanting. Petals definite,
mohly five. Stamens indefinite, except in Myosurus; their
anthers incorporated with the filaments. Gerns several,
indfinite or definite, rarely solitary, placed on a common
receptacle; each of them furnished with a style, which is
rarely wanting, and a simple stigma. Capsules, or rarely
berries, as many as the gerns; in some infames singly
feeded, and not burrfting; in others many-fed, splitting
half way down, at their inner margin, into two valves,
bearing the seeds at the edges. Corculum minute, lodged in a
cavity at the upper part of the large horny albumen. Stem
generally herbaceous. Leaves alternate; rarely (in Cle-
mais and Atragene) opposite; some of them half sheathing
the stem; some compound, pinnate or fingered; some, as
is more frequently the case, simple, and these are mostly
palmate or lobed, their sinuses often pale at the base. See
RANUNCULUS.

Vol. XXIX.

Jullieu divides the order in question into four sections.
Seft. 1. Capsules single-feeded, not burrfting; branes in
Hydrophilas.
This section consists of Clermanis, Atragene, Thalictrum,
Hydrophilas, Anemonis, Hemerodyas of Commeron, Adonis,
Ranunculua, Ficaria, and Myosurus.
Seft. 2. Capsules many-fed, splitting at the inner edge.
Petals irregular.
The calyx in this section is often coloured, being what
Linnaeus terms corolla; that author considering the petals
of Jullieu asnectaries. The genera are Trollius, Helleborus,
Scoparia, Nigella, Gerardia, Aquilegia, Delphinium, and
Acouium. Some species of Delphinium have but a single
capsule.
Seft. 3. Capsules many-fed, splitting at the outer edge.
Petals regular.
Calla, Paeonia, Zanthorrhiza, Cimicifuga.
Seft. 4. German solitary. Berry of one cell, with many
seeds, affixed to a single lateral receptacle.
The only genera are Alcea and Podophyllum, and these
we feel disposed to remove to Jullieu's next order, Pap-
VERACEAE. See that article.

We cannot but remark that the petals, as Jullieu terms
them, in Trollius and Helleborus are by no means definite,
and that they greatly exceed the number five. Neither
are they irregular in Trollius. As to the other genera of
his 2d section, the parts in question are such obvious
nectaries, that they can have no other function to perform,
except possibly in Aquilegia, where their limb partsakes of
the nature of petals.

RANUNCULOIDES, a genus of Vaillant's, founded
on the Ranunculus heteraceus and aquatilis of Linnaeus,
and named from its refameblance or affinity to RANUNCULUS;
see that article. No one has followed Vaillant in this
inference, nor is there any real mark of distinction for his
supposed genus. Ranunculoides is, besides, the specific name
of a rare British Anemone, but ranunculina would have been
better Latin; as in Helleborus ranunculina, Sm. Pl. ic.
fac. 2. t. 37. Wild. Sp. Pl. v. 2. 1356. See Hel-
LEBORUS.

RANUNCULUS, an ancient name, whose origin is as
obvious as its sense is obscure. The word is, no doubt,
derived from ran, and means a little frog. The Greeks
call the same plant Bexexi, which is nearly fynomimous.
Most etymologists suppose this name to allude to the native
itation of the plant, in bogs and watery places, such as
frogs frequent. But the original Bexexi of Dioecides is the
beautiful Ranunculus afictus of Linnaeus, or Garden
Ranunculus, which inhabits corn-fields, and does not grow
in wet places; though indeed the other three species, de-
scribed by that ancient writer, do; there are our langinosus,
murcacina, and aquatilis. It seems probable that the divisions
of the leaves in all these plants may have suggetted the idea of
a frog's foot, which suaption is confirmed by the
Englih name, Crowfoot. Ambrofius hints at a renfem-
bance between the root and the foot of a frog, which is
not, to us, by any means apparent.—Linn. Gen. 281.

Gen. Ch. Cal. Perianth of five ovate, concave, fome-

3 G
what coloured, deciduous leaves. *Cor.* Petals five, obtuse, polished; with small claws. Nectary a cavity in each petal, just above the claw. *Stam.* Filaments very numerous, half the length of the corolla; anthers firmly united throughout, erect, oblong, obtuse, of two separate lobes. *Pyl.* Germens numerous, collected into a head; styles none, stigmas reflexed, very small. *Peric.* none. *Receptacle* becket with extremely minute flasks, to which the seeds are attached. *Seeds* numerous, naked, irregular, uncertain in figure, with a reflected point.

Obf. The essential mark of this genus consists, as Linnaeus remarks, in the nectary, the least of the parts being uncertain; hence he takes occasion to point out the use of advertising to that organ, which before his time had been neglected, and which his opponents accuse him of sometimes making of too much importance. The great Jussieu will not, in this obvious case, use the language, though he adopts, unacknowledged, the idea of Linnaeus; nor will he allow the manifest nectaries of some of his *Ranunculaceæ* (see that article) to be other than petals. "Such," to use his own words, in his preface, p. 26, "is the love of undivided praise!"

The nectary in *Ranunculus* says Linnaeus, is, in some species, a naked pore; in some it is bordered with a cylindrical margin; in others closed with a notched scale. *Excaria* of authors has only a three-leaved calyx, with a superabundance of petals. The seeds in some species are roundish; in others depressed, prickly, and fewer in number. *R. hederaceus* has but five flaments; *falcatus* has a sword-shaped point to each seed, and appendages to the base of the calyx; *coronatus*, and a few besides, have an awl-shaped receptacle, and consequently a spiked fruit.

Eff. Ch. Calyx of five leaves. Petals from five to eight, with a honey-bearing pore in the claw of each. Seeds naked.

This extensive genus is divided into two sections, by the form of the leaves. The species are all herbaceous, generally of an acrid quality. The prevailing colour of the flowers is yellow; we know of none that are blue, except by accidental variation in *R. arcticus*. They are plants of temperate or cold climates; some of them alpine. Linnaeus, in Sp. Pl. ed. 2, enumerates twenty-eight species; the 14th edition of Sylv. Veg. has forty-four, and Willdenow reckons up sixty-one. Fifteen are natives of Britain, as mentioned in Fl. Brit.; but the 11th species in that work, *parvulus* of Linnaeus, must be expunged, as a mere variety of *hirfatus*, n. 8. The original number is, however, made up, by a newly discovered Scottish species, the *alpestris*, figured in Eng. Bot. v. 34. t. 2390.

So many additions have been made to this genus by the labours of Poiret in Lamark's Dict. v. 6, and the discoveries of Michaux and Pursh, that, with some necessary corrections, and a few communications of our own, the whole subject requires to be detailed.

Seéct. 1. *Leaves simple and undivided.*

1. *R. Flammula.* Leffer Spear-wort. Linn. Sp. Pl. 772. Wildl. n. 1. Ait. n. 1. Fl. Brit. n. 1. Eng. Bot. t. 387. Curt. Lond. f. 6. t. 37. (R. flammeeus minor; Ger. Em. 961., and R. flammeeus ferratus; ibid. 962.)—Leaves ovato-lanceolate, bluntish, stalked. Stem declining. —Native of watery places throughout Europe, flowering most part of the summer. Root perennial, of long sinue fibre. *Herb* hissing, not quite smooth, very various in size and luxuriance. Stems spreading in every direction, round, leafy, hollow. *Leaves* many-ribbed, either entire or variously ferrated. *Flowers* numerous, solitary, on long stalks, of a bright golden yellow, half an inch or more in diameter. The whole plant is of an excessively acrid burning quality, said to produce inflammation in the viscera of sheep, whence the name *flammula*, a little flame. Dr. Withering recommends the distilled water, as preferable to all other medicines, for procuring instantaneous vomiting in cases of poison.

2. *R. reptans.* Creeping Spear-wort. Linn. Sp. Pl. 773. Leff. ed. 2. 198. t. 3. f. 5. Light. 289; fig. in frontispiece to v. 1. Fl. Dan. t. 188.—Leaves linear-lanceolate. Stem creeping. —About the margins of alpine lakes, on a sandy soil; common in Scotland, flowering in June and July. We have always thought this a variety of the former, as mentioned in Fl. Brit.; but Willdenow contends for the contrary. He truly affirms that it differs in having a thread-shaped creeping stem; linear entire leaves, tapering down into their footstalks; flower-footstalk solitary, erect, single-flowered; and much smaller flowers. Nevertheless, we have seen no intermediate varieties, and such a disposition in weak plants of the *Flammula* to take root at their joints, that we most incline to our original opinion, suggested first by Linnaeus himself in his Sp. Pl.

5. *R. filiformis.* Slender Creeping Crowfoot. Michaux Boreal.-Amer. v. 1. 320. Pursh n. 4. Lamarck Dict. n. 4.—"Stem thread-shaped, creeping, jointed, almost naked. Leaves linear-awl-shaped, obtuse. Flowers axillary, solitary, stalked."—In inundated places, on the banks of the river St. Lawrence; at Hudson's bay and Labrador; flowering in June and July. This is described as a very small, slender, smooth species, very much resembling *R. reptans*, n. 2. We have been few specimen.

7. *R.*
10. *R. ophionifolius*. Serpent's-tongue Crowfoot. Willd. n. 8. (R. ophionifolius; Villars Dauph. v. 3: 731. t. 49.)—Stem simple, erect, leafy. Lower leaves ovate, or heart-shaped, many-ribbed, on long flarks; upper linear-lanceolate, sessile.—Found between Toulou and Hyeres in Provence, by M. Villars, who mentions having seen a drawing of the same plant in the royal collection at Paris, marked R. lefibus paludris, ophiofoli folio; Tourn. Cor. 20. The root is described by Villars as somewhat bulbous, or tiberos, with many whorls of fibres. *Stem erect, a foot high.* Leaves smooth, rather fleshy. Flowers small, yellow, with fusing petals. Seeds in a small round head. He conceives it somewhat allied to *R. Flammula. The resemblance of the leaves, in his plate, to paranaffius, seems to have induced Willdenow to range it here. We have seen no specimen.

11. *R. amplexicaulis*. Plantain-leaved Crowfoot. Linn. Sp. Pl. 774. Willd. n. 9. Ait. n. 7. Curt. Mag. t. 266. (R. folio plantaginis; Ger. Em. 563.)—Leaves ovate, pointed, glaucous, clasping the many-flowered stem. Root falcate.—Native of the Alpennine and Pyrenaeen mountains, but not, as far as we know, of the Swiss Alps, Haller having mitaken his n. 1179, which is paranaffius, for this species. It is a hardy perennial in our gardens, not difficult of culture, yet not common, flowering in May. The herbage is glaucous. *Stem erect, leafy, twelve or fifteen inches high, branched above. Leaves generally more or less fringed with soft hairs. Calyx green, smooth, concave, partly membranous and white at the edge. Petals of a pure and brilliant white. Anthus yellow, as in other species. We have never seen the ripe seeds.*

12. *R. heterophyllus*. Various-leaved Slender Crowfoot. (R. bonaricen; Lamarec Dic. n. 9.)—Leaves flaked, toothed, heart-shaped or ovato-lanceolate, with three central ribs. *Stem erect.* Flowers flaked, solitary, opposite to the leaves. Seeds obtuse, granulated.—Gathered by Commeron at Bueos Ayres, in marshy places. *Root fibrous.* Stem erect, a foot or more in height, slender, smooth, striated, branched, leafy. Leaves alternate, on long flarks; the lower ones ovate, or heart-shaped; the upper lanceolate, or ovate; all obtuse, more or less crenate or toothed, about an inch long, smooth, furnished with three central ribs, and several lateral branching veins. Footstalks bordered at their base; the lowermost much the longest. Flowers very small, whitish, on solitary, straight, simple, lateral flarks, an inch or an inch and half long, opposite to the leaves. *Fruit ovate.* Seeds obtuse, or obovate, rough with minute points. The calyx is smooth and reflexed, often remaining till the seeds are ripe.

13. *R. flageliformis*. Long-flaked Crowfoot.—Leaves on long flarks, heart or kidney-shaped, wavy or crenate. Stem creeping, thread-shaped. Flowers flaked, solitary, opposite to the leaves. Petals ovate. Seeds obtuse, dotted.—Native of Chili and New Granada. We have specimens from Mutis and Cavanilles, but this species does not seem to be any where described. The flanks are long, thread-shaped, much branched, proliferating, creeping or perhaps floating, fusing out from each joint long fibrous radicles, and one or more smooth, roundish, heart-shaped or kidney-shaped leaves, hardly an inch wide; their footflasks measuring from two to three inches. Flowers very small, white, solitary, opposite to the leaves, on slender flarks, rather shorter than those of the foliage. Stamens few. *Fruit rather oblong.* Seeds obovate, obtuse, compressed, minutely dotted. This *Ranunculus* is perhaps most nearly akin to our British *belleranus*, hereafter described, though very certainly distinct, and as the species are at present arranged, they must remain
RANUNCULUS.

at a distance. In habit and general resemblance they closely accord.

15. *R. falvifugius.* Salt-marsh Crowfoot. "Pallas's Travels, small edition, v. 3. 173." Willd. n. 11. (R. ruthenicus; Jacq. Hort. Vind. v. 3. 19. t. 31. R. repens, flore in caule angulatis, foliis variis fœcitis; Amm. Ruth. 81. t. 13. f. 2.)—Leaves ovate, somewhat heart-shaped; toothed at the extremity. Stem creeping, thread-shaped. Flower-flanks solitary, mostly single-flowered. Petals obovate. Fruit nearly globose.—Found by GMelin, on the banks of the Neva; *Amnann*; by Pallas in the salt plains of Siberia, beyond the lake Baiscal. The flowers are yellow, as big as our common Crowfoots, being more than ten times the size of the leaf. Their petals are about ten, obovate. The root sends out long runners, like a garden strawberry. GMelin's specimen is much smaller than Jaccquin's figure.

16. *R. bulbost.* Portugal Crowfoot. Linn. Sp. PL 774. Willd. n. 10. Ait. n. 8. (R. ruthenica; Dod. Pemp. 249. R. autumnalis Clulî; Ger. Em. 953. R. linutancia Clulî; ib. 955.)—Leaves ovate, serrated. Flower-flanks radical, single-flowered, hairy.—Native of Portugal and the north of Africa, cultivated in England before 1649, but now scarcely seen. It flowers in May and June, and has a perennial fibrous root, more like Gerarde's fig. 10 than 11. *Leaves* all radical, flattened, ovate, ribbed and veiny, somewhat hairy, strongly and unequally serrated, an inch or an inch and half long; sometimes, according to Clulî, bifurcated. *Flowers* yellow, on simple, hairy, upright, radical flanks, three or four inches long. *Petals* more than five, narrow-obovate. The old authors delineate two kinds, generally supposed to be varieties, but which may possibly be species. We have not seen either, except in a dried state.

17. *R. Ficaria.* Pilewort, or Lesser Celandine. Linn. Sp. PL 774. Willd. n. 12. Ait. n. 9. Pl. Brit. n. 4. Engl. Bot. t. 584. Curt. Lond. f Ac. 2. t. 39. Mart. Rul. t. 21. Bullard t. 43. (Cheolodium minus; Matth. Valgr. v. t. 578. Fuch. Hift. 837. Ger. Em. 816.)—Leaves heart-shaped, angular, smooth, flattened. Petals numerous.—Native of waste ground throughout Europe, in moist, shady, or bubbly places, flowering in the early spring. Dr. Sibthorp found it common in Greece; and there can be no doubt of its being, as all botanists have judged, *xiphium* in many, the Lesser Celandine, of Dioscorides. *Root* perennial, fibrous, with many fleshy, pear-shaped, annual knobs, whose appearance gave rise to the Latin, as well as English, name of this species, and to an idea that the plant might be servicable in the piles, with those who believe, may confult Gerarde for the mode of application. The *flèmes* are pellucid, and mostly single-flowered. *Flowers* yellow, or white; *flèmes* flattened; with three, sometimes five, leaves to the *calyx*; and eight, occasionally ten, elliptic-oblong, highly polished *petals*, which fade to white in bright sunshine.

18. *R. frigidus.* Alpine Siberian Crowfoot. Willd. n. 13.—Radical leaves wedge-shaped, ovate, five-toothed at the extremity; thence of the *calyx* sessile, palmate.—Native of the Alps of Siberia. Willdenow says he received this by the name of *gracilis*, meaning *glacialis*, with which it agrees in the size, and perhaps colour, of the *flowers*, but abundantly distinct in the *leaves*.

Several Siberian named specimens, in the Linnean herbarium, answer exactly to Willdenow's description. The radical leaves are several, flattened, between half an inch and an inch in length, smooth; rounded and entire at the base; abrupt and variably cut into broad blunt teeth, we might almost say lobes, at the summit. *Stems* erect, usually single-flowered, with two or three, alternate, sessile, more deeply lobed, or palmate, *leaves*. *Calix* brown, hairy. *Petals* five, inerzely heart-shaped, apparently white. The *flower* is like *glacialis*, that we cannot but suspect the difference of the *leaves*, however great, to be but casual. At any rate, they are sometimes so deeply cut, that this species might perhaps, without violence, have been placed in the following section, next to *glacialis*.

19. *R. Thora.* Kidney-leaved Crowfoot. Poison-root of the Swiss. Linn. Sp. Pl. 775. Willd. n. 14. Ait. n. 10. Jacq. Altr. t. 442. Obs. f Ac. 2. t. 25. t. 13. (Thorà major et minor; Camer. Epit. 825, 826. Th. valdenis, et montis Baldis; Ger. Em. 960. Pseudo aequorium pardalianches; Matth. Valgr. v. 2. 430.)—Leaves kidney-shaped, abrupt, crenate, reticulated; the radical ones on long flanks. Stems with one or two flowers. Bracteae lanceolate.—Native of the Alps of Switzerland, Austria, and Greece, as well as of mount Baldus, near Verona, flowering rather early in summer. It is said to have been formerly in the English gardens, but has never fallen under our observation. *Root* perennial, of thick, tapering, fleshy fibres or rather knobs. *Stem* solitary, smooth, fimple, near a span high; terminating in one, rarely more, long-flaked golden *flowers*, about half an inch wide; its *calyx-leaves* lanceolate, colored, smooth, like every other part of the plant. *Leaves* about two inches wide, and one long, rather concave, strongly reticulated with veins, nearly crenate, terminating either abruptly, with a notch, or elongated into three acute, entire, triangular, central lobes; the uppermost, or floral, ones, lanceolate and entire; the radical ones only on longer flanks. *Fruit* globular, of a few, large, tumid, ovate *seeds*, with hooked points. The *root* of this plant is reported to be extremely acid and poisonous, its juice having been used formerly, by the Swiss hunters of wild goats, to envenom their darts, whose wound by that means becomes speedily fatal and incurable. Hence the name, from *gräs*, corruption, or venom. We can see no possible reason for distinguish the greater and smaller kinds, even as permanent, or well-marked, varieties.

Section 2. *Leaves* diffused and divided.

20. *R. creticus.* Cretean Crowfoot. Linn. Sp. Pl. 775. Willd. n. 15. Ait. n. 11. (R. creticus latifolius; Clulî. Hift. v. 1. 259. Ger. Em. 963.)— *R. macrophyllus*; Desfont. Atlant. v. 1. 437. Lamarec Dièd. n. 39. Radial leaves kidney-shaped, crenate, somewhat lobed; *flèmes* in three deep, lanceolate, entire segments. *Stem* many-flowered.—Native of Crete; cultivated in the Oxford garden in 1658, but perhaps now lost. The *root* is perennial, of many thick, tapering, fleshy fibres. *Stems* thick, moderately branched, eighteen inches, or more, in height, hairy as well as the rest of the herbage. *Radial leaves* from two to four inches long, and more in breadth, kidney-shaped, reticulated with fleshy veins, light green, downy, unequally divided into about seven three-leafed, or coarsely notched, shallow lobes; *flèmes* alternate, in three deep, oblong, obtuse, entire lobes; the base tapering or wedge-shaped. *Flowers* several, yellow, nearly as large as *R. Linnaea*, n. 3. *Calyx* reflexed, ovate, loosely hairy. 2 appears, by the account of M. Desfontaines, to differ merely in having the lower
lower leaves more deeply lobed than usual, and somewhat less hairy.

21. R. cassubicus. Casubian Crowfoot. Linn. Sp. Pl. 775. Willd. n. 16. Ait. n. 12. (R. aconitifolius, folio rotondo, ad radicum praefolante; Lecf. Prull. 225. t. 72.) —Radical leaves roundish-heart-shaped, crenate, undivided; stem-leaves in several deep, lanceolate, toothed and jargar segments. Stem many-flowered.—Native of Prussia and Siberia, flowering in May. Meliss. Loddiges are said to have introduced it into England, in 1794. Though the character of this approaches the last, the two plants are very different. The radical leaves of the present, though heart-shaped, are almost orbicular, their two lobes meeting each other; their margin sharply crenate, but not at all divided; their surface minutely downy. Stem much branched; smooth below; downy above; bearing several fingered, venous, smooth, fiddle leaves; the lower ones larger, many-lobed, and jagged; the upper with only three lanceolate, entire leaves. Flowers rather small, deep yellow. Calyx hairy towards the base. Fruit ovate. Seed hairy, roundish, slightly compressed, each with a strongly revolute beak.

22. R. auricomus. Wood Crowfoot, or Goldlocks. Linn. Sp. Pl. 775. Willd. n. 17. Ait. n. 13. Pursh n. 9. Fl. Brit. n. 5. Engl. Bot. t. 624. Curt. Lond. falc. 2. t. 41. Fl. Dan. t. 605. Ger. Em. 954. (R. internum species sylyctris; Buchf. Hift. 156. Dalech. Hift. v. t. 1092.)—Radical leaves kidney-shaped, deeply three-crenate, crenate; stem-leaves divided to the base into linear segments. Stem many-flowered. Calyx coloured.—Native of woods and shady places, throughout Europe; also in Pennsylvania; flowering in April and May. Root fibrous, perennial. Herb of a pale pleasant green, and distinct of the acrimony usual in this genus. Stems a foot high, erect, branched, scarcely downy, except near the top. Leaves generally a little downy; the radical ones on long stalks, deeply divided into three or five, wedge-shaped, crenate, or cut lobes; the reft in many linear, entire, or partially cut, spreading divisions. Flowers terminal, erect, solitary at the top of each branch, of a bright golden hue. Calyx pale yellow, hairy, fearce at all reflexed. Notary a naked pore in each petal, not closed by any scale. In cold backward seafons the petals are sometimes wanting, or rather identified with the calyx, which is then dilated, and more coloured than usual.

23. R. abortivus. Small-flowered Virginian Crowfoot. Linn. Sp. Pl. 776. Willd. n. 18. Ait. n. 14. Pursh n. 6.—Radical leaves heart-shaped, undivided, crenate; lower stem-leaves pedate; upper in three deep linear segments. Calyx reflexed, coloured. Petals bisce. In wet places, by the sides of ponds and ditches, from New York to Carolina, flowering in July and August. Pursh. In ponds at Buenos Ayres, Commerfon. This species appears to have been cultivated in Chelsea garden 100 years ago, but it has, long since, disappeared, nor has any author given a figure of the plant. Its habit is more like feleratus, n. 26. Root perennial, of many long fibres. Herb smooth. Stem from six to eighteen inches high, branched, leafy. Radical leaves like those of a violet, not an inch long, crenate, smooth; their stalks two inches, or more, in length: lower stem-leaves ternate, their lateral leaflets deeply divided, all cut or crenate; uppermost leaves nearly fiddle, in three deep, lanceolate, entire divisions. Flowers small; yellow according to Pursh, but Commerfon, in his MSS. calls them flesh-coloured; each stands on a simple solitary stalk, half an inch or an inch long, either from the forks of the branches, or at their summits. The calyx is reflexed, large, membranous and coloured. We find scarcely any certain traces of petals, but the plant may be variable in those parts, like au- ricosus. Stems few. Germs large, globose.—Linnceus took his specific character, caule fibrentis, from specimens not fully grown; yet he had an authentic one by him, with above thirty flowers. In Commerfon the upper leaves are more falked than usual.

25. R. trilobus. Three-lobed Barbary Crowfoot. Del. font. Atlant. v. t. 237. t. 113. Willd. n. 19.—Stem erect, much branched. Leaves smooth, deeply three-lobed, cut; uppermost linear, obtuse, undivided. Flower-stalks filiform. Seeds compressed, tuberculate.—Gathered by Desfontaines, in moist fields, near Mayane, in Barbary. He describes it as akin to R. parviflorus, except in its upright growth, and smooth, deeply three-lobed leaves. The lowest leaf of all is undivided and crenate. Flowers very small, yellow, situated as in the two last. Seeds in a round head, small, compressed, orbicular with a point, covered with tubercles on both sides. To us this species seems, by its seeds, allied to parvifolius of Linnæus, which is a variety of bifolius, hereafter described.

27. R. aconiifolius. Aconite-leaved White Crowfoot. Linn. Sp. Pl. 776. Willd. n. 21. Ait. n. 16. Curt. Mag. t. 204. (R. montanus quadrotus; alias R. pleno flore albo; Clus. Hift. v. t. 236. R. aconi folio; Ger. Em. 954. R. albus multiformus; ib. 957. R. albus, flore denfo; Bum. Hift. v. 3. 844. not 865.)—Leaves veiny, smooth, in five deep, pointed, toothed lobes; the middle one three-creflet: floral leaves fiddle, fingered, lanceolate, cut. Stem branched, many-falked.—Native of the alps of Switzerland, France, Austria, &c; a hardy and long-ecflablitied perennial in our gardens, flowering in May and June; generally in a double fiate, as figured by Curtis. He remarks that it requires moisture, shade, and a pure air. The stem is one and a half or two feet high, partly purplish, smooth, with spreading branches. Leaves dark green, with a gla- cious hue beneath; the radical ones on long stalks; the reft nearly fiddle; all composed of more or less distinctly separate, often falked, leaflets, strongly veined and coarsely toothed; the uppermost smaller, more fimple, quite fellite. Flowers
**RANUNCULUS.**

Flowers white, three-quarters of an inch in diameter, not very ornamental in their single wild state, but much admired when double, and formerly called Fair Maids of France. Their pearly whiteness is enhanced by the violet calyx.

28. *R. platanifolius.* Plane-tree-leaved White Crowfoot. Linn. Mutt. 79. Willd. n. 22. Ait. n. 17. Fl. Dan. t. 111. (R. albus, flore simplici; Ldb. t. 1. 658. R. alpinus albus; Ger. Em. 951.) —Leaves veiny, smooth, deeply palmate, five-lobed, cut and toothed; the middle ones three-cleft; floral leaves feifile, tongue-like, linear-awl-shaped, entire. Stem branched, many flowered. —Native of the Alps of Germany, Norway, Switzerland, Italy, and of the Pyrenees, in shady places. Said to have been introduced into the English gardens in 1765, by Meffrs. Kennedy and Lee. This is very different from the last, with which Linnaeus originally confounded it. The leaves are larger, not divided quite to the base, though their lobes are more cut and jagged; the floral ones are remarkably long, slender, and entire. Flowers twice as large, and rather more abundant. The radical leaves of both have occasionally seven or nine lobes, instead of five.

29. *R. ficaria.* Spicke-fruited Crowfoot. Desfont. Atlant. v. 1. 438. t. 115. Willd. n. 23. —Leaves radical, five-lobed, toothed. Stem nearly simple, hairy, Fruit cylin- drical, thrice as long as the calyx. —Gathered by Desfontaines in marshes at Algiers. Root perennial; of numerous, oblong, feby, tapering knobs. Stem solidary, erect, a span high, hairy, simple, except at the top, where it divides into two or three simple, single-flowered stalks; sometimes accompanied by a few bracteas, in three or four deep linear segments; sometimes naked. Leaves all radical, on hairy stalks, heart-shaped, rounded, five-lobed, strongly toothed, villous, about an inch and a half broad. Calyx of five ovate-oblong, coloured, hairy, spreading leaves. Petals five, obovate, yellow, the size of *R. acris.* Fruit cylindrical, slender, an inch and a half or two inches long. Seeds very numerous, ovate, compressed, bordered each with a hooked, prominent beak.

30. *R. palustris.* Marsh Crowfoot. Poiret Voy. en Barb. v. 2. 184. Lamarck n. 22. Desfont. Atlant. v. 1. 439. —"Downy. Lower leaves in three deep, many-cleft, fan-shaped segments; upper simple, linear, entire. Stem branched, many-flowered. Calyx erect." —Gathered by Poiret, in the borders of extensive marshes, near la Calle, and in some other parts of Barbary. Root fibrous, densely fasciculated. Herb downy, with short, clove-prefed hairs. Stems several, eight or ten inches high, with spreading leafy branches, bearing abundance of widely-spread, deep-yellow flowers, the size of the foregoing, on slender stalks of various lengths. Radical leaves stalked; the earli-est ones ovate, undivided, deeply toothed; the rest almost pinnate, with three long, narrow, deeply cut, fan-shaped segments; those on the lower part of the stem leaf compound: the uppermost linear, undivided, acute, entire. Fruit oval, or almost elliptical, obtuse. Seeds oblong, smooth, compressed, scarcely pointed.

31. *R. illyricus.* Ilyrian Silky Crowfoot. Linn. Sp. Pl. 776. Wild. n. 24. Ait. n. 18. Jacq. Ant. t. 222. Ger. Dod. Pemp. 428. Em. 953. (R. grumosae radice quadrata; Chuf. Hift. v. 1. 240.) —Leaves fragrant with silky hairs, linear-lanceolate, serrate, entire. Calyx silky, reflexed. Stem branched. Flower-stalks woolly. —Native of Hungary, France, Italy, Austria, Thrace, and of the Swedish isle of Oeland; cultivated here in Gerarde's time. Clusius received his specimen, from a physician of Ferrara, with the name of *R. illyricus,* which has been retained, ab- surdly enough, for a plant found in so many different countries, and for which so many expressive apppellations might easily have been contrived. The root is perennial, composed of numerous, small, round granulations. Whole herb more or less clothed with fine-white, silky, or partly cottony, down. Stem a foot high, or more, somewhat branched, bearing several bright lemon-coloured flowers, nearly the size of *R. lithosperma,* their calyx-leaves ovate, reflexed, externally silky. Leaves all linear-lanceolate, entire, seldom divided; the radical ones on long stalks, terete or pinnate; those almost in the middle of the stem terete, almost flesille; upper ones simple; the usual length of each leaf or leaflet is two or three inches. —Dodonaeus takes this for the second *R. japonicus,* or *Ranunculus,* of Dioecides, with whose description it in some measure accords. This species is said to be extremely acrid. Hence Dodonaeus, who is copied by Gerarde, supposes our plant may be the *Gelatophyllum* of Pliny, which caused those who took it to dye laughing. But this opinion depends on too many conjectures to deserve attention; even if any benefit could accrue from ascertaining the point. We must obverse however that Dr. Sibthorp thought the above *Ranunculus* of Dioecides to be our *laungwofalis,* which is a common Greek plant, and answers better to his description.

32. *R. flabellatus.* Fan-leaved Crowfoot. Desfont. Atlant. v. 1. 438. t. 114. Wild. n. 25. Sm. Fl. Græc. Sibth. t. 520, unpublished. (R. alter falcatus, aphpkedi radice; Colam. Ecphr. 312. t. 313.) —Radial leaves undivided or twice ternate, toothed or deeply cut, stalked; upper ones ternate or simple. Stem hairy, simple below, few-flowered. Fruit elliptical. —Found by Desfontaines, near Algiers, on most uncultivated hills, flowering in winter: by Sibthorp on the northern mountains of Greece. Root perennial, of many oblong, tapering, clustered fibres, rather than knobs. Stem a span high, hairy, somewhat divided above, and bearing two or three yellow flowers, the size of our common *R. bulbosus,* accompanied by deeply two or three-cleft bracteas. Leaves chiefly radical, on longish stalks; several of the earliest undivided, fan-shaped, strongly toothed; the rest deeply three-cleft, and subdivided.

33. *R. asiaticus.* Persian Crowfoot, or common Garden Ranunculus. Linn. Sp. Pl. 777. Willd. n. 26. Ait. n. 19. Mill. Ec. t. 216. Sm. Fl. Græc. Sibth. t. 518. unpublished. (R. asiaticus, grumosa radice; Chuf. Hift. v. 1. 240-243. Ranunculi varii; Ger. Em. 956-960. *Ranunculus asiaticus,* Dioec. book 2. chap. 206.) —Leaves once or twice ternate; leaflets three-cleft, cut. Stem hairy, branched. Petals thrice as long as the calyx. Fruit cylindrical. —Found by Dr. Sibthorp wild in various parts of Asia Minor, but most plentifully in the isle of Cyprus, where it still retains one of its ancient names, mentioned by Dioecides, *R.* *asiaticus,* or Wild Parsley. In the gardens of Europe it has been cultivated, ever since the latter part of the sixteenth century, under the form of innumerable varieties, chiefly double, of every variegated hue. In a wild and single flate the large and splendid petals are of a most vivid crimson, occasionally varying to yellow. The root is perennial, of numerous, brown, feby, tapering knobs. Stem twelve or fifteen inches high, erect, round, downy, hoary, leafy, branched from the middle or lower part, and bearing from three to five large long-flaked flowers, whose calyx is brown, hairy, and reflexed, but one-third the length of the broad, obovate, concave petals. Leaves rather hairy, mostly stalked, variously three-cleft and notched, more or less compound; the floral ones, as usual, narrower and more simple. Fruit cylindrical. Seeds oblong, with recurved points.

34. *R. japonicus.* Japan Crowfoot or *Ranunculus.* Thunb. Tr. of Linn. Soc. v. 2. 337. Willd. n. 27. (R. asiaticus, var. *japonicus,* or 'White Crowfoot.')

36. R. glaucdes. Alpine Hairy-capped Crowfoot. Linn. Sp. Pl. 777. Fl. Lapp. ed. 196. t. 3. f. 1. Willd. n. 29. Ait. n. 21. Fl. Dan. t. 19. (R. montanus purpureus, calyce villosa, Felcicis Plateri ; Bauh. Hiift. v. 3. b. 846. Schenckz. Alp. v. 1. 399, and 159. t. 20. f. 1.)—Leaves ternate, three-cleft, cut; their segments elliptical. Stem nearly simple. Calyx very hairy. — Native of the highest Alps of Lapland, Switzerland, Dauphiny, Germany, &c., in the neighbourhood of ice and snow, flowering in June and July. Root perennial, with very long strong fibres. Stem from three to six inches high; simple and naked in its lower part; leafy near the top, bearing one or two, very rarely three, flowers, on long, smooth stalks. Leaves green, scarcely hairy, rather fleshy; the radical ones more or less compound, on long stalks; their segments broader, more elliptical, and blunter than in the former. Flowers large and handsome, of five broad, roundish, white petals, rose-coloured or purple underneath; the calyx purplish-brown, singularly rough, with shining wavy hairs. When we contemplate the great diversity of subdivision in the foliage of this species, we are disposed to believe our frigidus, n. 18, may possibly be a mere variety. Their flowers precisely as well as their general habit.

37. R. Seguieri. Sharp-leaved Alpine Crowfoot. Villars Dauph. v. 3. 737. t. 49. Willd. n. 30. (R. Columnar ; Allion. Pedem. v. 2. 50. t. 67. f. 3. 4. Wulf. in Jacq. Coll. v. 4. 345. R. alpinus aplo folio, flore albo magno ; Pont. Comp. 117. Seguieri Veron. v. 1. 490. t. 12. f. 2. 3.)—Leaves ternate; segments wedge-shaped, subdivided, decurrent, acute. Stem branched, about three-flowered. Calyx smooth.—Native of mount Baldus, where it was first found by Pontederia; as well as of the mountains of Dauphiny, Piedmont, and Carniola; in many situations. This resembles some of the most luxuriant varieties of glaucides, but differs in the acute and decurrent segments of its leaves, as well as its smooth pale calyx; for Villars is incorrect in describing that part "externally downy." It is quite smooth, in its own and Allion's specimens; the hairs being confined to the top of the flower-flails, where it is very dense and conspicuous; while the same part in glaucides is smooth, up to the bafe of the hairy calyx. The petals, and even the necks, are white. Villars is purely right in removing the synonym of Colonna, cited by Allioni, which we refer, with hardly any scruple, to flabellum, n. 32, a very different plant.

38. R. rivulm. Palmate Alpine Crowfoot. Linn. Sp. Pl. 778. Fl. Lapp. ed. 2. 195. t. 3. f. 2. Willd. n. 31. (Excluding the variety.)—Leaves palmate, five-lobed, spreading, entire; those of the stem feife. Stem single-flowered, smooth. Calyx hairy, half the length of the petals.—Found by Linnæus in Lapland, by the alpine rivulets on the snow-covered mountains of that country. Martens had previously gathered it at Spitsbergen. The root is fihureous, and fender. Stem simple, erect or ascending, smooth, leafy, about six inches high. Radical leaves two or three, on long flender stalks, heart-shaped at the base, rather deeply palmate, in five broad, divaricated, ovobovate, entire lobes, veny and quite smooth; flum-leaved one or two, feife, with five deeper, longer, more lanceolate lobes; the uppermost only three-lobed, or occasionally quite undivided. Flower solitary, on a long, terminal, hairy flail. Calyx of five ovate yellowish leaves, rough, with blackish hairs. Petals yellow, obovate, twice the length of the calyx.

39. R. pygmaeus. Dwarf Small-flowered Alpine Crowfoot. Purib. n. 10. (R. nivalis pygmaeus ; Linn. Fl. Lapp. ed. 2. 196. t. 3. f. 3. R. lapponicus ; Fl. Dan. t. 144.)—Leaves palmate, somewhat pedate, five-lobed, spreading entire; the upper ones almost feife. Stem singeflowered. Calyx nearly smooth, rather longer than the petals.—Native of Lapland and Labrador. Perennial, flowering in May and June. Much smaller than the foregoing. Middle lobe of the radical leaves very deeply seifed. Stem-leaves less perfectly fife, and with narrower segments, than in nivalis. Flower not a quarter the size of that species; its petals yellow, roundish, scarcely so long as the calyx, which is likewise small, and very slightly hairy.

40. R. montanus. Yellow Mountain Crowfoot. Willd. n. 32. Ait. n. 22. (R. nivalis; Jacq. Aultr. t. 385. 326. Sibth. in Prodr. Fl. Græc. n. 1272 ? Villars Dauph. v. 3. 742. Crantz Aultr. f. 2. 92. t. 4. f. 3. 4. R. n. 1168. Hall. Hiift. v. 2. 71, excluding the references to Linnæus. R. minimus alpinus lutescens ; Bauh. Hiift. v. 3. 845, two upper figures.)—Leaves five-lobed, rounded, cut; those of the stem feife, with deep, lanceolate, entire segments. Stem single-flowered, rough with cefef hairs. Calyx hairy. — Very abundant on the alps of Switzerland, Dauphiny, and Germany; not of Lapland. It was one of those alpine plants, introduced into the English gardens in 1775, by a perfon sent on purpose to collect them, at the expense of Dr. Fothergill and Dr. Pitcairn. This species has been confounded with the Linnæan nivalis, by all writers previous to Willdenow; yet they are truly distinct. The montanus has remarkably long, subdivided, puberulent roots, with very long strong fibres. Stem hairy throughout, the hairs cefef; sometimes quite leaflets. Lobes of the radical leaves unequal.
equally cut and toothed, not entire. Calyx-leaves narrower, and less hairy. Petals larger, and of a deeper yellow. This is the "nivalis" of most botanists, few having seen the true Linnaean Lapland plant. The variety of montana with a leafless stem, figured in Jacquin's t. 326, at the right hand, was taken for a new species, and called acutilobus, by Fawr and Keynner, as appears by their dried specimens.

43. R. lapponicus. Long-flaked Lapland Crowfoot. Linn. Sp. Pl. 778. Fl. Lapp. ed. 2 p. 194 t. 3 f. 4. Lapland Tour, v. 1. 155, 352.) —Leaves smooth, in three very deep, dilated, blunted notched lobes. Flower-flanks elongated, naked, single-flowered. Petals the length of the smooth calyx.—This rare species, not known out of the limits of Lapland, was discovered by Linnaeus in two or three different places, near the river Juchtan, flowering in June. Professor Swartz also gathered it, many years after, near Luloa. It grows in watery situations, and is very different from all others of this genus. The aspect of the plant, at first sight, recalls the idea of Adoxa Moeschatellina. The root is long, thread-shaped, and creeping, throwing up here and there, from its joints, a little, short, simple, solitary, smooth stem, sometimes an inch or two high, sometimes scarcely distinguishable. Leaves one from the base, and another from the top, of the stem, on slender, weak foot-flanks, two or three inches in length; each leaf an inch or an inch and half wide, smooth, veiny, rather fleshy, somewhat kidney-shaped, in three very deep, almost distinct, broad wedge-shaped lobes, having a few broad and rounded, blunt notches, each tipped with a minute glandular point. Flower-flanks from three to five or six inches high, terminating the stem, solitary, simple, naked, smooth, each bearing a small yellow flower, scarcely half an inch in diameter. Calyx of three elliptical, concave, smooth, pale, reflexed leaves. Petals five or six, ovate, ribbed, about the length of the calyx; their nectar closed by a scale. Stamens from nine to twelve. Pifflis from six to twelve. Seeds in a round head, ovate, smooth, with strongly recurved points.

44. R. hyperboreus. Arctic Crowfoot. Retz. Scand. ed. 2 p. 131. Wild. n. 36. "Rothb. in Copenh. Trans. v. 10. 458. t. 4. f. 16." (R. Fl. Dan. t. 331, excluding the synonym of Ammann, which belongs to R. falcatifolius, n. 15. R. n. 50.) Gmel. Sib. v. 4. 204. t. 83, b, excluding the Linnaean synonyms.)—Leaves smooth, in three deep divaricated lobes; the lateral ones crenate. Stem creeping. Flower-flanks the length of the leaves. Petals scarcely longer than the smooth calyx.—Native of Iceland, Greenland, Norway, and Siberia, in watery places. Gmelin and Linnaeus confounded this with Heracleum hereafter mentioned; Gunner mitook it for R. falcatifolius, which he called R. Ammanni, Fl. Norv. n. 826. From both, as well as from lapponicus, it is very distinct. The stems are long and creeping, or floating, throwing out from each joint, several simple, very long, fimbriate radicles, with a flaked leaf, not a quarter the size of lapponicus, whose lobes are by no means toothed or crenate, the lateral ones only being simply crenate. The flowers are small, pale yellow, solitary, each on a lateral, but not axillary, flalk, whose length is about equal to the adjoining leaf and its foot-flake. Calyx-leaves only three or four, smooth, coloured. Petals about the same number, and scarcely longer, ovate. Seeds ovate, gibbous, with a hooked, but very short, beak.

45. R. montbéliardii. Montpellier Crowfoot. Linn. Sp. Pl. 778. Wild. n. 37. (R. faxatilis, magno flore; Bau. Prodr. 6. Sauv. Monsp. 181.)—"Leaves in three deep crenate segments. Stem simple, villous, nearly naked, single-flowered."—Native of rocky places about Montpellier, according to Bauhin, who thus describes his plant. "Root composed of long capillary fibres. Leaves from the root several; on long, somewhat woolly, flalks, each leaf hardly so broad as the nail, in three small segments, which are again divided into two or three acute ones. The stem is about three inches high, slender, woolly, bearing one large flower, of a brilliant golden yellow, composed of five petals, with many reddish filaments." We know no authentic specimen nor figure of this plant. Linnaeus has marked it as never seen by him; but a specimen sent him by Gouan, from the Pyrenees, marked R. alpinus bumilis, magno flore, which we have been disposed therefore to confider as R. Gouani, n. 41, answers very well to Bauhin's description, and it is not impossible that thee supposc two species are one and the same. Yet Poiret, who profeess to have gathered R. montbéliardii at Montpellier, and in Barbary, speaks of them as distinct, though, it must be confessed, his description is hardly sufficient to establish the point in dispute.

cylindrical. Seeds compriified, with straight beaks.—Native of low meadows, from Canada to Pennsylvania, but rare, flowering in July and August. This species was sent by professor Thunberg, in 1785, to Kew garden, from whence we procured a specimen the same year. Mr. Aiton makes it biennial; Jacquin and Pursh perennial. The stem, like the *footsflakes*, is very hairy. Whole herb of a light green, two feet or more in height, branched, many-flowered. Leaflets one and a half or two inches long, strongly veined, with spreading segments. *Flower-flake* terminal, longish, furrowed, rough with clove-preened hairs. Flowers small, their little, round, yellow petals not so long as the calyx, which is smooth and bent downward. Seeds in a cylindrical head, numerous, ovate, gibbous, compriified, smooth, very minutely dotted, each tipped with a short, sharp, erect, or slightly infixed, beak. *Receptacle* hairy. Mr. Pursh's description does not in every circumstance, answer to the Linnean plant; for the flowers are not near so big as *R. acris*, nor are their *flakes* round.

Thumb. *Jap.* 241. Wild. n. 39.—Calyx reflexed. Leaves all ternate; leaflets three-eleft. Stem many-flowered. *Native of the Japancse island of Nipon, flowering in May. Nothing more is known of this species, concerning whole peculiar characters, or affinities, we can form no precise opinion.*

48. *R. biternatius*. Twice-ternate Magellanic Crowfoot.—Leaves smooth, twice ternate, cut; segments ovate, acute. Stem creeping. Stalks single-flowered, the length of the leaves. Petals obovate, the length of the smooth calyx. Gathered by Commerfon, in the straits of Magellan. No author appears to have taken up this species, of which a specimen, from Commerfon's herbarium, was given by Thouin to the younger Linneus. The whole plant is smooth. The leaves bear a considerable resemblance to those of *R. Seguieri*, but are rather smaller, and diffusely twice ternate. The habit of the plant more accords with *lapponicus* and *hyperboreus*, however unlike at first sight. The flower is thread-shaped and creeping, arising from every joint, a few fibrous radicles, a pair of upright, flaked leaves, two or three inches in height, and one flower, whose simple, naked *flake* is about as tall as the leaves. *This flower appears to be extremely like that of* lapponicus, though scarcely more than half so large. The dried petals have the fame opaque whitekefs as is observably in that species, and others, on their upper surface, and are probably yellow when fresh.

49. *R. pedunculatis*. Long-flaked Magellanic Crowfoot.—Leaves ternate, deeply cut, somewhat hairy. Stems hairy, taller than the leaves, two-flowered. Calyx reflexed, nearly smooth. Seeds globose, smooth, with recurved, hooked beaks.—Gathered by Commerfon in the straits of Magellan, with the preceding. This has a general likeness to several common European kinds, which we shall next describe, but is essentially distinct. The radical leaves are several, on hairy flanks, four inches long, their circumcission roundish, measuring an inch, or inch and half, acrosf; the leaflets almost always quite distinct, with short partial flanks, their form wedge-like, or fan-flaked, more or less deeply cut, seldom regularly three-cleft. Stems several, erect, flaked, roth, with spreading hairs; imple and naked to the height of four or five inches, then dividing into two upright, hairy, simple *flower-flakes*, greatly elongated, (from one to seven or eight inches), after flowering, and accompanied at their base by a solitary, flaked, deeply divided, palmate or fingered, leaf, an inch long. The flowers are much like those of *bulbosus*, or *acris*. Calyxes ovate, concave, reflexed, bearing a few external hairs.
Lamarck) describes them in his *R. agrarius*, cited above.—
This species has been very little understood. It is remark-
able that any botanist should confound it with *bulbosus*, or
with *fertilus*, and that Mr. Curtis, in labouring to difting-
guish it, did not advert to the decifive character of the
tuberculated roots, by which it approaches a very different
tribe, hereafter described, confifling of *parviflorum, murrucatus*,
&c. Even Ehrhart has not noticed this circumstance.
We are obliged to Mr. Edward Forrester, F.L.S. for tracing
the identity of *R. parvifolus* and *hirsutus*, and we cannot
but prefer Curtis's original name for the species, rather than
Ehrhart's pedantic one of later date. On the account of
priority *fertilus* perhaps ought to have been retained; but
this name is founded on a very dubious opinion, that
the plant of which we are speaking caused the Sardonic
laugh. Valerius Cordus, indeed, fays it grows copiously
in Sardinia, and it has certainly the appearance of Smallage,
*Apium*; so far answering to the ancient history. But the
account of Cordus feems taken from Dioscorides, whose
"second Ranaeculus" is more probably the Linnean *lan-
ginifolus*, a much more general plant of the south of Europe
than that of which we are speaking. After all, the famous
Sardinian herb, compared to Smallage, may be actually
wild Smallage or Celery, *Apium gravoifolus*, which is suffi-
ciently acrid and poisonous to warrant our suspension,
though it becomes sweet and wholesome by culture. In
this uncertainty it is merely bleft to call our plant *R. hir-
sutus*.

MSS. (R. orientalis palustris, apio folio, caule bifurcifuto; 
Tourn. Cor. 26.) Leaves hairy, in three or five deep fe-
gments, bluntly notched, with rounded dilated finifhes. Stem
erect, branched, almoft leafles. Calyx spreading. Seeds
ovate, compressed, very smooth, with a fhort recurved beak.
—Native of the Levant. An oriental specime, with Tour-
nefort's synonym, is preferred in the Linnean herbarium,
and named *palaceras*, but we can find no mention of it efe-
where. This is certainly a moft difficult species, though not
taken up by any recent-author. The root confifts of many
fleky knubs, tapering into fibres, and refembling thofe of
*R. officinarum*, though not fo thick. Stem two feet or more
in height; hairy below; much branched, and almoft leaf-
les above; the branches tanate. Leaves chiefiy radical,
on long hairy flalks; their outline fomewhat pentagonal;
heart-shaped at the base; hairy on both fides, about two
inches wide; their three principal lobes spreading, deeply
separated by wide rounded finifhes, and notched inequally
at the extremity with broad, rounded, abrupt teeth; the
upper or floral leaves are fmall, fhort, linear, undivided.

Flowers, as far as we can judge, yellow, not largé. Calyx
haired, spreading widely, but fearfly reflexed. Seeds in a
round head, brown, fhinifh, quite smooth, compressed, molt
like thofe of *bulbosus*, but more ovate, and with a longer,
more recurved, and fomewhat hooked, beak. Their edge
is green, fimple, not triple-ribbed as in the lai.

Willd. n. 42. Lamarck Dict. n. 38.—Radical leaves pal-
mate, with wedge-shaped, three-toothed fegments; fef-
leaves fefile, fngerfed. Stem many-flowered. Root fonna-
culated. Calyx spreading. Seeds ovate, compressed, smooth,
with a blunt beak.—Native of Siberia. Root fculptured,
perennial. Radical leaves like *R. frreralus*, three-lobed;
their lateral lobes two-lobed, wedge-shaped like the leaf
itfelf, their fegments bluntly three-toothed. Stem a finger's
length, fimple, erect or acclining, two or three from one
root. Stem-leaves fefile, fngerfed, wedge-shaped at the base;
their fegments linear, blufhing, entire. Flower-flalks two,
three, or four, long, fingle-flowered, round, not furred,
very finely downy like the stem. Calyx-leaves coloured,
smooth, obtuse, spreading. Petals yellow, the size of *R.
bulbosus*. Fruit roundifh. Seeds ovate, compressed, smooth,
crowned with the permanent blufh *figma*. Wildflower.

By the above description this species appears related, in
many points, to the lai, though they can hardly be the fame.

Mart. Rulf. t. 29. (R. pratensis, etanique hortensis; Ger.
Em. 951.)—Leaves tanate, three-creft, flat, hairy. Stems
acclining. Runners creeping. Flower-flalks furred. Caly-
x hairy, spreading. Seeds ovale, compressed, even.—Very
common in meadows, waste ground, church-yards, neglected
gardens, and fields, throughout Europe. Mr. Pursh obferved
it in fhady wet woods, particularly on the mountains, from
Pennsylvania to Virginia. It flowers from June to August,
and is perennial, being often a troublesome weed. *Rex*
fibrous. Beside the upright *flews*, which are of humble-
growth, leafy, branched, bearing feveral flowers, the root
fends forth long trailing creeping shoots, whose joints pro-
duce leaves, and some shorter fimler flews. The whole
herb is rough and hairy, of a dark green. Leaves flatked,
tanate, more or less three-creft, flatly cut or toothed;
often marked with dark purple, or black, sometimes pale,
spots; the uppermoft linear-lanceolate and entire. Calyx
haired, spreading, not reflexed. Petals deep yellow, generally
enarginate. Nectary covered by a heart-shaped fcale. *Fruit
globule.* Seeds ovate, compressed, smooth at the fides, often
hairy at the edge, their beak fhort and blunt.

n. 35. Pl. Francoiff. n. 3. 1797.—Leaves tanate, three-
creft, very hairy. Stems entirely prostrate, creeping, zig-
zag. Calyx fMOOTH.—Native of dry fitty places about
Paris. Lamarck and Poiret feem this a diftinct species
from the lai, not only because its herbage is much smaller
and more hairy, but because the *flews* are, even when in
flower, entirely prostrate. We have never met with any
thing anfwering to this description in England. The flowers
are faid to refeemble *repens*, having likewise a smooth calyx.

Our *reps* has hairs on that part.

56. *Q. intermedius*. Intermediate Crowfoot. Lamarck
Dict. n. 44.—Lower leaves three-lobed, cut; upper some-
what fingerfed. Flower-flalks moltily folitary. Calyx re-
flexed. Seeds compressed, smooth. Root fibrous.—Foun-
ded at the borders of ponds in France, about Paris and at
Fontainebleau. This plant, according to Poiret, is, as it were,
intermediate between *bulbosus* and *reps*, having, besides,
many characters in common with *prostratus*. The root
is fibrous, fculptured. Stems fveral, low, fearfly branched,
almoft leafles except at the bottom, weak, fariated, flightly
downy, often forked above. Radical leaves on long flalks,
almoft smooth, in three rounded, often cut, lobes; the
*flews-leaves* have three linear or lanceolate irregular lobes;
the uppermoft are very narrow, almoft fingered. Flowers
axillary, or terminal, two or three on each branch, on very
long and slender, nearly smooth, flalks. Calyx-leaves re-
flexed at the time of flowering, as in *bulbosus*, coloured,
cone, bearing fome very fine long hairs. Petals of a fine
yellow, fariated, middle-fixed. *Fruit oval or globle.* Seeds
smooth, compressed, roundifh, with a green border. We
know nothing of this species but from the above defcrip-
tion.

57. *R. lucidus*. Shining-leaved Crowfoot. Lamarck
Dict. n. 36.—Leaves with three or five lobes, somewhat pinna-
tifid, fhinifh, smooth. Stem erect, many-flowered. Calyx re-
flexed.—Suppofed to be a native of the Levant; cultivated
in
in the botanic garden at Paris. Root perennial. Stems one or two feet high, branched, leafy, very smooth, tender, striated. Leaves alternate, stalked, widely spreading, smooth, shining as if varnished on their upper surface, divided into three or five dilated lobes, the two lowermost contracted at their base, unequally cut, obtuse. Flowerstalks long, somewhat downy, dilated at their base into a broad membranous base. Flowers numerous, situated at the ends, as well as on the forks, of the branches, on long, simple, cylindrical, rather downy flalsks. Calyx-leaves coloured, smooth, concave, reflexed after the flower expands. Petals rather large, roundish, of a fine shining yellow. This plant has some agreement with R. repens, from which it differs in showing in a nearly upright flalsk and a reflexed calyx, as well as in shorter more dilated lobes of the leaves. Such is Poiret's account. This surely cannot be our polyfhyria, n. 52, which has hairy leaves, and no tendril or affinity to repens; neither could the intelligent author have overlooked Turningeet's synonym for that plant.

58. R. polyanthemum. Many-flowered Crowfoot. Linn. Sp. Pl. 779. Willd. n. 44. Ait. n. 28. Lamarck n. 41. Lob. t. 666. (R. yelveriis secundus; Dod. Pempl. 427. R. serrati secundus; Ger. Em. 561, as to the figure. R. yelveriis; Tabern. Kretz. 59. t. 12. R. pinnatifidus; Crantz t. 90. t. 4. f. 1, 12.)—Leaves in five deep, repeatedly subdivided lobes; segments all linear. Stem erect, many-flowered. Flower-flalsks furrowed. Calyx spreading. Seeds ovate, bordered, compressed, smooth. Native of moor, elevated, rich meadows, in Uppland, and elsewhere in Sweden, but rarely. Linneas. In Germany, and perhaps in Switzerland, on the authority of various writers. Root perennial. Stem erect, two or three feet high, branched, many-flowered; leafy, clothed with upright, or submersed spreading, hairs. Radical and lower flas-leaves three inches wide, on very long hairy flalsks, divided to the base into three lobes; the lateral lobes again divided almost to the base, so that the leaf may truly be called, in the first instance, five-lobed; each lobe is deeply, more or less, cut, into three or more alternate, linear, bluntish, entire, single-ribbed, spreading segments, loosely hairy on both sides, paler beneath; the uppermost leaves are nearly sessile, in about three deep, linear, entire divisions. Flower-flalsks long, terminal, angular or furrowed, rough with upright hairs. Flowers large, yellow, drooping, not closing, in wet weather, according to Linneas. Calyx spreading, pale, externally hairy. Fruit globose. Seeds ovate, short, compressed, smooth at the sides, bordered and roughish at the edges, tipped with a broad, short, recurved beak. We have described this from the authentic Linneas specimen, which seems distinct from the following, and agrees extremely well to the figure of Tabernemontanus more especially, nor does it ill accord with that of Dodoneus, reprinted in Gerarde's herbal. The last-named author however certainly applies that figure to the common English R. ar cris, which he says he found double. Hence some doubt may arise whether the true polyanthemus was ever cultivated in England, as it seems to depend on Gerarde's authority only for a place in Hort. Kew. We have never seen it alive. Possibly it may be found in a double state in some old garden. The above description of the leaves, and the greater size of the entire plant, will distinguish it from ar cris. The calyx is hairy in both, notwithstanding Willdenow's remark to the contrary.

A dwarf alpine variety was brought by Mr. Dawson Turner from wet rocks, near the summit of Snowdon, whose flein is but three or four inches high, and bears one or two flowers. This when cultivated in a garden gradually attains the size and habit of the common kind.

60. R. breyniisus. Woolly-flowered Alpine Crowfoot. Crantz Auffl. t. s. 91. t. 4. f. 2. (R. breyniisus, by mitake; Lamarck Dict. n. 59. R. n. 1170; Hall. Hall. v. 2. 72.)—Leaves deeply three-lobed, cut and toothed, very hairy beneath. Stems spreading, few-flowered. Calyx spreading. Seeds smooth. Receptacle woolly. Native of the Aurifia and Swifs Alps. Haller says it is the smallest of all the species. The flein are several, two or three inches long, oblique, simple or somewhat branched, hairy, bearing one or two flowers, which are of a varnished yellow. Radical leaves numerous, deeply divided than in ar cris, very hairy beneath. Fruit globose. Seeds smooth, hooked. Receptacle woolly, which Crantz says he had not observed in other species, and by which we presume this is most essentially distinguished, particularly from the above alpine variety of ar cris. We have not met with a specimen, nor was Mr. Davall acquainted with the plant of Haller.

61. R. lappaceus. Bur Crowfoot. Leaves ternate; leaflets flalked, three-lobed, sharply cut, hairy. Stem erect, many-flowered. Calyx spreading. Seeds ovate, keeled, reticulated, with elongated, revolute-pointed beaks. Native of Port Jacoffon, New South Wales; communicated by Dr. White. This has much of the habit of R. ar cris, but is very distinct. The flein are a foot, or more, in height, branched, roundish, rough with close-ribbed hairs. Radical leaves numerous, on long hairy flalsks, very hairy, about the size of re crist or repens, but remarkable for the partial flalsks, sometimes an inch or two long, that support the leaflets, especially the terminal one; the leaflets are broad, wedge-shaped, more or less deeply three-lobed, coarsely and sharply cut. The lower flein-leaves are narrower and leafs cut; the upper entire and lanceolated; the uppermost of simple and linear. Flowers larger than in ar cris, white in the dried specimen, but perhaps yellow when fresh, finely veined, on long, hairy, angular, terminal flalsks. Calyx spreading, clothed with long hairs. Nectar covered with a wedge-shaped scale. Fruit globose. Seeds ovate, tufted, keeled, reticulated with veins, smooth, each tipped with a prominent angular beak, nearly its own length, whose point is strongly recurved, and even revolute.

RANUNCULUS.

Doronicum. 

and Seeds Calyx Purfl. 1172; Leaves has R. lanuginofus. we R. fome Flower-ltalks Leaves BaVx»°» Stem Leaves 16. R. the weight, ftiort, Carolina, Purfl. sufficentl,y Flowers Thejlenis Willd. Calyx radiant 519, R. 70. 17. Purfl. Poiret. 397. their Fruit Poiret 71. 

Footstalks compressed, hooked. Wildenow, from a dried specimcn. 

Leaves heart-shaped, five-crefted, lobed, notched, fiky. Stem erect, many-flowered, hairy. Flower-falks round. Calyx spreading. Seeds ovate, compressed, with elongated, revolute-pointed beaks.—Native of Germany, France, Switzerland, Carniola, Greece, and North America. Mr. Purf. observed it in old fields and meadows, from Pennsylvania to Carolina, flowering from June to October. Dr. Sibthorpe found it in shady watery situations in the Peloponnesus, but most plentifully in the north of Greece, and with great reason concluded it to be the second Ranunculus of Dioscorides, with whose description it sufficiently well agrees, except being mild, rather than very acrid, in fenibile qualities, if we may trust modern authors. Linnaeus distinguishes two varieties, between which we can discover no difference, and Haller unites them. The opinion of this great Swifs botaniff however lofes some of its weight, by the doubt he expreffes whether this plant be different from R. repens, n. 54, to which it has indeed a flight general rcmblance, though differing totally in its upright flem, delittute of runners; its very soft fiky leaves, by which this plant is known at once from every other European Ranunculus; and the revolute taper points of its fefds, which nearly agree with lappaceus in that respect; but the fefds themselves are compressed, and, as far as we can see, delittute of reticulated veins. The root is perennial, with many long, flout, cylindrical, fiky fibres, or perhaps flender knobs, intermixcd with capillary branched radicles. Stem 12 or 18 inches high, branched, leafy, round, clothed with long, spreading or deflexed, hairs; its bafe purplish, as are also the long hairy falks of the radical leaves. Thefe and the lower flem-leaves are three inches wide, divided about half way down into five or even broad, sharply notched lobes, whose fiky fufines have a pale fpot, with a purple fpain, adjoining to their termination. The upper leaves are deeply three-crefted, with ovate and toothed, or lanceolate and entire, lobes. 

Flowers yellow, much like thofe of acris. Calyx hairy, spreading. Fruit globofe. Seeds with awl-shaped, very revolute beaks, by which this species is clearly diftinguifhable from repens, polyanthemus, acris, if fhuch a mark were neceffary, and by which it forms a chain of affinitv between thofe species and our lappaceus. It is somewhat remarkable that R. lungingina has not been found in Britain, and fhull more fu, that any obfcurity fhould envelope the botanical history of fo fimilr a fp. 

—Leaves ternate, very fiky; leaflets wedge-shaped, deeply three-crefted, jagged and toothed. Stem erect, manyflowered, fiky. Calyx spreading. Seeds ovate, compressed, with short erect beaks.—Gathered in the isle of Bourbon by Comonion, from whom we have fpecimens. 

Root, as well as the general habit and size of the plant, like the falk, but the whole herb is much more deficcated clothed with fiky hairs. The leaves are ternate, fome of them almost twice ternate; their lobes deeply and repeatedly cut, in a radiant manner, with fharp teeth. 

Flowers like the falk. Fruit ovate. Seeds with broad fhght beaks, longer, and not to much curved or hooked, as even thofe of acris.

65. R. tenuifolius. Shaggy Crowfoot. Lamarcq Dict. n. 70. Purfl. n. 17. Leaves downy, three-crefted or notched; the uppermoft oval, entire. Stem reclining, somewhat creeping, fiky, one or two-flowered. Calyx hispid, slightly reflyted.—Gathered in North Carolina, by M. Bofe. A small, almost creeping, very hairy plant, with fibrous roots. The flem are very low, and nearly proftrate, affending at their extremities, two or three inches long, tender, covered with whitifh tufted hairs, defipofed in two rows. Leaves flaked, thick, downy, generally with three lobes, which are either difficult or confuent; fome leaves are merely crenate and rounded. Footfalks long and hairy. The uppermoft flem-leaf is fiky, oval, acute, entire. Flowers one or two, on terminal, unequal, fimple falks, clothed with two rows of hairs. Calyx hispid, a little reflyted. Petals white or yellow, rounded at the end. 

Petals have been foon fpecimens, nor did Mr. Purf. meet with the plant himself. 

Stems fimple, erect, downy, Bender, about ten inches high; Poiret by miftake, as we preufe, lays ten feet. Leaves radical, on long downy falks, ternate; the two lateral ones oppofite, falked; all with three confluent, lanceolate, acute, cut lobes; their upper fpot green; the under paler and whifht, almost smooth. There are no other flem-leaves than what fland almost fefild, at the bafe of the flower falks, and either have three or five ftallov irregular lobes, or are fimply cut. 

Flowers two or three, terminal, on short, scarcely downy, falks. Calyx smooth, reflyted. Petals rather large, oval, rounded at the end, pale yellow. Poiret. 

67. R. recurvatus. Recurved Crowfoot. Lamarcq Dict. n. 65. Purfl. n. 19.—Leaves in three deep, acute, cut, wedge-shaped lobes. Stem many-flowered. Calyx and corolla reflyted. Petals nearly linear. Seeds compressed, dotted, with revolute, awl-shaped beaks.—Native of shady woods, from New York to Carolina, flowering from June to August. Purfl. We received fpecimens from the Rev. Dr. Mohlenberg, of Lancaster, Pennsylvania. The root is perennial. Stems a fpan high, very hairy; branched and leafy at the upper part. Leaves two or three inches wide, rather hairy, on very hairy falks; their fide-lobes for the most part deeply cleft. 

Flowers flaked, small. Calyx pale-purplish, ribbed, clothed with fine long hairs. Petals small, narrow, almost white. Fruit glabrate. Seeds ovate, lenticular, minutely dotted, smooth, with Bender, revolute-pointed beaks.

68. R. septentrionalis. Smooth North-American Crowfoot. Lamarcq Dict. n. 64. Purfl. n. 20.—Leaves ternate, membraneous, smooth, deeply lobed, acute, cut. Stem two-flowered, hairy, like the base of the flower falks. Calyx reflected.
Reflexed.—Native of North America. Described by Poiret from Lamarck's herbarium, and adopted by Pursh. 

Root perennial, fibrous, fasciculated. Stems nearly simple, hollow, eight to ten inches high, almost leafless; downy in their lower part. Leaves flaked, thin, smooth, composed of three flaked leaflets, the central one having three deep spreading lobes, the others often but two; all sharp, cut and toothed. There is usually but one stem-leaf, which is nearly feathery, ternate, with narrower segments. Footstalks long, slender, mossy hairy towards their base. Flower-stalks two, terminal, unequal, very slender, smooth, each bearing, about half way up, one small leafy linear. Calyx reflexed, coloured, smooth, except a few terminal hairs, deciduous. Petals pale yellow, rounded. Fruit small, globular. Seeds nearly orbicular, lenticular, with sharp straight beaks. Poiret.

71. R. multifidus. Many-cleft Arabian Crowfoot.—Forli. Egypt.-Arab. 102. Lamarck Dict. n. 67. —Leaves many-cleft; the lower ones pinnated. Stem many-flowered. Calyx the length of the corolla. Seeds ovate, acute.—Gathered by Forli, in ditches near the town of Taes. He describes the stem two feet high, erect; round in the lower part; peltate above; hairy. Fruit oval. We have no other authority, than the authors quoted, for this species or the last.

72. R. pedatifidus. Radiating-leaved Crowfoot.—Leaves deeply peltate, with linear, obtuse, divided or three-cleft, radiating, entire segments. Stem one or two-flowered. Seeds ovate, hairy, with small recurved beaks.—Native of Siberia. Four species from that country are in the Linnaean herbarium, but the species, though very distinct, appears never to have been described. Root perennial, of many long, cylindrical, feathery fibres, and crowned with numerous capillary remains of old footstalks. Stem a span high, erect, round, peltate, leafy, simple or divided, clothed with long, soft, lax hairs. Radical leaves on long hairy stalks, deeply cut, in a pedate manner, into five, seven, or more, narrow, linear, obtuse, elegantly radiating segments, some of which are deeply three-cleft, and their lobes again clowen, others merely divided, and others univalved; all entire at the edges, and somewhat hairy on both sides, with long, lax, white hairs. The stem-leaves are mostly feathery, less divided; the uppermost in three, rarely more, deep, linear, simple segments. Flowers apparently yellow, the size of R. acris. Calyx woolly at the base; its segments partly dilated and coloured, all shorter than the petals, and closely pressed to their under side. Fruit ovate. Seeds not very numerous, ovate, tumid, hairy, with short, awl-shaped, reflexed beaks.

73. R. cherophyllus. Chervil Crowfoot. Linnaeus Sp. Pl. 780. Wild. n. 48. Lamarck Dict. n. 32. (R. tenuissimus, grumofol radice, forsensiles limo italicus; Bar. Inc. c. 581 ? bad).—Leaves thrice compound, with linear segments. Stem silky, with few flowers. Calyx reflexed, hairy. Root with tapering feathery fibres.—Native of the south of Europe. The only certain specimen of this plant, that has ever come under our observation, exists in the Linnaean herbarium. The root conflits of numerous, long, feathery, gradually tapering, downy fibres. Stem erect, about a span high, slender, silky, slightly leafy, branched, bearing three or four flowers. Radical leaves few, divided, repeatedly ternate, with numerous linear, or somewhat lanceolate, entire segments, hairy beneath. Flower-stalks an inch and half long, hairy; dilated, membranous, and ribbed at the base. Stem-leaves few, much less compound, and often nearly sessile. Flowers solitary, on long, terminal, simple, hairy, quadrangular stalks. Calyx strongly reflexed, coloured; externally hairy. Petals yellow. Fruit not sufficiently advanced to be described. At the back of this specimen Linnaeus has written Ranunculus lybius, pulsatilla foliis, T. Cor.; but there is no such passage in Tournefort's Corolla, nor any thing to which it can refer, except R. lybius, pulsatilla foliis, flore parvo, a species unknown to us. A very different plant from the true R. cherophyllus, was given by the abbe Pouret to the younger Linnaeus, under that name. It seems rather to be Fribellatus, n. 32, a species allied, in many points, to what we are describing.

74. R. milfoiliatus. Milfoil Crowfoot. Vahl. Synb. v. 2. 65. t. 37. Desfont. Atlant. v. 1. 441. t. 116. Wild. n. 49. Lamarck Dict. n. 33. Sm. Fl. Grec. Sibthorp. t. 521, unpubl. (R. montanus leptophyllum, alphodeli radice; Column. Epchr. 312. t. 311).—Leaves thrice compound, with elliptic-linear segments. Stem silky, with few flowers. Calyx erect, somewhat hairy. Root with ovate knobs.—Native of Italy, Greece, Syria, and Barbary. The root, in Dr. Sibthorp's specimens, confits of many oval feathery knobs, scarcely half an inch long, intermixed with fibres. Columna describes and delineates the fibres as terminating the knobs; a very material difference. The flaves, in the Greek and Italian specimens, are simple and single-flowered; in the more luxuriant ones from Aleppo and Tunis, somewhat branched, bearing two or three flowers. The stem-leaves are more numerous, as well as more compound, than in the last. Flowers large. Calyx closely pressed to the corolla; sometimes nearly smooth. Fruit oblong. Seeds with small recurved beaks. We can scarcely doubt, notwithstanding the above-mentioned divergency respecting the root, that the synonym of Columna belongs to the present, rather than the foregoing, species.

75. R. oxyspermus. Sharp-leaved Crowfoot. Wild. n. 51. Lamarck Dict. n. 37. —Radical leaves oblong, obtuse, deeply and unequally toothed; stem-leaves fimbriate, fingered, cut. Seeds awned.—Native of Siberia, near the river Terek. Root apparently annual. Radical leaves flaked, obtuse, obtuse, with unequal deep teeth; hairy, like their footstalks, on both sides. Stem erect, branched, hairy, a foot or more in height. Stem-leaves digitate; the segments of the lower ones unequally pinnatifid; of the upper linear and entire. Calyx reflexed. Corolla yellow, the five of R. bulbosus. Fruit elliptical. Seeds rather compressed, acute,
acute, with upright, awl-shaped, bristly points. \textit{Willdenow.}

76. \textit{R. arvensis.} Corn Crowfoot. \textit{Linn. Sp. Pl.} 780. Wildl. n. 52. Ait. n. 32. \textit{Fl. Brit.} n. 12. Engl. Bot. t. 125. Curtt. Lond. s. f. 36. Mart. Ruffl. t. 56. \textit{Fl. Dan.} t. 219. Bulliard. t. 117. Brugnon Mem. de l’Acad. de Turin, v. 4. 108. t. 3. (\textit{R. arvenseum} ; \textit{Ger.} \textit{Em.} 951.)—Leaves ternate, three-cleft, with linear segments. Seeds prickly at each side. Stem erect.—Frequent in corn-fields throughout Europe, flowering in the middle of summer. \textit{Root} biforous, annual. Stem one or two feet high, much branched, many-flowered, leafy, nearly smooth. \textit{Leaves} of a light green, thinly hairy, flaked, once or twice ternate, as well as deeply three-cleft; the ultimate segments almost linear, entire, or rarely notched. \textit{Flowers} small, lemon-coloured, flaked, lateral and terminal. \textit{Calyx} spreading, hairy. \textit{Petals} obovate, veined. \textit{Fruits} depressed. Seeds very large, compressed, with ereti, awl-shaped, hooked beaks; their siles armed with numerous, prominent, awl-shaped prickles, largest towards the margin. From the observations of M. Brugnon, this appears to be one of the most virulent of its genus, especially when young, causing speedy inflammation and gangrene in the flomachis of sheep and oxen; who nevertheless eat it with avidity. \textit{Vinegar} much diluted with water, poured down their throats, proved a quick and certain remedy. The expressed juice of the plant, given to dogs, is no less fatal.

77. \textit{R. moricatus.} Spreading Prickly-fed Crowfoot. \textit{Linn. Sp. Pl.} 780. Wildl. n. 53. Lamarck Dicht. n. 75. Ait. n. 33. Pursh n. 24. Sm. Fl. Græc. Sibth. t. 522, unpublished. (R. creticus \textit{echinatus} latifolius; \textit{Alpin.} Exot. 263. t. 262. R. Apulei quibufdam; \textit{Cluf. Hist.} v. 1. 233. R. parvs \textit{echinatus}; \textit{Ger. Em.} 965. R. palustris \textit{echinatus}; \textit{Bauh. Hist.} v. 3. 846. \textit{Feuill. Peruv.} 58. t. 18. f. 1.)—Leaves simple, three-lobed, notched, blufihnt, smooth. \textit{Stipulas} dillently fringed. Seeds prickly at each side. Stem diffuse.—Native of wetter places in various parts of the south of Europe; frequent in Greece. It occurs also in North America, in old fields, from Virginia to Carolina, flowering in June and July, according to Mr. Pursh. The \textit{root} is annual, confifling of numerous long fibres. \textit{Herb} smooth and succulent, bright green. \textit{Stems} several, various in length, spreading, and mollily procumbent, leafy, round, shining; purplish in the lower part. \textit{Leaves} an inch and a half to three inches wide, veiny, in three rather deep lobes, broadly and irregularly notched. \textit{Foskalls} from one to four inches, or more, in length, with a concave feathing base, bordered with a membranous \textit{fipula}, whose edges are regularly fringed with dilatant hairs. \textit{Flowers} the size of the last, yellow, foliary, on axillary flals, rather shorter than the leaves. \textit{Calyx} reflexed, nearly, or quite, smooth. \textit{Petals} obovate, almost twice as long as the calyx, at least in the European specimens, though they appear to be but of the same length in American ones. \textit{Fruit} capitale. \textit{Seeds} large, ovate, compressed, with broad, awl-shaped, angular, somewhat recurved beaks; their siles covered with smaller, more uniform prickles, than in \textit{R. arvense}. Commeron gathered, by the sea-flore at Monte Video, a variety of this with more luxuriant herbage, and smaller flowers, of which \textit{Venentat} makes a species of the name of \textit{oeutricus}, founding its character on the inflated bases of the \textit{fosskalls}, of which, however, we can see nothing, in our original specimens from Thouin's herbarium. Its \textit{fipulas} are fringed precisely as in our \textit{European} \textit{morica}; to which we agree with Poir et in referring it, though we can scarcely do the fame by the following.
(Melampyrum hteusum; Ger. Em. 90. Lob. t. 37.)—Leaves linear-wedge-shaped, in three deep many-cleft lobes. Seeds with sickle-shaped beaks. Stalks radical, single-flowered.—Native of corn-fields in the south of Europe, and the Levant; cultivated by Miller at Chelsea in 1739. A small annual, flowering in the early part of summer. Root thread-shaped, with a few fibres. Stem none. Leaves several, pale green, downy, about two inches long; their segments narrow and entire. Stalks simple, downy, taller than the leaves, each bearing a small yellow flower, whose calyx is erect. Fruit large, ovate, or nearly cylindrical, beget on all sides with the long, prominent, ascending, incurved, compresse, downy, spinescent-pointed beaks of the seeds.

83. R. polyphyllus. Many-leaved Water Crowfoot. "Waldfl. et Kitabul Hung." Willd. n. 58. — "Leaves under water oblong, falked, capillary; floating ones wedge-shaped, three-lobed; thofe above the water elliptic. Stem erect."—Native of the waters of Hungary. Annuall. Stem nine inches high, erect; branched in the upper part. Leaves that are under water very numerous, entirely covering that part of the stem, oblong, the length of the nail, each supported by a capillary footstalk an inch long: the floating leaves small, wedge-shaped, three-lobed, entire, as long as the former, their footstalks thicker and shorter. Branches an inch long, erect, rising above the water, and bearing elliptical obtuse leaves, tapering each way, from four to five lines long on short footstalks. Flowers extremely small, yellow. Willdenow. 

85. R. aquatilis. White Floating Crowfoot. Linn. Sp. Pl. 781. Willd. n. 60. Ait. n. 37. Fl. Brit. t. 15. Eng. Bot. t. 101. Ger. Em. 829.—Leaves capillary under water; above somewhat peltate. Stamens numerous. Seeds corrugated.—Native of pools, ditches, and rivers, throughout Europe, mantling the surface with its copious white blossoms, in the early part of summer. The roots are long, fibrous, and perennial. Stems floating under water, long, round, branched, leafy. Leaves falked, smooth; the uppermost floating, usually peltate, with various blunt notches; the next deeply three-lobed, or even ternate; the lowermost immersed, repeatedly three-lobed, with innumerable capillary segments. Flowers floating on very fimple stalks, opposite to the leaves. Petals obovate, much longer than the calyx, white, with yellow claws. Notary tubular. Stamens thirty or more. Fruit like the half, but the seeds more numerous, and generally brilly, somewhat obovate. Varieties, as we deem them, of this species are, 18, that whole leaves are all imbered, and entirely capillary, figured in Ger. Em. 827. f. 3: 2dly, the cirrinitus of Sibth. Oxon. 175, figured in Pl. Ftl. Phyt. 1. 55. f. 2, whose leaves are all likewise in capillary divisions, but finer and smaller than the former: 3dly, the flavonitis of Willdenow, n. 61, pseuconnaeis of Desfont. Atlant. Pl. 50. t. 376, whose leaves are not only in capillary segments, but considerably elongated, by the influence, as we conceive, of the running water, in which this fort is always found. The seeds indeed are not brilly, in our specimens of this last variety, but naked, as in hederaceus, which species agrees with every variety of aquatilis, in the corrugations of the seeds, as above described.

We have thus added twenty-four species to Willdenow's number, following his arrangement, for the present at least, not only for the convenience of our readers, but because it would be very difficult to make a perfect one on any known principles; the several species being allied by to many characters, and so dissimilar in others, that nothing could be more precarious than to seek the clue of nature through such a labyrinth. The seeds perhaps ought to form the basis of a specific arrangement, if they might not even lead to generic distinctions.

No small curiosity in the history of this genus is the R. alatus, of Poiret in Lamy's Dict. n. 72, which, by his description, proves to be no other than Gymnophyles peregrinum of Jullieu. (See Gymnostyle.) The panicula of Poiret, n. 82, appears to us a variety of aquatilis, growing in shallow, and perhaps fluctuating, waters; whereas, though its leaves are all deeply cut, their segments are not quite capillary, but linear and obtuse. We have Swiss specimens answering to this author's description.

Ranunculus, in Gardening, contains plants of the hardy, herbaceous, perennial kind, of which the species cultivated are, the Persian crownfoot, or garden ranunculus, (R. afati- catus); the acanth-leaved crownfoot (R. aerofolius); the upright meadow crownfoot (R. acris); the creeping crownfoot (R. reptans); and the embracing-leaved crownfoot (R. amplexicaulis). But there are other species that may be cultivated for variety.

Of the first species the varieties are exceedingly numerous, being sometimes divided into two classes, as the old Turkey kinds, and the Persia kinds, the varieties of the latter amounting to many hundreds, and being considerably more various, rich, and beautiful in colour than those of the others.

But in the former of these sorts they rise with a strong generally unbranching stalk a foot high, terminated by one large double flower, sometimes emitting one or two smaller ones from its sides, and of which there are red-flowered, scarlet-flowered, yellow-flowered, and scarlet turban-flowered, &c.; but being seldom tinged with different colours, as in the Persian kinds.

And in the latter kind the plants rise eight or nine inches high, generally branching from the bottom, producing from five or ten to twenty or more flowers on each root, and of which there are fingle-flowered, semi-double-flowered, full-double-flowered, large and full like a double rose, being generally filled with petals to the very centre, forming a regular globular body, of admirable elegance, of all sorts of the most beautiful colours in different varieties, and of numerous degrees of deeper and lighter shades, stripes, and tinges in the several colours. Indeed Martyn observes, that the varieties produced of late years from the seeds of semi-double flowers are unbounded; and that Mr. Maddock remarks that they are more numerous than of any

other
other flower. Accordingly his catalogue, he says, boasts nearly eight hundred, all with their proper names: ranged under the heads of—dark and dark purple; light purple and grey, &c.; crimson, &c.; reds, &c.; roys, &c.; orange, &c.; yellow and yellow spotted, &c.; white and white spotted, &c.; olive, &c.; purple and coffee-striped, &c.; red and yellow-striped; red and white striped.

And according to the above flower gardener a fine ranunculus should have a strong straight stem from eight to twelve inches high. The flower should be of an hemispherical form, at least two inches in diameter, consisting of numerous petals gradually diminishing in size to the centre, lying over each other, so as neither to be too close nor too much separated, but having more of a perpendicular than horizontal direction, in order to display the colours with better effect. The petals should be broad, with entire well-rounded edges; their colours dark, clear, rich or brilliant, either of one colour or variously diversified, on an ash, white, sulphur or fire-coloured ground, or else regularly striped, spotted or mottled, in an elegant manner.

In the second species there is a variety with double flowers, which has been obtained by seeds, and is preferred in many curious gardens for the beauty of its flowers. It is by some gardeners called the Fair Maid of France. The root is perennial, and composed of many strong fibres: the leaves are divided into fine lanceolate lobes; the four side-lobes are upon footstalks coming from the side of the principal stalk, and the middle one terminates it; they are deeply serrate, and have several longitudinal veins. The flasks rise a foot and half high, and branch out at the top into three or four divisions, at each of which there is one leaf, of the same shape with the lower, but smaller. The flowers are pure white, and very double, each standing upon a short footstalk. The flowers come forth in May.

In the third sort there is also a variety with double flowers, which is the root most generally cultivated in the garden. It is frequently among other herbaceous perennials, under the name of Yellow Bachelor’s Buttons.

And in the fourth species there is a variety with double flowers, which is the root cultivated in the gardens for its ornamental effects.

**Method of Culture.**—The first sort and different varieties may be readily increased by the off-sheets taken from the root, and new varieties may be raised from seed. In the third of these methods the off-sheets should be separated from the roots in dry weather, in the latter end of summer, when the flowering is over, and the stems and leaves are declining, being placed in bags or boxes, in a dry place, till the autumn, when they should be planted out in rows six or eight inches apart, and fix of them to each, in separate beds, prepared with light sandy earthy compost, to the depth of two or three feet; taking care to protect them carefully from the frost during the winter. When the buds begin to break through the ground they should be kept perfectly clear from weeds, protecting them from frosts; and when they have flowered and the stems are decayed, the root should be taken up; cleared from dirt, and placed in bags or boxes till the autumn, when they must be planted again.

But in the second mode, the seed should be collected from the bell plants of the semi-double kinds, and be sown in flat pans or boxes, filled with light rich earth, in August, covering it in about a quarter of an inch thick with the same sort of earth, placing them in a shady situation, so as to have a little of the morning sun. The pots should remain here till the beginning of October, when the plants sometimes appear, though it is often later before this happens, when they should have a more open exposure with the full sun; but when frosts are apprehended, they should be removed under a common hot-bed frame, being only covered in the nights and bad weather with the glass, guarding them well against rains and frosts. In the spring following they should be exposed to the open air, being very slightly refreshed with water, having a situation to enjoy the morning sun; and when their leaves and roots begin to decay, the roots may be taken up, dried in a proper place, and then put up in bags to be planted out in the same manner as the old roots in October.

In the following summer they will produce flowers; when such as are good should be marked, and the others removed from them. The plants intended to flower should not be suffered to run to seed, as roots which have produced seeds seldom furnish fine flowers afterwards. The disappointments experienced in purchasing these roots, chiefly depend upon this circumstance.

It may be noticed that the roots intended for the borders should be planted towards the spring in little clumps or patches, three, four, or five roots in each, putting them in either with a dibble or trowel, about two inches deep, and three or four shovels in each patch, and the patches from about three to five or ten feet distance, placing them in a varied manner in the borders.

And in regard to their general culture after planting, each of the forward autumnal-planted roots of the choice sorts in beds as have shot above ground, should in winter, where convenient, have occasional shelter from hard frosts, by mats supported on low hoop arches; or in very severe weather be covered close with dry long litter, removing all covering in open weather; and in the spring, when the flower-buds begin first to advance, shelter them in frothy nights with supported mats, suffring them, however, to be open to the full air every day; but the latter plantings, that do not come up in winter, or very early in spring, whilst frothy nights prevail, will not require any protection, and all those distributed in patches about the borders must also make their chance in all weather: those of the different shades of planting will succeed another in flowering from the beginning of April until the middle of June, though the May blow generally flews to the greatest perfection. After the blow is past, and the leaves and flanks withered, the roots should be taken up and dried in the shade, then cleared from all off-sheets and adhering mould, putting them up in bags or boxes till next planting season, when they must be planted again, as directed above.

But in each season of planting, it is highly necessary, in the principal fine varieties, to put them either in entire new beds, or the old ones refreshed with some fresh rich earth or compost, working the old and new well together, in order to invigorate the growth of the plants.

All the other species are capable of being easily raised by the roots, which should be clipped or parted in autumn when past flowering, or in the spring before they begin to shoot, and the slips be either planted at once, where they are to remain, or in nursery-rows for a season, then planted out finally. They succeed in any common foil and situation, and may be dispersed about the different flower-borders and clumps, where they constantly remain, only trimming them occasionally; and once in a year or two, or when they have increased into large bunches, taking them up in autumn or spring, to divide them for further increase, replanting them again directly.

In having feed for raising new varieties, it must be suffered to continue on the plant till it becomes brown and dry,
Naturalists divide birds into rapacious, carnivorous, and frugivorous.

The characteristic notes of rapacious birds, which are the Accipitres of Linnaeus, are, that they have a great head, and a sharp neck; hooked, strong, and sharp-pointed beak and talons, fitted for tearing of flesh; strong and brawny thighs, for flinging down their prey; a broad thick fleshly tongue, like that of man; twelve feathers in their train; and twenty-four flag-feathers in each wing, and the two appendices, or blind guts, are always very short.

Rapacious birds have a membranous stomach; and not a mucilaginous one, or a gizzard, such as birds have which live on grain.

They are very sharp-fighted, and gather not in flocks; but, generally speaking, are solitary; though vultures will fly yearly or yearly in a company.

RAPAKIV, in Mineralogy, a name given to the aggregate of felspar and mica: its colour is brown, or brownish-red; it moulders by exposure to air, but that is only when the mica is in excess. When the felspar exceeds, it forms a durable stone, called in Italy "Granitone." Kirwan.

RAPALLO, in Geography, a town of the Ligurian republic, situated on a bay to which it gives name; 12 miles E.S.E. of Genoa.

RAPANEA, in Botany, according to De Theis, its vernacular name in Guiana; though Aublet says nothing to that effect.—Aubl. Guian. v. i. 121. Jull. 288. Lamarck Illistr. t. 122.—Clade and order, Pentandria Monogyria. Nat. Ord. Berberiditae, or rather perhaps Rhamnii, or Sapone; Jull.

Gen. Ch. Cal. Perianth inferior, minute, of one leaf, with five or fix teeth, permanent. Cor. of one petal; tube very short; limb in five or fix deep roundish segments. Stam. Filaments five or fix, inserted in the tube at the base of each lobe of the limb; anthers oblong, quadrangular, of two cells. Fil. German superior, rondish, of five or fix cells; style very short; stigma obtuse. Pet. Drupa globular, of one cell. Seed solitary, globose.

Eff. Ch. Corolla in five or fix deep segments, opposite to the stamens. Anthers quadrangular. Drupa superior. Seed solitary, globose.

1. R. guianensis. Aubl. Guian. t. 46. (Samara floribunda; Willd. Sp. Pl. v. i. 665. —Native of thickets, in the skirts of meadows, in Cayenne and Guiana, bearing flowers and fruit in December. A small tree, whose trunk is five or six feet high, and four or five inches thick, crowned with branches; the wood white, not very compact. Leaves alternate, on short stalks, ovate, obtuse, entire, smooth, two or three inches long, with one rib, and many transverse veins scarcely visible when fresh. Flowers copious, small, white, in dense lateral tufts. Fruit violet-coloured.—Mr. Brown, in his Prodromus Nov. Holl. v. i. 533; speaks of this shrub as belonging to the genus Myrsine, see that article; consequently Jullian was most correct in hinting its affinity to his Sapone, an order from which Ventenat and Brown have separated their more recent one of Myrsineae, to which we refer the reader.

RAPATAE, apparently a vernacular name of the plant in Guiana, Aubl. Guian. v. i. 507. t. 118. Jull. 44.—Lamarck Illistr. t. 226. See MNAUS.

RAPAX, in Ichthyology, a name given by Schleuneveld to the Porus pictus of some writers, a species of chub or cyprin, called Rapp by the Germans, and by Géfner and others capito fluviatilis rapax.

RAPE, RAPITR, in Latino, a ravifying; or the having carnal knowledge of a woman by force, and against her will.
will. If the woman conceived, the law formerly esteemed it no rape; from an opinion, that the cannot conceive, unless she confented. But this opinion has been since questioned.

Coke on Litt. lib. ii. cap. 11.

This crime, by the Jewish law, Deut. xxii. 25, was punished with death, in case the damsel was betrothed to another man; and in case she was not betrothed, then a heavy fine of fifty shekels was to be paid to the damsel's father, and she was to be the wife of the raverisher all the days of his life; without that power of divorce, which was in general permitted by the Mosaic law.

The civil law (cod. 9. tit. 15.) punishes the crime of ravishment with death and confiscation of goods; including under this crime both the offence of forcible abduction, and all that of forcibly dishonoring; either of which, without the other, is in that law sufficient to constitute a capital crime.

And the dealing away a woman from her parents or guardians, and debauching her, is equally penal by the emperor's edict, whether the consent, or is forced.

Rape was punished by the Saxon laws, particularly those of King Athelstan, with death; which was also agreed to by the old Gothic or Scandinavian constitution. Instead of this, another punishment was inflicted by William the Conqueror, viz. castration and loss of eyes, which continued till after Barton wrote in the reign of Henry III. But it was then the law, and still continues in appeals of rape, that the woman should immediately after go to the next town, and there make discovery to some credible persons of the injury she has suffered; and afterwards should acquit the high constable of the hundred, the coroners and the sheriff, with the outrage; the time of limitation for this purpose was by flat. Weilm. 1. cap. 13. extended to forty days. But there is now no time fixed; for as it is now usually punished by indictment at the suit of the king, the maxim of law takes place, mulum tempus occurrat regi: however, the jury will rarely give credit to a female complaint. During the former period it was also held for law, that the woman (by consent of the judge and her parents) might redeem the offender from the execution of his sentence, by accepting him for her husband, if he also was willing to agree to the exchange, but not otherwise.

In the 3 Edw. I. by the flat. Weilm. 1. cap. 13. the punishment of rape was much mitigated; the offence being reduced to a trespass; if not prosecuted by the woman within forty days; and subjecting the offender only to two years imprisonment, and a fine at the king's will. But in the 13 Edw. I. it was found necessary to make the offence of rape felony, by flat. Weilm. 2. cap. 34. And by 18 Eliz. cap. 7. it was made felony without benefit of clergy; as also the abominable wickedness of carnally knowing or abusing any woman-child, under the age of ten years; in which case the consent or non-consent is immaterial, as, by reason of her tender years, she is incapable of judgment and discretion. Sir Matthew Hale is indeed of opinion, that such profligate actions committed on an infant under the age of twelve years, the age of female discretion by the common law, either with or without consent, amount to rape and felony, as well as farce, as before the statute of Queen Elizabeth; but the law has in general been held only to extend to infants under ten. A male infant, under the age of fourteen years, is presumed by law incapable of committing a rape; and, therefore, cannot be found guilty of it.

The civil law seems to suppose a prostitute incapable of any injuries of this kind; not allowing any punishment for violating the chastity of her who hath indeed no chastity at all, or at least hath no regard to it. But the laws of England hold it to be felony to force even a concubine or harlot; because the woman may have forsoaken that unlawful course of life.

As to the material facts requisite to be given in evidence and proved upon an indictment of rape, we shall here only observe, that the party ravished may give evidence upon oath, and is in law a competent witness; but the credibility of her testimony must be left to the jury, upon the circumstances of fact that concur in that testimony: e. gr. if the witness be of good fame; if she presently discovered the offence and made search for the offender; if the party accosted fled for it; and the like are concurring circumstances, which give greater probability to her evidence. But, on the other side, if the be of evil fame, and stands un supported by others; or if the concealed the injury for any considerable time after she had opportunity to complain; if the place, where the fact was alleged to be committed, was where it was possible she might have been heard, and the made no outcry; and the like circumstances carry a strong, but not conclusive, presumption, that her testimony is false or feigned. Moreover, if the rape be charged to be committed on an infant under twelve years of age, the may still be a competent witness, if the hath fewe and understanding to know the nature and obligation of an oath; and, even if the hath not, it is thought by Sir Matthew Hale that the ought to be heard, without oath, to give the court information; though that alone will not be sufficient to convict the offender. And, indeed, it is now settled, that infants of any age are to be heard; and if they have any idea of an oath, be to be sworn: it being found by experience, that infants of very tender years often give the clear and truest testimony. Blackft. Com. book iv.

The civilians make another kind of rape, called subornation, rape of subornation, or seduction; which is, when a person seduces or entices a maid to uncleanness, or even marriage, and that by gentle means; provided there be a considerable disparity in age or condition between the parties. In this case, the father and mother intend their action reciprocally for the crimes rape, or subornation.

The French laws make no difference between the rape of violence and that of solicitation, or subornation; they make both capital. This kind of rape our laws call Ravishment; which fee.

Rape of the Forrest, is a trespass committed in the forest by violence.

This is mentioned in the laws of Henry I. as one of the crimes cognizable alone by the king.

Rape is also a name given to the wood or flalls of the clusters of grapes, when dried, and freed from the fruit.

The rape is used in making vinegar, serving to heat and four the wine: but it is first put into a place to four itself, before it be cast into the vineyard vessel; to which end, presently after the vintage, it is carefully put up in barrels, lest it take air, otherwise it would heat itself and be spoiled. There is no other way of keeping rape hitherto discovered, but to fill the vessel, in which it is contained, with wine or vinegar.

Rape, Rape, is also used for a part or division of a county; signifying as much as a hundred.

Though sometimes rape is taken for a division containing several hundreds. Thus Sufflet is divided into fix rapes; viz. those of Chicheleur, Arundel, Bramer, Lewes, Pevensey, and Hastings; every one of which, besides its hundreds, has a castle, a river, and forest belonging to it.

The like parts in other counties are called tithings, lathes, or wastepotes.

Rape, in Botany. See NAPUS.

Rape, Broom. (See Orobanch. ) It frequently grows 1
to the roots of genista or broom, whence it is called *rapum gentile* or broom rape: it is also found among corn. The herb preferred, or its syrup, is said to be of excellent use in ptenile and hypochondria disorders, and an ointment prepared of it with ivine's fat, is good for hard and scirrhous tumours.

**Rape, Wild.** See Mustard.

**Rape, in Gardening,** the common name of a plant of the cabbage kind. The variety called the French turnip, or *Brassica napus,* has been long cultivated upon the continent, and preferred to the common turnip as a culinary vegetable. And it has been lately noticed in the *Transactions of the Horticultural Society,* that it has been brought to the principal London markets for more than twelve years past by one person only, and sold chiefly to foreigners, though, when once fully known, it will be found a very useful and acceptable root in most families, as being more delicate in its flavour than the common turnip. It is used in much the same manner. It enriches soups, and there is not any necessity for cutting away the outer skin or rind, but only to separate it, as it is a great deal thinner than that of the turnip. When stewed with gravy it forms an excellent dish, and being white and shaped like the carrot, when laid alternately with those on a dish, they become very ornamental. The French dress them somewhat in this manner.

The roots are to be washed quite clean by means of a brush; then quartered, cutting a thin slice away from the top and bottom parts, so as to make them all of equal lengths: after which boil them in water, with a little salt, until they are tender; then put them into a saw pan, with a Gill of veal gravy, two spoonsfull of lemon pickle, one of mushroom ketchup, a little mace, and salt, letting them boil simmer, but by no means boil, for a quarter of an hour; afterwards thicken the gravy with flour and butter, serving the whole up quite hot. Some add a few spoonfuls of cream mixed with yolk of egg to this, just before dishing up; and others dress them in a similar manner to the above, sliced rather thinly, with Madeira, or other wines, after they have been fried to a brownish colour. See Brassica.

**Rape, in Agriculture,** the name of a plant much cultivated for its seed, and also as a green food for cattle and sheep. The methods of culture and management that are necessary in raising crops of this sort, have been already described and explained. (See Cole.) It may, however, be here necessary to detail a few of the experiments that were made under the direction of the Dublin Society, by Mr. Whyn Baker, about the years 1769 and 1770, as they tend to throw additional light on the nature of the plant, as well as its cultivation, though the soil was not the most suitable for it. It was a shallow soil, of a strong adhesive nature when wet, and when perfectly dry, in lumps, almost impregnable; but between wet and dry, reducible. It lies upon a bed of lime-stone quarry, and has a natural declivity to the north-west; naturally very poor, and, he believes, never received any manure until he dressed it. Three acres of this land were, in 1768, under potatoes, in the ordinary method of the country, in seven-foot beds, and four-foot trenches. In 1769 they were under drilled turnips.

The frost, snow, hail, and rain which they had this year in the months of March and April, rendered it impossible to get the ground in any tolerable condition for the rape seed before the 28th day of April. On that day twenty

broad sets were sown, with twelve ounces of rape-seed to each set or ridge. He intended to have sown it earlier, but the event will shew, that, as it was, he sowed it too early, at least upon this ground.

It was flow in coming up, and made but a poor figure until July. After which it shot forward; but instead of affording a plentiful mowing crop for the purpose of foddering cattle, it soon began to run up very tall, broke out into branches, with few and small leaves, like rape in blossom from the autumn sowing, but with strong branches and few leaves; and, in a short time after, began to grow hard, pipey, and the feed to form.

It September he began to sow it for cattle, and they ate it with great eagerness, but every day it became morey, by growing harder; infomuch, that before it was exhausted there was very great waste, as to the object of fodder, but it wonderfully raised the dung-hill, which, in his mind, is of the first moment to the farmer: for if he has manure in plenty, and disposits of it judiciously, there is hardly any thing he need to fear, except climate.

It was pretty far in October before all his rape was cut, (and the feed coming forward very fast,) although it was brought home in great profusion. It was so strong, that the mowing of it could not be accomplished with a common scythe; it would have broken an hundred; but he had by him a short strong scythe, with a thick back, intended to mow bulks and other rubbish; with this instrument he got it mowed, but not so close to the ground as he wished, it being next to impossible to mow such strong plants as these were close to the ground; and he became the before-mentioned. He was, in fact, to the saying, as the leaves fall from the trees, so do the fields from the hand of the harrower, or the rape shooting up in tall stems, he gave up his intention of mowing the ground with wheat, as was originally intended. Hence he concludes, that the rape was sown much too early.

On the 16th of July he transplanted some of this rape in rows upon ridges four feet wide; these plants flourished much better than the former, and were at leaf four times the size of any of those left in the ground where they were sown. Nevertheless, they also ran to feed; but the cold nights coming on prevented their forming their feed like the former. They were vastly more fappy, and much better food for cattle.

On the 24th of July, he drilled rape-feed upon the same ground.

N° 1. Six ridges four feet wide, and thirty-two perches long in single rows.

N° 2. Six ridges the same length and breadth, in double rows, ten inches asunder.

It is observed, that the double and single rows were drilled alternately on the same ground, on the 18th day of July.

N° 3. Six ridges four feet wide, and thirty-two perches long, drilled in single rows.

N° 4. Six ridges the same length and breadth, in double rows, ten inches asunder.

He remarks, that these were sown in alternate rows, on the same ground, on the 24th of July. And that the several rows were thinner the latter end of August, and twice horse-hod during the summer. On the third of April 1771, he had a row of each of these cut and weighed, and the produce was as follows:

On the whole, it is stated, that the last sowing in July afforded considerably greater produce than the first, for the plainest reason, that the earlier we sow this feed, the sooner it runs; and consequently affords the least produce for the purpose of foddering cattle in the yards for making dung, and seems to account very strongly for the failure of the first experiment.

And the double rows produced uniformly more than the single rows; and indicate that the double are to be preferred in drilling rape for foddering cattle.

The following trials are on sowing rape-feed broad-cast. On the 24th of July two acres were sown broad-cast, with ten pounds of feed to each acre, in the same field where the other experiments were carried on; but the soil not so stiff by a good deal, has abundantly fewer loose stones in it, is very shallow, and poor, to an incapability of producing any thing to profit, without great allowance of manure.

In July he manured it with the dung of his yard, confuming of that of horned cattle, horses, and swine. The drilling was indeed very high; about two smart one-horse cart-loads to a perch. He having ever found that one acre, highly improved, is much more valuable than five imperfectly handled, was the reason why he gave this poor piece so liberal a dressing.

The rape came up but slowly for a time, as he finds to be the nature of the plant, but at length it shot forward, and flourished away; but in winter it met with a fate which he was not aware of, nor did he expect. The wood-pigeons lay upon it prodigiously, and did it great damage. Some plants he observed in the frost to appear as if they had been tilled; whether that was owing to the worms given by the birds, and thereby giving the frost the greater force, or whether it was owing entirely to the severity of the frost, is not in his power to determine. However, very early in the spring this rape shot forward, and as the days lengthened the visits of the pigeons were less frequent, until they totally left it.

From this rape breaking out into blossom sooner than he expected, he is inclined to believe that the 24th of July is too early to sow it for the purpose of foddering cattle in the yard.

However, early in April he began to sow this rape for the horned cattle, such as cows, plough bullocks, young cattle, calves, and swine. They all ate it with the greatest eagerness, and were foddered with it every evening, until the 10th of May inclusive, and wheat sown in a morning, three or four calves of the preceding year; and they were foddered twice a day with rape, and had straw before them also, and thrown upon it hastily better than the other cattle; for no other reason, he believes, than because they were allowed more than the others: in short; they were in such order, that he dares believe the butchers would have been glad to have had them for killing.

Exp. 1. April sowing.  Ran. not answering the purpose.
11. Ditto transplanted.  Ran. but not so soon as the other.

Double rows ditto 32 12 23
Double ditto 35 18 0 9
11. September sowing on wheat rubble ditto 15 0 0 0

Rape is a great deal cultivated in some districts in the county of Essex for the feed. The system is very profitable, but this sort of crop is found to draw or exhaust the land a good deal. It is thought bome to prepare well for wheat, especially when fed off upon the land. In some places they, however, consider it more beneficial to till, after this crop has been fed for spring corn, than to put in wheat, which, however, is still the most common practice. Clover would certainly be better than either method.

In some places they conceive that feeding rape is much on the decline, from the general experience, that it leaves the best prepared land in an unfavourable state for oats and clover,
clover, and is consequently prejudicial to the next succeeding winter crop. Other districts think very differently on this point. In feeding the crop, the produce is here considered to be in general from twenty-nine to thirty-four bushels the acre. In the greatest crops and best seasons, in particular parts it is supposed to rise even to fifty and sixty quarters the acre.

In Berkshire this sort of crop is not so much cultivated as it should be, as it will succeed well on soil where turnips will not, and with equally beneficial effects to the future crops, when fed off on the ground. When employed it is usually sown and managed as to come into a high rate of perfection in the earlier spring months, when sheep feed is, most likely scarce. It is grown by some to supply the deficiency, and by some remarkably useful, one acre of it affording more feed than two of turnips.

This sort of crop is still less grown in Oxfordshire, though occasionally had recourse to, especially on the rich red land about Banbury. Some few it in mixture with the tankard turnip feed, for the purpose of weaning lambs upon; they begin with the rape, and it teaches them to eat the turnips, it is found to be a very good food for this sort of flock.

In the county of Suffolks, the South Down sheep farmers hold it in great estimation, sowing it either alone or in mixture with tares as a food for their sheep; very rarely for the purpose of feeding. The ewes and lambs are fattled upon it in the spring, and it is very generally allowed to be most efficacious, and highly nutritious to the young lambs. Some, at the lambing season, hardly allow their ewes any other food but this; as the rape is found to produce a larger supply of milk than turnips; which, it is supposed, has the effect of extending the udder, without affording any considerable flow of milk. This crop is conjectured, however, in some cases, to have the effect of causing the flipping of the lambs, where the ewes are fed upon it. But such an effect is very improbable to arise in this way; other causes may have been overlooked. In some cases on Down land ray-grafs is sown with the rape for sheep feed, one gallon of rape-feed and two of ray-grafs to the acre. The rape is first fed off; and after that the ray-grafs rife and affords a bite for the spring selenium. The rape crop is usually put in about June, or the following month, one gallon to the acre. When folded off, a rowd and a half is a sufficient daily consumption for a flock of six hundred sheep, or rather more.

As it has been found in the improving of peat boggy moratory lands, that what is principally wanted is a crop which can be sown and reaped in the summer months; and which may require neither labour nor attendance during the moist feasons of autumn, winter, and spring; the writer of the "Treatise on Landed Property" has suggested that fortunately, such a crop is natural to, and has long been ingrown to the climate of this island, as well as one of the most profitable in the agriculture of it; and that this is rape: which is not only sown, but reaped, in the very height of summer; and which is known to delight in a foil of this nature. It has, however, only lately been found capable of being raised with advantage on rough moor ground, as a first crop after draining, from some recent trials made in the north, after the above operation, levelling, paring and burning, and turning the ashes in. The result of which was, though the crop was too late in being put in, and the land laid in an improper manner, such as to prove clearly that rape-feed may be raised with profit as a first crop on drained moorish foils. And it is thought highly probable that many extensive tracts of land, which now lie entirely waste, and as nuisances in their neighbourhoods, may through this means be improved with immense profit to their proprietors. The experiment may be tried at a small expense. The cost of the labour and feed required for a sufficient trial are inconceivable. The proof, it is supposed, is not whether rape will thrive as herbage, but whether it will mature its feed, on the given foil, in the given situation.

After being recomputed for the previous expenses, in one or more rape crops, as there is here no danger of the exhaustion of the soil,—of impoverishing, perhaps, ten feet depth of vegetable mould, it remains to lay the foundation of more permanent profits, which is to be done by fowling grasses feeds either with or over the rape crop, or by light cautious flocking after removing the flalles, as may be necessary, until there is a firmness of surface and a fitness for mixed cultivation, which may be much hastened by the use of heavy calcareous and earthy substances at any time during the process of improvement.

Rape Cake, the refuse or cake remaining after the oil has been expressed from rape-feed. It is said to be useful as a manure. See MANURE.

This substance is found by chemical trials to contain a large quantity of muckleigh, some albuminous matter, and a small quantity of oil. It should be kept dry, as possible before it is applied to the soil, and be employed in that way as soon as it is in a fresh state. It is successfully applied in several ways and intentions, and affords an excellent dressing for turnips. See the next article.

Rape Dyi, the small reduced parts of the dried refuse of rape-feed, or the rape cake, after the oil has been obtained from it. This sub stance has been found useful as a top-dressing for crops of different kinds.

The rape cake, when reduced into powder or dust by means of a machine, has been extensively used in Norfolk; and when for turnips crops, it has been the custom to sow it some weeks before the feed of that root is put into the ground. In the practice of Mr. Coke of that district, it has, however, been found, that by having it brought into a fine powder it may be drilled from the same machine, at the same time with the turnip feed; and that, by thus delivering the manure and the feed from the same pipes and shares of the drill machine, a ton of dust does fix acres in the place of three. See TURNIP.

In Lancashire some farmers use it with great advantage as a manure for potatoes, putting it in with the lets in the proportion of about thirty-two bushels to the statute acre; but if the ground were well prepared, and the dust carefully deposited for the reception of the lets, it is supposed, a much smaller quantity would be sufficient. It produces much luxuriance in the crops, and a very fine produce.

Rape Oil, the oil obtained by means of expression from the feeds of this plant, in mills constructed for the purpose. The refuse oily substance of this kind may be employed as manure in mixture with rich earthy matters, with great advantage, wherever it can be procured in any quantity at a reasonable price.

RAPEL, in Geography, a river of Chili, which runs into the Pacific ocean, S. lat. 34° 8'.—Alto, a town of Chili, on the forementioned river; 70 miles S. of Valparaiso.

RAPERLAH, a town of Hindooftan, in the Carnatic; 13 miles N.E. of Ongole.

RAPHAE, in Anatomy. See RAPHE.

RAPHAEL, one of the seven archangels, who are said to be continually before the throne of God, and ready to perform his commands. We have no such name in the Old or
RAPHAEL.

or New Testament; but his history occurs in the book of Tobit, c. xii.

If the story of Tobit be true, it is not improbable that the angels, both good and bad, whose names do not appear to have been known before the Babylonish captivity, are figurative personages; and Raphael might only denote the futal protecting agency of divine providence, fo diffusing events as to produce a happy issue.

Raphael Sanzio, da Urbino, in Biography, during whose life, and by the exertion of whose talents, in conjunction with those of Leonardo da Vinci, Titian, Michael Angelo, and some few others, the art of painting reached its acme in modern times, was born in the city of Urbino, on the morning of Good Friday, in the year 1483. He was descended from a respectable family, and many of his ancestors had been painters; as was his father Giovanni Sanzio, whose talents, however, did not elevate him to the first rank. He cultivated with care the inclination which his son Raphael exhibited, at an early age, for painting; and was soon repaid by the affluence he acquired from him, in several of the pictures he was employed to paint in his native city of Urbino. But finding that the taste of Raphael merited more skillful guidance than he was able to give it, he placed him under the tuition of Corradini, better known by the name of Carnevale, for a short time, till he could be received as a pupil by Pietro Perugino, at Perugia.

This matter was then in very high esteem, though his style was dry and meagre, in comparison with that of Ma- faccio, and others of the Florentine school. It is not surprising that Raphael, endued as he was by nature, and trained as he had been in art, should soon become the rival, rather than the pupil, of such an artist. Accordingly we find, that his aptitude for the practice of art enabled him to quickly acquire his master's manner, and that in so perfect a degree, that connoisseurs were puzzled in their judgments upon the works which proceeded from Perugino's studio; and ordinary observers completely deceived. Vafari speaks of an Assumption of the Virgin, crowned by her Son, and the twelve apostles below, round her tomb, contemplating the celestial glories; with three small pictures in the same frame below it, of the Annunciation, the Adoration of the Magi, and Simon embracing the Saviour, painted at this period by Raphael, as being wrought with extreme beauty, and precisely like the work of Perugino.

We have to lament that we are left ignorant of the time when Raphael went as a pupil to Pietro, how long he remained with him, or when he left him, or rather was left by him; as that matter returned to Florence, to finish some pictures he had begun there some time before. He must certainly have been very young, from the number of pictures which he subseqently executed, previous to his going to Rome in his 25th year, and probably not more than 16 or 17, when he acquired his liberty by the departure of Perugino.

From Perugia he went to Citta di Castello, where he painted a St. Nicola crowned by the Virgin and St. Augustin, for the church of St. Augustine; and for that of St. Dominico, a picture of the Crucifixion of Christ, accompanied by angels, the Virgin, St. John, &c.; which would certainly have been considered as Perugino's, if Raphael had not set his name to them. But he was considered to have much surpassed him in another work, representing the marriage of the Virgin and St. Francisco, for the church of St. Francisco, in the same city. He acquired by these productions a great and deferred extent of fame; and thus early entered with success that course, which conducted him to the highest pinnacle of renown as an artist.

Attached to his patron by friendship, and attracted by his skill as a designer, Pinturicchio, then employed by Pope Pius II. to adorn the library of the Duomo at Sienna, sought the affiance of Raphael, and engaged him to compose designs for his work. This he undertook, but proceeded only to the preparation of some of the cartoons, when his ambition and his curiosity were kindled, and his work interrupted, by the renown spread through the country of the cartoons painted by those great rivals, Leonardo da Vinci and M. Angelo, for the council-hall at Florence. He immediately determined, in conjunction with almost all his brother artists of the day, upon going to see and form his judgment upon them for himself; and consequently left his engagement with Pinturicchio, and proceeded to Florence.

In this city he found so many attractive beauties, both of nature and art, that he resolved to fix his residence there for some time. His agreeable person and manners, combined with the extraordinary talents he had manifested, flavored him friends; and he became intimate with several artists of celebrity, among whom were Ghirlandio, St. Gallo, and Taddeo Taddi; the latter of them, a learned man, and friend of cardinal Benotto, took the youthful painter to his house and table, and thus afforded him the best introduction to the world, while he purified his more immediate studies. This kindled the gentle heart of Raphael accepted with grateful emotion; and as he presented several pictures during his residence in that city, he presented two of them to Taddi. One of these pictures, a Madonna with the Child, and St. John, bringing a little bird to him, the heirs of Taddeo fold to the archduke Ferdinand Charles of Austria at a great price: the other is lost sight of. He also presented a picture to his friend Lorenzo Nafi, which afterwards found a place in the Medicean gallery, and a duplicate in that of the monastery of Valombrosa.

From Florence Raphael was recalled to Urbino, by the death of both his father and mother; and there, when he had arranged his private affairs, he was engaged by Giudobaldo de Montefeltro, and several others, to paint religious subjects for the altars of their chapels; and among those he painted at this time, were the two little St. Georges, now in the gallery of the Louvre. These commissions he executed with great taste and delicacy; and Vafari, who enumerates them, more particularly speaks of one of Christ praying in the garden, painted for Francesco Maria, duke of Urbino, as being faulted with all the neatness of a miniature. What is become of most of these pictures, it is not easy to ascertain; but it is a curious fact, that not one of them remains at this time to adorn the native city of this great artist.

Thence he returned to Perugia, and painted several pictures. For the church of the Frati de Servi, one of the Virgin, with St. John Baptist, and St. Nicholas. For that of St. Stevens, in the chapel of our Lady, he painted in fresco a picture of Christ in glory, with God the Father, surrounded by angels and six saints, three on each side. Upon this picture he wrote his name in large letters of gold, and very conspicuously, as if he himself was pleased with the performance of it. He also painted here a picture for the nuns of St. Antonio da Padua, of our Lady with the Infant upon her lap, and near her St. Peter, St. Paul, Sta. Cecilia, and Sta. Catherina. The airs and attire of the two female heads were regarded as the most tasteful work of the time, wrought with the greatest degree of beauty and grace. Above the picture, in a semicircle, was represented
Raphael.

represented the Almighty Father; and at the foot of it, in three compartments, were the scenes of our Lord's sufferings, viz. his agony in the garden, carrying his cross, and dead upon the lap of the Virgin. It is not known what is become of the centre picture, or the uppermost compartment; the lower ones formed a part of the Orleans collection. The execution of these works was performed in a style much improved upon that of Perugino; with more breadth, more softness, and more freedom and variety of action; proving that he had not ill spent the time he had devoted at Florence to the study of the works of other painters. Hence we may date the commencement of what is termed his second manner, from his first visit to that city.

Soon after he had produced these works at Perugia, that zeal for cultivation, which always accompanies true genius, led him to determine upon again visiting Florence, at that time the emporium of science and of art. Though the native strength and purity of his mind were such as to conduct him, under favourable circumstances, to his future prominent station; yet he does not appear to have been so extraordinary and original an inventor in the art itself as Michael Angelo, or his great predecessor and rival, Lionardo da Vinci. He knew how to take a hint of what was offered to his view, and to cultivate and improve it to his purpose; but it yet remains a problem, whether Raphael, alone, and without the leading aid of those great and original artists, would have ever been the fulmine of painting. His power may rather be said to have consisted in ability to employ the materials furnished by their invention, viz. the style of Michael Angelo, in form; and of Lionardo da Vinci, in chiaro-fuoco and colour; in beautiful conceptions, illustrative of the character and passions of man; and in an admirable felicity of subject, and mode of conveying it.

He himself appears to have been conscious of this; for we find him in the midst of honourable employment, leaving the execution of it, to study and improve himself by a constant observation of the works of other renowned artists, and again repairing to Florence, where alone he could find the true source of sound cultivation, and in which he made so good use of his time, as to fit him in great measure for the glorious field of exertion which awaited him.

On his return to the renowned abode of the great artists, from whose works he sought improvement, he had a letter of recommendation and introduction from the duchess of Urbino to Pietro Soderini Gonfaloniere of the city; and was thus introduced to the bell circle of improvement and information.

It would have been highly gratifying to have been enabled to trace the steps of a man so distinguished in the art, from the earliest commencement of his studies; but the neglect of dates, by his biographers, counteracts every wish to follow them more closely; and the record of facts leaves us only the means of conjecture. That he began to paint original pictures very soon after he was placed with Perugino is evident, and he must then have been very young, for it is on record, that the pictures by Pinturicchio, for which he made the cartoons at Sienna, were completed in 1503, at which time he was 20. If we allow, as we reasonably may, two years for their execution, it will place his first visit to Florence in 1501, at the age of 18; and it certainly cannot have been far from that period. In every part of his life, modelly, ingenuity, and the ardour of a mind entirely devoted to his art, characterized his conduct. His industry and ingenuity seem to have kept equal pace; and the rapidity and certainty with which he must have painted, to produce so many pictures in so short a space of time as he lived, are not the least extraordinary part of his history.

On this, his second abode at Florence, he studied deeply the works of Mafoacco, and the cartoons of Angelo and Da Vinci; and attached himself in friendship to Baccio della Porta, better known by the name of Fra Bartolomeo; than whom no one was better qualified to direct him rightly in whatever was grand and dignified, and from whose judicious information in the art of cultivating draperies and of colouring, Raphael evidently improved exceedingly; while he had the pleasure, in return, of communicating to his friend the principles of perspective. Yet notwithstanding these helps, he did not entirely free himself from the formal and dry manner of his master, though he painted affably both in portrait and history. In the former he produced the portraits of Angelo Doni and his lady Maddalena Strozzi; and in the latter he painted for Dominico Canggigioni, a Madonna, with the Infant playing with St. John brought by Elizabeth, who regards St. Joseph as he stands near, leaning both his hands upon a stick, and inclining his head towards her. This picture appears to have been re-touched, or possibly completed only in 1516, as the name of Raphael, with that date, in letters of gold, is written upon the drapery of the Virgin. He also made a cartoon during his residence in Florence for a picture which he had previously engaged to paint for the Baglioni family at Perugia, and left the city to go and paint it in the church of St. Franceso in that place. The subject of it was our Saviour carried to the sepulchre, accompanied by the Virgin, St. John, &c.; and it was exceedingly admired for the beauty and expression of the figures, and the skill and perfection of the draperies. This picture was removed from Perugia by pope Paul V., and a copy, by Cefare d'Arpino, placed in its stead; it afterwards found a location in the Borghese palace at Rome.

When Raphael had completed this work, he returned to renew his studies at Florence, and was employed by the family of Dei, to paint a picture for their altar in Santo Spirito, which he began, and conducted through the preparatory parts; and in the mean time painted another for the city of Sienna, of the Madonna in an open country, with the Child standing by her, and St. John kneeling before him, but was interrupted, in its execution, by a summons from pope Julius II. to Rome, and left it in the hands of his friend Ghirlandao, to finish a piece of blue drapery which it wanted. This picture was afterwards sold to Francis, king of France, and is at present in the French collection, known by the name of the Belle Jardiniere. The unfinished sketch of the picture begun for the Dei family, was bought, after the death of Raphael, from his heirs, by Baldassare Turini, and placed by him, in its original state, at the altar of his country church; it afterwards came into possession of the house of Buonvicino di Pefcia, and was sold, by that family, to the grand duke Ferdinand, who, on removing it, placed a copy by Carlo Sacconi in its stead. This was done at night, and with the utmost secrecy, for fear of a disturbance among the populace, by whom it was highly prized.

Raphael was indebted for the high patronage of the pope, which placed him in the proper sphere for the exercise of talents such as he possessed; to the friendship of his relation Bramante d'Urbino the architect; and never was recommendation better supported by ability. Upon his arrival in Rome, in 1508, he was received with great courtesy by Julius, and the Camera della Segnatura, in the Vatican, allotted to him. He immediately began the preparation for his first picture, which was the School of Theology, better known by the name of the Dispute of the Sacrament, and in observing which, it is worthy
RAPHAEL.

worthy of remark how his mind enlarged, in regard to style in the art, as he became accustomed to consider largely of his work; and according to the field of employment which he found before him. The difference in style between one part of the picture, and that of the other, evidently points out where he began it; viz. on the right of the upper part, where the remains of the school of Perugino appears, and is spread through the centre, where the glory which surrounds our Saviour is represented in the Gothic manner, by rays of gold. As he proceeded, his style enlarged, and the lower part of the picture exhibits an immense improvement, and is almost equal to any of his subsequent productions.

In the same room are the pictures of the School of Athens, the Panathenaeum painted in 1512, (where surrounding Apollo and the Muses, he has introduced portraits of the great poets, both of antiquity and of his own time,) and the Jurisprudence, comprising two subjects, one of the emperor Julianus delivering the digest of his code of laws to Tribonius, and another of pope Gregory IV. giving the decretal to a member of the consilium. Over each of these subjects, respectively, are painted circular ones of single figures, representing Theology, Philosophy, Poetry, and Juicice.

When pope Julius saw the superior taste and talent with which Raphael produced the former of these works, he immediately ordered the whole of the flanze, or chambers, which it was intended to decorate, to be entrusted to him; and all that had previously been done by Perugino, Pietro del Borgo, II Sodoma, and Bramante di Milano, to be removed. But of this order Raphael made only a partial use; preferring entirely the work of his master, and, partially, the ornamental labours of II Sodoma.

While he was engaged upon these great works, he was not altogether indifferent to the more allowable exercice of the pencil, and he painted for the church of the Augustines, the pictures of the prophet Isaiah, and the Sibyls who are supped to have predicted the coming of Christ. He also painted the portrait of his great patron, Julius, now in the Louvre, and several smaller cabinet pictures of Madonnas, and other religious subjects. Of these labours he acquired the renown they so well merited, and his manners appear to have been in perfect accordance with the beauties of his mind. His person also was handsome, and he was beloved, efeemed, and admired. Yet he continued to study, and to improve his talents, employing persons to collect specimens and make drawings from Grecian remains. Full of taste and feeling, he spared no pains to perfect his powers by a thorough knowledge of all that had been done in art, both ancient and modern. In consequence, however, the task, related by Vasari, may be doubted, of his being admitted, while Michael Angelo was absent, to see the work of that great artist in the chapel of Sixtus IV.; the task in which he wrougt became aggrandized, and similar to that introduced by M. Angelo. About this time he painted the Galatea for Agostino Ghigi, and the Madonna di Foligno, at the defire of Sigismondo Conti, secretary of pope Julius II., for the great altar of the church at Araceli, and which is now at the Louvre.

In another chamber of the Vatican he painted four other large pictures, the subjects of which are, the miracle of Bollena, when the officiating priest, who doubted of the real presence in the Eucharist, is offering up the bolt, and perceiving, with astonishment, that it difulls drops of blood; the releafe of St. Peter from prison; the Heliodorus; and Attila arrested, in his journey to Rome, by a vision of St. Peter and St. Paul; these were completed in 1512, 13, and 14.

In these pictures his great improvement in colouring and style is most evident, and he continued to carry it still further into practice in another room, for which also he had compos’d four other subjects, known as the Incendio del Borgo; the coronation of Charlemagne by Leo III.; the fame pope defending his conduct to the same emperor; and the defeat of the Saracens at the port of Oltia.

Whilst Raphael was engaged on the Heliodorus, his first great patron, Julius II., died; but fortunately for the arts, if not for the tiara, he was succeeded by another, Leo X., who was even more attached to them, and more fond of the renown arising from the cultivation of whatever adorns society. By him, therefore, Raphael was ardently encouraged to proceed with his labours, and he continued to make designs for other apartments, particularly for the great hall of Conflantine, as it is now called; but he did not live to execute them. The Incendio del Borgo was the last upon which he himself wrought; the rest were completed by Giulio Romano. He was also employed by Leo to make the cartoons now at Hampton Court, as exemplars for works in tapestry, to be executed in Flanders, and which were completed at the expense of 70,000 crowns. Fortunately for us the originals were never returned to Rome, and were purchased afterwards by Charles I.

Upon the death of Bramante, in 1514, the superintendence of the architectural concerns of the Vatican was entrusted to Raphael, who had already exhibited his knowledge and taste in that art, by the introduction he had made of it in his pictures. He invented and began a palace for himself, and made several designs for others.

Notwithstanding the immense application necessary for the invention and completion of these important labours, together with the desire he composed for the ornamental parts, and the scriptural subjects on the ceilings and the covings of the loggias and flanze of the Vatican, he found time to execute in fresco the designs which adorn the palace of Agostino Ghigi; the capital portrait of his great friend Leo X., with the cardinals de Medici and Roffi, now in the Louvre; the St. Michael, and the vision of Ezekiel, both in the great grand depôt; a Madonna, Child, and St. Anne, for Florence; and a large picture of Christ curing his Cross, for the monastry of St. Maria della Spina at Palermo. Of this picture it is supposed, that being sent on shipboard to go to Sicily, the vessel was beaten from its course by a tempest, and the mariners lost; when it drifted to Genoa, and of course its preservation was attributed to the divine influence of this great work. The Geneoche chose also to suppofe that the hand of God had thus pointed out their city as the proper place for its residence; and would not relinquish it for a length of time, till the papal influence interfered, when it was consigned to its original destination. He also painted the picture of St. John, which adorned the Orleans collection; and last of all, the Transfiguration; which indeed he had not quite finished when the unrelenting hand of death fet a period to his labours, and deprived the world of further benefit from his talents, when he had only attained an age at which most other men are but beginning to be ufeful.

The immediate cause of his death is allowed to have been brought on by too great an indulgence in gallantry, and, Vasari adds, by mismanagement of his physicians, who bled him when they ought to have administered reforatives. On his death bed he made his will, leaving his favourite pupils, Giulio Romano and II Fattore, his heirs, and ordering his burial
burial to take place in the Pantheon (the church of Santa Maria Rotunda), where a monument still remains to his honour. He died on the same day of the year on which he was born, Good Friday, in 1520, at the age of 37, deeply lamented by all who knew his value. His body lay for a while in state, in one of the rooms wherein he had displayed the powers of his mind, and he was honoured by a public funeral; his last produce, the Transfiguration, being carried before him in the procession; and, that Rome might not be deprived of so noble a memorial of this extraordinary man, it was placed by the cardinal de Medici in the church of St. Pietro a Montorio, instead of being sent to France, as was originally intended.

Mr. Fuseli, in his edition of Pilkington, has given so discriminating and just an idea of the peculiar excellencies of Raphael, that we shall conclude our history of him by quoting it. "The general opinion has placed Raphael at the head of his art, not because he possessed a decided superiority over every other painter in every branch, but because no other artist ever arrived at uniting with his own peculiar excellence all the other parts of the art in an equal degree with him.

"The drama, or in other words the representation of character in conflict with passion, was his sphere; to represent this, his invention in the choice of the moment, his composition in the arrangement of his actors, and his expression in the delineation of their emotions, were, and are, and perhaps will be unrivalled. And to this he added a style of design dictated by the subject itself, a colour suited to the subject, all the grace which propriety permitted, or sentiment suggested, and as much chiaro-fucre as was compatible with his supreme desire of perpécuity and evidence. It is therefore only when he forgoes the drama, to make excursions into the pure epic or subline, that his forms become inadequate, and were inferior to those of M. Angelo: it is only in subjects where colour from a vehicle becomes the ruling principle, that he is excelled by Titian; he yields to Correggio only in that grace and that chiaro-fucre which is left the minifter of propriety and sentiment, than its charming abufe, or voluptuous exces; and which facrififes to the eye what was claimed in vain by the mind.

"Michael Angelo appears to have had no incapacity: if he had, we are not acquainted with it; his earliest works equal in principle and elements of style the vigorous offprings of his virility: Raphael we see in his cradle, we hear him thunder: but propriety rocked the cradle, and character formed his lips. Even the trammels of Pietro Perugino, dry and servile in his style of design, formal and gothic in his composition, he traced what was essential, and separated it from what was accidental, in figure and subject. The works of Leonardo, and the cartoon of Pifa, invigorated his eye, but it was the antique that completed the sytem which he had begun to establish on nature. From the antique he learned discrimination and propriety of form. He found that in the construction of the body, the articulation of the bones was the true cause of ease and grace in the action of the limbs, and that the knowledge of this was the true cause of the superiority of the ancients. He discovered that certain features were fitted for certain expressiions, and peculiar to certain characters: such as a head, such hands, and such feet, are the elements or the growth of such a body, and on phyzogonomy established uniformity of parts. When he designed, his attention was immediately directed to the primary intention and motive of his figure, next to its general measure, then to the bones and their articulation, from them to the principal muscles or those eminently wanted, to their attendant nerves, and at last to the more or less essential minutiae; but the character part of the subject is unfailingly the characteristic part of his design, whether it be a rapid sketch, or a more finished drawing. The strokes of his pen or pencil themselves are characteristic: they follow the direction and texture of the part; sick in their rounding, tendons in slanting, bones in angular lines.

"Such was the felicity and propriety of Raphael, when employed in the dramatic evolutions of character! both suffered when he attempted to abstract the forms of sublimity and beauty; the painter of humanity, not often wielded with success over-human weapons. His gods never rose above prophetical or patriarchal forms; if the finger of Michael Angelo impressed the divine countenance oftener with terrifies than awe, the gods of Raphael are sometimes too affable or mild, like him who speaks to Jacob, in a ceiling of the Vatican; or too violent, like him who separates light from darkness, in the loggia of the same place. But though, to speak with things, he was chiefly made to walk with dignity on earth, he feared above it in the conception of Christ on Tabor, and still more in the crown of the angelic countenance that withers the strength of Heliodorus.

"Of ideal female beauty, though he himself, in his letter to count Caligilone, tells us, that from its fecracy in life, he made attempts to reach it by an idea formed in his own mind, he certainly wanted that impassable which guided him in character: his goddesses and mythologic females are no more than aggravations of the generic forms of Michael Angelo. When the drama inspired Raphael, his women became definitions of grace and pathos at once. Such is the exquisite line and turn of the half-averted kneeling female with two children, among the spectacles of the punishment inflicted on Heliodorus; her attitude, the turn of her neck, supplies all face, and intimates more than he ever expressed by features."

Raphael, in Geography, a fertile and healthy district, being the well-embossed in the Spanish part of St. Domingo. Its northern boundary is found in part of the French parish Gonvales. The air round St. Raphael is very favorable, but the town, which is in a hollow, is very hot; to leagues S. of Cape Francois.

Raphael, St., Cape, lies at the S. end of St. Domingo, and is the S.E. limit of Samana bay.

Raphanea, in Ancient Geography, a city of Syria, between which and Arca, or Arac, a city of Judea belonging to the kingdom of Agrippa, the Sabbothical river flowed. Joseph de Bell. l. vii. c. 24. Raphanea is, perhaps, the Arpal of scripture. 2 Kings, xviii. 34. xix. 13. II. x. 9. xxxvi. 19. xxxvii. 13. Jerem. xlil. 23.

Raphania, in Medicine, an appellation given by Linneus, and afterwards by Dr. Cullen and others, to a fever and fatal disease, which has been described as epidemic in Sweden at particular feasons, and imputed to the use of the raphanous raphanitrum of Linneus as food.

It is not necessary to describe the symptoms of this disease in this place; since it is, in fact, the famine malady which has been epidemic in various other countries of Europe, during feasons of scarcity; and has been attributed to various other species of unwhole-fome grain, but more especially to diseased rye, affected with the ergot, to the folium temulentum, to charlock, &c. We have already entered at great length into the history of the symptoms and imputed causes of this formidable malady, which has been more commonly denounced ergot, from one of its supposed sources. (See Ergot.) We have endeavoured also to shew, that it constituted one of the varieties of epidemical diseases, described by the ancients, under the appellation of Ignis Saer (which see); and that, instead of being properly imputed to the admixture
admixture of any of these fabulances with the corn used for food, the disease is to be ascribed with more probability to the insufficient nourishment afforded by damaged corn, or the actual death of it, which usually occur together; especially as these diseases have commonly been epidemic in years of scarcity, which is the only circumstance that can be observed in common to all the epidemics described by authors. In addition to the works on ergot and ignis facer, formerly referred to, consult, for an account of raphania, Pulterey's View of the Writings of Linnaeus; Rothman's Paper, in the Amenitates Academ. of Sweden; Tilloot. Epitope Med. Pract.

RAPHANUS, in Botany, the name by which the Attic, among the Greeks, called the radish; for the word raphanus, or raphanum, with them, does not express the radish, but the cabbage. The Greek of all other places concurred in calling the radish raphanus, and the cabbage cranes; and it is owing to this that we have many authors who confound together these two plants, though to very unlike one another in appearance and use. It is generally to be understood, that wherever Theophrastus mentions the word raphanus, he means by it the cabbage; and the same being observed, in regard to all the other Attic writers, the whole danger of confusion and error will cease.

RAPHANISTRUM, a name given by botanists to the wild radish, and designed to express its affinity to the cultivated one. See Raphanus.

Gen. Ch. Cal. Perianth inferior, erect, of four oblong, parallel, converging, deciduous leaves, gibusous at the base. Cor. cruciform, of four invertebly heart-shaped, spreading petals, whose claws are rather longer than the calyx. Nectariferous glands four; one at each side, between the shorter limb and the fillet; and one at each of the opposite sides between the longer limb and the calyx. Stem. Filaments six, awl-shaped, erect; two opposite ones the length of the calyx; the rest as long as the claws of the corolla; authors simple. Pét. Górna oblong, tumid, tapering, the length of the flaments; style very short; stigma capitate, unci- vided. Peric. Pod oblong, pointed, swelling here and there, imperfectly jointed, without valves. Seeds roundish, smooth.

Ofb. Raphanus of Tournefort and Gartner has a spiny fruit, of two cells, not burbling. Raphanistrum of the same authors has a jointed fruit, separating at the joints.

1. R. faüius. Common Garden Radish. Linn. Sp. Pl. 935. Willd. n. 1. Alt. n. 1. Ger. Em. 237. (R. primus; Matth. Valgr. v. 1. 399.)—Leaves laciniate. Pod roundish, tumid, of two cells.—The native country of this well-known plant, so commonly cultivated in gardens, is not ascertained. Linnaeus mentions China; but his authority does not appear. Its chief value with us consists in the root, esteemed for its grateful pungency, mixed with a watery coelebs. The shape of this part varies, from its natural spindle-like figure, to a globular one, and the colour of the skin from purple to white. We doubt much whether the R. niger of Baillou, commonly called the Black Spanish Radish, which Linnaeus marks μ, can belong to this species. Its firmness, and black rugged coat, seem to indicate more than a mere variety. We have not examined the herbage. The leaves of R. faüius are laciniate, notched, and rough, especially the lower ones; the upper part of the herb is smoother, and somewhat glaucous. Stem branched. Flowers purple, corymbose; stam. racemose. Pods erect, tumid, juicy, pale, glaucous, smooth, slightly flinted, various in length and thickness, tipped with a spiny-lobed head. Linnaeus cultivated at Upsal a Chinese variety, or possibly species, whose leaves are broader and smoother, and its whole habit more lax. The oil of the seeds is said to be used in China.

2. R. caudatus. Long-tailed Radish. Linn. Nat. 95. Linn. fl. Plant. Rar. fac. t. 19. t. 10. Willd. n. 2.—Leaves laciniate. Pod compressed, of one cell, wavy, longer than the whole plant.—Native of Java, where, according to the younger Linnaeus, it is cultivated, and the pickled pods known by the name of Mougli. In Sweden, as well as in England, it may be treated as a hardy annual, like the foregoing; but the present species does not occur in Hort. Kew., though Mr. Lambert met with it last year in a country garden in Wiltsire. The appearance of the plant, weighed down to the ground by its inordinately long ter- pentine pods, is altogether extraordinary. The lobes and indentations of the leaves are sharper than in the Common Radish, but the flowers and other parts, except the pods, scarcely betray any difference.

3. R. Raphanistrum. Wild Radish, or Jointed Charlock. Linn. Sp. Pl. 935. Willd. n. 3. Alt. n. 2. Fl. Brit. n. 1. 240. Eng. Bot. t. 856. Curt. Lond. fac. t. 4. 240. Mart. Rust. t. 71. Fl. Dan. t. 1. 15. (R. sylvestris; Ger. Em. 240.)—Leaves laciniate, lyrate. Pod round, jointed, even, of one cell. A trouble-fome weed in the corn-fields of England, flowering in June and July. The root is annual, small, and tapering. Stem branched, round, glaucous, rough with prominent bristles, leafy. Leaves rough, lyrate; the upper ones oblong, simply toothed. Flowers numerous, lemon-coloured, changing to white in decay, with purple veins; sometimes the petals are white from the stam. Pods cylindrical, or rather tapering, beaked, knobbed or imperfectly jointed, smooth, becoming flinted as they ripen. In a young state they are divided into two cells, but the partition is obliterated, and confined in one spiny mass, as they ripen. Linnaeus was of opinion that the seeds of this plant caused a convulsive disease, thence termed by him Raphania, of which he has given a history in Amen. Acad. v. 6. 458; with a figure, and elaborate synopsis of the plant. We have never met with any circumstance to corroborate this hypothesis.

4. R. maritimus. Sea Radish. Sm. Engl. Bot. t. 1643. Alt. n. 3. (R. Raphanistrum; Fl. Brit. t. 1. 723. R. maritimus, floru liceo, filiquis articulatis, secundum longitudinem emineret frutis; Rau Syn. 296. Raphanistrum filiquis articulatis fruticis maxima; Morit. v. 3. 266. Raufl. Hist. v. 1. 856.)—Radical leaves interruptedly lyrate. Pod round, jointed, smooth, deeply furrowed, of one cell. — Found on the sea-shore in various parts of Britain, flowering in May. The late Rev. Dr. Walker, and Mr. J. Mackay, observed it on the western coasts of Scotland; and the former cultivated this plant, till his death, as an eculent root, preferable to horseradish; he also found that cattle were very fond of the leaves. Mr. Turner and Mr. W. Borrer gathered the leaves on rocks, near Beacly Head, Suffolk. 'The root is large and succulent, lifting two or three
three years. **Stems** three or four feet high, round, roughish at the base. **Leaves** all rough, and rather sharply toothed; the radical ones interruptedly lyrate, which we have never observed in the last described species. **Flowers** of a deeper yellow, and less velvety. **Pods** strongly jointed, and very deeply furrowed longitudinally, definate of hairs or other roughnesses. There can be no doubt of this being a distinct species from the former, though generally confounded therewith.

5. **R. fibricius**. Siberian Radish. In Bot. Trav. v. 3. append. 751. t. I. f. 3. 1827. R. n. 3. (Ehrh. Sel. n. 38. (Chorispermum tenellum; Brown in Ait. H. Kew. v. 1. 1827.)—Leaves pinnatifid, somewhat toothed. Pod round, headed, downy, of one cell.—Native of Siberia. The seeds were sent by Prof. F. H. O. Willdenow to the Goettingen garden, where the plant flowered in June. **Root** annual, long, and slender. **Stems** from three to six inches high; or more, as the seeds ripen, ascending, leafy, hairy, simple or branched. **Leaves** sometimes elegantly and neatly pinnatifid, almost pinnate, either in a simple or interrupted manner, roughish at the edge only, sometimes more dilated, with distant and broader lobes. **Flowers** large, yellow, sweet-scented in an evening, their petals strongly emarginate. **Pods** inflated, copiously and neatly beaded in appearance, rather than distinctly jointed, downy, each with a flimsy taper beak.

6. **R. tenellus**. Slender Purple Radish. Pallas Trav. v. 2. t. 162. t. 18. 1773. R. n. 3. (Chorispermum tenellum; Brown in Ait. H. Kew. v. 2. t. 162.)—Leaves smooth, oblong, toothed; the lowermost pinnatifid. Pod awl-shaped, jointed, smooth, of two cells.—Native of deserts near the Caspian Sea. A hardy annual in our gardens, flowering in June and July. **Root** long, fimbry, tapering, and slender. **Flower** smooth, scarcely branched, leafy. **Leaves** elliptic-oblong, toothed or pinnatifid, tapering down into longish footstalks. **Flowers** small, purple. Beak of the pod very long and slender. The ingenious Mr. Brown separates this from **Raphanus** chiefly, as it seems, because the coryledons are flat, not folded.

7. **R. arcuatus**. Curve-podded Radish. Willd. n. 6.—"Leaves oblong-lanceolate, toothed. Pod awl-shaped, curved, two-celled, smooth."—Native country unknown. Willdenow cultivated the plant, which he describes as annual, with an erect branched stem, hardly a span high. **Leaves** stalked, oblong-lanceolate, very smooth, with broad shallow teeth. **Flowers** small, violet. **Pods** round, of two cells, jointed, curved, smooth, striated, with an awl-shaped beak. The figure of *Hesperis arvensis*, Desfont. Atlant. v. 2. t. 162, answers exactly to this plant, except the pods. **Willdenow.**

8. **R. lanceolatus**. Lanceolate Radish. Willd. n. 7.—"Leaves oblong-lanceolate, somewhat toothed at the apex. Pod tumid, smooth, two-celled, with a squarish beak."—Native of the West Indies. **Stem** a foot and half high, erect, zigzag, with short branches, smooth like every other part of the plant. **Leaves** stalked, oblong-lanceolate; the uppermost lanceolate, narrow, entire; the lower ones bluntly toothed at the extremity. **Flowers** of a midding size, yellow, in a terminal cluster, six inches long. **Pods** half an inch long, with a long, obtuse, obscurely quadrangular beak. **Willdenow.**

9. **R. pilosus**. Hairy-stalked Radish. Willd. n. 8.—"Leaves lanceolate-linear, pinnatifid at the base. Stem rough with bristly hairs. Pod round, smooth, jointed, of one cell."—Native of Guinea. **Stem** two feet, or perhaps more, in height, branched, divaricated. **Leaves** three inches long, narrow, smooth, pointed; pinnatifid at the base; toothed in the middle; entire at the extremity. **Flowers** axillary from every leaf, of few flowers. **Pods** an inch and half long, round, jointed, of one cell, with a short beak, all of them turned one way. **Willdenow.**

R. *erucoides*, Linn. Suppl. 299, is rightly referred by Mr. Brown, in Ait. H. Kew. v. 4. t. 126, to *Sinapis Alba*, Jacq. Hort. Vind. v. 2. t. 168. Willd. Sp. Pl. v. 3. 557. (See *Sinapis*.) Willdenow cites it, doubtfully, under *Brassica Chiranthus* of Villars, a very different plant; for which he also by mistake quotes Barret. t. 1016, a synonym properly belonging to *Sisymbrium Barrelieri*.

Linnéus once referred *Bunias Cabile* to this genus of *Raphanus*.

**Raphanus**, in Gardening, contains plants of the herbaceous, annual, eulent kind, of which the species cultivated is, the common garden radish (*R. sativus*).

There are several varieties; some of which have the appearance of distinct species, from their shape, size, and colour of the roots; as the *long-rooted*, which is that commonly cultivated in kitchen-gardens for its roots. Of this there are several subordinate variations; as the small-topped, and the long-topped striped radish. The small-topped is most commonly preferred by the gardeners near London, as they require much less room than those with large tops; for as forward radishes are what produce the greatest profit to the gardener, and these are commonly sown upon borders near hedges, walls, or pales, the large-topped sorts would be apt to grow mossy at top, and not swell so much in the root as the other, especially if the plants should be left pretty clofe.

The small round-rooted, which is not very common here, but in many parts of Italy it is the only one cultivated; the roots of this are very white, round, small, and very sweet. It is now frequently brought to the London markets in the spring, generally in bunches, and is sometimes mistaken there for young turnips when eaten young, it is crisp, mild, and pleasant.

The large turnip-rooted, or white *Spanibhs*, which has a moderately large, spherical white root, and is esteemed chiefly for eating in autumn and the early part of winter. Both these sorts are commonly called indiscriminately turnip radishes.

The black turnip-rooted *Spanibhs*, which has a root like the preceding, white within, but with a black skin; and is greatly esteemed by many for autumn and winter eating.

There are likewise some other subvarieties of the radish noticed by gardeners, as the common *Salmon radibis*, and the short-topped early *Salmon radibis*. Also the small red *turnip-rooted radibis*. Gardeners, too, often call the long-topped sort the *fallow radibis*.

**Method of Culture.**—These are raised from seed by different sowings from the end of October till April, or the following month. They should have a light fine mould, and the more early sowings be made on borders, under warm walls, or other similar places, and in frames covered by glass. The common spindle-rooted, short-topped sorts are mostly made use of in the early sowings, the seed being sown broadcast over the beds after they have been prepared by digging over and raking the surface even, being covered in with a slight raking. Some few carrots with the early crops of radishes.

It is usual to protect the early sown crops in the borders, during frosty nights and bad weather, by mats or dry wheat straw, which should be carefully removed every mild day. By this means they are brought more forward, as well as form better roots. When marts are used, and supported by pegs or hoops, they are readily applied and removed.
A second or general sowing should be made in January or February. When the crops have got their rough leaf, they should be thinned out, where they are too thick, to the distance of two inches, as there will be constantly more thinning by the daily drawing of the young radishes.

When the weather is dry in March, or the following month, the crops should be occasionally well watered, which not only forwards the growth of the crops, but increases the fize of the roots, and renders them more mild and crisp in eating.

And the sowings should be continued at the distance of a fortnight, till the latter end of March, when they should be performed every ten days, until the end of April or beginning of the following month. In sowing these latter crops, it is the practice of some gardeners to sow few cobs-lettuces and spinach with them, in order to have the two crops coming forward at the same time, but the practice is not to be much recommended, where there is sufficient room.

But in sowing the main general crops in the open quarters, the market-gardeners generally put them in on the same ground where they plant out their main crops of cauliflower and cabbages, mixing spinach with the radish-seed as above, sowing the seeds firm, and raking them in, then planting the cauliflowers or cabbages; the radishes and spinach come in for use before the other plants begin to spread much, and as soon as these small crops are all cleared off for use, hoe the ground all over to kill weeds and loosen the soil, drawing earth about the items of the cauliflowers and cabbages.

The turnip radishes should not be sown till the beginning of March, the plants being allowed a greater distance than for the common spindle-rooted sort. The seeds of this sort are apt to degenerate, unless they are set at a distance from that kind.

The white and black Spanish radishes are usually sown about the middle of July, or a little earlier, and are fit for the table by the end of August, or the beginning of September, continuing good till frost spoils them. These should be thinned to a greater distance than the common sort, as their roots grow as large as turnips, and should not be left nearer than six inches.

To have these roots in winter, they should be drawn before hard frost comes on, and laid in dry sand, as practiced for carrots, carefully guarding them from wet and frost; as in this way they may be kept till the spring.

In regard to the culture of the general crops, they require very little, except occasional thinning where they are too thick, when the plants are come into the rough leaf, either by hoeing or drawing them out by hand; though for large quantities, small hoeing is the most expeditious mode of thinning, as well as most beneficial to the crop by loosening the ground; in either method thinning the plants to about two or three inches distance, clearing out the weakest, and leaving the strongest to form the crop.

In order to have the seed, about the beginning of May some ground should be prepared by digging and levelling, then drawing some of the straightest and best-coloured radishes, plant them in rows three feet distant, and two feet asunder in the rows; observing, if the seed be dry, to water them until they have taken root; after which they will only require to have the weeds hoed down between them, until they are advanced so high as to overspread the ground.

When the seed begins to ripen, it should be carefully guarded against the birds. When it is ripe, the pods will turn brown: then it must be cut, and spread in the sun to dry; after which it must be threshed, and laid up for use, where no mice can come at it.

Method of Culture on Hot-beds.—This method is sometimes practiced in order to have the roots early, as in January or the following month. They should have eighteen inches depth of dung to bring them up, and six or seven inches depth of light rich mould. The seed should be sown moderately thick, covering it in half an inch thick, and putting on the lights; the plants usually come up in a week or two; and when they appear, the lights should be lifted or taken off occasionally, according to the weather; and in a fortnight thin the plants to the distance of an inch and half or two inches, when in six weeks they will be fit to draw. Where there are no frames to spare, the beds may be covered with mats over hoops, and the sides secured by boards and slat-boards. And when in want of dung, if the beds be covered with frames, and the lights put on at night and in bad weather, the plants may be raised for use a fortnight sooner than in the open borders.

RAPHE, in Anatomy, a Greek term, signifying future, applied to some parts of the body; thus we have the raphe corporis calli in the brain (see Brain); raphe perim. recti, and peris. See Generation.

RAPHELLENGIUS, sometimes called Raulenghien, Francis, in Biography, a learned orientalist, was born in 1539 at Lanoy, near Lille, in Flanders. He had the early part of his education at Ghent, but on the death of his father, it was intended to bring him up to trade, and for that purpose he was sent to Nuremberg. Here he had access to books, resumed his studies, and took an opportunity of going to Paris, where he made great progress in the Greek and Hebrew languages. The civil wars obliged him to quit France, and he came to England, where, for some time, he taught Greek in the university of Cambridge. After this he returned to the Low Countries, and became a corrector of the press to the celebrated printer Plantin, whose daughter he married in the year 1565. He made himself very serviceable in the printing office, especially with respect to the famous Antwerp Polyglot Bible, printed in 1571 by order of Philip II. of Spain. When Plantin removed to Leyden, he left his business at Antwerp under the care of Raphelengius, and upon his return the latter went to Leyden. The curators of the university of that place conferred upon him the professorship of Hebrew, which was added to that of Arabic. He died in 1597. His literary works were "Varia Lectiones et Emodationes in Chaldaicum Bibliorum Paraphrasis," "Grammatica Hebrea," "Dictionarium Chaldaicum," and "Lexicon Arabicum." He had a son of the same name, a man of talents and learning, who published "Notes upon Seneca's Tragedies," and "Eulogies, in Verfe, of fifty Persons, with their Portraits."

RAPHIA, in Botany, from jasus, a point or needle, so that it ought to have been Rhaphia, a genus of Palms, with a very pointed fruit, established by Palisot Beauvois, in his "Flora d'Orient et de Bein," fasc. 8.

RAPHIA, in Ancient Geography, a famous city in the Mediterranean, between Gaza and Rhinocorura. This was perhaps Gath of the Rephaim. Raphia is famous for the victory of Philopator, king of Egypt, over Antiochus the Great, king of Syria. (3 Maccab. i. 11.) Josephus says (Antiq. i. xiii. c. 21.) that Raphia was taken by Alexander Jannæus, and after being ruined in the wars, was repaired by Gabinius. There are extant some ancient medals struck at Raphia, and some bishops of this city are found in the lists of the eastern councils.

RAPHIDIA, in Entomology, a genus of insects of the order Neuroptera, of which there are two species. The generic character is as follows: Mouth with a curved toothed
RAPID

toothed horny mandible; the thorax is long and cylindrical; it has three flammata; the wings are deflected; the antennæ filiform, as long as the thorax, the anterior part is elongated and cylindrical; it has four feelers, which are short and filiform; the tail of the female is terminated by a large recurved bristle.

* Ophiopus. The wings of this species are immaculate. It inhabits divers parts of Europe in woods, and preys on other insects.

* Notata. Wings with a brown marginal spot. It inhabits England, and has been thought to be only a variety of the former. The body is black; the head is also black with a tawny spot; the legs are tawny; the appendage of the female is as long as the body.

RAPHOE, in Geography, a bishopric of Ireland, in the ecclesiastical province of Armagh, which comprises the greater part of the county of Donegal, being 44 miles in length from north to south, and 32 in breadth, comprehending 515,250 Irish acres. It contains 31 parishes, in which are 32 churches. The dean, archdeacon, and four prebendaries, compose the chapter. The patronage of 6 parishes, which form the corps of the deanery, is in the crown; of 15 others, in the bishop; of 7, in the university of Dublin; and of 3, in lay hands. It is not precisely known at what time this fee was founded, but it must have been as early as the ninth century, since bishops of Raphoe are mentioned at that time. Beaufort.

RAPHE, a small post-town of Ireland, the parish church of which serves as a cathedral, where is the bishop's palace. It is 107 miles N. by W., from Dublin.

RAPHON, a township in Lancaster county, Pennsylvania, containing 2814 inhabitants.

RAPHON, in Ancient Geography, a city beyond Jordan, on a brook, not far from Carnain.

RAPICIO, Grovita, in Biography, an Italian man of letters, was born about the year 1480, at Chiari, in the territory of Brescia. Devoting himself to the instruction of youth in literature, he first opened a school at Bergamo, where he wrote a Latin treatise on the education of youth, which was afterwards printed at Venice. He next taught at Vicenza, and various other cities in Italy, and was for many years employed at Venice in instructing, in polite literature, the youths defined for public life, and among others, the care and instruction of the sons of cardinal Bembo were devolved upon him. Cardinal Pole, in one of his letters, speaks of Rapicio in high terms of commendation.

He died at Venice in 1555. He was author of various harangues, poems, and epistles, but his chief work was entitled "De numero Oratorio," in five books, printed at Venice in 1544. "In this," says his biographer, "he minutely investigates the principles of writing the Latin language with sweetness and harmony, and he replies to Melation's affront, that rules of this kind are rendered useless by our ignorance of the ancient pronunciation.

Moreri.

RAPIDAX, in Geography, a small river of Virginia, which runs into the Rappahanock, about 10 miles above Fredericksburg.

RAPID PLAT, life au, a small island of Upper Canada, in the river St. Lawrence, in front of the township of Maitla, containing about 200 acres.

RAPID RIVER, a river which runs into Hudson's Bay.

RAPIDES, a county of the territory of Orleans, containing three parishes, viz. Rapides, including 2200 inhabitants, Catahula 1164, and Avoyelles 1209.

RAPIER, properly denotes a long, ordinary, old-fashioned cutting sword, such as those worn by the common folders.

The word is formed from the French rapier, of the Greek ῥαπίς [rapiς], ceders, or spire, or strike.

In this sense do the French still use the term; so that among them, to take the rapier, is to enter in the army.

RAPIER, in a modern sense among us, usually denotes a small sword, as contradistinguished from a back-sword, or cutting-sword.

RAPILLO, in Mineralogy, the name given by the Italians to the sand or powders (improperly called ashes) thrown from the craters of volcanoes in immense quantities, towards the conclusion of an eruption. See VOLCANO, and VOLCANIC Products.

RAPIN, Rext, in Biography, a Jesuit, was born at Tours in 1621. He entered the society in 1639, and was a teacher of the belles lettres in it during nine years. He became eminent by several publications in the Latin and French, and obtained a high rank among the literary characters of his time. It is, however, as a Latin poet that he is chiefly known: his didactic poem on Gardens, entitled "Hortorum, lib. iv." first printed in 1605, has passed through many editions, and has been regarded as one of the most elegant and classical pieces of modern Latin verse. By others it has been thought a work of art and study, rather than an effusion of poetical feeling and fancy, and treated on gardening more as a branch of rural economy than as one of the fine arts. His other Latin poems are faced elegies, heroic, elegiac, and lyric poems. Father Rapin died at Paris in 1697. He was no less esteemed for his virtues and amiable qualities, than admired for his talents; and he polished all that polish and fineness for the society of the great world, which have distinguished this order from other religious communities. His works were collected and published, in 3 vols. 12mo. 1684. There is a fine edition of his "Hortorum," published by Brotier at Paris, in 1780. Rapin was great as a critic, in which line he is known by his "Reflections sur l'Eloquence, sur la Poésie, sur l'Histoire, et sur la Philosophie," and also by his "Comparaisons de Virgile et d'Homère," printed in 2 vols. 4to. Bayle.

Moreri.

RAPIN DE THOYRAS, PAUL, well known as the historian of England, was born at Caixres, in Languedoc, in 1601. He was descended from a noble family of Savoy, which came into France in the reign of Francis I. for the fake of professing the reformed religion. The subject of this article, after having received his education, went to his father, who was an advocate in the chamber of the edict at Nantes, for the purpose of studying the law. He was in due time admitted an advocate, but the chamber being suppreied in the same year, he went with his father to Toulouse. On the revocation of the edict of Nantes, in 1625, he withdrew to England, after which he went to Holland, and entered into a company of French cadets at Utrecht. In 1689 he followed the prince of Orange into England, and obtained an appointment in lord Kinglston's regiment, which went to Ireland. He was engaged in several battles, particularly at the siege of Carrickfergus and Limonick, and at the battle of the Boyne, and to much distinguished himself, that he obtained a captain's commission. In 1693 he was nominated governor to the son of the earl of Portland, relinquished his commission to a younger brother, and received from the crown, for his palt services, 1000 a-year. He travelled to different countries in company with his pupil, and resided with him some time at the Hague. By the death of king William he was deprived of his pension, and his engagement as private tutor being over, he retired, in 1707, to Wevel, in the duchy of
of Cleves, where he devoted himself to the composition of the history of England. Here he died in 1725. He had, previously to his decease, published in the year 1717, "Differentia fur les Whigs et Tories," which was translated into English. His great work, "L’Histoire de l’Angleterre," was printed at the Hague in 9 vols. 4to. in the years 1725-6. It commences with the remotest periods, and is brought down to the proclamation of William and Mary. It has been twice translated into our own language, and was, till the appearance of Hume, the most popular history of England, and Tindal’s, or rather Birch’s, and other continuations, have been adapted to it. It is written in a prolix and unanimated style, and, of course, praiseworthy, as much so as it is now possible to obtain. In reference to that important period, he has flattered historical difficulties with censure, and in alluding the merits and demerits of parties, he has weighed evidence with a laudable ferocity. (See Shepherd’s Syllabic Education.) Rapin, during the collection of his materials, undertook the useful labour of making an "Abridgment of Rymer’s Fosseer," which was published in Le Clerc’s "Bibliotheque Choixée," and translated into the English by Mr. Stephen Whatley, and published in 1733, under the title of "Aeta Regia," and in folio.

RAPINE, RAPINA, in Law. To take a thing in private; against the owner’s will, is properly theft; but to take it openly or by violence, is rapine, or robbery.

RAPINIA, in Botany, was so called by Loureiro, Fl. Cochinch. 127, after father Rene Rapin, a French Jesuit, author of an elegant Latin poem on gardens, who died in 1687, aged 66. If this writer contributed nothing to improve the science of botany, he has, doubtlesse, helped to promote a love of plants, and may therefore claim a botanical wreath. A Jesuit of his day’s doubly entitled to respect, for having, like the good Loureiro, turned his mind to an elegant and improving pursuit, from those two corruptors of the human heart and understanding, political intrigue, and scholastic divinity, in which most of his brethren sought their temporal, and oftenfiably their eternal, good. The Rapina of Loureiro however, proved, on the examination of his specimens by the late Mr. Dryander, to be the Spinescula of other authors; and this last-mentioned name is now generally adopted. See that article.

RAPINO, in Geography, a town of Naples, in Abruzzo Citra; nine miles S. of Civita di Chieti.

RAPISTRUM, in Botany, originally the wild turnip, so called from its affinity to Ropo, the cultivated one. Tournefort, however, uses the word generically, for some species referred by other botanists to Myagrum. In this he is followed, as far as concerns M. panciulatum, by Gertner, and by the writer of the present article, in the Prodr. Fl. Græc.—Tourn. t. 99. Gärtn. v. 1. 285; t. 141. Sm. Prodr. Fl. Græc. Sibth. v. 2. 1. Brown in Ait. Hort. Kew. v. 4. 74.—Clafs and order, Tetradynamia Siliculosa. Nat. Ord. Siliculose, Linn. Crucifera, Jufii.

Gen. Ch. Cal. Perianth inferior, of four oblong, spreading, deciduous leaves, gibbous at the base. Cor. cruciform, of four obovate, entire, spreading petals, whose claws are shorter than the calyx. Stem. Filaments fix, about the length of the calyx, the four opposite ones rather the longer; anthers simple. Figl. Germen oblong; style ovate-shaped, the length of the calyx; stigma obtuse. Peric. Pouch lenticular, pointed, coriaceous, of two cells, and two cohering, not spontaneously separating, coriaceous valves; partition membranous. Seeds roundish, solitary in each cell; cotyledons flat.

Eff. Ch. Calyx spreading. Pouch of two cells, and two convex valves, not burbling.

1. R. panciulatum. Punicated Rapistrum. Ait. n. 2. (R. arvense, f. auriculato acuto; Tour. Inf. 211. Myagrum panciulatum; Linn. Sp. Pl. 894. Wildl. Sp. Pl. v. 3. 409. Fl. Dan. t. 202. Myagro simplici, filifquo rotundae; Baut. Prodr. 52.)—Native of cultivated fields in various parts of Europe, from Sweden to Greece, but not, as yet, observed in Britain. Stem about two feet high, erect, round, roughish, leafy, branched. Leaves oblong, acute, undivided, rough, somewhat tooth, clasping the stem with their arrow-shaped base. Flowers small, yellow, in numerous clusters, which become greatly elongated when in fruit. Pouch scarcely bigger than multilateral, a little abrupt, finely reticulated. One of the seeds is often, but not always, abortive. Mr. Brown refers to this genus the Bunus ypressias, of Linnæus, which agrees with our R. panciulatum in having flat, not spirals, cotyledons, but with otherwise the characters of Bunias.

Rapistrum is also a species of the sea-cabbage, or crambo.

RAPOLLA, in Geography, a town of Naples, in Basilicata, the see of a bishop, united to Meliti; six miles W. of Venusia. N. lat. 40° 38’. E. long. 15° 44’.

RAPORE, a town of Naples, in Principato Ultra; 9 miles E. of Conza.

RAPOSO, a town of South America, in the country of Popayan.—Alfo, a river of Popayan, which runs into the Pacific ocean, N. lat. 3° 48’. Alfo, a small island in the Pacific ocean, near the coast of Popayan. N. lat. 4°.

RAPPANNOCK, a large navigable river of Virginia, which rises in the Blue Ridge, and runs about 150 miles from N.W. to S.E., and enters the Chesapeake bay, between Windmill and Stinger towns. It waters, in its course, the towns of Falmouth, Fredericksburg, Port-Royal, Leeds, Tappahannock, and Urbanna.

Rapé, in Commerce, a money of account in Switzerland, of which are equal to a good baton; and 6 are equal to a plappert, fishing, or calefac. This is the cafe at Basl, but at Lucern the plappert is only 3 rappen, and the Zurich calefac = 33 rappen.

Rapé, in Ichthyology, a name given by fome to the scopio fluidathus rapas of Gellner, more frequently known by the name of the corus pilaet.

RAPPERSCHWEIT, in Geography, a town of Switzerland, and capital of a district to which it gives name; situated on the N. side of the lake of Zurich, over which there is a bridge, 1852 paces in length, built in 1358 by the counts of Habiburg. The town was founded in 1094, and formerly had its own counts. In 1358 it was sold to the sons of Albert, archduke of Austria. In 1264 it put itself under the cantons of Uri, Schwartz, Unterwalden, and Glarus, with a reverse of its liberties; but the cantons gradually made themselves masters of it. At the peace of Auroa in 1712, its liberties were restored, though the country remains subject to theovereignity of Zurich and Berne; 45 miles N.E. of Zurich.

RAPPIN, a town of Anterior Pomerania; 7 miles N. of Bergen.
RAPPO Rappo, a bay on the coast of Mowee, one of the Sandwich islands.

RAPPOLTSKIRCHEN, a town of Austria; five miles S. of Tulln.

RAPPORT, Fr. in music, is sometimes used for proportion, and sometimes for relation, words which will be explained in their places.

RAPPS, in Geography, a town of Austria, on the river Taya; four miles S.W. of Droffendorf.

RAPSO, a town of Istrià; 52 miles S.E. of Capo d'Istrià.

RAPTEC, a river of Hindoostan, which runs into the Dewah, five miles S.W. of Shkampour.

RAPTU redes, in Law, an ancient writ which lies for taking away an heir, holding in loco; of which there are two forms; one when the heir is married, the other when not. See Ravishment.

RAPTURE, Raptura, an extasy, or transport of mind. See Exstasy, Enthusiasm, Rhapsody, &c.

RAPUNCULUS, in Botany, the Rampion, owes its name to a resemblance in the root to a Rapse, or oblong Turnip. This root, Campanula Rapunculus of Linnaeus, is biennial, fearlessly larger than a radish, which it resembles also in shape, but the colour is white. Its flavour is sweet and mild, notwithstanding some degree of milkiness in the juices, in which it accords with other, usually bitter and acrid, species of its genus. The Rampion is now much less cultivated than formerly, and almost a stranger at our tables.

RAPUNTINUM, a name used by Tournefort and Morison for some plants referred to Lobelia by Linnaeus. See Lobelia.) Gartner, having adopted Plumier's Lobelia, the Linnean Scrofula, reverts Rapuntium; but such a measure could now lead to inconvenience only.

RAPUTIA, so called by Aublet, because the plant grows in the forests of Orapi in Guiana. Jussieu and Lamarck have retained this curious name. Schreber has changed it for Scoua; see that article hereafter.

RARAKIT, in Geography, a town of the island of Ceram, at the foot of a mountain covered with trees, which serves as a harbour for pirates.

RARE, in Physics, denotes a body that is very porous, whose parts are at a great distance from one another, and which contains but little matter under a great deal of bulk.

In this sense rare stands opposed to dense.

The corpuscular philosophers, viz. the Epicureans, Gaffendiis, Newtonians, &c. assert that bodies are rarer some than others; in virtue of a greater quantity of vacuity included between their pores. The Cartesians hold, that a greater rarity only consists in a greater quantity of matter subtilis included in the pores. Lastly, the Peripatetics contend, that rarity is a new quality superinduced upon a body without any dependence, either on vacuity, or subtilis matter.

RARECOURT, in Geography, a town of France, in the department of the Meuse; 10 miles S.W. of Verdun.

RAREE, a town of Hindoostan, in Concan; 20 miles N.N.W. of Goa.—Alfa, a town of Hindoostan, in Bahar; 11 miles N.N.W. of Durbunag.

RAREFACT, Rarefacto, in Physics, the act by which a body is rendered rare; that is, is brought to posse more room, or appear under a larger bulk, without accedion of any new matter.

Rarefaction is opposed to condensation.

Our more accurate writers refrain rarefaction to that expansion of a mass into a larger bulk, which is effected by means of heat. All expansion from other causes they call dilatation.

The Cartesians deny any such thing as absolute rarefaction: extension, with them, constituting the essence of matter, they are obliged to hold all extension equally full.

Hence, they make rarefaction to be no other than an accedion of freth, subtilis, and inelastic matter, which, entering the parts of the body, feebly detends them. See this disproved under Vacuum.

It is by rarefaction that gunpowder has its effect; and to the fame principle also we owe our volatiles, thermometers, &c.

The degree to which the air is rarified exceeds all imagination: Merianus, long ago, by means of an intense heat, found that air might be rarified so as to posse more than twenty times its former space.

Mr. Boyle afterwards found, that air, by its own elasticity, and without the help of any heat, would dilate itself so as to take up nine times its former space; then 31 times; then 60; then 150; at length, by many degrees, he found it would reach to 8000 times, then 10,000, and finally to 130,079.

Such is the rarefaction of common air, from its own principle of elasticity, and without any previous condensation; but if it be compresed, the fame author found its greatest space when most rarified, is to its least when most condensed, as 55,000 to 1.

Such an immense rarefaction, sir Isaac Newton shows, is inconceivable on any other principle than that of a repelling force inherent in the air, on which its particles mutually fly from one another.

This repelling force, he observes, is much more considerable in air than in other bodies, as being generated from the most fift bodies, and that with much difficulty, and fearlessly without fermentation; those particles being always found to fly from each other with the most force, which, when in contact, cohere the most firmly. See Air.

The members of the French Royal Academy have bestowed much attention on the different rarefactions, or rather the different rarities of the air at different heights. M. Mariotte established this as a principle, from experiments, that the different rarefactions, or condensations, of the air, follow the proportion of the weights with which it is press'd.

Hence, supposing the mercury in the level of the sea suspended to twenty-eight inches, which is the weight of the whole atmosphere; and that fifty feet height of air are equivalent to a line, or one-twelfth of an inch of mercury; so that the barometer, at the height of fifty feet from the sea, would fall a line; it is easy finding what height of air would be equal to a second, or any other line of mercury; for as twenty-eight inches of mercury one-twelfth are to twenty-eight inches, so is the height of fifty feet of air to a fourth term, which is the height of air corresponding to a second line of mercury.

And after the same manner may the height of air corresponding to each line be found; which will make a geometrical progression, the sum of which will be the whole height of the Atmosphere (which see); and, of consequence, a certain part of that sum will be the height of a mountain, at whose top the barometer shall have sunk a certain quantity.

Mellrs. Caffini and Maraldi, upon measuring the heights of several mountains, found, that this progression of M. Mariotte was defective; that it always gave the height of the mountains, and consequently the rarefactions, less than they really were; and from some farther experiments, M. Amo-
M. Amontons found, that the principle will only hold in the mean rarefactions, not in the extremes. See Barometer.

RAREN, or Raron, in Geography, a town of the Valais, and capital of a tithing; 21 miles E. of Sion.

RARGIARA, a town of Hindooftan, in Bahar; 32 miles S.W. of Bahar.

RARITON, a river of America, in New Jersey, formed by two considerable streams, called the north and south branches; the one rises in Morris county and the other in the county of Hunterdon. This river passes by Brunswick and Amboy, and, uniting with the waters of the Arthur Kull found, helps to form the fine harbour of Amboy. At Rariton hills, through which this river passes, is a small cascade, with a fall of water from fifteen to twenty feet, romantically situated between two rocks. Copper ore has been found upon the upper part of this river.

Rariton, a town of New Jersey, situated between the mouth of the N. branch of the above river and Boundbrook; 12 miles N.W. of Brunswick.

RARO, a town of Hungary; 8 miles E.S.E. of Altenburg.

RARONHAKON, a large lake of Thibet. N. lat. 34° 4'. E. long. 85° 52'.

RARUM, Non-Spartium, in the Ancient Music. See APPEXON.

RAS, in Geography, a town of Syria, anciently called "Conna," situated near the source of the Orontes; 24 miles N. of Balbec.

Ras Abad, or Baba, a cape on the coast of Arabia, in the Red sea; 10 miles S.S.W. of Jiddah.

Ras-Acon-affer. See CANINES.

Ras Addar. See Cape Bon.

Ras Ahabaz, a cape on the coast of Arabia, in the Red sea. N. lat. 18° 19'. E. long. 37° 48'.

Ras Ain, or Ain Verdev, a town of Asiatic Turkey, in the province of Diarbekir; 80 miles S. of Diarbekir. N. lat. 36° 34'. E. long. 39° 48'.

Ras el Amoushe, a cape of Africa, on the coast of Algiers; 42 miles E. of Cape Tennes. N. lat. 36° 41'. E. long. 2° 48'.

Ras Alsh, a cape on the coast of Abyssinia, in the Red sea. N. lat. 13° 8'. E. long. 43° 10'.

Ras el Camir or Kazifir, or cape of the wild boar, a town of Syria, in the pachalic of Aleppo, near a cape on the sea-coast; 16 miles W. of Alexandria.

Ras el Doar, a cape on the coast of Nubia, in the Red sea. N. lat. 21° 21'. E. long. 36° 9'.

Ras el Anf or Enf, i.e. cape of the Rofe, a cape on the coast of Egypt, in the Red sea; without tree or herb; in the front of the point are the remains of a large temple. N. lat. 23° 57'.

Ras Fartach. See FARTACH.

Ras Filham, a cape on the E. coast of Arabia; 18 miles S.E. of cape Mozendum. N. lat. 29° 56'.

Ras Ibrahim, a cape of Arabia, in the Red sea; 6 miles S. of Ghunfude.

Ras Leggidi, or Ras el Jidd, a cape of Nubia, in the Red sea; near which is a harbour, resembling a cauldron, and round as the arch of a circle; the entrance is formed by two points, N. and S. of each other, with 18 fathoms of water, and in the harbour 13. This port is subject to no inconvenience, except from the eait. N. lat. 22° 15'. E. long. 36°.

Ras al Makkees, a cape of Africa, on the coast of Tripoli. N. lat. 32° 18'. E. long. 11° 49'.

Ras Mohammed, a cape on the coast of Arabia, in the Red sea. N. lat. 27° 54'.

Ras al Mar, a town of Persia, in the province of Segestan; 200 miles S.W. of Zareg.

Ras al Nassaf, a cape of Egypt, in the Red sea. N. lat. 23° 16'.

Ras Rouzé, a cape on the E. coast of Arabia. N. lat. 21° 40'.

Ras Verb, a cape on the coast of Arabia, forming the S. point of the gulf of Curia Murra. N. lat. 17° 25'.

Ras Zafra, a cape on the coast of Egypt, in the Red sea; 32 miles S.S.E. of Suez. N. lat. 29° 14'.

RASA, a small island in the Indian sea, near the coast of Africa. S. lat. 17° 8'.

RASAIN, a town of Persia, in the province of Fars or Farshian; 110 miles N.W. of Schiras or Shiraz.

RASAL, or RASAL-SAM, Cape, a cape of Africa, on the coast of Tripoli. N. lat. 32° 36'. E. long. 21° 10'.

RASALEMA, a river of Africa, which waters the city of Fez.

RASALGATA, Cape, or Ras Rosse, a cape on the E. coast of Arabia. N. lat. 22° 25'. E. long. 58° 15'.

RASANT, or RAZANT flante, in Fortification. See FLANK.

The defence of the bastion is rafante.

RASANT FUR. See FIRE.

RASCA, in Geography, a river of Servia, which joins the Ibar; 16 miles N.E. of Jenihafer.

RASCETA, a word used by the Arabian physicians to express the writ or ankle.

RASCH, in Geography, a town of Bavaria, in the territory of Nuremberg; two miles S.S.E. of Altorf.

RASCOLA, or RIZANA, a town of Servia; eight miles S. of Parakim.

RASCOWITZ, a town of Bohemia, in the circle of Leitmeritz; four miles E. of Auffhe.

RASCIA, a port of Servia, watered by the Rafea.

RASCINES, a town of Spain, in the province of Bilbao; 21 miles S.E. of Santander.

RASE, RASHEM, in our Old Writers, seems to have been a measure of corn now diffused; toll shall be taken by the rafe, and not by the heap or cantel.

RASE, in the Mange. To rafe, or glance upon the ground, called in French raser le tapiz, is to gallop near the ground, as our English horses do.

RASEB, AL, in Geography, a fortified pala in the mountains of Grand Bucharia; 60 miles N. of Valthберgd.

RASEBOURG, a sea-port town of Sweden, in the gulf of Finland; 30 miles S.E. of Abo.

RASEC, a town of Persia, in the province of Segestan; 60 miles S.W. of Zareg.

RASGRAD, or RASGRAT. See HRASGRAD.

RASH, in Clock-Work. See RATCH.

Rash, in Medicine, an eruption or efflorescence upon the skin, thrown out in fivers, or surface.

RASHUA, in Geography. See RASSAGU.

RASHED, a town of Nubia, in Sennara; 15 miles N. of Gieffim.

RASICULMO, CAPE, a cape on the N. coast of Sicily. N. lat. 38° 18'. E. long. 12° 49'.

RASIERE, or RASIERE, in Commerce, a measure of corn in Dunkirk and Flanders. At Dunkirk, they have the cafe rasiere, and the land rasiere; 8 of the former being = 9 of the latter; 54 rasiere or 606 land rasiere answer to 31 English quarters. Each rasiere contains 988. 4 inches, and each land rasiere contains 986 inches; 17. 40 of the former, and 19. 57 of the latter, are equal (each) to 10 English
RAS

English quarters. At Dixmude 29.51 raifers are equal to 10 English quarters, and each raifer contains 5821 inches. At Gravelines 21.29 raifers are equal to 10 English quarters, and each contains 8080 inches. At Nieuport 16.93 raifers are equal to 10 English quarters, and each raifer contains 10733 cubic inches. At St. Omer 21.77 raifers = 10 English quarters, and each contains 7000 cubic inches. At Lifte or Lille, the raifer is divided into 8 parts; of these there are two forts, one, used for wheat or rye, the other, called raifer de Mars, for oats or beans; 38 of the former, and 40 of the latter, are reckoned for one raft. The raifer of wheat weights about 128 lbs., and 41 of these are equal to 19 feet, Paris measure, or about 10 English quarters; 39.64 raifers of Lille are equal to 10 English quarters, and each contains 4339 cubic inches.

RASILIS ZANOUCO, in Material Medica of the Ancient, one of their kinds of verdigris. It was prepared in the following manner; they set some sharp vinegar over the fire in a strong earthen vessel, and covered it with a brass pot inverted, well cleaned, and without any vent-hole. And after some time the vessels were to be separated; and the verdigris, which was found concreted on the inside of the brass pot, was scraped off, and put up for use.

RASILITA, in Geography, a town of Italy, in Friuli; 26 miles S.E. of Friuli.

RASIN, a town of Hindoostan, in Dowlatabad; 18 miles W.S.W. of Carmullah.

RASINTA, a town of Italy, in Friuli; 14 miles N. of Udina.

RASKOW, a town of Poland, in the patinate of Bracalow; 54 miles S. of Bracalow.

RASMAN, an island in the Red sea. N. lat. 13° 58'.

RASMEND, a mountain of Peria, in the province of Larak; 60 miles N.E. of Nehaven.

RASNO, an island in the Adriatic. N. lat. 44° 6'. E. long. 15° 25'.

RASO, or Ell of Turin, in Commerse, is equal to 25 Genevese palmis, or 237 English inches; the foot 143.2 French lines, or 3:4 English inches; hence 180 Piedmontese rai are equal to 119 English yards, and 33 Piedmontese feet = 35 English inches. At Caglari, 166.7 rai = 100 English yards, and each of them equal to 21.6 English inches. At Chambery 158.5 rai = 100 English yards, and each = 22.7 English inches. At Nice, 166.7 rai = 100 English yards, and each = 21.6 English inches; 154.5 rai of Turin = 100 English yards, and each = 23.3 English inches.

RASP, a coarfe sort of file.

RASPACK, in Geography, a town of Austria; eight miles E. of Zwett.

RASPUTORIUM, (from radix, to scrape,) a surgical instrument with which the periodotum was, by the old practitioners, scraped from the bones, and the bones themsefes sometimes rasped.

RASPBERRY BUSII, in Botany. See Rubus.

For the dietetic and medicinal use of raspberries, see SUMMER Fruits.

RASPECON, in Ichthyology, a name given by fome to the uranocope, or ilar-gazer.

RASPBURG, in Geography, a town of Germany, in the principality of Weimar, near which are some medicinal springs; 12 miles N. of Weimar. N. lat. 51° 13'. E. long. 11° 35'.

RASPHUYS, or Raps-houye, a celebrated work-house, or house of correction, at Amsterdam. See Work-house.

Vol. XXIX.

RAT

RAPUGLY, in Geography, a town of Bengal; four miles S. of Calcutta.

RASSADES, a cl.uster of small islauds, in the river St. Lawrence. N. lat. 48° 15'. W. long. 68° 48'.

RASSAGU, one of the Kurile or Kurilskoye islauds, lying 40 verfs from Mutova, and in extent about 30 verfs measured either way. It has lofty mountains and steep rocky shores, with very few sandy bogs. On the mountains, here and there, is a good fervices of birch, alders, and the nut-bearing pine; the vale, and flats abound in herbs. On the land is no other animal besides the fox, but the cliffs of the rock afford nesting-places for all kinds of fca-birds; and the beavers and fæals he scattered on feral parts of the land. Here are no streams that yield fish. The Kurile on this island are not numerous, and none of them are baptized.

N. lat. 48° 20'. E. long. 154° 14'.

RASSE CORONDE, in Natural History, a name given by the Ceylonese to a peculiarly fine kind of cinnamon, which is the bark of a tree, growing no where but in that island. The name they give it signifies sharp or biting cinnamon. This choice kind was formerly exported annually, in considerable quantity, by the Dutch East India company, who prohibited the mixing any other kind of cinnamon with it, under a very severe penalty. Phil. Trans. No. 409.

RASSOLOPOUR, in Geography, a town of Hindoofan, in the circar of Nagore; 22 miles N.W. of Didwana.—Also, a town of Hindoofan, in the circar of Go-hud, on the Junnna; 40 miles E. of Go-hud.

RASSOVAT, or Axiospoli, a town of European Turkey, in Bulgaria; 24 miles N. of Driftra. N. lat. 44° 25'. E. long. 27° 37'.

RASTADT, a town of the duchy of Baden, situated on a large plain on the river Merg; the town is new, and regularly built, and the principal street is broad and handsome; 16 miles S.W. of Durlach. N. lat. 48° 52'. E. long. 8° 15'.—Also, a town of Bavaria, in the bithopric of Bamberg; five miles N.W. of Bamberg.—Also, a town of the duchy of Wurzburg; three miles S. of Melrichadt.

RASTAGARA, a town of Egypt; 90 miles E. of Cairo.

RASTEDE, a town of Germany, in the country of Oldenburg; 11 miles N. of Oldenburg.

RASTENBURG, a town of Prufia, in the province of Natangen, founded in 1329, and after having been destroyed by the Lithuanians in 1348, was rebuilt, together with its castle, and put into a better state of defence; it is enclosed by a wall, and, in 1669, surrounded by a rampart. The burghefs, molf of whom are Lutherans, are about 200. The inhabitants derive their subsistence from a little commerce, brewing, agriculture, and mechanic trades; 46 miles S.E. of Königberg. N. lat. 53° 58'. E. long. 21° 27'.

RASTICO HARBOUR, Grand, a bay in the gulf of St. Lawrence, on the N. coast of the island of St. John. N. lat. 46° 25'. W. long. 62° 50'.

RASTORFF, a town of Austria; seven miles E. of Ehrnfprunn.

RASTOWICA, a river of Poland, which runs into the Rieper, on the borders of Russia.

RASURA, a word used by the pharmaceutic writers to express the shavings of woods, or other hard substances, to make them readily yield their virtues by decoction. Physicians also use it to express the corrodon of acids or humour.

RASURE in a Deed, in Law. See Deed.

RASZNA, in Geography, a town of Servia; 24 miles N. of Nifia.

RAT, in Zoology. See Mus.
RAT.

It has been observed that this country was formerly infested with two kinds of rats, the house-rat and the water-rat; but that it is believed that the latter, within this last half century, has destroyed the former. This is probably, however, only imaginary, since it is well known that the house-rats are frequently brought, in great abundance, into the different sea-ports of the kingdom, in corn, and other vessels. It seems not improbable, but that these different varieties of rats may intercommunicate, and by that means the latter become house-rats, as there is considerable diversity in the colours of the house-rats, some approaching nearly black, which is the natural colour of the water-rat, while the genuine house-rat is always of a darkish or dapple brown. In their habits they have some circumstances in which they agree, as in that of making burrows in the ground; but the water-rat is capable of living much in the water, and of feeding on fish and other aquatic animals, while the house-rat mottily lives upon grain, and other produce of that kind. The water-rats are also said, by Dr. Darwin, to eat the foliage as well as the seeds and fruits of vegetables, as he has seen a young rat of this kind devour a large leaf of the water-plantain (Alisma plantago). They likewise, as well as the house-rats, are destructive of young animals, such as ducklings, geese, chickens, and rabbits. But the great mischief which the water-rats produce, is in feeding on, and destroying, the roots of a great variety of vegetables, in their innumerable burrows. The above writer remembers to have seen some new-planting apple-trees taken out of the ground with nearly the whole of their smaller roots eaten, and the larger ones peeled by them. With the house kind, they are, likewise, extremely destructive of the food of poultry, and swine, and of course are highly detrimental near waters. It is remarked by the above able writer, that as these animals, like the dog, are of a lairous nature, and, as some materials have a strong scent, resembling, perhaps, that of their venereal organs, they are liable to be attracted by such smells, as dogs are, on the same account, he supposes, inclined to roll themselves in putrid carrion; and male cats to eat marum valerian, and cat-mint. It is of this principle that rat-catchers avail themselves, and by indulging the propensity, deceive them to their destruction, by blending with their favourite foods different strong-scented sublunacies, such as the essential oil of rhodium, or musk, with the poisonous powders of thrychohus nux vomica, or of delphinium flaviflagra, or perhaps of arsenic.

The first step taken by rat-catchers, in order to clear a house, &c. of those vermin, is to allure them all together, to one proper place, before they attempt to destroy them; for there is such an instructive caution in these animals, accompanied with a surprising sagacity in discovering any cause of danger, that if any of them be hurt, or purfued, in an unusual manner, the rest take the alarm, and become so fhy and wary, that they elude all the devices and stratagems of their purifiers for some time after. The place where the rats are to be collected, should be some closet, or small room, into which all the openings, but one or two, may be secured; and this place should be, as near as may be, in the middle of the house, or buildings. It is the practice, therefore, to attempt to bring them all together in some such place before any attempt to be made to take them; and even then to avoid any violence, hurt, or fright to them, before the whole be in the power of the operator. In respect to the means used to allure them to one place, they are various; one of those most easily and efficaciously practiced is the trailing some piece of their most favourite food, which should be of the kind that has the strongest scent, such as toasted cheese, or broiled red-herring, from the holes or entrances to their cells or in every part of the house, or contiguous buildings, whence it is intended to allure them. At the extremities, and in different parts of the course of this trailed tract, small quantities of meal, or any other kind of their food, should be laid, to bring the greater number into the tracks, and to encourage them to pursue it to the centre place, where they are intended to be taken; at that place, where time admits of it, a more plentiful repast is laid for them, and the trailing repeated for two or three nights. But besides this trailing, and way-haunting, some of the most expert of the rat-catchers have a shorter, and, perhaps, more effectual method of bringing them together, which is, the calling them, by making such a kind of whifling noise as resembles their own call, and by this means, with the assistance of the way-banks, they call them out of their holes, and lead them to the repast prepared for them at the place designed for taking them. But this is much more difficult to be practiced than the art of trailing; for the learning the exact notes, or cries, of any kind of beasts or birds, fo as to deceive them, is a peculiar talent, not easily attained to in other cafes.

And in practicing either of these methods great caution must be used by the operator to suppress, and prevent, the scent of his feet and body from being perceived; which is done by overpowering that scent by others of a stronger nature. In order to this the feet are to be covered with cloths rubbed over with affafoetida, or other strong smelling substances; and even oil of rhodium is sometimes used for this purpose, but sparingly, on account of its dearness, though it has a very alluring, as well as disguising effect. If this caution of avoiding the scent of the operator's feet, near the track, and in the place where the rats are proposed to be collected, be not properly observed, it will very much obtrude the nuances of the attempt to take them; for they are very shy of coming where the scent of human feet lies very fresh, and intimates, to their vagarious instinct, the presence of human creatures, whom they naturally dread. To the above-mentioned means of alluring by trailing, way-haunting, and calling, is added another of very material efficacy, which is the use of oil of Rhodium, which, like the marum fyriacum in the case of cats, has a very extraordinary fascinating power on these animals. The oil is extremely dear, and therefore very sparingly used. It is exhaled in a small quantity in the places, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be left brought together in order to their destruction; and it is used also, by immersing it on the surface of some of the implements used in taking them, by the method before described, and the effect it has in taking off their caution and dread, by the delight they appear to have in it, is very extraordinary.

It is usual, likewise, for the operator to disguise his figure as well as scent, which is done by putting on a coat of gowns or cloak, of one colour, that hides the natural form, and makes him appear like a pott, or such inanimate thing; which habit must likewise be scented as above, to overpower the smell of his perfon; and besides this he is to avoid all motion, till he has secured his point of having all the rats in his power. When the rats are thus enticed and collected, where time is afforded, and the whole in any house or out-buildings are intended to be cleared away, they are suffered to regulate on what they most like, which is ready prepared for them; and then to go away quietly for two or three nights; by which means those which are not allured the first night are brought afterwards, either by their fellows, or of the
the effects of the trailing, &c. and will not fail to come duly again, if they are not disturbed or molested. But many of the rat-catchers make shorter work, and content themselves with what can be brought together in one night or two; but this is never effectual, unless the building is small and entire, and the rats but few in number.

With respect to the means of taking them when they are brought together, they are various. Some entice them into a very large bag, the mouth of which is sufficiently capacious to cover nearly the whole floor of the place where they are collected; which is done by means of a vessel, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of proper food. This bag, which, before it was laid flat on the ground, with the mouth spread open, is to be suddenly closed when the rats are all in it. Others drive or frighten them, by flight noises or motions, into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being secured. Others, again, intoxicate or poison them, by mixing with the repast prepared for them the cocculus indicus, or the nux vomica. A receipt for this purpose has appeared, which directs four ounces of cocculus indicus, with twelve ounces of oatmeal, and two ounces of treacle or honey, to be made up into a moist pale with strong beer; but if the nux vomica be used, a much less proportion will serve than is here given of the cocculus. Any similar composition of these drugs, with that kind of food the rats are most fond of, and which has a strong flavour, to hide that of the drugs, will equally well answer the end. If, indeed, the cocculus indicus be well powdered, and infused in strong beer for some time, at least, half the quantity here directed will serve as well as the quantity before mentioned. When the rats appear to be thoroughly intoxicated with the cocculus, or fick with the nux vomica, they may be taken with the hand, and put into a bag or cage, the door of the place being first drawn to, lest those which have strength and sense remaining should escape. By these methods, when well conducted, a very considerable part of the rats in a farm, or other house, and the contiguous buildings, may be taken and destroyed. But various other methods have been practised.

In the Transactions of the Bath Agricultural Society, the following compositions are advised for destroying these mischievous creatures, and which are flated to have been attended with great success. First, to a quart of oatmeal, add six drops of oil of rhodium, one grain of mufk, and two or three of the nuts of nux vomica finely powdered, make them into pellets, and put them into the rat-holes. This, it is said, was at first greedily eaten, and did great execution; but the wise animals, after a time, ceased to eat it. Secondly; this consisted of three parts of oatmeal and one of flave's acre, mixed well into a pale with honey. Pieces of this pale were laid in their holes, and again did great execution. Thirdly; this is a method of destroying them by laying a large box down on its front side, with the lid supported open by a string over a pulley; and by trailing toasted cheese and a red-herring from their holes to this box, and placing oatmeal and other food in it, which they are for a few nights to be permitted to eat unmolested; and finally to watch them by moon-light, the inside of the box being painted white; and, when many of them are seen, to let down the lid; by which contrivance sixty of them are flated to have been taken at one time.

But though the usual ways of destroying rats by traps and poison, Mr. Forfith advises never to use arsenic, or corrosive sublimate, for that purpose, except under particular circumstances, as they are deadly poisons: nux vomica will, he thinks, generally answer the end as well, without the danger. He recommends it as a very good plan, to prevent accidents, to encole the traps in cages, having holes in the ends of them large enough to admit rats, but small enough to exclude dogs, cats, &c. And that, as a bait for rat-traps, the following composition may be made use of with advantage. Take a pound of good flour, three ounces of treacle, and fix drops of the oil of caraway: put them all in a dish; and rub them well together till they are properly mixed; then add a pound of crumb of bread. The traps baited with this mixture should be set as near their haunts as possible, but, for two or three days, so that not to fall or strike on the rats going in, but letting them have free liberty to go in and out at pleasure, as this makes them fearful. Some of the bait should also, he thinks, be laid at the rat-holes, and a little of it scattered quite up to the traps, and so on to the bridge of each trap, where a handful may be placed. It may also, he thinks, be proper to scent the traps with the following mixture, for the purpose of enticing the rats into them. Take twenty drops of the oil of rhodium, five or seven grains of mufk, and half an ounce of oil of nux vomica; put them in a small phial, and shake it well before using; then dip a piece of twisted paper or rag in the mixture, and rub each end of the trap with it, if a box trap, and put two or three drops on the bridge, leaving the paper or rag in the trap. Of whatever kind the trap is, it should be fecented; but once in a twelvemonth will be sufficient. Then throw some chaff mixed with a little wheat about the bottom of the trap, in order to deceive the rats; for they are very vagacious, and will not enter a fuphisious place. This will be necessary to be done only at the first time of setting the traps; for, after some rats have been caught and have watered and dugged in them, rats will enter boldly when they find others have been there before them: do not, therefore, wash or clean out the trap, as some people do before they set it again, but let the dung and urine remain in it. Keep the places where the traps are fet as private as possible; and when they are set for catching, mix no bread with the bait, as the rats will, in that case be apt, to carry it away.

And it is useful, this writer remarks, when the holes are found quiet, and that no rats use them, to dip them up with the following composition. Take a pint of common tar, half an ounce of pearl-ashes, an ounce of oil of vitriol, and a good handful of common salt, mix them all well together in an old pan or pot. Take some pieces of paper, and lay some of the above mixture very thick on them, then dip the holes well up with them, and build up the mouth of the holes with brick or stone; and mortar; if this be properly done, rats will, he affirms, no more approach these while either smell or taste remains in the composition.

But with a view to destroy rats in places where traps cannot be set, it is recommended to take a piece of the above bait, then to rasp into it three nuts of nux vomica, and add a quarter of a pound of crumb of bread, if there was none before; mix them all well together, and lay it into the mouth of their holes, and in different places where they frequent; but first give them of the bait without nux vomica, for three or four succeeding nights; and when they find it agrees with them, they will eat that mixed with the nut with greediness.

However, as it is frequently found that rats are very troublesome in sewers and drains, in such cases arsenic may be used with success in the following manner. Take some dead rats, and having put some white arsenic, finely powdered, into an old pepper-box, shake a quantity of it
on the fore-parts of the dead rats, and put them down the holes, or avenues, by the sides of the fewers at which they come in; this puts a stop to the live ones coming any further: for when they perceive the arsene, they will retire immediately; whereas, if they were put down without the arsene, the live ones would eat them.

It is by means of arsene, notwithstanding the above observations, that the most certain method of destroying these troublesome vermin, (provided they can be made to eat it,) takes place; which we have found to answer well, when it is prepared by being finely levigated, and mixed up with very strong old cheese and oatmeal.

In a note in the Agricultural Survey of Lancashire, it is stated, that it is greatly to be lamented that Mr. Heathcote’s method of destroying rats and mice is not generally known and practised; if it were, there would be a total extermination of those obnoxious and destructive animals; for in one night he totally destroys them (where he is employed), be they ever so numerous, as can be well attested by hundreds in the neighbourhood of Ormkirk, who have employed him. And it is added, that the composition he makes use of he puts in their holes and burrows, and from the small quantity he uses, it is astonishing it should have such an effect: it will keep good two years. It is also stated, that a farmer recommends, for the destruction of rats, one ounce of pounded quick-lime to four ounces of tallow cake, to be beaten together and made into balls, and placed in their runs, which has cleared many buildings. But it has been proved by experience, as is said, that an ounce of aerated barytes finely powdered, mixed with the tallow, in place of lime, is more effectual. And it has been remarked by the author of Physiologia, with the view of destroying the water-rats, that they poifon some kind of ingenuity similar to the beaver in the confection of their houses near the bricks of rivers and pools; which have two apertures, one above ground amongst the grass, and the other beneath the surface of the water; and unless they can hide their upper opening amid weeds, or grafs, they forfake the situation. Thus, if a rim, three or four feet in breadth, round a fish-pond be kept so low as to rise only two, three, or four inches above the level of the water; and if this be kept clean from high grass or weeds, the rats will defert the pond.

But after all, it is probable that this highly destructive animal, and great pest to the farmer, might be more readily exterminated by parishes uniting for the purpose, and raising certain sums of money to be applied in this way, under the direction of a proper person who is fully acquainted with the business.

In many grain and other districts in the kingdom these animals prevail very much, especially the grey kind, particularly in all those where there are no regular raised fladdles or flandas for the grain to stick to, which is the case in a great number. The mischief, injury, and destruction of grain which is produced in this way, is scarcely to be calculated; and they are besides very mischievous, troublesome, and inconvenient in several others; so that they should be everywhere extirpated as much as possible. And in corn tracts, flandas or fladdles should everywhere be provided in order to prevent mischief being done by them. See Vermes, and Stand, Corn.

Rat, Norway or brown, Mus Norvegicus, (Mus decumanus) is a rat whose head, back, and sides are of a light brown colour, mixed with tawny and ash-colour; the breast and belly are of a dirty white; the feet naked, and of a dirty flesh-colour; the fore-feet are furnished with four toes, and a claw instead of the fifth; the length from the note to the tail is nine inches, and the tail is of the same length. This animal is more strongly made than the common black rat, or Mus rattus.

This species of rat, which is the same animal that is called in the East Indies a bondicote, now inhabits most parts of Europe; whether it is supposed to have been brought within the last century, in some of the India ships. It came into Great Britain about 75 or 80 years ago, but has not been known in the neighbourhood of Paris above half that time. They swarm in Petersburg, and are known in Prussia; but have not yet reached the opposite side of the Baltic, as Linnaeus takes no notice of this species. These were probably the more Capfii of Aelian, which made periodical visits in great multitudes to the countries bordering on the Caspian sea, swimming boldly over the rivers, holding by one another’s tail. (Aelian. Hist. An. 17. cap. 17.) They burrow, like the water rat, on the sides of ponds and ditches; swim and dive well; live on grain and fruits, but will destroy poultry and game; increase fast, producing from fourteen to eighteen young at a time; are very bold and fierce; will turn, when closely pursed, and stolen on the flick or hand that offers to strike them; they have destroyed the common black rat in most places: they inhabit the fields part of the year, but migrate in great numbers into houses, and do much mischief. The bite of these rats is not only very bad; but the wound being immediately attended with a great swelling, and healing very slowly. Pennant. See Mus Decumanus.

Rat, Norway, is also a name given by some writers to the lemming, or fable mouse. See Mus Lemmus, and Sable Mouse.

Rat, Water. See Mus Amphibius.

Rat, in the Sea Language, is used to express a part of the sea, where there are rapid and dangerous currents, or counter-currents.

Rat-Goose, in Ornithology, the name of a small species of wild goose, common in some of the northern counties of England.

Rat-Tails, in the Manage. See Arrets.

Rat-Tailed. A horfe is thus called that has no hair upon his tail.

Rat-Tailed Worms, in Natural History, a species of fly-worms with long tails, resembing thole of rats, whence they have their name. They are of several sizes, and found also in different places, but all change into two-winged flies, having very much the resemblance of bees, and commonly called bee-fly. See Drone-Fly.

Rat, Cape, in Geography, a cape of Africa, in the Red Sea. N. lat. 14° 55′.

Rat Island, a small island in Milford Haven.—Also, an island in the Red Sea. N. lat. 14° 55′.—Also, a small island in the East Indian sea, near the W. coast of Sumatra. S. lat. 3° 57′. E. long. 101° 55′.—Also, a small island in the Mergui Archipelago, S.W. of Olive island.

Rata pro Rata. See Pro rata.

Onerando pro Rata portionis. See Onerando.

Ratapiia, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruits, particularly of cherries and apricots.

Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel in which brandy has been long kept;
kept; then adding to them the kernels of cherries, with strawberries, figs, cinnamon, white pepper, nutmegs, cloves; and to twenty pounds of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then closed close for two months before it be tapped.

Ratafia of apricots is prepared two ways; viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy, with figs, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days; then straining the liquor, and putting it up for use; or else by infusing the apricots, cut in pieces, in brandy, for a day or two; pouring it through a straining-bag, and then putting in the usual ingredients.

RATAN, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 58'. E. long. 20° 39'.

RATCH, or Rash, in Clock Work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, to make the clock strike.

RATCHETS, in a Watch, are the small teeth at the bottom of the fife, or barrel, which flop it in winding up.

RATCHIN Lupa, in Geography, a large lake of Thibet. N. lat. 30° 43'. E. long. 82° 27'.

RATCLIFF, a town of America, in Maryland; 22 miles S. of Salisbury.

RATE, a standard or proportion, by which either the quantity or value of a thing is adjusted. The rates of bread, &c. in London, are fixed by authority. See Alfife of Bread.

The rate of interest, as now established by law in England, is five per cent. The rate of interest in Italy, is three per cent.; in Sweden, fix; in France, five; in Spain, ten; in Barbadoes, ten; in Ireland, twelve; in Turkey, twenty. Low rates of interest advance the prices of land.

The rates or fares of hackney-coachmen, chairmen, and watermen, are fixed by act of parliament. See Hackney Coaches, &c.

The rates of exchange, factorship, &c. are different. See Exchange, Factorage, &c.

Rate of a Ship of War, is its order, degree, or distinction, as to magnitude, burden, force, &c.

The British fleet is accordingly distributed into fix rates, exclusive of the inferior vessels that usually attend on naval armaments; as fleets of war, armed ships, bomb-ketches, fire-ships, and cutters or schooners, commanded by lieutenants.

Ships of the first rate mount a hundred cannon, and some more, having forty-two-pounders on the lower deck, twenty-four-pounders on the middle deck, twelve-pounders on the upper deck, and fix-pounders on the quarter-deck and forecastle. They are manned with eight hundred and fifty men, including their officers, seamen, marines, and servants.

In general, the ships of every rate, besides the captain, have the master, the boatswain, the gunner, the chaplain, the purser, the surgeon, and the carpenter; all of whom, except the chaplain, have their mates or assistiants, in which are comprehended the sail-maker, the master at arms, the armorer, the captain's clerk, the gunsmith, &c. The number of other officers is always in proportion to the rate of the ship. Thus, a first rate has five lieutenants, fix master's mates, twenty-four midshipmen, and five surgeon's mates, who are considered as gentlemen; besides the following petty officers: quarter-masters, and their mates, fourteen; boat- swain's mates, and yeomen, eight; gunner's mates and assistiants, fix; quarter-gunniers, twenty-five; carpenter's mates, two, besides fourteen assistiants; with one lieutenant, and Cleward's mate to the purser.

Ships of the second rate carry ninety-eight and ninety guns upon three decks; of which those on the lower battery are thirty-two-pounders; those on the middle, eighteen-pounders; on the upper deck, twelve-pounders; and those on the quarter-deck, fix-pounders, which usually amount to four or fix. Their complement of men is seven hundred and fifty, in which there are five lieutenants, four master's mates, twenty-four midshipmen, and four surgeon's mates, fourteen quarter-masters and their mates, eight boat-swain's mates and yeomen, fix gunner's mates and yeomen, with twenty-two quarter-gunniers, two carpenter's mates, with ten assistiants, and one Cleward and Cleward's mate.

Ships of the third rate carry from sixty-four to eighty cannon, which are thirty-two, eighteen, and nine-pounders. The eighty-gun ships, however, begin to lose their repute, and give way to those of seventy-four, seventy-five, &c. which have only two whole batteries; whereas the former have three, with twenty-eight guns planted on each; the cannon of their upper deck being the same as those on the quarter-deck and forecastle of the latter, which are nine-pounders. The complement in a seventy-four is fix hundred and fifty; and in a sixty-four, five hundred men: having in peace, four lieutenants, but in war, five, and when an admiral is aboard, fix. They have three master's mates, sixteen midshipmen, three surgeon's mates, ten quarter-masters and their mates, fix boat-swain's mates and yeomen, four gunner's mates and yeomen, with eighteen quarter-gunniers, one carpenter's mate with eight assistiants, and one Cleward and Cleward's mate under the purser.

Ships of the fourth rate mount from sixty to fifty guns, upon two decks and the quarter-deck. The lower tier is composed of twenty-four-pounders; the upper tier, of twelve-pounders; and the cannon on the quarter-deck and forecastle are fix-pounders. The complement of a fifty-gun ship is three hundred and fifty men, in which there are three lieutenants, two master's mates, ten midshipmen, two surgeon's mates, eight quarter-masters and their mates, four boat-swain's mates and yeomen, one gunner's mate and one yeoman, with twelve quarter-gunniers, one carpenter's mate and fix assistiants, and a Cleward and Cleward's mate.

All vessels of war under the fourth rate, are usually comprehended under the general name of frigates, and never appear in the line of battle. They are divided into the fifth and sixth rates, the former mounting from forty to thirty-two guns, and the latter from twenty-eight to twenty. The largest of the fifth rate have two decks of cannon, the lower battery being of eighteen-pounders, and that of the upper deck of nine-pounders; but those of thirty-fix and thirty-two guns have only one complete deck of guns, mounting twelve-pounders, besides the quarter-deck and forecastle, which carry fix-pounders. The complement of a ship of forty-four guns is two hundred and eighty men; that of a frigate of thirty-fix guns, two hundred and forty men. The frigate has three, and the second two lieutenants; and both have two master's mates, fix midshipmen, two surgeon's mates, fix quarter-masters and their mates, two boat-swain's mates and yeomen, one gunner's mate and one yeoman, with ten or eleven quarter-gunniers, and one purser's Cleward.

Frigates of the sixth rate carry nine-pounders; those of twenty-eight guns having three-pounders on their quarter-deck, with two hundred men for their complement; and those of twenty-four, one hundred and sixty men; the former has two lieutenants; the latter, one; and both have two master's mates, four midshipmen, one surgeon's mate, four quarter-masters and their mates, one boat-swain's mate and one yeoman, one gunner's mate and one yeoman, with fix or seven quarter-gunniers, and one purser's Cleward.
The floops of war carry from eighteen to eight cannon: the largest of which have six-pounders; and the smallest, viz. those of eight or ten guns, four-pounders. Their officers are generally the same as in the fifth rates, with little variation; and their complements of men are from one hundred and twenty to sixty, in proportion to their force or magnitude.

Bomb-vessels are on the same establishment as floops; but fire-ships and hospital-ships are on that of fifth rates. If the dimensions of all ships of the same rate were equal, it would be easy to collect them into one point of view in a table; but as there is no invariable rule for the general dimensions, we shall select those of some of a late construction in each rate.

Ships of one hundred guns, and above, and downwards to sixty-four, are termed ships of the line.

Ships of the line, fifties, frigates, and royal yachts, are commanded by post-captains; ships of war, bomb-vessels, fire-ships, armed ships, foreships, and armed en flûte, under fifty guns, by commanders; schooners, cutters, &c. by lieutenants; sloops-vessels occasionally by masters; and craft by midshipmen, who have passed for lieutenants.

Ships of the second rate, and those of the third, which have three decks, carry their arms remarkably well, and labour very little at sea. They are excellent in a general action, or in cannonading a fortres. Those of the third rate, which have two tiers, are fit for the line of battle, to lead the convoys and squadrons of ships of war in action; and, in general, to suit the different exigencies of the naval service. The fourth rates may be employed on the same occasions as the third rates; and may be also defined for service among the foreign colonies, or on expeditions of great distance; since these vessels are usually excellent for keeping and maintaining the sea. Vessels of the fifth rate are too weak to suffer the shock of a line of battle; but they may be defined to lead the convoys of merchant ships, to protect the commerce in the colonies, to cruize in different latitudes, to accompany squadrons, or be sent express with necessary intelligence and orders. The fame may be observed of the fifth rates.

The frigates which mount from twenty-eight to thirty-eight guns upon one deck, with the quarter-deck, are extremely proper for cruising against privateers, or for short expeditions, being light, and usually excellent failers. Falconer.

**RAT**

RATE, in Geography, a town of Hindustan, in Myfore; 25 miles E. of Rattinghley.

RATEEN, or RATTEN, in Commerce, a thick woollen stuff, quilted, woven on a loom with four threads, like ferges, and other stuffs that have the whale or quilting.

There are some rateens drenched and prepared like cloths; others left simply in the hair; and others where the hair, or knap, is frized.

Rateens are chiefly manufactured in France, Holland, and Italy; and mostly used in linings.

The frize is a sort of coarse rateen; and the drugget is a rateen half linen, half woollen.

RATEL, in Zoology, a name given by the Hottentots to an animal inhabiting the Cape of Good Hope, which lives on honey, and is a great enemy to bees; hence called the *Viverra Meliorea*: which fee. It has a blunt black nose; no external ears, but a small ring round the orifice; a rough tongue, short legs, very long claws, which are straight like those of a badger, and guttered beneath; the colour of the forehead, crown, and whole upper part of the body, is a cinereous grey; the cheeks, and space round the ears, throat, breast, belly, and limbs, black; from each ear to the tail extends along the sides a dully line, leaving beneath another of grey. Its length from the nose to the tail is forty inches, and the tail twelve.

This animal preys in the evening, and ascends to the highest parts of the desert to look about; and will then put one foot before its eyes, to prevent the dazzling of the sun. The reason of its going to an eminence is for the sake of seeing or hearing the honey-guide cuckoo, or ecuclus indicator, which lives on bees, and, as it were, conducts it to their haunts. Pennant.

RATENSTADT, in Geography, a town of Hungary; 16 miles S.E. of Bae.

RATESPONTE de Mulher, a town of Portugal, in the province of Entre Duero e Minho; 15 miles N.E. of Vila de Conde.

RATH, a word used in the classification of names of places in Ireland, as Rathdruun, &c. It signifies an increscence, or fort.

RATH, ripe, in Agriculture, a term applied to some early ripe corn crops, and which have a degree of redness in the straw; such as some varieties of barley, &c.

RATHKANGAN, in Geography, a post-town of the county of Kildare, Ireland, situated on the Athy branch of the Grand Canal; 283 miles W. from Dublin, and 5 miles N.N.W. from Kildare.

RATHCRONRATH, a small town of the county of Westmeath, Ireland, which gives name to a barony. It is 42 miles N. by W. from Dublin, on the road to Lanesborough, and 3 miles W. from Mullingar.

RATHCOOLE, a small post-town of the county of Dublin, Ireland, where fairs are held for cattle and pedlars' wares. It is on the great southern road, 32 miles S.W. from Dublin.

RATHCORMUCK, a post-town of the county of Cork, Ireland, which returned two members to the Irish parliament, before the union. It has gone much to decay, in consequence of the prosperity of Fermoy, which is little more than three miles distant. It is near the river Bride, 111 miles S.W. from Dublin, and 13½ N.E. from Cork.

RATHDOWNY, a post-town of the Queen's county, Ireland; 50 miles S.W. from Dublin.

RATHDRUM, a post-town of the county of Wiclow, Ireland, situated on the river Ovoca. It has a monthly fair
fair for flannels, of which there is a considerable manufacture. The adjoining country is very interesting, and the Wicklow copper-mines are not far distant. Rathdrum is 29 miles S. from Dublin.

RATHENAU, or RATEMAO, a town of the middle mark of Brandenburg, on the Havel; 38 miles W. of Berlin. N. lat. 52° 38'. E. long. 12° 30'.

RATHER, or NETHEN, a river of England, which runs into the Lune, four miles N. of Kirkby Lonsdale, in the county of Westmoreland.

RATHERIUS, in Biography, a very learned prelate in the tenth century; commenced his ecclesiastical career by embracing a monastic life at the abbey of Lobbes, or Laubes, in Flanders. Here he distinguished himself by his abilities and acquirements. In the year 928, after Hilduin had been driven out of the fee of Liege, he accompanied him into Italy; and in 931 he was, by the express order of the pope, put in possession of the fee of Verona. As, however, this was in direct hostility to the king of the country, he was exposed to much persecution, and at length banished from Italy. After spending five years in exile, he returned with the hope of regaining his bishops' see; but he was unsuccessful, and was ordered to withdraw. He obeyed, and retired into Provence: from this place he went to the abbey of Lobbes, where the remembrance of the honour, which he had formerly reflected on that establishment, secured him a welcome reception. Shortly after this, he was sent for by the emperor Otton, who placed him near the perill of his brother Bruno. This prince, having been made archbishop of Cologne in the year 953, preferred Ratherius to the bishopric of Liege; from which, however, he was driven in about two years. As the emperor Otton was at this time in Italy, our prelate made an effort to recover his former fee of Verona. Accordingly he laid his cafc before a synod assembled at Pavia, which palled a decree that he should be re-establishcd in that bishopric. His peace was soon interrupted by controversies with the clergy, who could not endure his reproofs of their irregularities and corruptions; till at length they became fo irksome to him, that he determined to take his final leave of Italy. He accordingly went to France, where he purchased some estates, and obtained the abbeys of St. Amand, Aumont, and of Aunay. He died at Namur, about the year 973. His works are numerous, some of which are inserted in father d'Achéry's 'Spicilegium.' They are said to afford evident proofs of great sagacity and judgment, while they breathe throughout an ardent love of virtue. They also show, that he was most zealous and intrepid in exposing the irregularities and vices of the times, and particularly the corrupt morals of ecclesiastics. Moreri. Mofheim.

RATHRILAND, in Geography, a poll-town of the county of Down, Ireland. It is situated on a rising ground, and has four great straight roads leading up to it, and entering in the town. It is on the road to Downpatrick, and much frequented. The neighbourhood abounds with granite of a close texture, and is fit for building. On the summit of the hill are the ruins of a castle, formerly one of the residences of the Magennis, lords Ieach. Rathriland is 5 1/4 miles N. from Dublin, and 7 1/2 miles N.E. from Newry.

RATHKEALE, a post-town of Ireland, in the county of Limerick. It is situated on the river Deel, and was formerly a corporation town, and of much more consequence than at present. It has several fairs, one of which for horses is much frequented, as are also its races. In the reign of queen Elizabeth, it sustained an attack of the English army. The ruins of a priory, founded by a person of the name of Harvey, are still remaining. Rathkeale is 108 miles S.W. from Dublin, and 14 miles W.S.W. from Limerick.

RATHLACKEN, a post-town of the county of Mayo, Ireland, on the sea-coal, nor far from Rathlacken or Reaghan head, and west of the entrance to Killala bay. It is 132 miles W.N.W. from Dublin, and 5 miles N. from Killala.

RATHLIN, RAGHILIN, or Raghery, an island situated between the north coal of Antrim, in Ireland, and Scotland, and considered as belonging to the former. It is about five miles in length, and three quarters of a mile in breadth, being bent in an angle towards the middle. This angle lies opposite to Ballycastle, and forms a tolerable bay, called Church bay; but in a westerly wind, though the anchorage is good, few vessels can ride it out, from the swell along the coast. The number of plantation acres is about 2000, which support a population of about 130 or 140 families, amounting to about 1100 persons. The cultivated land is kindly enough, and produces excellent barley. But kelp is the great source of wealth to this island, 100 tons of which have been exported from it in one year. The horses, as well as the sheep, are small, but serviceable; and the black cattle are not large, though they do well when brought to the main land, and better foil. The inhabitants are a simple, laborious, and honest race of people, much attached to their own island, and regarding Ireland as a foreign country. The monuments of antiquity are small tumuli, in one of which, when opened, a stone coffin was found, beside which an earthen vessel stood. Within the tumuli lay a considerable number of human bones, which might have been the remains of more ignoble men than the peron whose remains the coffin covered. Brazen swords and spear-heads have also been found. The remains of a fortress are visible, where Robert Bruce is said to have defended himself for some time, when obliged to fly from his country. N. lat. 55° 22'. W. long. 6° 5'.

RATHMANSdorf, a town of Sileia, in the principality of Neisse; 4 miles N.N.W. of Weidenau.

Rathown, a poll-town of the county of Wee-muth, Ireland, near the borders of Longford; 48 miles W.N.W. from Dublin.

RATHSCHACH, or Radesche, a town of the duchy of Carniola, on the Saue; 9 miles W.N.W. of Gurkfeld.

RATHSPRESENTGERS, in Commerce, silver coins of Aix-la-Chapelle, being double, fingle, or half pieces of 22, 16, and 8 marks. By the affay, the rathsprentger is worse than the English standard of 11 oz. 2 dwt.; by 4 oz. 2 dwt. Its weight is 4 dwt. 15 gr.; its content in pure silver 56.9 gr.; and its value in flerling 8 d. The double of the same is worse by 2 oz. 15 dwt.; its weight 6 dwt. 235 gr.; its content in pure silver 116.3 gr.; and its value in flerling 12. 44 d. This coin bears on one side an eagle within a circle, marked 16 on his breast, (3p on the double piece,) and within another circle the legend, REGNUM CURIA PRINCIPALIS PRIMA; and next the edge, URBES IN/URBES REGALIS. REGNI SEDES; on the other side, or revers, an altar, with two swords and a crown over it, on the double piece; but on the fingle, a crown and the date within a circle; the legend on both is LOCUS CESAREA CONIARATONIS, Caeasar being a general title for the emperor. Kelly's Un. Cambil.

RATI, in Geography, a small island in the Grecian Archipelago, near the S. coast of Nicaragua.

RATIBOR, a town of Sil-a, in a principality of its name, on the Oder, which here becomes navigable; 70 miles
miles S.E. of Breslau. N. lat. 50°. E. long. 18° 51'. The principality is bounded N. by the principality of Oppeln, on the E. by Poland, on the S. by Toden, and on the W. by the principality of Jagendorf. Its soil is better than that of Oppeln, as it produces a sufficient supply of wheat, rye, and barley, with fruits; and besides, it has also good pasture grounds. Its only river is the Oder, which passes through its western part; but it is abundantly watered in all its parts with streams, ponds, and lakes. It contains only three cities, and the inhabitants are universally Polish. It became a principality in 1884, and about 200 years afterward it was united to Oppeln, from which it has never been separated.

**RATIFICATION**, a act, approving of, and confirming, something done by another, in our name.

A treaty of peace is never secure till the princes have ratified it.

All procuration imports a promise of ratifying and approving what is done by the proxy, or procurator; and then treating with a procurator, agent, factor, &c. a ratification is frequently necessary on the part of his principal.

**Ratification** is particularly used, in our Laws, for the confirmation of a clerk in a benefice, prebend, &c. formerly, is given him by the bishop, &c. where the right of patronage is doubted to be in the king.

Ratification is also used for an act confirming something we ourselves have done in our own name.

An execution, by a major, of an act passed in his minority, is equivalent to a ratification.

**RATING.** See Ratio.

**RATINGEN,** or Raittingen, in Geography, a town of the duchy of Berg; 4 miles N.E. of Dusseldorp. N. lat. 51° 15'. E. long. 6° 47'.

**RATINO,** a town of Naples, in the county of Molife; 6 miles S.E. of Molife.

**RATIO,** in Arithmetic and Geometry, that relation of homogeneous things, which determines the quantity of one from the quantity of another, without the intervention of any third.

The homogeneous things, thus compared, we call the terms of the ratio; particularly that referred to the other, we call the antecedent; and that to which the other is referred, the consequent.

Thus, when we consider one quantity by comparing it with another, to see what magnitude it has in comparison of that other; the magnitude this quantity is found to have in comparison with it, is called the ratio of this quantity to that: some think would be better expressed by the word comparison.

Euclid defines ratio by a mutual relation of two magnitudes of the same kind in respect of quantity. But this definition is found defective; there being other relations of magnitudes which are constant, yet are not included in the number of ratios; such as that of the right line, to the line of the complement in trigonometry.

Hobbes endeavoured to improve Euclid’s definition of ratio, but without success: for in defining it, as he does, by the relation of magnitude to magnitude, his definition has not only the same defect with Euclid’s, in not determining the particular kind of relation; but it has this farther, that it does not express the kind of magnitudes which may have a ratio to one another.

Ratio is frequently confounded, though very improperly, with proportion. Proportion, in effect, is an identity or similitude of two ratios.

Thus, if the quantity A be triple the quantity B; the relation of A to B, i.e. of 3 to 1, is called the ratio of A to B. If two other quantities, C, D, have the same ratio to one another that A and B have, i.e. to be triple one another, this equality of ratio constitutes proportion; and the four quantities A : : B : C : D, are in proportion, or proportional to one another.

So that ratio exists between two terms; proportion requires more.

There is a twofold comparison of numbers: by the first, we find how much they differ, i.e. by how many units the antecedent exceeds, or comes short of, the consequent.

This difference is called the arithmetical ratio, or exponent of the arithmetical relation or habitat of the two numbers. Thus, if 5 and 7 be compared, their arithmetical ratio is 2.

By the second comparison, we find how oft the antecedent contains, or is contained in, the consequent; i.e. as before, what part of the greater is equal to the less.

This ratio, being common to all quantity, may be called ratio in the general, or by way of eminence: but it is usually called geometrical ratio; because expressed, in geometry, by a line, though it cannot be expressed by any number.

Modern authors distinguishing ratio, with regard to quantity in the general, into rational and irrational.

**Ratio, Rational,** is that which is as one rational number to another; i.e. gr. as 3 to 4.

**Ratio, Irrational,** is that which cannot be expressed by rational numbers.

Suppose, for an illustration, two quantities, A and B; and let A be less than B. If A be subtracted as often as it can be from B, e. gr. five times, there will either be left nothing, or something. In the former case, A will be to B, as 1 to 5; that is, A is contained in B five times; or A = 5 B. The ratio here, therefore, is rational.

In the latter case, either there is some part, which, being subtracted certain times from A, e. gr. 3 times, and likewise from B, e. gr. 7 times, leaves nothing; or there is no such part: if the former, A will be to B as 3 to 7, or A = 7 B; and therefore the ratio, rational. If the latter, the ratio of A to B, i.e. what part A is of B, cannot be expressed by rational numbers; nor any other way than either by lines, or by infinite approaching series.

The exponent of a geometrical ratio is the quotient arising from the division of the antecedent by the consequent. Thus, the exponent of the ratio of 3 to 2, is 1 1/2; that of the ratio of 2 to 3, is 3/2; for when the less term is the antecedent, the ratio, or rather the exponent, is a proper fraction. Hence the fraction 2/3 = 3/2. If the consequent be unity, the antecedent itself is the exponent of the ratio; thus, the exponent of 4 to 1, is 4. See Exponent.

If two quantities be compared, without the intervention of a third; either the one is equal to the other, or unequal: hence, the ratio is either of equality or inequality. If the terms of the ratio be unequal, either the left is referred to the greater, or the greater to the lefts: that is, either the less to the greater, as a part to the whole, or the greater to the less, as the whole to a part. The ratio, therefore, determines how often the less is contained in the greater, or how often the greater contains the less; i.e. to what part of the greater the less is equal.

The following distinctions of ratios are sometimes found in early authors.

The ratio which the greater term has to the less, e. gr. 6 to 3, is called the ratio of the greater inequality: the ratio which the less term has to the greater, e. gr. 3 to 6, is called the ratio of the lesser inequality.

This ratio corresponds to quantity in the general, or is admitted.
admitted of by all kinds of quantities, discrete or continued, commensurable or incommensurable; but discrete quantity, or number, does likewise admit of another ratio.

If the lefs term of a ratio be an aliquot part of the greater, the ratio of the greater inequality is said to be: multiplex, multiple; and the ratio of the lefs inequality, submultiplex.

Particularly, in the first case, if the exponent be 2, the ratio is called dupla; if 3, tripda, &c. In the second case, if the exponent be \(\frac{1}{2}\), the ratio is called subdupla; if \(\frac{1}{3}\), subtripla, &c. 

E. gr. 6 to 2 is in a triple ratio; because 6 contains two thrice. On the contrary, 2 to 6 is a subtriple ratio; because 2 is the third part of 6.

If the greater term contains the lefs once, and over and above an aliquot part of the fame; the ratio of the greater inequality is called superparticularis, and the ratio of the lefs sub-supraparticularis.

Particularly, in the first case, if the exponent be \(\frac{1}{2}\), it is called sesquialterate; if \(\frac{1}{3}\), sesquiquartate, &c. In the other, if the exponent be \(\frac{1}{3}\), the ratio is called subsesqui-tertiate; if \(\frac{1}{4}\), subsesqui-quartate, &c.

E. gr. 3 to 2 is in a sesqui-alterate ratio; 2 to 3 in a sub-sesquialterate.

If the greater term contains the lefs once, and over and above several aliquot parts; the ratio of the greater inequality is called superparticulars; that of the lefs inequality is sub-supraparticulars.

Particularly, in the former case, if the exponent be \(\frac{1}{2}\); the ratio is called superduplapes quarta; if the exponent be \(\frac{1}{3}\), supertriples quartae; if \(\frac{1}{4}\), superquadruples septima, &c. In the latter case, if the exponent be \(\frac{1}{3}\), the ratio is called subsupraparticularis tertias; if \(\frac{1}{4}\), subsupraparticularis quartas; if \(\frac{1}{5}\), subsupraparticularis quintas, &c.

E. gr. the ratio of 5 to 3 is superquetertial tertias; that of 3 to 5, subquetertial tertias.

If the greater term contains the lefs several times, and, besides, some quota part of the fame; the ratio of the greater inequality is called multiplex superparticularis; and the ratio of the lefs inequality, multiplex sub-supraparticularis.

Particularly, in the former case, if the exponent be \(\frac{1}{2}\); the ratio is called dupla sesqui-tertiae; if \(\frac{1}{3}\), tripula sesqui-quartae, &c. In the latter case, if the exponent be \(\frac{1}{3}\), the ratio is called subdupla sesqui-tertiae; if \(\frac{1}{4}\), subtripla sesqui-quartae, &c.

E. gr. the ratio of 16 to 5 is tripula sesquiquinta; that of 5 to 9, dupla sesquiquarta.

Lastly, if the greater term contains the lefs several times, and several aliquot parts of it besides; the ratio of the greater inequality is called multiplex superparticulars; that of the lefs inequality, multiplex sub-supraparticulars.

Particularly, in the former case, if the exponent be \(\frac{1}{2}\); the ratio is called dupla super Triples quarta; if \(\frac{1}{3}\), tripula superquadripures septima, &c. In the latter case, if the exponent be \(\frac{1}{3}\), the ratio is called subdupla superparticulars tertiae; if \(\frac{1}{4}\), subtripla superquadripures septima, &c.

E. gr. the ratio of 25 to 7 is tripula superquadripures septima; that of 7 to 8, dupla subsupraparticulars tertiae.

These are the various kinds of rational ratios; the names of which, though they occur but rarely among the modern writers (for in lieu of them they use the small terms of the ratios, e. gr. for dupla 2:1, for sesquialterate 3:2); yet are they absolutely necessary to such as converse with the ancient authors.

Clavius observes, that the exponents denominate the ratios of the greater inequality, both in deed and name; but the ratios of the less inequality, only in deed, not in name; but it is easy finding the name in thefe, if you divide the denominator of the exponent by the numerator.

E. gr. if the exponent be \(\frac{1}{2}\), then \(5:8 = 1\); whence it appears, the ratio is called superparticularis quintas. As to the names of irrational ratios, nobody ever attempted them.

Some, or identic ratios, are those whose antecedents have an equal respect to their consequents, i.e. whose antecedents divided by their consequents, give equal exponents. And hence may the identity of irrational ratios be conceived.

Hence, first, as oft as the antecedent of one ratio contains its consequent, or whatever part it contains of its consequent, so oft, or such part of the other consequent does the antecedent of the other ratio contain: or, as oft as the antecedent of the one is contained in its consequent, so oft is the antecedent of the other contained in its consequent.

Secondly, if A be to B as C to D; then will A : B :: C : D; or A : B = C : D. The former of which is the usual manner of representing the identity of ratios, the latter is that of the excellent Wolthus; which has the advantage of the former, in that the middle character, =, which denotes the sameness, is scientific; i.e. it expresses the relation of the thing represented, which the other, ::, does not. See Character.

Two equal ratios, e. gr. B : C = D : E, we have already observed, constitute a proportion: of two unequal ratios, e. gr. A : B and C : D, we call A : B the greater, if A : B > C : D; on the contrary, we call C : D the lefer, if C : D > A : B.

Hence, we express a greater and lefer ratio thus: e. gr. 6 to 3 has a greater ratio than 5 to 4; for, 6 : 3 = 2 : 1 > 5 : 4 (== 1\(\frac{1}{2}\)). But 3 to 6 has a lefer ratio than 4 to 5; for \(\frac{3}{4} > \frac{2}{5}\). Compound ratio is that made up of two or more other ratios, which the fum of the antecedents of two or more ratios has to the fum of their consequents. Thus, 6 to 72 is in a ratio compounded of 2 to 6, and 3 to 12.

Particularly if it be compounded of two, it is called a duplicate ratio; if of three, a triplicate; if of four, quadruplicate; and, in the general, multiplicate, if it be composed of several similar ratios. Thus \(48 : 3\) is a duplicate ratio of 4 : 1 and 12 : 3.

RATIO, Additive. See ADITIV.
RATIO, Alternate. See ALTERNATE.
RATIO, Ordinate. See ORDINATE.

RATIO Modularis and Modulus, were terms introduced into use by Cotes, but more modern authors do not use them always in the same fene: according to Cotes, the modulus in logarithms is that number which connects any system of logarithms with the hyperbolic system, or that number by which the hyperbolic number of a logarithm must be multiplied, or by the reciprocal of which it must be divided, in order to transform it to another system; and this modulus, is, therefore, always the reciprocal of the hyperbolic logarithm of the radic of that system to which the modulus belongs.

This is what Cotes calls the modulus, to whom we owe the introduction of the term; and the reciprocal of it he calls the ratio modularis: but some modern authors, as Lagrange, &c. ufe the term modulus to denote the ratio modularis of Cotes.

The modulus of the hyperbolic system is 1, this being the reciprocal of the hyperbolic logarithm of 2.71828182, the radix of this system; and the modulus of the common logarithmic
RATIO.

Logarithmic system is \(\log_{10}\), which is the reciprocal of 2.3025809, the hyperbolic logarithm of \(e\), the radius of this system. It is shown under the article Logarithms, that

\[
\log a = \left(\frac{a}{r} - 1\right) - \frac{1}{2} \left(\frac{a}{r} - 1\right)^2 + \frac{1}{3} \left(\frac{a}{r} - 1\right)^3 + \frac{1}{4} \left(\frac{a}{r} - 1\right)^4, \quad \&c.
\]

where \(r\) is the radius, and may be assumed at pleasure, and the reciprocal of this whole denominator is indicated as the modulus. In the hyperbolic system the whole denominator is assumed 1, which makes \(r = 2.7182818\); and in the common system \(r\) is assumed \(e\), and the whole series becomes \(2.3025809\), which is the reciprocal of the modulus; and since, in the former case, we have

\[
\text{hyp. log. } a = (a - 1) - \frac{1}{2} (a - 1)^2 + \frac{1}{3} (a - 1)^3, \quad \&c.
\]

it follows also that in any other

\[
\text{hyp. log. } r = (r - 1) - \frac{1}{2} (r - 1)^2 + \frac{1}{3} (r - 1)^3, \quad \&c.
\]

whatever be the value of \(r\); therefore, in every system, the modulus is the reciprocal of hyp. log. of the radius. See Logarithms.

Ratio, Denominator of a. See Denominator.

Ratio, Properties of. — 1. Ratios similar to the same third are also similar to one another; and those similar to similar, are also similar to one another.

2. If \(A : B :: C : D\); then, inversely, \(B : A :: D : C\).

3. Similar parts \(P\) and \(p\) have the same ratio to the wholes \(T\) and \(t\); and if the wholes have the same ratio, the parts are similar.

4. If \(A : B :: C : D\); then, alternately, \(A : C :: B : D\).

And hence, if \(B - D\), \(A = C\); hence, also, if \(A : B :: C : D\); and \(A : F :: C : G\), we shall have \(B : F :: D : G\). Hence, again, if \(A : B :: C : D\); and \(F : A :: G : C\); we shall have \(B : G :: D : F\).

5. Those things which have the same ratio to the same, or equal things, are equal; and vice versa.

6. If you multiply any quantities, as \(A\) and \(B\), by the same, or equal quantities; their products \(D\) and \(E\) will be to each other as \(A\) and \(B\).

7. If you divide any quantities, as \(A\) and \(B\), by the same, or equal quantities, the quotients \(F\) and \(G\) will be to each other as \(A\) and \(B\).

8. The exponent of a compound ratio is equal to the sum of the exponents of the simple ratios.

9. If you divide either the antecedents or the consequents of similar ratios, \(A : B\), and \(C : D\), by the same \(E\); in the former case, the quotients \(F\) and \(G\) will have the same ratio to the consequents \(B\) and \(D\); in the latter, the antecedents \(A\) and \(B\) will have the same ratio to the quotients \(H\) and \(K\).

10. If there be several quantities in the same continued ratio \(A, B, C, D, E, \&c.\), the first \(A\) is to the third \(C\), in a duplicate ratio; to the fourth \(D\), in a triplicate; to the fifth \(E\), in a quadruplicate; &c. ratio of the ratio of the first \(A\), to the second \(B\).

11. If there be any series of quantities in the same ratio, \(A, B, C, D, E, \&c.\), the ratio of the first \(A\) to the last \(F\) is compounded of the intermediate ratios \(A : B, B : C, C : D, D : E, E : F, \&c.\)

12. Ratios compounded of ratios, of which each is equal to each other, are equal among themselves. Thus the ratios \(90 : 3 :: 960 : 32\), compounded of \(6 : 3 :: 4 : 2\), and \(3 : 1 :: 12 : 4\); and \(5 : 1 :: 20 : 4\).

For other properties of similar or equal ratios, see Proportion.

RATIOS, Reduction of. — It is obvious that there is a variety of cases in which the real ratio of two quantities may be expressed in terms too great to be applied to any useful purpose; of which we have an example in the construction of planetariums, and similar astronomical instruments. The ratios of the times in which the several planets perform their sidereal revolutions, are expressed in very large numbers, far exceeding the number of teeth that can be introduced into the machinery of a planetarium; and it, therefore, becomes necessary to find smaller numbers, which, though they do not express the true ratio, may approximate as near to the truth as the limits of the table of the calendar will admit. Another instance, in which a reduction of the ratio of large numbers to others expressed in lower terms becomes necessary, occurs in the calendar; for, according to the common reckoning, the year is supposed to be 365 days, whereas it is known to be nearly 365 days 6 hours; it, therefore, becomes necessary to have some means of expressing the ratio between the true and the assumed length of the years, in order that, by a proper intercalation, we may preserve an uniformity in the seasons, with reference to the months, as we should otherwise find the shortest day transferred to the middle of June, and the longest to the month of December.

This reduction of ratios is best performed by means of continued fractions, of which a sketch is given under that article, as also under the article Indeterminate Analysis; but which we shall probably treat at greater length in a supplement to the present work, on which account it is not our intention to enter much into the rationale of the theory in this place, but merely to state the rules by which the required reduction is to be performed.

To reduce a ratio expressed in large numbers, to others nearly equivalent, but represented in simpler terms.

Rule 1. — Divide the greater of the two numbers by the less; then the divisor by the remainder, and fo on, as in finding the greatest common measure of two numbers, and refer the several quotients, which may be denoted by \(a, b, c, d, \&c.\), from which the series of converging fractions or ratios will be derived as follows; viz. the first fraction will have unity for its numerator, and the first quotient, \(a\), for its denominator; the second will have the second term, \(b\), for its numerator, and for its denominator \(a\); and the denominators of all the succeeding fractions will be found, by multiplying the numerator last obtained, by the succeeding quotient in the above series, and adding to the product the preceding numerator. And the denominators are obtained by precisely the same rule, merely changing the word numerator into denominator.

In this rule we have supposed the ratio to be less than 1, or the numerator less than the denominator; if the denominator be less than the numerator, it must be reversed, making the numerator what we have called the denominator, and the denominator the numerator.

The last fraction of this series will be the same as the original fraction proposed, and the others will be so many approximate or converging ratios, each of which will approach nearer to the original fraction than the preceding one, and nearer than any other fraction whose terms are not expressed by greater numbers. This rule may be exhibited analytically as follows:

Let \(A\) be the proposed fraction, and \(a, b, c, \&c.\) the quotients obtained by the divisions as above, then the converging
verging fractions will be \( \frac{1}{a}, \frac{b}{ab+1}, \frac{bc+1}{(ab+1)c+a}, \ldots \), which will be found to agree with the preceding rule; and these fractions will be alternately greater and less than that proposed, which will be the last of the series.

Let us illustrate this rule by an example. Required a series of converging fractions towards \( \frac{314159}{100000} \), which is the fraction commonly employed for expressing the ratio of the diameter to the circumference of a circle.

**Operation by Division.**

\[
\begin{array}{c}
100000)314159(3 = a \\
300000 \\
14159 \hspace{1cm} 7 = b \\
99115 \\
887 \hspace{1cm} 15 = c \\
13305 \\
854 \hspace{1cm} 1 = d \\
854 \\
854 \hspace{1cm} 25 = e \\
825 \\
29 \hspace{1cm} 33 = f \\
29 \\
29 \hspace{1cm} 7 = g \\
28 \\
1 \hspace{1cm} 4 = h \\
4 \\
0 \\
\end{array}
\]

Having thus obtained our quotients, the several fractions will be easily formed by the preceding rule; thus,

\[
3 \quad 7 \quad 15 \quad 25 \quad 4 \quad 7 \quad 4 \\
3 \quad 22 \quad 333 \quad 9208 \quad 9563 \quad 314159 \\
1 \quad 106 \quad 113 \quad 2931 \quad 3044 \quad 2423 \quad 100000 \\
\]

the last of which is the same as the original fraction. These fractions are formed according to the preceding rule, which will be understood from one example; thus, the fifth fraction is formed from the two preceding fractions as follows:

\[
\frac{355 \times 25 + 333 = 9208}{113 \times 25 + 106 = 2931},
\]

and all the others are obtained in the same manner.

Each of these fractions represents an approximate ratio towards the original one, and each of them nearer than any preceding fraction in the series, and nearer than any fraction expressed in less numbers, or than any fraction having a less denominator than the succeeding fractions.

Thus, \( \frac{3}{1} \) is a nearer approximation than any fraction whose denominator is less than \( 3 \), and \( \frac{355}{113} \) nearer than any fraction whose denominator is less than \( 2931 \); \&c.

Our original fraction exhibited the ratio usually employed to denote the ratio of the diameter to the circumference of a circle, and amongst our approximations we find some of those commonly employed by former writers; as \( \frac{7}{2} \), being that given by Archimedes; \( \frac{106}{333} \), which is another ratio formerly used; also \( \frac{113}{355} \), which invented by Peter Metius. Each of these ratios is alternately too small and too great, to express the ratio of the diameter to the circumference of the circle. Thus, \( \frac{1}{1} \) is too small a ratio, \( \frac{7}{2} \) too great, \( \frac{106}{333} \) too small, and \( \frac{113}{355} \) too great; and so on.

We may therefore divide the above series into two distinct classes, one of which shall exhibit the ratios all in excess, and the other all in defect, which will stand as follows: viz.

**Ratios in defect.**

\[
\begin{array}{c}
3 \quad 333 \quad 9208 \quad 76149 \\
1 \quad 106 \quad 2931 \quad 24239 \\
\end{array}
\]

**Ratios in excess.**

\[
\begin{array}{c}
22 \quad 355 \quad 9563 \quad 314159 \\
7 \quad 113 \quad 3044 \quad 100000 \\
\end{array}
\]

And between every two consecutive fractions we may now interpolate as many fractions of the same kind, as is one less than the number of units in the quotients from which it was formed. If we write the first of the above series, with the corresponding quotients above their terms, we shall have

\[
\begin{array}{c}
15 \quad 25 \quad 7 \quad 4 \\
3 \quad 333 \quad 9208 \quad 79149 \\
1 \quad 106 \quad 2931 \quad 24239 \\
\end{array}
\]

We may therefore interpolate, between the two first fractions, fourteen others, which will pollute the fame property as the principal fractions above, viz. of approximating nearer to the true ratio than any other fractions expressed in less terms, but all in defect. Between the second and third we may interpolate twenty-four fractions; and between the third and fourth, six; all of them less than the proposed ratio. But if we take the second series and their corresponding quotients, they will stand thus:

\[
\begin{array}{c}
1 \quad 1 \quad 1 \quad 4 \\
22 \quad 355 \quad 9563 \quad 314159 \\
7 \quad 113 \quad 3044 \quad 100000 \\
\end{array}
\]

which shews, that no fraction can here be interpolated either between the first and second, or between the second and third; but there may be three interpolated between the third and fourth, which will, of course, be all in excess. This interpolation is performed as follows: to the numerator and denominator of the left fraction add, once, twice, three times, &c. the numerator and denominator of the principal fraction which interpolates between the two, which will form the interpolated fractions required. Thus, because \( \frac{76149}{24239} \) is the principal fraction interpolated between \( \frac{314159}{100000} \), and \( \frac{3044}{324239} \), the intermediate or interpolated fractions will be

\[
\begin{array}{c}
9563 + 76149 = 85712 \\
3044 + 24239 = 27283 \\
9563 + 2.76149 = 161861 \\
3044 + 2.24239 = 51522 \\
9563 + 3.76149 = 238010 \\
3044 + 3.24239 = 75761 \\
\end{array}
\]

And
RATIO.

And in the same manner we may interpolate fourteen fractions between $\frac{3}{1}$ and $\frac{333}{106}$; twenty-four between $\frac{333}{106}$ and $\frac{9208}{2931}$; and six between $\frac{9208}{2931}$ and $\frac{16149}{24339}$.

Having thus explained the nature of the operation, we shall enter lets into detail in the following example.

Example 2.—According to M. de la Caille, the solar year is $365^{24} \frac{1}{2}$, and consequently longer by $5^h 48^m 49''$ than the common year of $365$ days. If this difference were exactly 6 hours, it would make one day at the end of four common years: but if we wish to know exactly at the end of how many years this difference will produce a certain number of days, we must seek the ratio between $24^h$ and $5^h 48^m 49''$, which we find to be $\frac{86400}{20929}$.

So that at the end of $86400$ common years, we must intercalate $20929$ days, in order to reduce them to tropical years.

Now as the ratio of $86400$ to $20929$ is expressed in very high terms, let it be required to find ratios in lower terms, as near this as possible.

For this purpose, we must perform upon these numbers the same operations as in the preceding case; thus:

\[
\begin{align*}
20929 &) 86400(4 = a \\
83716 & \\
2684 &) 20929(7 = b \\
18788 & \\
2141 &) 2684(1 = c \\
2141 & \\
543 &) 2141(3 = d \\
1629 & \\
512 &) 543(1 = e \\
512 & \\
31 &) 512(16 = f \\
496 & \\
16 &) 31(1 = g \\
16 & \\
15 &) 16(1 = h \\
15 & \\
1 &) 15(15 = i \\
15 & \\

From which quotients we derive the following converging fractions, viz.

\[
4 \quad 7 \quad 1 \quad 3 \quad 1 \quad 16 \quad 1 \quad 15
\]

\[
4 \quad 29 \quad 33 \quad 128 \quad 161 \quad 2704 \quad 2865 \quad 5569 \quad 86400
\]

\[
1^4 \quad 7 \quad 8 \quad 31 \quad 39 \quad 655 \quad 694 \quad 1349 \quad 20929
\]

Now we see from the above fractions, that the simplest intercalation is that of one day in four common years, which is the foundation of the Julian calendar; but that we should approximate with more exactness, by intercalating only 7 days in the space of 29 common years, or 8 in the space of 33 years, and so on.

It appears farther, that as the fractions $\frac{4}{1}, \frac{29}{7}, \frac{33}{8}, \frac{2704}{694}, \frac{2865}{694}, \frac{5569}{1349}, \frac{86400}{20929}$, are alternately less and greater than the fraction $\frac{86400}{20929}$, or $\frac{24^h}{5^h 48^m 49''}$, the intercalation of 1 day in 4 years would be too much, of 7 days in 29 years too little, of 8 days in 33 years too much again, and so on; but each of these intercalations will be the most exact, that it is possible to make in the same space of time.

Now if we arrange in two separate series, the fractions that are less, and those that are greater, than the given fractions, we may infer or interpolate between certain of these fractions, as in the preceding examples.

Taking first those fractions that are less than the given one, and their corresponding quotients, we shall have,

\[
1 \quad 15 \\
4 \quad 33 \quad 2865 \quad 86400
\]

\[
1^4 \quad 8 \quad 694 \quad 20929
\]

Hence it appears, that the only interpolation that can be performed is between the two fractions $\frac{2865}{694}$ and $\frac{86400}{20929}$, which will admit of 14 intermediate fractions; which being supplied, as in the former example, gives the following series of converging fractions, each less than the fraction originally proposed, viz.

\[
\begin{array}{cccccccc}
\frac{4}{1} & \frac{33}{8} & \frac{161}{39} & \frac{2865}{694} & \frac{8434}{2043} & \frac{14003}{3392} \\
\frac{19572}{4741} & \frac{25141}{6090} & \frac{30710}{7439} & \frac{36279}{8788} \\
\frac{41848}{10137} & \frac{52986}{12835} & \frac{58555}{14184} & \frac{64124}{15533} \\
\frac{69633}{16882} & \frac{75262}{18251} & \frac{80831}{19580} & \frac{86400}{20929}
\end{array}
\]

And as the last fraction is the same as the given fraction, it is evident that this series cannot be carried farther: hence, if we choose to admit those intercalations only in which the error is too much, the simplest and most exact will be those of 1 day in 4 years, or of 8 days in 33 years, or of 39 in 161 years, and so on.

Let us now consider the decreasing fractions:

\[
7 \quad 3 \quad 16 \quad 1
\]

\[
\frac{29}{7} \quad \frac{128}{31} \quad \frac{2704}{655} \quad \frac{5569}{1349}
\]

Here it appears, that we may place 6 fractions before the first, 2 between the first and second, 15 between the second and third; but between the third and fourth no such fraction can be inferred.

These interpolations being made, we shall have the following series of decreasing fractions, viz.

\[
\begin{array}{cccccccc}
\frac{5}{1} & \frac{9}{2} & \frac{13}{3} & \frac{17}{4} & \frac{21}{5} & \frac{25}{6} \\
\frac{29}{7} & \frac{62}{15} & \frac{95}{23} & \frac{128}{31} & \frac{289}{70} & \frac{450}{109} \\
\frac{611}{148} & \frac{772}{187} & \frac{933}{226} & \frac{1094}{265} & \frac{1255}{304}
\end{array}
\]
RATIO.

\[
\begin{array}{cccccccc}
1416 & 1577 & 1738 & 1899 & 2060 \\
343 & 382 & 421 & 460 & 499 \\
2221 & 2382 & 2543 & 2704 & 2865 \\
538 & 577 & 616 & 655 & 1349 \\
\end{array}
\]

which are all less than the proposed fraction, and expressed in less terms; and each of which is nearer than any other fraction that can be expressed in less terms.

Hence we conclude, that if we only attend to the intercalations in which the error is too small, the simplest and most exact are those of 1 day in 5 years, of 2 days in 9 years, of 3 days in 13 years, of 4 days in 17 years, and so on.

In the Gregorian calendar, only 97 days are intercalated in 400 years; but it is evident, from the preceding table, that it would be much more exact to intercalate 109 days in 450 years.

But it must be observed, that, in the Gregorian reformation, the determination of the year given by Copernicus was made use of, which is \(\frac{365\frac{1}{4}}{400}\) \(=\) \(\frac{445}{400}\); and substituting this instead of the fraction \(\frac{86400}{20929}\), we shall have \(\frac{86400}{20929}\) or \(\frac{131}{54}\); whence we may find, by the preceding method, the quotients 4, 8, 5, 3; and from them the principal fractions

\[
\frac{4}{1}, \frac{8}{3}, \frac{5}{4}, \frac{3}{1}
\]

which, except the two first, are quite different from those before determined. However, we do not find amongst these fractions \(\frac{131}{54}\), which is that adopted in the Gregorian calendar; and this fraction cannot even be found among the interpolated fractions, which might be inserted in the two series, \(\frac{4}{1}, \frac{169}{41}, \frac{33}{8}, \frac{540}{131}\); for it is evident that this could only be between the last two fractions, between which, because of the number 3, (the corresponding quotient,) there can be but two fractions interpolated, which are \(\frac{202}{49}, \frac{371}{90}\); whence it appears, that it would have been more exact, if, in the Gregorian reformation, they had only intercalated 90 days in the space of 371 years.

If we reduce the fraction \(\frac{131}{54}\) so as to have for its numerator the number 86400, it will become \(\frac{86400}{20952}\), which estimates the tropical year at \(365\frac{1}{4}\) \(=\) \(12\frac{2}{16}\). In this case, the Gregorian intercalation would be quite exact; but as observations shew that the year is shorter than this by more than \(1\frac{1}{2}\), it is evident that, at the end of a certain period of time, we must introduce a new intercalation.

If we adopt the determination of de Caille, it follows, as the denominator 97 of the above fraction, \(\text{viz.} \frac{400}{97}\), lies between the denominators of the fifth and sixth principal fractions already found, that, from what has been stated above, the fraction \(\frac{400}{97}\) will be nearer the truth than \(\frac{161}{39}\).

But as astronomers are still divided with regard to the exact length of the year, we shall refrain from giving a decisive opinion on this subject. For more on the reduction of ratios, see Lagrange's Additions to Euler's Elements of Algebra.

RATIOS, Prime and Ultimate, is a species of computation, which we owe to the fertile genius of Newton. The ancients, in order to extend the geometry of right lines to curvilinear figures, had recourse to the method of exhaustion, in which they made use of what is called the reducion ad absurdum method, which, though logical, is extremely tedious, and to avoid which, Cavalierius proposed his method of indivisibles, published in 1635 under the title of "Geometria Indivisibilibus," in which he was followed by Dr. Wallis and others of the 17th and 18th centuries. In this method every line was supposed to consist of a number of other lines indefinitely small; every curve was considered as a polygon of an infinite number of sides, each side being indefinitely small; a solid was supposed to consist of an infinite number of plane sections, or of indefinitely thin laminae, and so on; hypotheses which in many infinities led those, who adopted them, into errors and inconsistencies, which indeed it was very difficult to avoid.

To obviate both the tediousness of the ancients, and the inaccuracy of the moderns, Newton introduced his method of prime and ultimate ratios, the foundation of which is contained in the first lemma of the first book of his "Principia." Many difficulties have been started, and much controversy concerning the proof of it; all of which would have been avoided, had either the author or his readers observed, that he is in reality laying down the definition of a term, \(\text{viz.} \) being ultimately equal, and not proving a proposition. Taking, therefore, this first lemma for a definition, it may be illustrated as follows.

Let there be two quantities, one fixed and the other varying, fo related to each other, that, if the varying quantity continually approaches to the fixed quantity; and, 2dly, that the varying quantity never reaches or passes beyond that which is fixed; 3dly, that the varying quantity approaches nearer to the fixed quantity than by any affigned difference. Then is such a fixed quantity called the limit of the varying quantity; or, in other words, the varying quantity may be said to be ultimately equal to the fixed quantity. If these three conditions may be expressed more distinctly thus. 1. The difference between the varying quantity and the fixed quantity must continually decrease. 2. This difference must never become either nothing or negative. 3. This difference must become less, in respect of the fixed quantity, than by any affigned ratio; or the difference between the two quantities must become a less part of the fixed quantity than any fractional part that is affigned, however small the fraction expressing such part may be. Wherever these properties are found, the fixed quantity is called the limit of the varying quantity; or the varying quantity is said to be ultimately equal to the fixed quantity. The last expression, however, must not be understood in its strict literal sense, there being no ultimate state, no particular magnitude, that is the ultimate magnitude of such a varying quantity. Under the word quantity in this definition, must be included not only numbers, lines, &c., but more especially ratios considered as a peculiar species of quantity; but as the con-
federation of ratios which have limits is difficult, we shall begin with examples of other quantities.

11. Let there be formed a series, whose first term is 1; second, \( \frac{1}{2} \); third, \( \frac{1}{4} \); fourth, \( \frac{1}{8} \), and so on; every term being half the preceding one, viz.,

\[
1, \frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \frac{1}{32}, \&c.
\]

and let the sum of an indefinite number of terms in this series be continually increased by the accension of a new term; thus, the sum of the first two terms is 1\(\frac{1}{2}\), of three terms is 1\(\frac{3}{4}\), of four terms is 1\(\frac{7}{8}\), \&c. I say then, that the varying sum of the terms of this series continually approximates to the fixed number 2, as its limit. For the difference between 2, 1\(\frac{1}{2}\), 1\(\frac{3}{4}\), \&c. terms and the number 2, will be the numbers 1, \( \frac{1}{2} \), \( \frac{1}{4} \), \( \frac{1}{8} \), \( \frac{1}{16} \), \&c. successively, in infinitum. Here it is evident, that the terms in this last series, which express the successive differences between the increasing sum of the former series and the number 2, each, continually decrease; and secondly, no term in this series of differences can become either nothing or negative; and thirdly, we may continue this series of successive differences, till we arrive at a term which shall be a less part of the fixed number 2, than any fractional part of it that can be assigned; or so that this difference shall be less, when compared with the number 2, than any ratio assigned. The number 2, therefore, having the conditions laid down in the definition, is to be called the limit of the sum of the terms of the infinite series 1, \( \frac{1}{2} \), \( \frac{1}{4} \), \( \frac{1}{8} \), \( \frac{1}{16} \), \&c.

And the fame is to be understood of any other infinite series; viz. if a number can be found having the above conditions, that series is said to have a limit; and the finding of this limit, is what is to be understood when mathematicians speak of finding the sum of such an infinite series.

No number less than 2, for instance 1\(\frac{1}{2}\), can be taken for the limit; for, in this case, it will not answer the second condition of the definition. In the above example, the sum of four terms of the series is equal to 1\(\frac{3}{4}\), and the sum of five terms exceeds it; therefore, the difference between this sum and the number 1\(\frac{1}{2}\) proposed as a limit is, in the former case zero, and in the latter negative. Neither can any number greater than 2, as for example 3, be taken for the limit, because here the last condition will be wanting; for if the sum of any assigned number of terms be less than 2, that sum must always want more than unity of the number 3, and consequentlly cannot approach nearer to 3, than any assigned quantity, as 1.

In like manner the sum of the series 1, \( \frac{1}{3} \), \( \frac{1}{9} \), \( \frac{1}{27} \), \&c. continued in infinitum, will be 1\(\frac{1}{2}\); the series of successive differences being \( \frac{1}{2} \), \( \frac{1}{6} \), \( \frac{1}{18} \), \( \frac{1}{54} \), \&c. in infinitum.

Now, in order to make the preceding example general, let \( a : b \) express the common ratio of any series of numbers in continual proportion, whose first term is unity, I say then, if \( a \) be greater than \( b \), such a series will have for its limit the quantity \( \frac{a}{a-b} \); or, in other words, the sum of all the terms of such an infinite series will be \( \frac{a}{a-b} \).

For the terms of this series will be \( \frac{b}{a}, \frac{b^2}{a}, \frac{b^3}{a^2}, \&c. \)

Whence the sum of 1 term is \( \frac{a+b}{a} \)

of 2 terms \( \frac{a^2+ab+b^2}{a^2} \)

of 3 terms \( \frac{a^3+ab^2+b^3}{a^3} \)

of 4 terms \( \frac{a^4+a^2b^2+b^4}{a^4} \)

Let each of these sums be subtracted from the limit \( \frac{a}{a-b} \) and we have the successive differences \( \left( \frac{b}{a-b} \right), \left( \frac{b}{a-b} \cdot \frac{b}{a} \right), \left( \frac{b}{a-b} \cdot \frac{b^2}{a^2} \right), \&c. \) or if \( n \) be any assigned number of terms, the difference between the sum of that number of terms and the limit \( \frac{a}{a-b} \) will be \( \frac{b}{a-b} \cdot \frac{b^n}{a^n} \). Whence we may observe, 1st, that as the number of terms whose sum is required increases, this difference continually decreases, because \( \frac{b}{a} \) being a fraction less than unity, its powers continually decrease. 2dly. This difference can never become nothing or negative; the powers of a fraction, though they decrease, being always real and affirmative. 3dly. This difference may become less in respect of \( \frac{a}{a-b} \), than by any assigned ratio.

For \( \frac{a}{a-b} : \frac{b}{a} \cdot \frac{b^{n-1}}{a^{n-1}} = a^n : b^n \); or as \( \frac{a^n}{b^n} \) to 1; or as \( \left( \frac{a}{b} \right)^n \) to 1; and since \( \frac{a}{b} \) is greater than 1, and \( n \) indeterminate, the former term of the ratio may become greater than any assigned quantity, and therefore the ratio itself less than any ratio assigned.

The quantity \( \frac{a}{a-b} \), having, therefore, the required conditions, is the limit of the above series, or is equal to the sum of all the terms continued in infinitum.

What has been proved above may be shewn more concisely by dividing \( a \) by \( a-b \), in the manner of division in algebra, for the quotients will be the very series proposed in the example: for instance,

\[
\frac{a-b}{a} \frac{a}{a-b} \left( 1 + \frac{b}{a} + \frac{b^2}{a^2} + \frac{b^3}{a^3} + \&c. \right)
\]

\[
\frac{b}{a} \frac{b}{a} - \frac{a}{a}
\]

\[
\frac{b^2}{a^2} \frac{b^3}{a^3} \frac{b^4}{a^4} \frac{b^5}{a^5} \frac{b^6}{a^6}
\]

And
And it may be further confirmed by multiplying the proposed series by $a - b$; for the product will be $a$, all the terms except the first destroying each other.

We may also observe, that if every term of the foregoing series be multiplied by any number $c$, it will become $c + \frac{b e}{a} + \frac{b^2 c}{a^2} + \frac{b^3 c}{a^3} + \&c.$; a series having the same ratio, but whose first term is $c$; and it is therefore evident, that, in this case, to find the sum of all the terms, we must multiply the former limit by $c$, whence it will become $\frac{a e}{a - b}$.

Before we begin to consider ratios, it may not be amiss to caution the reader against confounding the terms of a ratio with the ratio itself: the terms of a ratio may vary in some cases through all degrees of magnitude, and yet the ratio remain constant or invariable. In other instances, varying the terms in infinitum, likewise varies the ratio in infinitum; while in others, though varying the terms may also vary the ratio, yet the last ratio can never exceed certain limits.

Let $x$ be any varying quantity; make $4x^3 + 3x = A$, and $2x^2 + x = B$, then will $A$ and $B$ also be varying quantities, as depending upon $x$: when $x$ vanishes, $A$ and $B$ will both vanish; when $x$ is infinite, they will be both infinite. I say then the ratio of $A$ to $B$, while $x$ decreases in infinitum, approaches to the ratio of $3$ to $1$.

For, first, $A$ is to $B$, as $4x^3 + 3x$ is to $2x^2 + x$, or as $4x + 3$ to $2x + 1$; where it is obvious, that as $x$ decreases, the quantities $4x$ and $2x$ also decrease, and consequently the ratio of $4x + 3$ to $2x + 1$, or of $A$ to $B$, approaches to that of $3$ to $1$. Secondly, the ratio of $A$ to $B$ can never exceed $3$ to $1$. For $6x + 3$ is to $2x + 1$, as $3$ to $1$; but $4x + 3$ is a less quantity than $6x + 3$, therefore $4x + 3$ is to $2x + 1$, or $A$ is to $B$ in a less ratio than $6x + 3$ to $2x + 1$; that is, less than the ratio of $3$ to $1$.

Lastly, the ratio of $A$ to $B$ will approach nearer to the ratio of $3$ to $1$, than any assigned difference. For in the terms of this ratio, $4x + 3$ to $2x + 1$, the varying parts $4x$ and $2x$, by diminishing $x$, may become less than any assigned quantity, while the other parts, $3$ and $1$, remain the same; therefore the ratio of $A$ to $B$ will approach nearer to the ratio of $3$ to $1$, than by any assigned difference.

In like manner the ratio of $A$ to $B$, while $x$ increases in infinitum, approaches to the ratio of $2$ to $1$, as its limit.

For since $A$ is to $B$ as $4x + 3$ to $2x + 1$, or as $4x + \frac{3}{x}$ to $2 + \frac{1}{x}$, it is obvious, that as $x$ increases, the quantities $\frac{3}{x}$ and $\frac{1}{x}$ decrease, and consequently the ratio of $4 + \frac{3}{x}$ to $2 + \frac{1}{x}$, or of $A$ to $B$, approaches to the ratio of $4$ to $2$, or of $2$ to $1$. For $4x^2 + 2x$ is to $2x^2 + x$, as $2$ is to $1$; but $4x^2 + 3x$, is a greater quantity than $4x^2 + 2x$, therefore $4x^2 + 3x$ is to $2x^2 + x$, or $A$ is to $B$ always in a greater ratio than $2$ to $1$. Lastly, the ratio of $A$ to $B$ will approach nearer to that of $2$ to $1$, than by any assigned difference. For in the terms of this ratio, $4 + \frac{3}{x}$ and $2 + \frac{1}{x}$, the variable parts $\frac{3}{x}$ and $\frac{1}{x}$, by increasing $x$, may become less than any assigned fraction, while the parts $4$ and $2$ remain the same; therefore the ratio of $A$ to $B$ will approach nearer to the ratio of $4$ to $2$, or $2$ to $1$, than the assigned difference. Hence then we see that though diminishing $x$, and consequently diminishing the terms $A$ and $B$, we increase their ratio, and on the contrary increasing these terms, by increasing the quantity $x$, we decrease their ratio, yet there is a limit both to the increase and decrease of this ratio, although there be none to the terms themselves which compose it.

The ratio of $3$ to $1$, which limits the ratio of $A$ to $B$, when these terms decrease in infinitum, is called the ultimate ratio of the evanescent quantities $A$ and $B$. The ratio of $2$ to $1$, which is their other limit, is called the ultimate ratio of the quantities $A$ and $B$ increasing in infinitum.

Another example of a similar kind we have as follows. Let $x$ be a varying quantity, and $d$ a constant, one, then will $x + d$ and $x$ be two varying quantities capable of all degrees of magnitude. I say that the ratio of $x + d$ to $x$, while $x$ increases, will continually decrease, but not beyond a certain limit, which is the limit of equality. On the contrary, if $x$ decrease, the ratio of $x + d$ to $x$ will continually decrease more and more ad infinitum, and never come to a limit. For $x + d$ is to $x$, as $1 + \frac{d}{x}$ to $1$; now as $x$ increases, the fraction $\frac{d}{x}$ decreases, and may become less than any assigned fraction; but the number $1$, which is the other part of the antecedent of this ratio, remains the same, as does likewise the consequent, therefore the ratio of $1 + \frac{d}{x}$ to $1$, continually approaches to a ratio of equality. Secondly, it can never reach that ratio, because $\frac{d}{x}$ has always some magnitude, and consequently $1 + \frac{d}{x}$ always greater than $1$. It therefore can never reach the ratio of equality, and much less can it pass it, so as to become a ratio minoris inéqualitatis, or a ratio in which the antecedent is less than the consequent. Lastly, the varying fraction $\frac{d}{x}$, as $x$ increases, will become less than any assigned fraction, while the other part of the antecedent, and likewise the consequent of this ratio, remain the same. Therefore the ratio of $1 + \frac{d}{x}$ to $1$, will approach nearer to the ratio of equality, than by any ratio that can be assigned, however small such ratio may be; therefore the ratio of equality is the limit of the ratio of $1 + \frac{d}{x}$ to $1$, and consequently the limit of the ratio of $x + d$ to $x$, which continually decreases, while the terms which compose this ratio continually increase in infinitum.

If $x$ decrease then $\frac{d}{x}$ will increase, and may become greater than any assigned number, while the other part of the antecedent, and likewise the consequent, remain invariable; therefore the ratio of $1 + \frac{d}{x}$ to $1$, and consequently the ratio of $x + d$ to $x$, as $x$ decreases, will become greater than any assigned ratio whatever, having no limit to its increase.
We may farther observe, that though the terms of this ratio, viz. \(x + d\) to \(x\), never approximate nearer to each other, their constant difference being \(d\), yet the ratio of the terms approximates to the ratio of equality; that is, though the terms get no nearer in their difference, yet, if we may be allowed the expression, they get nearer in their ratio. The difference of the terms, and the ratio of the terms, are ideas very distinct from each other, and in no wise to be so connected, but that one may vary whilst the other is constant. Although the ratio of equality may strictly be called the limit of the varying ratio of the quantities \(x + d\) and \(x\), yet the terms of this ratio can never be strictly said to be equal, nor ultimately equal, as that supposes an ultimate finite in which they are equal; nor equal when they vanish into infinity, or, when they pass out of finite into infinity. There is no finite quantity next to infinity, no number, for instance, which is the next number to infinity. Nor is there any step from a state of nothingness into finite existence; there is no fraction so small as to be the very next fraction to nothing; no fraction can be assigned to small, but another fraction may be assigned that is smaller. Neither can we say, in strictness, that two infinitely great numbers with a finite difference are equal, it being a proposition obviously absurd and contradictory. There is no such thing in nature as an infinitely great number; and it is contradictory to say of any two numbers, both that they have a difference, and that they are equal. Whoever considers that the idea of infinity is a general or abstract idea, that the idea of number is always particular, that infinity is a property of numbers, a property of extension, &c., itself, will readily perceive that these and such expressions have no literal meaning. (See Locke, b. ii. ch. 16. and ch. 17.) As to the metaphorical use of them, to avoid circumlocution, or the introduction of new terms, it may be allowed, when once the literal meaning has been explained, in this, as well as on various other occasions both in science and in common life.

When the difference between any two quantities decreases, so as to become a less fractional part of the one of them than any assigned fractional part whatever; or when the difference between the terms of a ratio becomes less in respect of one of them (the greater for example) than any assigned ratio, this may be expressed by saying, that such difference vanishes in respect of that greater quantity.

But if the difference between two terms vanishes in respect to one of them, it will also vanish in respect of the other. It is true that at any assigned time, when the terms have a particular magnitude, the difference between the terms will always be a less fractional part of the greater term than it is of the less term; but as this difference continually decreases, it will become the same fractional part of the less term that it was before of the greater, however small that fractional part of the greater term may be; therefore, if the difference vanish with regard to one of them, it will vanish also with regard to the other. We may, therefore, instead of the third condition of our definition, say, that "the difference of an infinite number in respect of either of the fixed or of the varying quantity, since one of these implies the other."

The above is true as well for the case of two variables, as for one fixed and one variable, though both of such variables increase or decrease without limit. Thus, in the example above given, in which the terms were \(x + d\) and \(x\), and where \(x\) is continually increasing, the terms themselves both continually increase; for in this instance it is obvious, that if the difference vanish with respect to one of the terms, it will also vanish with respect to the other. Let \(x\) be to \(d\), at any assigned point of time, as \(n\) is to \(1\), and \(d\) at that instant of time will be the \(\frac{1}{n+1}\)th part of the greater term, and the \(\frac{1}{n}\)th part of the less term: now, though the contemporary value of these fractions can never be equal, yet in succession the value of the latter fraction will become whatever the former has been; therefore, if \(\frac{1}{n}\) become less than any assigned fraction, \(\frac{1}{n+1}\) will likewise; and thus, if the difference vanishes with respect to one of the terms, \(x + d\), it will also vanish with respect to the other, \(x\). And the same would be true if the terms were \(x\) and \(x - d\), all things else being as before.

Again, if \(x\) by decreasing vanish with respect to some fixed quantity \(n\), then will \(x\), multiplied by a given number \(n\), or \(nx\), vanish in respect of \(a\); or, which is the same, if \(x\) vanish in respect of \(a\), to likewise will the quantity \(nx\); bearing to \(x\) the assigned ratio of \(a\) to \(1\). For though at any particular point of time \(x\) is a smaller fractional part of \(a\) than \(nx\), yet \(x\) can be no assigned fractional part of \(a\) whatever; but by farther diminishing \(x\), the quantity \(nx\) may become the same fractional part of \(a\) that \(x\) was before. If, then, \(x\) may become equal to, or less than, any assigned fractional part of \(a\), to likewise may \(nx\); that is, if \(x\) vanish in respect of \(a\), to likewise will \(nx\).

For a like reason, if \(x\) vanish in respect of any quantity, it will likewise vanish in respect to that quantity multiplied or divided by any number; or it will vanish in respect of a quantity, bearing to \(a\) any assigned ratio, as that of \(m\) to \(n\). Thus, if \(x\) vanish in respect of \(a\), it will also vanish in respect of \(3a\), or \(\frac{2}{3}a\), &c. Or, if any fraction vanish in respect to the diameter of a circle, it will likewise vanish in respect of the radius. For whatever part of the diameter the line \(x\) may be at any assigned point of time, let \(x\) farther decrease, till it be half what it was at that assigned time, and it will now be the same part of the radius that it was before of the diameter; and the same with various other lines and quantities. We have shown, in the preceding part of this article, that the ratio which two quantities bear to each other may have a limit, although the terms themselves may increase or decrease perpetually without limit. I. If the terms approximate towards each other; 2, if the less never passes the greater; and, lastly, if their difference vanish in respect of either term, then the limit of their varying ratio is that of equality; and this, whether the terms themselves are fuchs, as by increasing they both become greater than any assigned quantity, or, which is more common, such as by decreasing become less than any assigned quantity, or as it is called, infinitely small. Because the idea of the terms of a ratio is less abstr. than that of the ratio itself, it is more usual to say that the terms themselves in this case are ultimately equal, though, strictly, it is the ratio only of the terms that comes to a limit, for the terms themselves are supposed to increase or decrease without limit, or as we commonly say, ad infinitum.

Prop.—In a circle whose centre is \(C\), (Plate XIII. Analysis, fig. 9.) radius \(CA\), diameter \(A\), let \(AB\) be the chord, \(FB\) the sine, and \(AD\) the tangent of the arc \(AB\). I say, that while the arc \(AB\) continually decreases without limit; ii, the sine continually approaches to the tangent; iii, the sine never exceeds the tangent; iv, their difference will vanish in respect of either line or tangent.

First: \(BF : DA :: CF : CA\), but while the arc decreases, \(CF\) approximates to \(CA\); \(BF\) approximates to \(DA\).
DA. 2dly. C F can never exceed C A; therefore B F can never exceed D A. 3dly. The arc continually decreasing without limit, vanishes in respect of the diameter, which is fixed; therefore the chord A B, which is less than the arc, likewise vanishes in respect of the diameter A a. But A A : A B :: A B : A F; therefore, if A B vanishes in respect of A a, A F will vanish in respect of A B; and much more will A F vanish in respect of A a; but if A F vanish in respect of A a, it will also vanish in respect of \( \frac{1}{2} A a \), or C A.

Now C A : C F :: A D : F B, and by division of proportion C A : C F :: A D : F B. Therefore, as A F vanishes in respect of C A, do A D — F B (the difference of the line and tangent) vanish in respect to A D the tangent, and consequently in respect of F B the fine. Whence we see, that while the arc continually decreases without limit, the fine approximates to the tangent; 2dly, the fine never exceeds the tangent; 3dly, although the fine and tangent both vanish in respect of the radius, yet their difference vanishes in respect of these quantities themselves. Therefore the ratio of equality is the limit of the varying ratio which the fine and tangent have to each other, while they both decrease perpetually without limit, or it is their ultimate ratio, or, as we may say, they are ultimately equal.

The fine is less than the chord; for in the right-angled triangle A F B, the side F B is less than the hypothenuse A B; the chord is less than the arc; this is self-evident, the chord being a straight line, and the arc a curve, both terminated by the same points A and B. The arc is less than the tangent; for from the point D draw another tangent to the circle in H; and the lines A B H, A D H, will be terminated by the same points A and H; and will have the concavities turned the same way; therefore the included arc A B H will be less than the sum of the two equal tangents D A and D H; consequently half that arc, or A B, will be less than half the sum of the tangents A D.

Cor. 1.—Hence the fine, chord, arc, and tangent, are all ultimately in a ratio of equality. This may appear because the chord and arc are included between the fine and tangent, but perhaps more plainly thus. Of these four quantities, viz. the fine, chord, arc, and tangent, the fine is the least, and the tangent the greatest; therefore, the difference between the fine and the tangent is greater than the difference between any other two of these four quantities. If, therefore, the greatest of all those differences vanish in respect of the least of all those quantities, much more will the difference between any other two of those four quantities vanish in respect of the quantities themselves.

Cor. 2.—Join B a, and in the right-angled triangle B F a, the hypothenuse B a is greater than the side F a; therefore A a — B a is less than A a — F a, or A F; but while the arc A B decreases continually without limit, A F vanishes in respect of A a; much more then does A a — B a, the difference A a and B a, vanish in respect of A a; and the ultimate ratio of A a to B a is that of equality; and the ultimate ratio of \( \frac{1}{2} A a \) or B C to B A, is that of 2 to 1. See other applications of these principles in Ludlam's "Rudiments of Mathematics," from which the preceding article has been abridged; Newton's "Principia," lib. 1.; Smith's "Fluxions"; and Saunderfon's "Arith."
RATIONALIBUS Divisi, is a writ that lies where two lords have signories joining together, for him that finds his wife encroached upon, within the memory of man, against the encroacher, thereby to rectify the bounds of the signories: in which repect, Fitzherbert says, it is of the nature of a writ of right.

RATIONALIS Dos, a third part of such lands and tenements as the husband was feailed of at the time of the efpousals, with which his wife was formerly endowed by the common law, if no specific donation was made at the church porche. See DOWER and JOINTURE.

RATIONAL, REASONABLE. See REASON.

Rational Fable. See FABLE.

Rational Fractions, in Arithmetic and Analysis, are those fractions into which no furd or radical quantity enters; as

\[ \frac{7}{8} \left( \frac{3x^2 + 1}{x^3 + x^2 + a - x} \right) \]

The decomposition of rational fractions into simple fractions, that is, the decomposition of them into other fractions whose sum is equal to that proposed, is an important problem, as connected with the integral calculus, or inverse method of fluxions, which was first investigated by Leibnitz, but has since been much extended and simplified by the researches of Euler, La Grange, La Croix, and other eminent analysts.

The decomposition of numerical fractions into their partial fractions, is, perhaps, rather a subject of curiosity than utility, yet as connected with, and leading to, the decomposition of rational algebraic fractions, it may not be amiss to here a sketch of the process by which it is accomplished, previous to entering upon the latter subject.

On the decomposition of rational numerical fractions, into others having prime denominators.

It is to be observed, that this can only be effected in the case of a composite denominator, or rather, there will be no difficulty in any other case, as it will require only a separation of the numerator into any parts at pleasure, the sum of which is obviously equal to the fraction proposed, we shall therefore only consider those fractions having composite denominators, which are to be resolved into others having prime denominators; and even in this case there may be fractions that will not admit of decomposition, as will appear from what follows. This decomposition is effected, when possible, by means of the indeterminate analysis; viz. let \( \frac{m}{ab} \) be the given fraction, and suppose, in the first instance, that its denominator consists of two prime factors, or \( a = ab \); it will then be to find \( \frac{m}{ab} = \frac{p}{a} + \frac{q}{b} \), or \( aq + bp = m; p \) and \( q \) being the required numerators of the two partial fractions, and which values of \( p \) and \( q \) are easily found from the above equation \( aq + bp = m \), on the principles explained under the article INDETERMINATE ANALYSIS, subject however to the same limitation there mentioned; viz. the above equation is always possible, provided \( m > ab - a - b \), but in other cases it may or may not admit of solution.

If the given fraction be \( \frac{m}{ab} \), then we may first resolve it into two fractions, and one of these into two others; thus, let \( \frac{m}{ab} = \frac{p}{a} + \frac{q}{b} \), then we have \( abq + cp = m \), from which equation \( p \) and \( q \) may be found.

Again, let \( \frac{p}{ab} = \frac{r}{a} + \frac{s}{b} \), which gives \( as + rb = p \), whence \( r \) and \( s \) may be determined, and we shall thus obtain

\[ \frac{m}{ab} = \frac{r}{a} + \frac{s}{b} + \frac{q}{c}, \]

as required. In all these cases it is obvious, that the fraction may be decomposed into partial fractions, in as many different ways as the indeterminate equation on which it depends admits of different answers.

Example.—Find two fractions, having prime denominators, whose sum shall be equal to \( \frac{19}{35} \) or to \( \frac{19}{35} \). Let the required fractions be \( \frac{p}{7} + \frac{q}{5} \), then \( \frac{5p + 7q}{35} = \frac{19}{35} \); therefore \( 5p + 7q = 19 \), whence \( p = 1 \), and \( q = 2 \) (see INDeterminate Analysis); and consequently the required partial fractions are \( \frac{1}{7} \) and \( \frac{2}{5} \).

Example 2.—Find three fractions, whose sum is equal to \( \frac{315}{401} \).

The three factors of \( 315 \) are \( 5, 7, 9 \), which are of necessity the denominators of the required fractions. Suppose then first, that \( \frac{401}{315} = \frac{p}{9} + \frac{q}{7} \), whence we have \( 9p + 35q = 401 \), which gives \( p = 20 \), and \( q = 4 \); therefore \( \frac{401}{315} = \frac{29}{9} + \frac{4}{7} \). Again, let \( \frac{29}{35} = \frac{r}{6} + \frac{q}{5} \), or \( 5r + 35q = 29 \); this gives \( r = 3 \) and \( q = 2 \), so that \( \frac{29}{35} = \frac{3}{5} + \frac{2}{7} \), and consequently \( \frac{401}{315} = \frac{3}{5} + \frac{2}{7} + \frac{4}{9} \), as required. And in the same manner the decomposition may be obtained in any other case, which falls within the limits above stated.

On the decomposition of rational algebraic fractions, and its application to the integral calculus.

Let

\[ \frac{N}{D} = \frac{a + bx + cx^2 + dx^3 + \ldots}{a' + b'x + c'x^2 + d'x^3 + \ldots} \]

be any rational fraction, whose denominator is \( \frac{m}{ab} \), and whose numerator is at least one degree lower than its denominator, to which form it may always be reduced by division, if it should present itself under a different form.

The denominator of this fraction, from the known theory of equations, may be supposed to be made up of as many simple factors as is equal to the highest power of \( x \) contained in it, and which factors may be found by determining the roots of the equation formed by putting the whole denominator equal to zero. Let therefore \( a' + b'x + c'x^2 + d'x^3 + \ldots \) = 0, and suppose the roots of this equation to be \( r, r', r'', r''' \), &c., and we shall have \( a' + b'x + c'x^2 + d'x^3 + \ldots = (x - r) (x - r') (x - r'') (x - r''') \), &c.

And therefore our proposed fraction \( \frac{N}{D} \) may now be put under the form

\[ \frac{N}{D} = \frac{a + bx + cx^2 + dx^3 + \ldots}{(x - r) (x - r') (x - r'') (x - r''')} \]

and these factors are now to form the denominators of the
the simple fractions sought. Let \( A, A', A'', A''', \&c. \) represent their numerators, so that
\[
N = \frac{A}{x-r} + \frac{A'}{x-r'} + \frac{A''}{x-r''} + \&c. \frac{A^{(n-1)}}{x-r^{(n-1)}}
\]

Reduce now the several simple fractions to a common denominator by the usual rule, and add their several numerators together; then comparing the co-efficients of the like powers of \( x \) in the numerator of this new fraction, with those in the numerator proposed, we shall obtain sufficient equations for determining the proper values of \( A, A', A'', \&c. \) and the decomposition will be effected as proposed. This will be better understood from a partial example.

Let us therefore assume the fraction \( \frac{6x^3 - 4x - 6}{x^3 - 6x^2 + 11x - 6} \) which it is required to resolve into its simple fractions.

Here the roots of the denominator, by making it equal to zero, are \( 1, 2, \) and \( -3 \), whence the proposed equation may be put under the form
\[
\frac{x^3 - 4x - 6}{(x-1)(x-2)(x+3)} = \frac{A}{x-1} + \frac{A'}{x-2} + \frac{A''}{x+3},
\]

which being reduced to a common denominator, and added together, give
\[
\frac{x^3 - 4x - 6}{x^3 - 6x^2 + 11x - 6} = \frac{A(x-2) + A'(x+1) + A''(x-1)}{(x-1)(x-2)(x+3)} + \frac{6A + 3A' - 2A''}{(x-1)(x-2)(x+3)}
\]

from which we readily draw \( A = 1, A' = 2, A'' = 3 \); so that the required fractions are
\[
\frac{1}{x-1} + \frac{2}{x-2} + \frac{3}{x+3}.
\]

If therefore the fluents of \( \frac{6x^2 - 4x - 6}{x^3 - 6x^2 + 11x - 6} \) were required, we might immediately reduce the problem to finding the fluents of \( \frac{x}{x-1} + \frac{2}{x-2} + \frac{3}{x+3} \), which are known, being hyp. log. \( (x-1) + 2 \) hyp. log. \( (x-2) + 3 \) hyp. log. \( (x+3) \) equal log. \( [(x-1)(x-2)(x+3)] \).

The same method may be employed for all rational fractions, whose denominators are resolvable into unequal simple factors, but as this cannot be generally effected when the highest power of the variable quantity exceeds the fourth degree, we are necessarily limited in our application of the rule, in consequence of the imperfect which still attends the general solution of equations. In the case, however, of equal factors in the denominator, a different process is required, which we will explain, after illustrating the above rule by two or three examples.

Required the fluent of \( \frac{1 + x}{x - x^3} \) by solving it into its simple fractions.

Here the factors of the denominator being \( x \) and \( 1 - x \), we make
\[
\frac{(1 + x)x}{x - x^3} = \frac{A}{x} + \frac{A'}{1 - x} = \frac{(A + (A' - A)x)}{x - x^3},
\]

whence \( A = 1, \) and \( A' - A = 1, \) or \( A' = 2, \) therefore
\[
\frac{(1 + x)x}{x - x^3} + \text{fluent of} \frac{1 + x}{x} + \text{fluent of} \frac{2x}{1 - x}
\]

which are known.

Required the fluent of \( \frac{(x-1)x}{1 - 4x + 2x^2} \), or of \( \frac{1}{2} (x-1)x \).

Here, by making \( x^2 - 2x + \frac{3}{4} = 0 \), we have \( x = 1 + \frac{1}{2} \sqrt{2} \) make, therefore,
\[
\frac{\frac{1}{2} x^{x-1} - \frac{1}{2} x}{x - 1 + \frac{1}{2} \sqrt{2}} = \frac{A}{x} + \frac{A'}{x} \text{ fluent of} \frac{1}{2} (x-1)x.
\]

Here we have \( A + A' = - \frac{1}{2} (1 - \frac{1}{2} \sqrt{2}) A + \frac{1}{2} \sqrt{2} A' \), whence we have \( A = - \frac{1}{2} \), and \( A' = \frac{1}{6} \), therefore fluent of \( \frac{(x-1)x}{x - x^3} \), or \( \frac{1}{2} \frac{x}{x - 1 + \frac{1}{2} \sqrt{2}} \text{ fluent of} \frac{1}{2} (x-1)x \).

We have hitherto considered the factors of the denominators of the proposed fractions to be all unequal; when any number of them are equal, a little difference in the operation is then required; for it is obvious that if two of our fractions were of the same form, for example \( \frac{A}{x - r} + \frac{A'}{x - r'} \), these two would form, in fact, but one fraction \( \frac{A + A'}{x - r} \), which leads us to no useful result.

In case of equal factors, therefore, we must proceed as follows: let the proposed fraction be
\[
a + bx + cx^2 + dx^3 + \ldots \frac{q}{x^{n-1}} \frac{x}{x - r} \frac{(x - r)^n}{x - r'} \text{ &c.}
\]

Assume it equal to
\[
\frac{A}{x - r} + \frac{A'}{(x - r)^n} + \frac{A''}{(x - r)^{n-1}} + \ldots \frac{B^{(n-1)}}{x - r'} + \&c.
\]

Where the upper line represents the fractions due to the \( n \) equal factors, and the lower those due to the \( m \) unequal factors.

Let now these fractions be reduced to a common denominator, and the co-efficients equated as before, which will give us the required values of the several numerators sought.

Example,—It is required to convert \( \frac{1 - 5x}{(1 - x)(1 + x)^3} \) into its equivalent simple fractions.

Assume
\[
\frac{1 - 5x}{(1 + x)^3} = \frac{A}{x} + \frac{B}{x + 1} + \frac{A}{x - 1}
\]

whence
\[
B + B' + A + (2A - B)x + (A - B)x^2 = \frac{A}{x} + \frac{B}{x + 1} + \frac{A}{x - 1}
\]

whence
\[
\frac{1 - 5x}{(1 - x)(1 + x)^3} = \frac{A}{x} + \frac{B}{x + 1} + \frac{A}{x - 1}
\]

whence
RATIONAL FRACTIONS.

whence

\[ B + B' + A = 1 \]
\[ 2A - B = -5 \]
\[ A - B = 0 \]

therefore

\[ B = 3, \quad B' = -1, \quad \text{and} \quad A = -1, \]

consequently

\[ \frac{1 - 5x}{(1 + x)^2 (1 - x^2)} = \frac{3}{1 + x} - \frac{1}{1 - x} - \frac{2}{x^2} \]

We have in both the preceding cases extended the calculation to a greater length than it is necessary to observe in practical cases, in order that the reader might see distinctly the principles on which the decomposition depends.

We shall now furnish him with an easier practical method, which we have extracted from Bonnycastle's Algebra, vol. i.

1. When the factors of the denominator of the given fraction are all unequal, or of the form

\[ \frac{N}{D} = \frac{A}{x - r} + \frac{A'}{x - r'} + \frac{A''}{x - r''} + \&c. \]

take that which constitutes the denominator of the simple fraction which is to be found, and let \( S \) denote the product of all the remaining fractions; then if the root or value of \( x \), in that factor, be substituted for \( x \) in the formula \( \frac{N}{S} \), it will give the numerator of the fraction required.

2. If some of the factors are equal and others unequal, or of the form

\[ \frac{N}{D} = \frac{A}{x - r} + \frac{A'}{(x - r)^n} + \frac{A''}{(x - r')^{n'}} + \&c. \]

let \( S \) denote the product of all the factors in the denominator, except one, as before; then find the simple fractions due to the unequal fractions as above, and for those of the equal factors proceed as follows:

1. \( B = \frac{N}{S} \), taking \( x \) in \( N \), and \( S = p \).

Let \( Q = \frac{N - BS}{x - p} \), then

2. \( B' = \frac{Q}{S} \), taking \( x \) in \( Q \), and \( S = p \).

Let \( Q' = \frac{Q - B'S}{x - p} \), then

3. \( B'' = \frac{Q'}{S} \), taking \( x \) in \( Q' \), and \( S = p \).

Let \( Q'' = \frac{Q' - B''S}{x - p} \), then

4. \( B''' = \frac{Q''}{S} \), taking \( x \) in \( Q'' \), and \( S = p \).

\&c. \&c.

Which operation being performed, the sum of the fractions thus obtained, together with the former, will give all the simple fractions into which the given fraction is resolvable.

Example 1.—It is required to convert the rational fraction \( \frac{1 + x^3}{x - x^2} \) into its equivalent simple fractions.

Here \( \frac{1 + x^3}{x - x^2} = \frac{A}{x + x} + \frac{A'}{x - x} + \frac{A''}{x = x} \) whence, by the preceding rule,

\[ A = \frac{N}{S} = \frac{1 + x^3}{x - x^2} = 1; \quad \text{being} \quad \frac{1}{x} = x \]

\[ A'' = \frac{N}{S} = \frac{1 + x^3}{x - x^2} = 1; \quad \text{being} \quad \frac{1}{x} = x \]

The required fractions are therefore

\[ \frac{1}{x} + \frac{1}{1 - x} + \frac{1}{1 + x} = \frac{1}{x} \]

Example 2.—It is required to convert the rational fraction \( D = \frac{1}{x^3} (1 - x^2) (1 + x) \) into its equivalent simple fractions. Here

\[ N = \frac{A}{x + B} + \frac{B'}{x + B'} + \frac{B''}{x + B''} + \frac{C}{x + C} \]

whence for \( x + x \), the first factor, we have

\[ A = \frac{N}{S} = \frac{1}{x^3 - 2x^2 + x^2} = \frac{1}{x}, \quad x \text{ being } = -1 \]

\[ B = \frac{N}{S} = \frac{1}{x - x^2 + x} = \frac{1}{x}, \quad x \text{ being } = 0 \]

Let now \( Q = \frac{N - BS}{x + \frac{Q}{S}} = \frac{1}{x + \frac{Q}{S}} = \frac{1}{x} - x^2 \]

\[ B' = \frac{Q}{S} = \frac{1}{x - x^2 + x} = 1, \quad x \text{ being } = 0 \]

Again, for \( (1 - x) \)

\[ C = \frac{N}{S} = \frac{1}{x + x^2} = \frac{1}{2}, \quad x \text{ being } = 1 \]

Let now \( R = \frac{N - CS}{x + \frac{R}{S}} = \frac{1}{x} - \frac{1}{x} - x^2 = \frac{1 + x + x^2}{x + x^2} \]

Therefore \( \frac{1}{x} + \frac{1}{1 - x} + \frac{1}{1 + x} = \frac{1}{x} + \frac{1}{x} + \frac{1}{x} \]

It is obvious, as we have before stated, that this decomposition of rational fractions must necessarily be affected as to its general application, by the imperfection of the theory of equations, which will not admit of a practical resolution of the denominator into its simple factors in all cases. It will also further appear, that, in case of any of the roots being imaginary, the same will necessarily enter into the numerators of the simple fractions. But this difficulty may be avoided: for since the imaginary roots of equations always enter in pairs, and the product of such pairs of roots being always real, being of the form \( x^2 + 2ax + a^2 + b^2 \), we may, instead of resolving the fractions into the simple fractions \( \frac{A}{x - r} + \frac{A'}{x - r'} + \frac{A''}{x - r''}, \&c. \) resolve it into as many of these fractions as it has rational simple factors, and into as many fractions of the form \( \frac{Bx + C}{x^2 + ax + a^2 + b^2} \), as it has pairs of imaginary factors, and then proceed as before.
We cannot extend our remarks to a greater length in this article; we must, therefore, refer the reader who wishes to see these principles more completely developed, to Euler's Analysis Infinitorum, vol. i. ch. 2 and 11; to La Croix's Algebra, and his Calcul Differentiel et Calcul Integral. See also Bonnycastle's Algebra, and Simpson's Fluxions.

Rational or true horizon, is that whole plane is con-

ceived to pass through the centre of the earth; and which therefore divides the globe into two equal portions, or hemispheres. See Horizon.

It is called the rational horizon, because only conceived by the understanding; in opposition to the sensible or apparent horizon, which is visible to the eye.

Rational integer, or whole number, is that of which unity is an aliquot part. See Number, and Aliquot part.

Rational mixed number is that consisting of an integer, and a fraction; or of unity, and a broken number.

Commensurable quantities are defined by being one to another as one rational number to another.

For unity is an aliquot part of a rational number; and a fraction has some aliquot part common with unity; in things, therefore, that are as a rational to a rational number, either the one is an aliquot part of the other, or there is some common aliquot part of both; therefore they are commensurable.

Hence, if a rational number be divided by a rational, the quotient is always a rational.

Rational Physician; in ancient medical history, the phy-

sicians of the dogmatic sect, who flood in opposition to the empiric sect; the former appealing to certain theoretical principles in the application of remedies, while the latter relied entirely upon experience, and disclaimed all knowledge of first principles. The tenets of both these sects have been handed down to us by a Neaer, Celsus, and have been given at length under a former article. See Empiric.

Rational Quantity, or number, a quantity or number commensurable to unity.

Supposing any quantity to be 1, there are infinite other quantities, some of which are commensurable to it, either simply, or in power; these Euclid calls rational quantities. The rest, that are incommensurable to 1, he calls irrational quantities, or irads.

Rational Ratio. See Ratio.

Rational Soul. See Soul.

RATIONALAE, a solution or account of the principles of some opinion, action, hypothesis, phenomenon, or the like.

Hence, Rationalae is also the title of several books. The most considerable is the "Rationale of Divine Offices," by Guil. Durandus, a celebrated school-divine, bishop of Mende, finished in 1286, as he himself tells us. See Printing.

Rationale also denotes an ancient facerdotal veilment, worn by the high-priest under the old law; and called by the Hebrews, J0YUJ, hhozhen; by the Greeks, bovev; by the Latinists, rationale and pectorale; and by the English translators, breast-plate.

The rationale was a piece of embroidered stuff worn on the breast, about a span square. Du Cange describes it as a double square of four colours, interwoven with gold, and set with twelve precious stones in four rows, on which were engraved the names of the twelve tribes, and fastened to the shoulder by two chains and two hooks of gold. The form of the rationale was prescribed by God himself, Exod. xxviii. 15-29.

A rationale appears also to have been anciently worn by the bishops under the new law. But authors are in doubt about its form; some will have it resemble that of the Jews; others take it to be only the pallium.

RATIONALIS, an officer mentioned in several ancient inscriptions.

Lampridius, in the life of Alex. Severus, uses rationalis as synonymous with procurator.

The rationallys were intendants or surveyors under the emperors; and though Lampridius pretends they were first established by Severus, it is evident there were some under Augustus.

RATIONARIUM, among the Romans, a book which contained the accounts of the empire. It was otherwise called breviarioum. See Breviary.

RATIONIS Ens. See Ens.

RATIONIS Difinitio. See Distinctio.

RATIONIS Or, in Anatomy, the bone of the forehead, otherwise called os frontis.

RATIBON, or REGENSBERG, in Geography, an imperial city of Germany, in the circle of Bavaria, and capital of a bishopric of the same name, situated at the confluence of the Regen and of the Danube. The town is large, populous, and fortified; and was anciently the capital of Bavaria, and the residence of its dukes. The emperor Frederic I. annexed it to the empire. This town is a staple, but neither its manufactures nor trade are very considerable; corn, wood, and provisions, are sent by the Danube to Vienna. The number of inhabitants is about 22,000; 62 miles N.E. of Augsburg. N. lat. 48° 55'. E. long. 12° 50'.

The bishopric of Ratibon comprehends about 1383 parishes; and was founded, as it has been supposed, by St. Boniface, in the year 736. The seat of the bishop is at Ratibon, where, however, he has no jurisdiction.

RATISKA, a town of Immeritia; 35 miles N.E. of Cotatis.

RATKAI, George, in Biography, born in 1613, of a noble family, in Hungary, entered into holy orders, and was made canon of the church of Zagrab. He obtained the efeem of the viceroy of Croatia, John Dralkovitz, who engaged him to compose the history of that province, and gave him free access to its archives. He accordingly published, in 1652, a very learned work, entitled "Memoria Regum et Barorum Regnorum Dalmatie, Crotie, Slavonie, Inchoata ab origine fua usque ad annum." Gen. Biol.

RATLINES, or, as the feamen call them, Rutlius, or Rutlines, are certain small lines which traverse the straits of a ship horizontally, at regular distances above the dead-eyes upwards, and forming a variety of ladders, whereby to climb to any of the mail-heads, or descend from them. Hence the term seems to be derived from rath, an oblique word, signify ing a hill. In order to prevent the rattling from slipping down by the weight of the sailors, they are firmly attached by a knot, called a close-hitch, to all the strands, except the foremost or aftermost; where one of the ends, being fitted with an eye-splice, is previously fastened with twin-thread or pack-thread. Falconer.

RATNO, in Geography, a town of Lithuania, in the patinate of Brzeze; 50 miles S.E. of Brzeze.

RATOATH, a poor village of the county of Meath, Ireland, which, before the union, had its representatives in parliament. It gave name to a barony, and is 12½ miles N.W. by N. from Dublin.

RATOLY, a town of Hindoostan, in the circar of Golph; 25 miles S.E. of Raat.

RATONES, a small island in the river La Plata, near Monte Video.

RATSCHA,
RAT

RATSCHA, or Ratzka, a fortress of Schleovia, on the N. side of the Save, opposite to the mouth of the Drin; 35 miles S.W. of Peterwardein.

RATSHI'Za, a town of Moravia, in the circle of Brunn; 10 miles N.E. of Brunn.

RATSUR, a town of Hindooftan, in the cincar of Auroungabads; 65 miles E. of Auroungabad.

RATTAK, a town of Bengal; 14 miles S.E. of Curruckpoor.

RATTAN. See RUATAN.

RATTAN Cane. See CANE.

RATTELSDORF, in Geography, a town of Bavaria, in the bishopric of Bamberg; 9 miles N. of Bamberg.

RATTEN. See RAATEN.

RATTEN, in Rural Economy, a provincial word, used to signify a rat.

RATTENBERG, in Geography, a town of the county of Tyrol, with a citadel on the Inn; 16 miles E.N.E. of Innsbruck.

RATTIKOW, a town of the duchy of Holstein; 6 miles N.N.E. of Lubeck.

RATTLE, among the Ancients, a musical instrument called by the Romans crepitaculum.

Mr. Malcolm takes the tinnitusabulum, crotalum, and stridulum, to have been only so many different kinds of rattles.

The invention of the rattle is ascribed to the famous mathematician Archytas; whence Aristole calls it Archytas's rattle. Diogenes adds the occasion of the invention; viz. that Archytas, having children, contrived this instrument to prevent their tumbling over things about the house. So that how much sooner some instruments have changed their uses, the rattle, we are sure, has preferred its original application.

RATTLE, or Rattel, in Commerce, a weight in Arabia; a rattle of coffee contains, at Betelfagui, 14 1/2 vaikias, and a farcel, or frazil, of 10 maunds, or 20 rattles, contains 200 vaikias; a farcel weighs 20 lb. 6 oz. 4 dr. avoidupois, and a bahar of 40 farcels = 815 3/16 lb. avoidupois; 10 farcels in Betelfagui are equal to 7 in Mocha; 16 vaikias of dates, candles, and iron, are reckoned to a rattle; but of all other sorts of goods 15 vaikias make a rattle. The rattle is used in the bazar, or market, only. At Jiddah, another sea-port of Arabia, in the Red Sea, the bahar contains 10 frazils, 100 maunds, or 500 rattles, and the rattle 15 vaikias. The bahar weighs 223 lb. English troy, or 183 lb. avoidupois; and the maund 29 oz. 4 7/16 dr. avoidupois. Kelly's Universal Compendium.

RATTLE, Yellow. See RHNANTHUS.

RATTLE-SNAKE. See SNAKE.

RATTLE-SNAKE Root, Senequa. See MILK-WORT.

RATTLE-SNAKE Root, Dr. Witt's, a species of Prenanthes; which see.

RATTLE-SNAKE Weed, a species of Eringium; which see.

RATTLE-SNAKE Island, in Geography, a cluster of small islands at the western extremity of Lake Erie.

RATTLE-SNAKE Mountains, mountains of New Hampshire; 38 miles N. of Concord.

RATTLING, in horsething, a term applied to a disagreeable noise produced in them by the entrance of the air between the internal parts of the sheath and the prepuce or covering, principally taking place in trotting or going fast.

RATTONNEAU, in Geography, a small island at the entrance of the harbour of Marsilles, which has a fortress erected in the 17th century by the duke of Guife.

RAT'TRAY HEAD, a cape of Scotland, on the N.E. coast of the county of Aberdeen; 7 miles N. of Peterhead. N. lat. 57° 12'. W. long. 1° 44'.

RATULAH, a town of Hindooftan, in Oude; 15 miles N.E. of Jyzabad.

RATWAH, a town of Hindooftan, in the cincar of Gohud; 27 miles E. of Gwalior.

RATZ, in Commerce, the name of a small coin, struck at Friburgh, &c. nearly of the same value with the blare, which, in France, is worth two sols and a denier.

RATZEBUR, in Geography, a town of the principality of Pomerania; 14 miles S. of New Stettin. N. lat. 53° 30'. E. long. 16° 14'.

RATZEBURG, a town of Germany, which gives name to a principality, situated on an island in a large lake; the lake is 30 miles long, and 9 broad, and boats pass by it to Lubeck with goods and passengers. It was burnt by the Danes in 1603, and since that disaster the streets have been regularly laid out, and the houses are built after the Dutch manner. In the market-place is the regency-office, and here is held the chief court of justice and the consistory; the garrison is quartered in barracks; 20 miles S. of Lubeck. N. lat. 53° 43'. E. long. 10° 46'. The principality of the same name is situated between Mecklenburg and Saxe-Lauenburg, and extends about 10 miles each way. The soil is fertile, and produces a considerable quantity of wheat, besides feeding a number of cattle. It was converted from a bishopric into a principality by the peace of Westphalia. It belongs to Mecklenburg-Strelitz.

RATZENSTEIN, a town of the duchy of Stiri; 5 miles S. of Windsdich Gratz.

RATZKINSCHA, a town of Hungary; 10 miles N.N.W. of Cakathurn.

RAVA. See Rawa.

RAVALEMENT, Fr. equivalent, among organ-builders and harpsichord-makers, to compas in English. The complete set of keys, or whole system of musical sounds, (said Rouffeau in 1768,) instead of confining itself to four octaves, like common keyed-instruments formerly, extends now to five octaves, adding a fifth below double C, and a fourth above C in alt., including five octaves between the lowest F and the highest. (This was the common compass of our harpsichords made by Tabel, Kirckman, and Shudi, long before 1768.) The word ravalement is confined to keyed-instruments; there are no others of so extensive a compass as five octaves. But in the year 1777, when Dr. Burney first composed and published duets “a quatre mains,” or for two performers on one instrument, the ladies, at that time wearing hoops, which kept them at too great a distance from each other, had a harpsichord made by Merlin, expressly for duets, with fix octaves; extending from the octave below double C in the base, to the octave above C in alt. in the treble. And as duets à quatre mains have been composed by all the great masters in Europe since that time, instruments with additional keys are now become general. At first it was only in the treble that the compas was extended, except in the instrument above-mentioned by Merlin; but at present notes are added in the base to complete the fix octaves: and, indeed, the additional notes in the base are better worth having for particular effects, than thofe in the treble; which often, from the shortness of the strings and feeble vibration, more resemble the tone of wood than wire; whereas the tone of thofe in the base of large piano forte, by the bell makers, is fo rich and full, that
that each found below double F resembles that of an organ-pipe in flow notes, more than the transient tone of a string.

Rouleaux very judiciously observes, that almost all instruments are limited in their compass below, except harps and instruments with keys. The violoncello can go no lower than double C, its 4th string, nor the violin below G. The flute and hautbois depend only to D and C. But the notes in alto. have been extended in the acute to sounds that are seldom in tune, and never pleasing. Like radical notes of difficult execution, they surprise, and the performer's dexterity is applauded; but neither the harmony nor the melody of very high or rapid sounds can excite rapture like those of moderate quickness, when produced with feeling and expression, in the middle of the scale.

RAV. ALISHE, in Geography, a town in Sweden, in West Gothland; 24 miles N.W. of Uddevalla.

RAVANA, in Hindoo Mythology. See RAVANA.

RAVANAK, in Geography, a town of European Turkey, in Macedonia; 16 miles E.S.E. of Saloniki.

RAUAN, a town of Peru, in the province of Kerman; 105 miles E. of Sirjan.

RAVA-POU, in Botany, Rheede Hort. Malab. v. 4, 99. t. 48, a plant erroneously cited by Linnæus for his very different Nycanthus birfuta. See Guettarda Speciosi.

RUAUC AVIS, in Ornithology, the name of a bird described by Nieremberg, as common about the lakes and rivers of America, and of the kingfisher kind, but nearly as large as a duck, and black on the crown, and white on the breast and belly. Its neck is naturally very long in proportion to its body, yet it can occasionally contract and shorten it in a very wonderful manner. It is a native of Mexico, and is esteemed very good for the table. Mr. Ray has placed this among the birds, the accounts of which he is dittruf of.

RAUCH, in Geography, a town of Germany, in the lordship of Schwarzenberg; 10 miles S.W. of Schefinfield.

RAUCHENEGG, a town of Austria; 2 miles W. of Baden.

RAUCIT, a town of Russia, in the government of Viborg, near lake Ladoga; 44 miles S.W. of Viborg.

RAUDANAGUR, a town of Bengal; 30 miles E. of Ramgur.

RAUDEN, a town of Prussia, in the palatinate of Culm; 10 miles N.E. of Culm.—Alto, a town of Silezia, in the principality of Ratibor; 12 miles N.E. of Ratibor.

RAUDNIZ, a town of Bohemia, in the circle of Schlan, 12 miles N.N.E. of Schlan.—Alto, a town of Bohemia, in the circle of Chrudim; 16 miles N.N.W. of Chrudim.

RAUDRI, a name of the Hindoo goddess Parwati, confrom of Siva, the destroying power. In this character she may be considered as his Sakti, or energy in his form of Rád Wait, or Fate. Rádri, and Radremsi, are other modes of writing this name of the goddess in her avengeing character, in which she does not apparently differ much from her attributes, as Sakti of Mahabala; under which name, and the others occurring in this article, distinguished by italics, farther and sufficient information may be sought. See also Thisak-devi, and TAMASI.

RAUDITEN, in Geography, a town of Silezia, in the principality of Wohlan; 18 miles N.W. of Wohlan. N. lat. 51° 20' E. long. 16° 15'.

RAVEL BREAD, a sort of bread, called alto blackwytldof, as being of a middle fineness between white and brown.

RAVELIN, in Fortification, was anciently a flat bastion, placed in the middle of a curtain.

RAVELIN is now a detached work, composed only of two faces, which make a salient angle, without and sometimes with flanks; and raised before the curtain on the counter-scarp of the place; serving to cover it and the joining flanks from the direct fire of an enemy.

A ravelin is a triangular work, resembling the point of a bastion, with the flanks cut off. (See Plate V. Fortification, fig. 4. lit. iii. &c.) Its use before a curtain is, to cover the opposite flanks of the two next bastions. It is used also to cover a bridge or a gate, and is always placed without the moat.

What the engineers call a ravelin, the soldiers generally call a demi-lune, or half-moon. See DEMI-LUNE.

There are also double ravelins, which serve to defend each other. They are laid to be double when they are joined by a curtain.

Ravelins, or demi-moons, are constructed by setting off 10 toises from the re-entering angle O of the counter-scarp (Plate VIII. Fortification, fig. 4.) on the capital O I of the ravelin, or on the perpendicular produced, and from the point L drawing lines to the shoulders A, B; whose parts L M, I N, terminated by the counter-scarp, will be the faces MO, ON, the semi-finals of the ravelin required. Others will have the faces of the ravelin to terminate on those of the bastions within three toises of the shoulders, in which case the ravelin cover the flanks better than the others. The ditch before the ravelin is 12 toises, and its counter-scarp parallel to the faces of the ravelins, and made in a circular arc before the salient angle. When the ravelins are made with flanks, the faces should terminate those of the bastions, at least 5 toises from the shoulders. These flanks are made by setting off 10 toises from the extremities of the faces, and from the points thus determined, the flanks are drawn parallel to the capital of the ravelin. When redoubts, or keeps, are formed in the ravelin, this is done by setting off 16 toises from the extremities of the faces, on the semi-gorges from N to B, and from M to A; and from the points B, A, the faces are drawn parallel to those of the ravelin; the ditch before this redoubt is 6 toises, and its counter-scarp parallel to the faces. This work should be covered in the faces by a wall, a foot or two thick, furnished with loopholes for the musketry to fire through; and it will serve to secure a retreat for the troops who defend the ravelin; they may thus prevent the enemy from making a lodgment in the outward part of the ravelin, or at least greatly obstruct their attempts for this purpose. Nor can they be drove from this place, until the enemy has erected a battery, and brought cannon on the ravelin to batter the redoubt. When the counter-guard (which see) is placed before the ravelin, 40 toises are let off on the capital of the ravelin from its salient angle to the salient angle of the counter-guard, and 10 on the counter-scarp of the ditch. For the construction of ravelin-works before the ravelin, see HOnX-eight. Within the ravelins are constructed a rampart of about 16 or 20 yards, and a parapet of about 6 yards; ramps are also annexed in the slope of the rampart, and a barbet, when it is proper, is constructed in a salient angle. In wet ditches, where the troops pass from the town to the ravelin in boats, it is proper to make, in the gorge of the ravelin, a kind of harbour, where the boats may be covered from the fire of the enemy. In dry fossés, there should be ramps or stairs in the gorge of the ravelin, to preserve a free communication, if the bridges should be broken down by the enemy's shot. The celebrated general Coehorn, in the ravelins which he built at Bergen-op-zoom, contrived a very good defence for the covered way before the faces of the bastions, by making retired flanks in the breasts of the ravelin, where one
one or two cannon might be placed as secure from the enemy’s fire as those behind the orillon of a bafion. See Military Construction.

RAVELLO, in Geography, a sea-port town of Naples, in Principato Citra, the see of a bishop, united to Scala; 11 miles W.S.W. of Salerno. N. lat. 40° 39’. E. long. 12° 10’.

RAVELWATER, a river of the county of Antrim, Ireland, rising in the mountains in the northern part, and flowing through Ravel glen to the river Main.

RAVEN, Corvus corax of Linnaeus, in Ornithology, a large bird of the crow kind, well known throughout the world, as being found in all climates, and all regions. The colour of the whole bird is black, finely glossed with a rich blue, the belly excepted, which is dusky. The raven builds in high trees, or upon the ruins of lofty buildings in the neighbourhood of great towns, being held in the same veneration as the vultures are in Egypt, and for the same reason; for devouring the carcasses and filth that would otherwise prove a nuisance. They lay five or six eggs, of a pale greenish colour, marked with small brownish spots. There are many fabulous stories of the longevity of the raven; but birds are in general long lived, and the crow kind not less so than the rest. The raven is a very docile bird, and may be taught to speak, as well as to fetch and carry. In clear weather, ravens are remarked to fly in pairs at a great height, making a deep loud noise, different from the common croaking; and their scent is remarkably good. See Corvus Corax.

The quills of a raven are used in tuning the lower notes of a harpsichord, when the wires are set at a considerable distance from the fitches.

It is rare to find this creature white, yet it happens sometimes. Boyle mentions one. There was also one shown to the Royal Society some years ago. Boyle’s Works abr. vol. ii. p. 46.

RAVEN, Night, an English name for a heron, which flies in the night, and makes a very odd and hoarse noise. It has been applied by some to the bittern, or ardea stellata, but improperly, belonging of right to the smaller grey heron, called nycticorax. See Heron.

RAVEN, Sea, or Corvusant. See Corvus Aquaticus.

RAVENA, in Hindoo Mythology, is the name of a celebrated king of Lanka, or Ceylon. Such was his prowess, and the oppression which he exercised over his subjects, that it became necessary for Vishnu, the preserving power of the deity, to defend on earth for his destruction, and the relief of the suffering world. He accordingly became incarnate in the person of Rama; and the wars that ensued between the forces of the tyrant and the divine general, for the recovery of Sita, his ravished spouse, are the subject of the fine epic poem, the Ramayana; under which article of this work, and under Rama, and others thence referred to, the poem, and the historical traditions connected with these points, are sufficiently described and discussed.

Although obscured by mythological fables, these persons and wars are admitted to have had historical existence; and some important points of chronology hinge upon them. We have, therefore, in this and other articles, noticed at some length the legends connected with these subjects.

In the Hindoo theogony, the origin of Ravana is thus related. Two ethereal warders of Vishnu’s palace carried the pride of office so far as to insult the seven Maharshis, (see Maharsni, or Rishi,) who had come to offer their adorations. The offended sages pronounced an impregnation on the insolent warders, condemning them to be adho-yoni, or born below, thrice in mortal forms, before they could be re-admitted into the divine presence. The impregnation of a Rishi, even if provoked by a god, is scarcely to be averted; and the offenders, in conflagration, appeared in their first birth as Hiranyaksha, or golden-eyed, and Hiranyakapu, or clad in gold; secondly, as Ravana and Kumblakarna; and lastly, as Kanfa and Sisupala.

The history, if such it may be called, of Ravana, Rama, &c. is perpetually alluded to in Hindoo writings: the Ramayana, containing an infinity of such legends, being one of the most popular works of the East. Ravana, or Ravan, has become a generic name for a tyrant. He is also called Dageviva, or the ten-necked; he being usually represented with that number of heads, and twenty hands, symbolical of specifion and prowess. A couplet in the Ramayana may be thus translated. “Where Ravana is, the sun loses his force, the winds cease to blow, the fire ceases to burn: the rattling ocean, seeing him, stills its waves.” Such are the hypothetical relations of his potency, obtained by the usual process of self-inflicted austerities. So ardent was he in this irrepressible spirit of merit, that he offered to Siva nine of his ten heads successively; and thus extorting the favour of the confounding deity, pleased with such an important sacrifice, he obtained a promise, with some equivocal stipulations, of whatever he should desire. This sort of austeritv is called Tapas, under which word some account is offered of various modes of practising it. The gods and demi-gods, alarmed at Siva’s promise, besought him to recall it. But such conduct is deemed unbecoming in deities, who, however, do not scruple to evade the performance of their promises by deceit or prevarication: and, on this occasion, Nareda was deputed to found Ravana as to what he would demand, which, as usual, was universal dominion, &c. Nareda artfully persuaded Ravana that Mahadeva (or Siva) was drunk, and had promised him what he could not perform: whereupon the vindictive giant tears up Kailafa, the paradise of Siva, which, being contrary to the stipulations, releases Siva from his promise, and he contends to the destruction of Ravana, which is brought about by the avatara, ordefeat, of Vishnu in the person of Rama. From this story we are told to learn that all worldly affairs are the predefined ordinances of providence; whose will, that any event should take place on earth, includes precently all the routine and detail of its accomplishment; although we only see the links of a chain of causes leading naturally to its effect.

We will here add an extract from the Hindu Pantheon, whence a considerable part of this article is taken, shewing how unceasingly the mythological machinery of that poetical people is introduced into their popular works. The names distinguished by capitals imply that articles are given under those words, in this work; and a reference may be made to them for any desired information.

“Respecting Ravana,” says the author of the publication adverted to, “I will notice but one more tale, as related to me by a Brahman; who, unable fully to make me feel the poetical beauties, or comprehend the morality of the Ramayana, bluffed while he developed its follies; which, in conformity with popular taste, or if taken separately, are apparently very numerous; although it must be confessed, they are so contrived as to be intimately connected with the main action of the poem. The following idle tale is of this description: but I shall not here explain the causes that led to the predicament, or the consequences that ensued.

“Ravana, by his power and infernal arts, had subjugated all
all the gods and demi-gods, and forced them to perform menial offices about his person and housetop. INDRA made garlands of flowers to adorn him withal. Agni, or PA-
vaka, was his cook. SUYRA, regent of the sun, supplied light by day; and Soma, regent of the moon, by night. VARUNA, the Hindoo Neptune, purveyed water for the
palace. KUVERA, their Plutos, furnished Orth. The whole NAVA-GRAHA (the nine planetary spheres, including RAHU and KETU) sometimes arranged themselves into a ladder, by which, they serving as steps, the tyrant ascended his throne. BRAMA (for the great gods were there also, and I give this anecdote as I find it in my memoranda, without any improved arrangement) was a herald, pro-
claiming the god's titles, the day of the week, month, &c. daily in the palace; a fort of speaking almanacs. MA-
HADEVA, in his character or incarnation of KANDEH-RAO, performed the office of barber, and trimmed the giant's
beards. VISHU had the honourable occupation of in-
structing and drilling the dancing and singing girls, and fe-
lecting the fairest for the royal bed. Ganea, or POLLEAR,
had the care of the cows, goats, and herds. VAYU swept the house. YAMA washed the linen. And in this manner were all the gods employed in the menial offices of Ravena, who rebuked and flogged them in default of industry and attention. Nor were the female divinities exempted: for PARVATI, in her form of SATWI, was head AYA, or nurse, to Ravena's children. LAKSHMI and SARASWATI were also among them, but it does not appear in what capacity. Earthly kings and queens were also forced into this de-
graded servitude, to the number of ninety-six royal families; as is said to be detailed in the RAMAYANA. But I have some doubt if such a relation be actually in this shape, in that poem: this we shall see, when its other books are trans-
fledged and published. In my abstract of it, however, such a godly predicament seems essential to the main action; RAMA being thereby impelled by every confideration of piety and duty to immediate and energetic measures, for the relief and liberation of the degraded divinities.

Ravena, as we have noticed, is turned Dasagriya, or the ten-headed. He is also called Vifrvana, or son of Vif-
rava, the father likewise of Kuvera. The brothers are sometimes named Pulafyga, or Paulafyga. (See these ar-
ticles.) Another of his names is equivalent to lord of
Rakithhas, a race of malignant beings, common agents in the hands of superhuman tyrants for the annoyance of the virtuous portion of mankind, or thwarting the benificent
views of the gods. Many particular varieties of these demons are enumerated in the frith book of the Ramayana, as aiding Ravena in defence of himself and his kingdom of Lanks. In pictures illustrative of the Ramayana, which are very common throughout India, they are depicted especially ill-
favoured, painted green, red, blue, &c. and engaged in fierce ecstasies with Rama's finian foldiers. Several legions of these Rakshas, each of 14,000, were destroyed by Rama.

See RAKSHA.

RAVENALA, in Botany, Adans. Fam. des Plantes, v. 2. 67. Jull. 62. See URANIA.

RAVENBACH, in Geography, a town of Germany, in the principality of Anfipach; four miles S.S.W. of Anfipach.

RAVENGLASS, a market-town and sea-port in the parish of Minclerar, Allerdear ward, above Darwent, county of Cumberland, England, is situated on the Solway Frith, near the confluence of the rivers Elk, Mite, and Ir. Though poffefling many advantages for trade, it is but a poor place, and chiefly supported by its oyster fishery, for which it is much celebrated. This town stands at the dif-
tance of 57 miles S.S.W. from Carlifte, and 287 N.W. by N. from London. The manor originally constituted part of the barony of Egremont, but was granted by Richad Lucy to the Penningtons, from whom the present owner, lord Muncafter, is lineally descended. The market
day is Saturday, weekly; and there are two annual fairs, one of which is held on the eve, day, and morrow, of St. James, and is remarkable for the ceremonies attending its proclama-
tion and continuance. On the first day, the earl of Egrem-
ont, or his proxy, attends, accompanied by the ferjeant of
the borough of Egremont, with the insignia, called the Bow
of Egremont; by the foresters, with their haws and arrows;
and by all the tenants of the forest of Copehand, who hold
their ceftates by the special service of attending the earl, or
his representative, during the fair. On the third day, at
noon, the earls, officers, and tenants of the forest, depart,
after proclamation; and lord Muncafter, and his tenants,
take formal re-poffelion of the place, and the day is con-
cluded by horse-racing, and various rustie diversions.

Near Ravenclafs, on the northern bank of the river Elk,
stands Muncafter-houfe, the seat of lord Muncafter; and
east from it, on the opposite side of the river, are seen ruins of considerable magnitude, respecting which no historical documents are known to exilt. They are now called the
city of Burnford; and its foundation is ascribed, by tradition, to the Danes, who are said "to have gathered for its inhabi-
tants the men of Drig, and the women of Beckermont," whence the popular faying, "let us go together like lads of
Drig and lades of Beckermont." These ruins extend
about three hundred yards in length from east to west, and
100 in breadth, from north to foulh; and are enclosed, ex-
cept at the east end, by a wall, nearly three feet in height.
"There appears," says Hutchifon, "to have been a long
street, with several erods ones; the remains of the house-
steads within the walls are not very numerous; but on the
outside they are innumerable, especially at the south side
and west end. The circumference of the city, and suburbs, is
nearly three computed miles; the figure is an oblong square.
There is an ancient road through the city, leading from
Ulpha to Ravenclafs. About the year 1750, a considerable
quantity of silver coin was discovered in the ruins of one of
the houses, concealed in a cavity formed in a beam." A
History of the County of Cumberland, &c. by William
Hutchifon, F.S.A., two vols. 4to. Beaitics of England
and Wales, vol. iii. 1802, by John Britton and Edward
Wedlake Brayley.

RAVENNA, a very ancient city of Italy, in the de-
partment of the Amon, fteated on the river Mentone, near
the Adriatic. This city, as Strabo informs us, was built
by the Thellians, on several islands, long before the war of
Troy, and they were driven out by the Tufcans. In the
time of this Greek writer, it was situated in the midft of a
marsh, and attached to the continent, and in process of time
the Po accumulated mud and fand, fo that the land was
raifed and the fea removed to a greater distance. The fame
writer informs us, that it was made a Roman colony by Au-
gibius; and Dion fays, that a fleet of 250 vejfels was fta-
tioned in this port by that prince, from which circumstance
it was called "portus chiuffi," or the port of the flet.
It flationed, fays Suefionius, one fleet at Mifenum, and another
at Ravena, for guarding the upper and lower fen. Tibe-
rius repaired its walls, and erected fome new gates, which
fihl bear an incription to this purpofe. Trajan also con-
tributed towards embellifhing this city. Honorius made it
the place of his residence, both before and after Albarie had cap-
tured and burned Rome. When Odoacer made a conquest
of Italy, he refided at Ravenna, and futfained here a hege

of three years, at the termination of which he was taken and slain by Theodoric. Theodoric fixed the seat of his empire in this place, and adorned it with magnificent churches and palaces, and re-constructed the aqueduct of Trajan. His daughter Amalafontha, and his grandson Athalaric, contributed towards the improvement of this city. When the Goths were driven from Italy by Narics, general of the emperor Julianus, he was made governor of Ravenna; and having continued in this situation for 10 years, he was recalled by Julian II., successor to Julianus; and in the year 567 he was succeeded by Longinus, who took up his residence at Ravenna, under the title of exarch. (See Exarch.) The famous battle of Ravenna was fought near this town between Gaetian de Foix, duke of Nemmes, and nephew of Louis XII., and the army of pope Julius II., Ferdinand, king of Spain, and the Venetians, in which the former young general, being only 24 years of age, having killed between 16 and 18,000 of the enemy, proved victorious, though he himself was killed by too ardently following the pursuit. This happened on Easter-day 1512. The French, enraged by the loss of their brave general, took Ravenna by storm, and pillaged the city with such severity that it has never recovered. On the road to Forli, by the banks of the little river Ronco, three miles from the city, a cress flew the spot where Galton de Foix was killed. Fresh water has always been so scarce at Ravenna, that it has occasioned a pleasant epigram by Martial. This city was of late the capital of Romagna, with the title of an archbishopric. It has produced several persons of eminence, as Fautinus, often mentioned by Martial; the sophist Anapinus, who lived under the reign of Alexander Severus; Caflodurus, chancellor to Theodoric, king of the Goths in Italy; pope John XVII.; Peter Danien, cardinal of Offa, and several others. Ravenna was also the seat of many councils at successive periods. The three last councils, in 1311, 1314, and 1317, were summoned for the purpose of reforming the corrupted manners of the ecclesiastics, which were, in those days, very debauched. It is now a mean and inconsiderable town; the houses are old and in a ruined state, and the number of inhabitants scarcely amounts to 14 or 15,000.

In the time of the Romans, it was fitted on a kind of bay formed by the Adriatic, and its harbour was celebrated; but it is now three miles from the sea. The mud thrown up by the tide having formed a tract of land, which is cultivated, and on which the city itself has been enlarged towards the sea. The air is insalubrious; but has been somewhat ameliorated by conveying along the sides of the city the rivers Mentone and Ronco, which carry off the salt water from the marshy grounds. It contains several churches, and 24 convents; 42 miles E. of Bologna. N. lat. 44° 27'. E. long. 11° 5'.

RAVENPOINT, a headland of the county of Wexford, Ireland, at the N. side of the entrance into Wexford haven. N. lat. 52° 25'. W. long. 6° 18'.

RAVENSARA, in Botany, a barbarous appellation, altered by Sonnerat from the Madagascar name of the plant, Ravenflora, or Pararavenflora, meaning, it seems, a good leaf, and applying to the aromatic qualities, and economical uses, of the leaves. Hence Jullien was induced to confine the apt generic name Agathophyllum, from σύκος, good or profitable, and σολάς, a leaf; under which this genus ought to have been described in its proper place, in our first volume. But one of our predecessors has, by mistake, referred the reader to Ravnflora, as a genuine Linnaean name, attributing Agathophyllum to professor Martyn; see that article. To correct this error, and supply the consequent deficiency, we subjoin an account of the tree in question, under its proper and received denomination.
Wellphalia. The approaching Congress (1814) may possibly fix its future destination.

RAVENSBURG, a town of Bavaria, which anciently belonged to the Guelphs, counts of Aiterf; but it was an imperial town before the time of king Rodolphus, and continued such till the year 1802, when it was given, among other indemnities, to the elector of Bavaria. The Roman Catholics and Lutherans are united with regard to the temporal and spiritual concerns of the place, and the magistracy is shared betwixt them. They have one church in common; but the Lutherans are exclusively poliessed of another, and the Roman Catholics have alo two parish-churches; 21 miles N.E. of Constance. N. lat. 49° 41'. E. long. 9° 38'.

RAVENSBURG, a town of the Rhenic palatinate, on the Elsaf; 16 miles W. of Heilbronn.

RAVENSCHROFT, Thomas, in Biography, an active English musician and publisher, who flourished from the beginning of the 17th century to 1635. He was the editor and composer of the first collection of psalm tunes in four parts, which had till then appeared in England. He was a bachelor of music, and a professor not only well acquainted with the practice of the art, but seems to have bestowed much time in the perfecting of the best authors, and in meditation on the theory.

This book, published in small octavo, 1621 and 1633, contains a melody for every one of the hundred and fifty psalms, many of them by the editor himself, of which a considerable number is still in use; as Windfor, St. David's, Southwell, and Canterbury. There are others, likewise, which are sung by the German, Netherlandish, and French Protestants. To these the base, tenor, and counter-tenor parts have been composed by twenty-one English musicians: among whom we find the names of Tallis, Dowland, Morley, Bennett, Stubbs, Farnaby, and John Milton, the father of our great poet. The tunes which are peculiar to the measure of the 100th psalm, the 113th, and 119th, were originally Lutheran, or perhaps of still higher antiquity. And though Ravenscroft has affixed the name of Dr. John Dowland to the parts which have been set to the 100th psalm, yet, in the index, he has ranked the melody itself with the French tunes; perhaps from having seen it among the melodies that were set to the French version of Clement Marot and Theodore Beka's Psalms, by Goudimel and Claude le Jeune. Ravenscroft, in imitation of these harmonists, always gives the principal melody, or, as he calls it, the psalm-song, to the tenor. This part, indeed, he sometimes erroneously terms Fa-burden. This is a corruption of base-bourdon, and base-borde, which originally implied such simple harmony as arises from a series of thirds and sixths to the base. Its publication is, in some measure, historical: for he tells us not only who composed the parts to old melodies, but who increased the common flock, by the addition of new tunes; as well as which of them were originally English, Welsh, Scots, German, Dutch, Italian, French, and imitations of these.

No tunes of triple time occur in Claude le Jeune, and but five in Ravenscroft: the principal of which are Cambridge, Martyrs, Manchellet, and the bins. This last is still much used, and often played by choirs: it is called an imitation of a foreign tune, and has the name of Richard Allison prefixed to it. Muller's German edition of the psalm tunes at Frankfort is exactly that of Claude le Jeune, in two parts only; except that he has transposed some of the melodies, and inserted easy leading and connective notes, to assist, not only the finger, but sometimes the tunes them-
RAVILLY, a small town of the county of Carlow, Ireland, in the barony of its name. It is situated on the river Slaney, 3 miles S. from Baltinglas, and 32 S. by W. from Dublin.

RAVINA, a town of European Turkey, in Albania; 52 miles E. of Valona.

RAVINE, in *Field Fortification*, a deep hollow, usually formed by a great flood, or long continued running of water; frequently turned to good purposes in the field.

RAVIS, the name with *raudoed*. See *Haoriness*.

RAVISHMENT, in Law, denotes an unlawful seducing either a woman, or an heir in ward; for which there is a remedy by a writ of ravishment, or action of trespass *et armis, de filio vel filia rapto vel adulato*, in the same manner as the husband may have it *de uxore rapta et abducta*, on account of the abduction of his wife. This action lay at the common law; and thereby the husband shall recover, not the possession of his wife, but damages for taking her away: and by statute Wilm. 1. 3 Edw. I. c. 13, the offender shall also be imprisoned two years, and fined at the pleasure of the king. Both the king and the husband may, therefore, have this action; and the husband is also entitled to recover damages in an action on the *cafe against such* as *perfuade* and *entice the wife* to live separate from him, without a sufficient cause.

Sometimes it is also used in the sense *femce as raphe*; which see.

RAVISHMENT de Garde, is a writ which anciently lay, and still lies, for the guardian for cognize against him who took from him the body of his ward, or pupil: but then he must account to his pupil for the damages he had recover'd. It is expressly provided by statute 17 Car. II. c. 24. that testamentary guardians may maintain an action of ravishment, or trespass, for recovery of any of their wards, and also for damages, to be applied to the use and benefit of the infants.

RAVITZ, or Rawisch, in Geography, a town of the duchy of Warfaw, most of the inhabitants of which are Lutherans: it has a considerable manufacture of cloth; 24 miles S. of Polen.

RAVIUS, or RAVE, Christian, in Biography, a learned German Orientalist, was born at Berlin in the year 1613. From a very early period he was attached to the study of the eastern languages, and after spending eight years in different universities on the continent, he came over to England in the year 1658, and took up his residence at the university of Oxford. He brought with him recommendations from Vossius, and other learned men; and was invited to Dublin by archbishop Usher, primate of Ireland, who settled upon him a handsome stipend, and engaged him to take a voyage into the East, for the purpose of collecting ancient manuscripts. About the same time he was invited by cardinal Richelieu to enter into his employment for a similar purpose, which he declined, having already accepted the proposals of Usher. In 1639 he became acquainted with our countryman, the learned Edward Pococke, at Constantinople, where he improved himself in many languages, to which he had already applied his talents; and made himself master of the Turkish, Arabic, and Persian languages. In the mean time he did not neglect the main object of his mission, but collected more than 500 choice manuscripts. For this service he was, on his return, amply rewarded. In 1642 he taught the Oriental languages at Gresham college, in London. During the following year he went to Holland, and was appointed professor of the Oriental languages at Utrecht. We find him again in England in 1648, when he took the covenant, and was made fellow of Magdalen college, Oxford, by the parliamentary visitors. In the course of a few months he left England, and went to Sweden, where he obtained the appointment of professor of the Oriental languages at the university of Uppsala. This place he was obliged to leave about the year 1657; the revenues, that ought to have been devoted to the Uppsala professors, having been applied towards defraying the expenses of the war between Sweden and Denmark. After this he for some time filled the chair of Oriental literature at the university of Kiel, and from thence he removed to occupy the same professorship at Frankfurt on the Main. He died in 1677, about the age of 64. His works are very numerous, of which the following are titles of the principal: *Obeliatio ad univerfam Europam pro dicendis Rebus et Linguis Orientalibus, ac conjuganda Africae atque Asiae Eruditione,* 1644; *Ortographiae et Ana logiae velo Etymologica Liber,* 1649; *Concordantiarum Hebraicarum et Chaldaearum Epitome,* 1651; *Chronologia Bibliica nova,* 1658; *Epitoleque variæ ad doct. Viro,* 1659. He gave also to the world a translation, from the Arabic language, of Apollonius's *Conic Sections*. He had a brother, named John Ravis, who was professor of philosophy at Rostock, about the year 1638. In 1642-5 he was appointed counsellor and librarian to the elector of Brandenburg. He was author of *Commentarius in Cornelium Nepotem,* 1635; *Summa Studiorum pro Nobilitate Danica,* 1636; *Aphorismi Militares,* and other learned works.

RAULIN, John, a French writer in the 15th century, was born at Toul in the year 1443. He pursued his studies at the university of Paris, where he obtained the degree of D.D. in 1480, and afterwards filled the professor's chair in theology with great distinction. He was elected grand master of the college of Navarre, and founded a good library in that seminary. Becoming disfurnished with the world, he embraced the monastic life at the abbey of Cluny, in Burgundy, in 1497. He died in 1514, at the age of 71. He attracted much attention as a preacher, and several of his sermons have been published, which exhibit striking specimens of the bad taste which prevailed in France in the 15th century. The works of this author were collected, and published at Antwerp, in 6 vols. 400., 1612. They are accompanied with a curious and valuable collection of "Letters," that illustrate the history, manners, and sentiments of the age in which he lived. They were first published after his death, in quarto, in 1521, under the title of "Ioannis Raulinis Epistolae Illustrium Virorum." Moteri.

RAULT, Felix, the favourite performer on the German flute at Paris, in 1770; where we heard him ourselves with as much pleasure as a flute can give, by neat execution, perfect intonation, and a melifluous embouchure. M. Laborde has rendered his biographical article interesting by a detail of his professional merits and private character.

"M. Felix Rault was born at Bourdeaux, in 1736. He was the son of Charles Rault, of the king's band, and first maître at the opera. Felix was received there in 1753, and in the king's band in 1768. His talents are so well known at Paris, as to be above praise. Since Blavet's time, no one has brought the art of playing upon the German flute to such perfection, especially in accompanying the voice; a much more difficult art than playing concertos of great execution, generally well studied at home previous to performance. But such study is useless to Rault; for no
one reads much more readily and with more facility, or gives it more meaning, than this performer. The beauty of his tone, the precision of his execution, the richness of his embroidery, however extraordinary, merit still less praise than his personal qualities, which outshine him to all his acquaintance." Laborde.

RAUMO, in Geography, a port-town of Sweden, in the province of Finland, on the E. coast of the Gulf of Bothnia; 56 miles N. of Abo.

RAUPNIKED, in Rural Economy, a provincial word used to signify flag-stalk, among trees, as an old overgrown oak, having the flumps of the boughs standing out.

RAURAH, in Geography, a town of Thibet; 26 miles N. of Jemlah. N. lat. 31° 2'. E. long. 81° 40'.

RAURAVA, a Sanscrit word meaning dreadful, and a name of one of the Hindoo hells; they reckoning twenty-one of these receptacles for sinners. Naraka is called Maharaurnava, or most dreadful.

RAURIS, in Geography, a town of the Archbishopric of Salzburg; 32 miles S. of Salzburg.

RAUSCHENBERG, a town of Helf; 4 miles N. of Marburg. N. lat. 50° 55'; E. long. 8° 53'.

RAUSCHENBERG, a town of Germany, in the principality of Culmbach; 36 miles N.N.E. of Neufstadt.

RAUSNITZ, a town of Moravia, in the circle of Brunn; 10 miles E. of Brunn.

RAUTLAAM, a town of Sweden, in the government of Krupio; 27 miles S.W. of Krupio.

RAUTENBURG, a town of Prussian Lithuania; 27 miles W. of Tilsit.—Also, a town of Prussia, in the province of Samland; 36 miles N.E. of Königsberg.

RAUTERN, a town of Austria; 6 miles W.N.W. of Dresdendorf.

RAUTIO, a town of Sweden, in the government of Ula; 36 miles S. of Brahefled.

RAUTPOUR, a town of Hindooftan, in Isabella; 18 miles N.N.W. of Corah.

RAUTY DUNCARE, a town of Hindooftan, in Guzerat; on the coast; 70 miles S.W. of Noangur.

RAUTY-MUMMY, or Raouty-mudum, flence-mummy, a name given by the people of the Eait Indies to a kind of foffile fubfance, much valued for its medicinal virtues. It is of the nature of the felonites, and is found upon the high rocks, and supposed to be generated of the dew which falls from the heavens; but this is an idle opinion, and the formation of it is evidently the fame with that of the European rhombo- boidal following. They beat it to powder, and after boiling it in milk, they give it in cafes of the venereal kind. In a common clop, they give half a scruple, night and morning.

RAUVEE, in Geography, a river of Asia, which rifes on the borders of Thibet, and joins the Chunaub in the country of Lahore, 28 miles N.E. of Moulant. The Rauvee is the "Hydrates" of Alexander, and though it is represented as a noble river, it is somewhat inferior in bulk to the Chunaub. Its sources are in the mountains near Nagorkote, a famous place of Hindoo worship; and it enters the plains near Shahpour (called also Rajapour), from whence the famous canal of Shah Nahr was drawn to Lahore, 42/4 common coffees in length. The space between the Rauvee and Chunaub, at their entry on the plains, is about 54 geographical miles; and they gradually approach each other during a course of 170 miles. The junction of the Rauvee with the Chunaub (or rather the Chunaub and Belhut collectively) is effected nearly midway between Touluma and Moulant. The Ayin Acharee allows 27 coffees between the junction of the Belhut and Chunaub, and that of the Rauvee with the Chunaub; but this distance must be applied to the course of the river, not to the road by land. When these three rivers are united, they form a stream equal to the Indus itself, at the place of confluence; which is from 20 to 30 miles below Moulant.

RAUWOLFIA, in Botany, was so named by Plumer, in memory of Leonard Rauwolf, a native of Augsburg, and a pupil of Rondel. He failed from Marieille, in 1573, for the Levant, and performed a laborious and dangerous journey through Syria, Mesopotamia, Palestine and Egypt; of which he has left an account in German, full of curious information relative to medical and other rare plants, with several wooden cuts. He died physician to the Austrian army, at Havany, in Hungary, in 1606, according to Dryander, Bibl. Banks. v. 395, though Haller says 1596. The latter writer mentions his being obliged to quit his country on account of his religion, which was Protestant. His splendid herbarium, once the property of queen Christine, and of Isaac Vollius, is preferred in the university of Leyden. From it Gronovius composed his Flora Orientalis.—Linn. Gen. 115. Schreb. 160. Willd. Sp. Pl. v. 1. 1217. Mart. Hill. Dict. v. 4. Ait. Hort. Kew. v. 6. 64. Perf. 148. Plum. Gen. 10. t. 40. Lamarck Illufr. t. 172. Germ. t. 52.—Clas and order, Pentandria Monogynia. Nat. Ord. Contorte, Linn. Apo--cines, Jull.

Gen. Ch. Cal. Perianth inferior, minute, with five segments, permanent. Cor. of one petal, falver-shaped; tube cylindrical, globular at the base; limb in five deep, rooundihed, emarginate, oblique segments. Stum. Filaments five, shorter than the tube; anthers erect, lanceolate, acute. Fil. Gernan roundihed; styles very short; stigma capitate. Peric. Berry nearly globose, marked with a furrow along one side, of one cell. Seeds two, convex at the base, tapering at the summit, compressed, divided, more or less completely, into two cells. Eff. Ch. Corollis oblique, falver-shaped. Stamens included. Berry globose, with two seeds, each of two cells.

1. R. nittida. Shining Rauwolfia. Linn. Sp. Pl. 303. Hort. Clift. 75. t. 9. Willd. n. 1. Ait. n. 1. (R. tetraphylla angulifolia; Plum. l. 232. t. 256. f. 1.)—Leaves in fours, lanceolate, pointed, very smooth and shining. Flowers axillary or terminal, cymose.—Native of mountainous woods in the West Indies. A fruct about twelve feet high, erect, very smooth and shining, abounding with viscid milk. Leaves four together at each joint of the branches, spreading, on short stalks, lanceolate, with a blunt point, entire, unequal in size, from two to five inches, or more, with one rib, and many fine transverse parallel veins. Flowers small, white, inodorous, in axillary, rarely terminal, flaked cymes, shorter than the leaves. Fruits, according to Jacquin, at first yellow, then purplish-black, thrice the size or larger, milky. Linnaeus tells us his figure in the Hortus Cliffortianus was drawn by Ehet, from a plant in the Chelsea garden; so that this Rauwolfia must have flowered under Miller's care, in the year 1736. In Ait. H. Kew. a later date is given. The corolla in the figure just mentioned is more concave in the limb, as well as more notched, than Plumer represents it.

2. R. glabera. Smooth Rauwolfia. Cav. l. c. v. 3. 50. t. 297. Willd. n. 2.—Leaves alternate, ovato-lanceolate, entire. Cymes opposite to the leaves, of few flowers.

Native of New Spain. The whole plant is smooth. Stem roughy, a yard high, with plant, round, leafy branches. Leaves scattered, rounded at the base, rather pointed, flanked, two or three inches long, on shortish footstalks. Flowers small, white, about four together, in small cymes or clusters,
chafers, opposite to the leaves. Berry obovate, with only one seed; at least in garden specimens, which very probably differ in these respects from wild ones. This species flowered at Madrid from August to October.

2. R. canescens. Hoary Rauwolfa. Linn. Sp. Pl. 353. Willd. n. 3. Ait. n. 2. (R. birtajata; Jacq. Amer. 47. R. tetraphylla latifolia; Plum. 1c. 232. t. 236. f. 2.)—Leaves in fours, elliptic-obovate, acute, downy. Flowers axillary or terminal. Segments of the corolla obtuse.—Native of dry, funny, bulby places in the West India islands, as well as on the neighbouring continent. It was cultivated by Miller at the same time with the first species. We received a specimen in flower, from the flowe at Kew, in June 1807. Jacquin says this species varies greatly in the size of all its parts, according to soil and situation, and in the height of its stem from one to eight feet. The young branches, flower-flasks, flowerstalks, and both sides of the leaves, are clothed with short dense pubescence, which almost entirely disappears by culture, though the upper side of the flowerstalks continues rough with bristly glands. The leaves are from one and a half to two inches long, obovate, more or less inclining to elliptical, acute, unequal. Flowers in small, axillary, downy, stalked tufts, or umbels. Corolla green with a tinge of red, its segments obtuse. Fruit cloven at the top, first red, then black, containing two seeds, as Jacquin well describes it. One cell of each seed is usuallu, according to him, abortive.

4. R. tomentosia. Downy Rauwolfa. Jacq. Amer. 48. Obst. fusc. 2. 9. t. 35.—Leaves in fours, obovate-lanceolate, downy, tapering at each end. Flowers axillary or terminal. Segments of the corolla acute.—Native of rocky places about Carthagea; sometimes on the floun walls of the town. Jacquin alone seems to have known this species, which principally differs from the last, as far as we can judge, in having white flowers, the segments of whose corolla are ovate and acute. The leaves moreover are rather tapering at each end; but that circumstance varies. Fruit the size of a pea, first red, then black. We have seen no specimen.

5. R. Pulatopis. East Indian Rauwolfa. Roxb. MSS. —Leaves in threes, elliptical, bluntly pointed, smooth and shining. Flowers terminal, in forked panicles. Corolla many times longer than the calyx. Sent by Dr. Roxburgh, from Calcutta, with the above name. We rely on him for the genus, having seen no fruit. This flower is smooth in nearly every part, with round branches. Leaves about three inches long, and above one broad, coriaceous and shining; their transverse veins very fine and numerous. Flower-flasks very minutely downy, as well as the imbricated bracteae, and keeled pointed segments of the calyx. Corolla apparently white, with a red tube, which is near three quarters of an inch long, cylindrical, swelling at the top: segments of the limb rounded.

RAUWOLFA, in Gardening, contains plants of the tender, exotic, shrubby kind for the flower, of which the species cultivated are: the shining Rauwolfa (R. nitida); and the hoary Rauwolfa (R. canescens).

Method of Culture.—These may be increased by the seeds or berries, which should be sown in pots filled with light mould, in the autumn or spring, plunging them in a mild hotbed. When the plants have attained some growth, they should be removed into separate pots, and have the management of other exotic flower plants. They may likewise be raised by layers and cuttings, laid down or planted out in pots, plunged in the hotbed in the spring and summer months, till they have stricken root, being afterwards managed as those from seed.

They afford much ornament and variety in hot-house collections, both in their foliage and flowers.

RAUZAN, in Geography, a town of France, in the department of the Gironde; 9 miles S.S.E. of Labouarbe.

RAUZZINI, Venanzio, in Biography, a native of Italy, who, when he arrived here in 1774, to succeed Milsigo at the opera, was a beautiful and animated young man, with a toporoan voice. He was an excellent musician, having studied counterpoint with as much application as the art of singing; so that he may truly be said not only to know his own business, but that of a maestro di cappella; having been as able to compose a opera as to perform a principal part in it. "Piramo e Tibia," and "La Vestale," may be influenced in proof of this affection.

His voice was not very powerful when he came hither from Munich, where we first knew him; and where he had enjoyed the highest favour several years. His taste, governed by science, was correct and exquisite. His voice, though not of great volume, was sweet, clear, flexible, and extensive; being in compass more than two octaves. But he is supposed to have injured his chest in early youth by a rage for counterpoint. He played the harpsichord neatly, accompanied well, and had real genius for composition, which inclined him to devote that time to the pen and the improvement of his hand, which, perhaps, in his fortune, would have been more usefully bestowed in nursing and exercising his voice.

It was some time before the extent of his merit and science were known in this country, and favoured by the public. Nothing can so speedily convey the merits of a singer to an audience, as a great and powerful voice. However, his taste, fancy, knowledge, and delicacy, together with his beautiful person, and spirited and intelligent manner of acting, before the first season was over, gained him general approbation and favour. And since he has quitted the stage, and made Bath his residence. Though he has been long obliged to discontinue singing in public, it is not too much to say that he has disseminated good taste throughout the kingdom, by the numerous scholars he has taught among the nobility and gentry, as well as by those whom he has prepared for public patronage, professionally.

RAW, in Agriculture, any fort of plant, sustenance, or material, which is in a green, unripe, or unaged condition, or which is employed in its more fresh and crude state; as, for instance, dung before it has been much reduced, and lost many of its nutritious principles or properties by the process of fermentation. See DunG.

RAW CREAM, in Rural Economy, such as is rained in the natural way, not seared or clotted.

RAW HIDE. See HIDE.

RAW LANDS. in Agriculture, a term applied to wet, cold, heavy lands, which are unfit to receive the feed.

RAW SILK. See SILK.

RAWA, or RAWA, in Geography, a town of the duchy of Warsaw, late capital of a palatinate of the same name. The castle is appropriated for the confinement of state prisoners. 45 miles S.W. of Warsaw. N. lat. 51° 55'. E. long. 20° 17'.

RAW, a town of Poland, in the palatinate of Belz; 18 miles S.W. of Belz.

RAW; See RAWA.

RAWAK, a small island in the Pacific ocean, near the N. coast of the island of Waygou, with which it forms a harbour. E. long. 141° 15'.

RAWAPSKITCHWOCK, a small westerly branch of Machias river. See Machias.

RAWAY, or Bridge-town, a truly commercial village of Middlesex county, New Jersey, on Raway river, four or five miles S.W. of Elizabeth-town, and 75 from Philadel-phia.
RAY

philip. It contains a post-office, a presbyterian church, and about 50 or 60 houses.

RAWDON, a town of Nova Scotia, 40 miles from Halifax, containing about 50 or 60 houses.

RAXTON, a township of the county of Hallings, in Upper Canada, N. of Sydney.

RAWLINSON, CHRISTOPHER, in *Biography*, of Cork-Hall, in Lancashire, was born in 1677, educated in Queen's College, Oxford, and died in 1733: he was much attached to Saxons and Northern literature, and published an edition of "King Alfred's Translation of Boethius de Confolatione," 8vo. 1698.

RAWLINSON, RICHARD, a distinguished relation of the preceding, and a learned antiquary, was the son of Sir Thomas Rawlinson, knight, and once lord mayor of London. He was educated at St. John's college, Oxford, and was admitted to the degree of doctor of the civil law in 1710. He devoted himself to antiquarian pursuits, and made large collections for a continuation of Wood's Athenae Oxonienses, and History of Oxford, and published the life of that influential antiquary. The principal work of Mr. Rawlinson was "The English Topographer," or, An historical account of all the pieces that have been written relating to the ancient natural history or topographical description of any part of England, 1726. He published the "Latin Letters of Abelard and Heloise," and "A Translation of Du Fresnoy's New Method of Studying History," 2 vols. 8vo. He died at Ealing in 1755, and by his will ordered that his heart should be deposited in the chapel of St. John's college, Oxford. That university was indebted to him for various benefactions of books, manuscripts, medals, &c. as well as landed property, and an endowment for an Anglo-Saxon lecture.

RAWLLOW, in Geography, a town of Hindostan, in Patna; 27 miles W.S.W. of Timerycotta.

RAY, JOHNS, in *Biography*, whom Haller terms the greatest botanist in the memory of man, and to whose transcendent merits we have already briefly adverted, in treating of the genus dedicated by Pluvius to his name, etc. RAYANIA was born at Black Notley, near Braintree, in Essex, Nov. 29, 1628. His father, Roger Ray, though in the humble station of a blacksmith, gave him a learned education; first at the grammar-school of his native town, at that time not very well conducted; and subsequently at Cambridge, where he entered at Catharine Hall, in his 16th year, June 28th, 1644, being designed for holy orders. In about a year and three quarters afterwards, he removed to Trinity College, where he found the young men occupied in a more liberal train of studies, with less of scholastic disputations and quibbles. Ray was fortunate in having for his tutor at Trinity, Dr. Duport, an eminent Greek scholar, under whose tutoring and partial care, he soon made up for all the deficiencies of his early education, in the learned languages, including Hebrew. By this gentleman he was always mentioned with peculiar regard. He was no less happy in a youthful literary friend and fellow-student, afterwards the celebrated Dr. Isaac Barrow. Even at this early period, Ray began to cultivate natural history; and distinguished himself by many schol exercises, as an orator, no less than by his general taste for study, his love of virtue, and his gentleness of manners, qualities which thence brighter and brighter to the latest period of his life. His merit occasioned him to be chosen a Minor Fellow of Trinity, along with his friend Barrow, September 8th, 1649. On taking his degree of Master of Arts, he became a Major or Senior Fellow; and afterwards, October 18th, 1651, Greek Lecturer of the college. At the end of two years he was appointed Mathematical Lecturer, and in two years more, October 2d, 1655, Humanity Reader. He subsequently filled several respectable offices in his college, as Junior Dean, College Steward, &c., and during his residence in the university, became tutor to many gentlemen of rank and fortune, who were sensible of the obligations to him; amongst whom the most eminently distinguished himself by personal worth, and congeniality of talents with himself, was Mr. Francis Willughby, of Middleton-hall in Warwickshire, so well known by his poetical works on Birds and Fishes, edited by the affectionate care of Ray.

At this period it was usual for young men of ability and learning, though not in orders, to deliver sermons, and common-place readings, as they were called; not only in the chapels or halls of their own colleges, but even before the university body, at St. Mary's church. In these Ray eminently distinguished himself. He was among the first who ventured to lead the attention of his hearers, from the unprofitable subtilties of scholastic divinity, and the trammels of Aristotelian philosophy, to an observation of nature, and a practical investigation of truth. The rudiments of many of his subsequent writings originated in these juvenile essays, particularly his celebrated book on the "Wisdom of God manifested in the Works of Creation," known all over the world by its numerous editions and translations, and universally admired for its rational piety, found philosophy, and solid instruction. This book is the basis of all the labours of following divines, who have made the book of nature a commentary on the book of revelation; a confirmation of truths, which Nature has not authority, of herself, to establish. In it the author inculcates the doctrine of a constantly superintending Providence; as well as the advantage, and even the duty, of contemplating the works of God. This, he says, is part of the conditions of a fateful day, as it will be, probably, of our employment through that eternal rest, of which the Sabbath is a type. Archibishop Tennion is recorded to have told Dr. Derham, that "Mr. Ray was much celebrated, in his time, at Cambridge, for preaching solid and useful divinity, instead of that enthusiastic stuff, which the sermons of that time were generally filled with." Two of his funeral discourses are mentioned with particular approbation; one on the death of Dr. Arrowsmith, master of his college; the other on that of one of his most intimate and beloved colleagues, Mr. John Nid, likewise a Senior Fellow of Trinity, who had a great share in Ray's first botanical publication, the *Catalogus Plantarum circa Cantabrigiam nescientum*, printed in 1665, which may be considered as the prototype of his *Synopsis*, hereafter mentioned. Indeed before this little volume appeared, its author had visited various parts of England and Wales, for the purpose of investigating their native plants, as he did several times afterwards; nor were his observations confined to natural history, but extended to local and general history, antiquities, the arts, and all kinds of useful knowledge. His amusing Itineraries were published, along with his life, by Dr. Derham, and a few letters to that gentleman, by the care of Dr. George Scott, F. R. S., in 1662, under the title of "Select Remains of the learned John Ray, M. A., &c." Ray's first botanical tour occupied nearly six weeks, from August 9th to September 18th, 1658. On the 23d of December 1665, he was ordained, both deacon and priest at the same time, by Dr. Sanderfon, then bishop of Lincoln. In 1661 he travelled with Mr. Willughby into Scotland, returning by Cumberland and Westmoreland; and the following year, with the same companion, he accomplished a more particular investigation of Wales. How critically he studied the botany of the countries,
countries he visited, is evident from the different editions of his *Catalogus Plantarum Angliae*, and *Synopsis Methodica Stir- 

pium Britannicurn.

All this while Mr. Ray continued to enjoy his fellowship, and to cultivate his Cambridge connections; but in September 1662, his tranquillity was disturbed by the too famous Bartholomew act, by which 2000 conscientious 

divines were turned out of their livings, and many fellows of colleges deprived of their maintenance, and means of literary improvement. Among the latter was the subject of our memoir, with thirteen honest men at Cambridge besides, of whose names he has left us a list. "One of them, Dr. Dillingham, was master of Emanuel college; but Ray was the only person of his own college who suffered this deprivation. The reader must not suppose that he, or perhaps any other person in this illustrious catalogue, was, in the least degree, deficient in attachment to the doctrine or discipline of the church of England, or that they had taken the oath called the Solemn League and Covenant; which Ray certainly had neither taken nor ever approved. They were required to swear to the infamous proposition, that the said oath was not binding to those who had taken it, and on this ground they conscientiously gave up their preferment. It is curious to read the apology made for Ray to Dr. Derham, on this subject, by a Mr. Brokeby—" that he was at that time absent from his college, 

where he might have met with satisfaction to his conscience; and was among some zealous non-conformists, who too much influenced him, by the addition of new heresies. And we may also ascribe somewhat to the prejudice of education in unhappy times." By this it appears, that the "heresies" of non-conformists were most favourable to the fancied 

of an oath; and that the "unhappy times" alluded to, were more advantageous to principle, than the golden days of Charles II.; whose ministers doubtless valued the obedience, 

far more than the honesty, of any man; nor is this taste, by any means, peculiar to them or their profligate matter.

Mr. Ray, or, as he wrote his name, for a while, about this period, Wray, having thus the world before him, made an arrangement with Mr. Willughby for a tour on the continent; and in this plan two of his pupils were included, Mr. Nathaniel Bacon, and Mr., afterwards Sir Philip, Skip- 

pon. They failed for Calais in April 1663, but being pre- 

vented, by the state of political affairs, from prosecuting their journey through France, they traversed the Low Countries, Germany, &c. proceeding by Venice into Italy; most of whose cities they visited, either by sea or land; 

as well as Malta and Sicily; and returned, by Switzerland, through France, into England, in the spring of 1666. Mr. Willughby indeed parted from the rest of the party at Montpellier, and visited Spain. An ample account of their observations was published by Ray, in 1673, making a 

thick octavo volume. The travellers appear to have been 

diligent and acute in everything relative to politics, literature, natural history, mechanics, and philosophy, as well as 

antiquities and other curiosities; but in the fine arts they 

assume no authority, nor display any considerate taste or knowledge. Mr. Willughby's account of Spain makes a part by itself; and a rich critical catalogue of such plants, 

not, for the most part, natives of England, as were observed 

in this tour, concludes the volume. Haller gives to Ray 

the credit of having discovered several species in Switzer- 

land, previously not known as natives of that country.

Ray passed the summer of 1666 partly at Black Notley, and partly in Suffolk, studying chiefly the works of Hook, Boyle, Sydenham on Fevers, and the Philosophical Trans- 

actions, "making few discoveries," says he, "fear of mine 

own errors." The following winter he was employed at 

Mr. Willughby's, in arranging that gentleman's museum of 

natural history and coins, and in forming tables of plants 

and animals for the use of Dr. Wilkins, in his famous work 
on an Universal Character. He now also began to arrange 
a catalogue of the English native plants, which he himself 
had gathered; rather for his own use, than with any imme- 
diate view of publication; "at present," as he wrote to Dr. 

Liker, "the world is gladdened with Dr. Merret's bungling 

Pinax. I resolve never to put out any thing which is not 
as perfect as is possible for me to make it. I wish you 

would take a little pains this summer about grappes, that fo 

we might compare notes." The above resolution of our 

author is, no doubt, highly commendable, but the world 

has rather to lament that so many able men have formed 

the same determination, at least in natural science. If it 

were universally adhered to, fearfully any work would see 

the light; for few can be so fensible of the defects of any other 

person's attempt to illustrate the works of nature, as a man 
of tolerable judgment must be of his own. This is espe- 
cially the case with those who, like Ray, direct their aspir- 

ings views towards sleek, and philosophical theory. 

Happily he did not try this arduous path, till he had trained 

himself by wholesome practical discipline, in observation 

and experience. His first botanical works assumed the hum- 

ble form of alphabetical catalogues. His and Mr. Will- 

ughby's labours in the service of bishop Wilkins, were 

indeed of a systematical description; and according to the 

author themselves were, more than any other person probably, 

dissatisfied with their performance. They relaxed from 

these labours in a tour of practical observation through the 

west of England, as far as the Land's-End, in the summer of 

1667, and returning by London, Mr. Ray was solicited to 
become a Fellow of the Royal Society, into which 

learned body he was admitted November 7th. Being now 

requested by his friend Wilkins to translate the "Real Char- 

acter" into Latin, he undertook, and by degrees accom- 

plished, that arduous performance, depositing his manus- 

cript in the library of the Royal Society, where it has ever 

since repos'd. The following summer was agreeably spent, 
in visits to various literary friends, and in a solitary journey 

to the north; for his former companion Willughby, being 

just married, stayed at home; there Ray joined him in Sep- 
tember 1668, and remained for most part of the ensuing 

winter and spring.

The excursion and leisure of the country, with the con- 

verve and affluence of such a friend, were favourable to the 

profession of a new subject of enquiry, which now strongly 

attracted the attention of our great naturalist, the theory 

of vegetation. The first leap of the two philosophers, in this 

little-explored path, was an examination of the motion of 

the sap in trees; and the result of their enquiries, communi- 
cated to the Royal Society, appeared soon after in the Phi- 

losophical Transactions. Their experiments clearly prove 

the ascent of the sap through the woody part of the tree; 

which is easily detected by boring the trunk, at different 

depths, before the leaves are unfolded; and they observed 

also the mucilaginous nature of the flowing sap, "preci- 

pitating a kind of white coagulum or jelly, which," says Ray, 

in a note preferred by Derham, "may be well conceived to 

be the part which, every year, between bark and tree, turns 

to wood, and of which the leaves and fruit are made. It 

seems to precipitate more when the tree is just ready to 

put out leaves, and begins to cease dropping, than at its first 

bleeding." The accuracy of the leading facts recorded by 

these ingenious men, is confirmed by subsequent observers, 

who have further pursued the same subject, which is now 

sufficiently
sufficiently well understood. They indeed, like the rest of
the world till lately, seem not to have suspected, that the
sap was quiescent till their perforations in the tree were
made; nor did they advert, as they ought, to phenomena
dependent on the principle of life, in the vegetable body.
See Circulation of the Sap.
At this time Ray began to prepare for the prefs his
"Collection of Proverbs," a curious book in its way, by
which he is perhaps better known to the generality of his
countrymen, than by any other of his literary labours.
The first edition was published in 1672; but the work was
subsequently much enlarged, and the author may almost be
said to have exhausted his subject. From its very nature,
delicacy and refinement must often be dispensed with; but
this is evidently not the fault, or the aim, of the writer.
His learning and critical acuteness diffuse light over the
whole, and make us overlook the coarse vehicle of our in-
struction.

The first edition of the Catalogue of English Plants, al-
ready mentioned, came out in 1670, and the second in 1677.
Their great author gave his work to the world with that
diffidence, for which he alone perhaps could perceive any
just foundation. We postpone our remarks till we speak
of the fame work in its systematic form hereafter.

About this period the health of Mr. Ray seems to have
been considerably impaired. He refused a tempting offer
to travel again on the continent, as tutor to three young noble-
men; nor could the powerful attractions of alpine botany,
which made a part of his prospect, overcome the reluctance
to leaving home, which arose from a feelle flare of body.
Indeed this very reluctance, or fickle-ness, is accounted for,
by the turn which his disorder took, as it terminated in the
jaundice. After this depreffing complaint had left him, he
refumed, with fresh alacrity, his botanical travels at home,
visiting the rich flores of the north of England, with a com-
panion named Thomas Willifick, whose name and discoveries
he afterwards, on many occasions, has gratefully comemo-
rated. Nothing forms a more striking feature in Ray’s
character, than the unrelished and abundant commendation,
which he always gave to his friends and fellow-labourers.
We are about to narrate an event, which called forth all his
affectionate feelings of this kind, as well as his most im-
portant and beneficial exertions; when, even to his own
prejudice, he fulfilled the sacred duties of friendship, and
delighted in adorning the bult of his friend with wreaths,
that he himself might justly have ascribed. On the 3d of July
1672, Mr. Willughby was unexpectedly carried off by an
acute disorder, in the 37th year of his age. The care of his
two infant sons was confided by himself to Mr. Ray, who
was also appointed one of his live executors, and to whom
he left an annuity of 60l. for life. The eldest of these
youths was created a baronet at the age of 20 years, but
died before he was 30. Their other Caffandra afterwards
married the duke of Chandos. Thomas, the
younger son, was one of the ten peers created, all on the
same day, by queen Anne, and received the title of lord
Middleton. His early youth was much indebted to the
care of his faithful guardian, who composed, for his and his
brother’s life, and published in 1672, a Nomenclator Classicus,
far more exact, epecially in the names of natural objects,
than any that had previously appeared. The care of his
pupils, and of the literary concerns of their deceased parent,
now interrupted Mr. Ray’s botanizing excursions, and
called him also to decline the offer of Dr. Lillter, then a
physician at York, to settle under his roof. Biphop Wil-
kins did not long survive Mr. Willughby, and his death
made another chasm in the scientific and socia circle of our
great natural philosopher, who felt these losses as deeply and
tenderly as any man. He fought contention in a domestic
attachment, fixing his choice on a young woman, of good
parentage, whose name was Margaret Oakeley, and who
resided in the family at Middleton-hall. He was married at
the parish church, June 5th, 1673, being then in the 45th
year of his age, and his bride about 20. This lady took a
share in the early education of his pupils, as far as concern-
ted their reading English. She is said to have been re-
commended by her character, as well as her person, to the
regard of her husband. She bore him three daughters,
who, with their mother, favoured him.

Ray’s communications to the Royal Society became now
very frequent, and extended to various subjects relative to
the natural history of animals, as well as to the physiology,
and even the botanical characters, of vegetables. He was,
the same time, in the course of the years 1674 and 1675,
much occupied in digesting Mr. Willughby’s zoological
papers. These were compiled in Latin, in which language
the Ornithology first appeared in 1676, making a folio vol-
ume, accompanied by 77 plates, engraved, at the expense
of the author’s widow, with his own drawings. An Eng-
lish translation by Ray, with still more additions than he had
supplied to the former publication, and in more plate, if
published in 1678. The account which Dr. Der-
ham received from the lips of Mr. Ray, about eight months
previous to his decease, respecting the primary intentions
of himself and his late friend, and which is recorded in his
life, p. 48, is too curious to be omitted here, as their project
and its execution form an epoch in the history of natural
science. “These two gentlemen,” says Derham, “finding
the history of Nature very imperfect, had agreed between
themselves, before their travels beyond sea, to reduce the
several tribes of things to a method; and to give accurate
descriptions of the several species, from a strict view of
them. And forasmuch as Mr. Willughby’s genius lay
chiefly to Animals, therefore he undertook the Birds,
Beasts, Fishes, and Insects, as Mr. Ray did the Vege-
tables.” Derham adds, that Mr. Willughby, during his short
life, “profected his design with so great application, as if he
had been to get his bread thereby.” The writer of the
present article has elsewhere observed, (Introductory
Discours, Tr. of Linm. Soc. v. 1.) that “from the affec-
tionate care with which Ray has cherished the fame of his
departed friend, we are in danger of attributing too much
to Mr. Willughby, and too little to himself.” His
own statement, no doubt, was correct, as to their
original aims; but it is impossible not to perceive that the fur-
vior executed or perfected what his friend, in many in-
stances, could only have projected, or fearfully begun.

Had Willughby lived, there can be little doubt of his career
being as glorious in the sequel as that of his friend; and
possibly, from the advantages of fortune which he enjoyed,
even more widely beneficial to science. Yet who can say
that he might not have flowered his course? Though he
gloriously avoided the flares of luxury and folly in his
youth, who shall say that politics or ambition might not
dazzle his riper age? or that he would always have es-
caped that ruinous vanity, which grapped at universal
knowledge, or rather at universal fame; and knowing noth-
thing deeply, is most flattered with any praise which is least
deferred. So often has this last been the case with literary
men, that one cannot but mistrust a character of the fairest
promise. What Ray has done, we know and can appreciate.
Equal to his friend in learning, talents, and zeal, the ad-
ventures of ample fortune were compensated by the leisure
and tranquillity of a fequestered country life. His duties
went hand in hand with his studies and recreations, and he enjoyed, as Haller observes, the rare felicity of giving 50 years uninterruptedly to his favourite science. His long-protracted studies, and ripened experience, enabled him to achieve what at first he could but regard at a distance, as the great object of his wishes, a systematic arrangement of the animal as well as vegetable kingdoms. Every body had, hitherto, been content with Aristotel's classification of animals, of whole imperfections Ray, daring to think for himself, could not but be aware. He invented a new one, founded on the structure of the heart. "The Harveian experiments, and doctrine of the circulation, had called the peculiar attention of philosophers to every organ which has a share in that phenomenon; and to this cause, probably, we owe the method of Ray." The mode of breathing in animals, whether by lungs or by gills, and the single or double structure of the heart, in the former cafe, constitute the body of his system; which, in its particulars at least, succeeding naturalists have adopted. His subordinate characters of the principal classes exhibit great skill and sagacity, and the Linnean sytem of Quadrupeds is highly indebted to that of our illustrious countryman.

His zoological publications indeed did not follow each other in rapid succession; for after the Ornithology had come forth in English, eight years elapsed before the Historia Piscium of Willughby was given, by his care, to the world. This was printed in folio, with 188 plates of fishes, in 1686, at Oxford, owing to the interest of bishop Fell, and the pecuniary allience of the Royal Society. It does not appear why the relief of Mr. Willughby withheld, in this instance, the contributions which had to much benefited her husband's former work, and which the fully owed to his fame. It seems that the intimate connexion of Ray with this family, was much impaired by the death of lady Caffandra Willughby, the mother of his friend, about the year 1675 or 1676, when the children were taken from his tuition, and he left Middleton-hall, fixing for a short time at Sutton Coldfield, four miles distant. At Michaelmas 1677 he removed from thence to Falbome-hall, in EIlvex, not far from his native village. On the 15th of March following, his mother, at the age of 58, died at Black Notley, "in her house on Dewlands," of whom he speaks with that reverence and regret, which has peculiarly marked the characters of some of the greatest and best men on the fame occasion. At Midsummer 1679, he finally settled at Black Notley, for the remainder of his days, or, for the short period of time he had yet to live in this world," as he himself expressed it; which period, however, extended to more than twenty-five years.

The first fruit of our author's leisure and retirement was his Methodus Plantarum Nova, published in 1682, making an octavo volume. His principles of arrangement are chiefly derived from the fruit. The regularity and irregularity of flowers, which take the lead in the system of Rinnis, make no part of that of Ray. It is remarkable that he adopts the ancient primary division of plants, into trees, shrubs, and herbs, and that he blamed Rinnis for abolishing it, though his own pretyfatory remarks tend to overtop that principle, as a vulgar and casual one, unworthy of a philosopher. That his system was not merely a commodious artificial aid to practical botany, but a philosophical clue to the labyrinth of Nature, he probably, like his fellow-labourers, for many years, in this department, believed; yet he was too modest, and too learned, to think he had brought this new and arduous design to perfection; for whatever he has incidentally or deliberately thrown out, respecting the value of his labours, is often marked with more difficulty on the subject of classification, than any other. He first applied his system to practical use in a general Historia Plantarum, of which the first volume, a thick folio, was published in 1666, and the second in 1687. The third volume of the same work, which is supplementary, came out in 1704. This vast and critical compilation is fill in use as a book of reference, being particularly valuable as an epitome of the contents of various rare and expensive works, which ordinary libraries cannot possess, such as the Hortus Malabaricus. The description of species is faithful and instructive; the remarks original, bounded only by the whole circuit of the botanical learning of that day; nor are generic characters neglected, however vaguely they are allumed. Specific differences do not enter regularly into the author's plan, nor has he followed any uniform rules of nomenclature. So ample a transcript of the practical knowledge of such a botanist, cannot but be a treasure; yet it is now much neglected, few persons being learned enough to use it with facility, for want of figures, and a popular nomenclature; and those who are, seldom requiring its assistance. A mere catalogue or index, like the works of Tournemont and Calplar Bauhin, which teach nothing of themselves, are of reader use. The Species Plantarum of Linneus unites the advantages of the clearest most concise specific definition, and, by the help of Bauhin, of an universal index.

But if the fame or the utility of Ray's great botanical work has, neither of them, been commenurate with the expectations that might have been formed, a little octavo volume, which he gave to the world in 1696, amply fulfilled all such defect; and proved the great scholar's own the truest mark of his reputation in this department of science. We speak of the Synopsis Methodica Stirpium Britannicarum. The two editions of his alphabetical catalogue of English plants being fold off, and some pettifogging reasons of his bookseller's standing in the way of a third, with any improvements, he re-modelled the work, throwing it into a systematic form, reviving the whole, supplying generic characters, with numerous additions of species, and various emendations and remarks. The ules and medicinal qualities of the plants are removed to the alphabetical index at the end. A second edition of this Synopsis was published in 1696, nor did its author ever prepare another. The third, now most in use, was edited twenty-eight years afterwards by Dillenius. (See that biographical article.) Of all the systematical and practical Floras of any country, the second edition of Ray's Synopsis is the most perfect that ever came under our observation. "He examined every plant recorded in his work, and even gathered most of them himself. He investigated their synonyms with consummate accuracy; and if the clearness and precision of other authors had equalled his, he would scarcely have committed an error. It is difficult to find him in a mistake or mis-conception respecting Nature herself, though he sometimes misapprehends the bad figures, or lame descriptions, he was obliged to consult." Tr. of Lin. Soc. v. 4. 277. Above a hundred species are added, in this second edition, and the cryptogamic plants, in particular, are more amply elucidated. A controversial letter from Rivinus to Ray, and its answer, with remarks upon Tournemont, are subjoined to this second edition. Much of the dispute turns upon the now obsolete distinction of plants, in a methodical system, into trees, shrubs, herbs, &c. The letters are well written, in Latin: and liberal, though perhaps hypercritical, in their style. Ray took no delight in controversy. Its inevitable
Ray.

The year 1690 was the date of the first publication of his noble work on "The Wisdom of God in the Creation," of which we have already spoken, and whose sale, through many editions, was very extensive. In 1700 he printed a book, more exclusively within the sphere of his favored profession, called "A Persuasive to an Holy Life!" a rare performance of the kind, at that day, as it would be at the present; being devoid of enthusiasm, mysticism, or cant, as well as of religious bigotry or party spirit, "and employing the plain and solid arguments of reason, for the best of purposes." His three "Physico-Theological Discourses, concerning the Chaos, Deluge, and Disolution of the World," of which the original materials had been collected and prepared formerly at Cambridge, came out in 1692, and were reprinted the following year. A third edition, superintended by Derham, was published in 1713. This able editor took up the same subject himself in a similar performance, the materials of which, like Ray's, were first delivered in sermons, at Bow church, he having been appointed reader of Mr. Boyle's lectures.

While Ray was from time to time intent on these moral and religious performances, in which he laboured equally to impress and elucidate the truths of natural and revealed religion, as well as to enforce its precepts and duties, he was no less attentive than formerly to his systematical studies. Dr. Tancred Robinson is recorded by Derham, as having first prompted our great naturalist to undertake a Synopsis Methodica, or classical arrangement, of the whole animal, as he had done of the vegetable kingdom. He even wished him to extend his attention to fossils, in short, what Linnaeus afterwards performed. Nor did he shrink from the task. Though now for some time oppossed with bodily infirmity, and particularly with very troublesome ulcers in his legs, his mind was tranquil and unimpaired. He soon finished his Synopsis Methodica Animalium Quadrupedum et Serpentium Generis, which came out in 1693, making it thin, but closely printed, octavo volume. We have already spoken of the originality of his method. The volume in question, however, is not confined to dry systematical arrangement. It enters deeply into the general and particular history of animals, their external forms, and internal structure, with abundance of entertaining and curious facts and observations. Linnaeus was pollied of this book from the year 1734, and appears to have studied it well. A similar volume on birds, and another on fishes, were prepared by the author; but the manuscripts of these lay neglected in the hands of some careless or ignorant bookeller, till they were discovered by Dr. Derham, and published in 1713. They contain more of particular descriptive and historical, than of general remarks; but otherwise accord with the plan of the Synopsis of Quadrupeds. Many things are supplied from materials obtained since the publication of Willughby's Ornithology and Ichthyology, and several figures of fishes were added by Derham, at the persuasion of Petiver, whose works they somewhat resemble.

Having accomplished so many great and laborious publications, our venerable naturalist began, as Dr. Derham informs us, to enjoy the thoughts of repose from his labours. He was nevertheless ready, at the call of his friends, to revive a translation of Rauwolf's Travels, the original having even then become very scarce, besides being unintelligible to mere English readers. This translation, with some other rare tracts annexed, and a catalogue of Grecian, Syrian, Egyptian, and Cretan plants, drawn up by Mr. Ray, issued from the press in 1693. See Rau-

We must not omit to notice that, in the preface to both editions of his Synopsis, the learned author, venerable for his character, his talents, and his profession, as well as by his noble adherence to principle in the most corrupt times, has taken occasion to congratulate his country, and to pour out his grateful effusions to Divine Providence. In a style worthy of Milton, for the establishment of religion, law, and liberty, by the revolution which placed king William on the throne. An honest Englishman, however retired in his habits and his pursuits, could not have withheld this tribute at such a time; nor was any loyalty ever more perfectly disinterred than that of Ray.

Possibly the Stirpium Europaeorum extra Britanniam notabilium Synopses, which appeared in 1694, originated in the author's attention being recalled, by the last-mentioned publication, to the contemplation of exotic plants. In this volume he collects from Clusius, Bauhin, Columna, and others, various additions to his own discoveries, and the whole are disposed in alphabetical order. A geographical view of the plants, which he had himself gathered in his foreign travels, is subjoined; and the volume concludes with alphabetical catalogues, selected from Boecke's Sicilian plants, and other recent authors. It is in the preface to this book, that he first adverts to the fyltem of Rovinus, not without just applause of that author's work, a copy of which had been presented to Ray. He commends the apt distribution of the genera, the clearness and conciseness of the style, the purity of the Latin, and the beauty as well as exactness of the plates. He, however, contends for the ancient distinction of plants into trees and herbs, which, as we have seen, he had himself mentioned as unphilosophical. In the rest of his criticisms, though "much may be laid on both sides," and though these controversies, like others, profit of the intricacies and anomalies of Nature, to make good their arguments, concealing themselves, like the cuttle-fish, in their ink; till we cannot but give our testimony to the greater solidity of Ray's principles, as derived from the fruits and seeds of plants, than from the seemingly more elegant ones of Rovinus, deduced from the flower; which last undoubtedly lead, in their practical application, to some paradoxical combinations. But on this subject we may fay more in its proper place. (See Rivi-

One advantage arose from the epitaphial alteration of Rivinus and Ray, that it led the latter to revive his own fyltem, and to republish it, in an improved state. Happy if such were more generally the fruit of contention, that each party should correct himself, instead of aggravating the defects of his adversary. Some notice is taken, in the preface to this edition, both of the fyltem of Tournefort and that of Hermann, which laft was most congenial to the principles of Ray. The work was finished in 1698, but not given to the public till 1703, recoufle having been had to a Dutch bookeller, who thought it for his interest to place an English publisher's name in the title-page; a proceeding which, however harmless, shocked the honest feelings of the author; and this perhaps excited the truthy Hollander's furb-
in order to make observations upon plants, for the greater perfection of this last edition of his Methodus, he was not able to walk into his neighbouring fields. He still, nevertheless, kept up to the last his correspondence with his friends, in the vivacity and clearness of style which was natural to him. Latin and English, it is said, were equally ready to his pen. So indefatigable was he in the cultivation of the study of Nature, that within a year or two of his death, he began to collect his scattered notes for a work on Insects, and actually drew up a Methodus Insectorum, which was printed, soon after his decease, in a little octavo of sixteen pages, and republished in the front of his Hiftoria Insectorum. This last book, comprising all his own and Mr. Willughby's descriptions of insects, came from the press in 1710, at the expense of the Royal Society, and under the superintendence of Dr. Derham. It consists of 375 quarto pages, besides an appendix of twenty-three more, on British Beetles, by Liner. Ray attributes to Willughby that part of his system which concerns insects supposed to undergo no metamorphosis. These are mostly the Insefts of Linnaeus, excluding the crufiacca, but admitting the nesus, earth-worms, and even leeches. All the descriptions and remarks of his departed friend are marked with the initials F.W. This work is a mass of accurate and authentic observation; but, for want of plates, has never come into popular use. Linnaeus studied it much, and has often cited the descriptions, the appropriation of which is, however, too difficult and uncertain to render them of general or extensive service. Those which regard the Le- pidoptera, and their caterpillars, are most copious.

The study of insects was probably the last that engaged the attention of this great and wise man; who, though on the verge of eternity, in the full possession of himself, and in the anticipation of the most glorious manifestations of his Creator, did not disdain or neglect to contemplate him in his least and lowest works. Such an example might serve for an occasional answer to those who affect to think the study of any of the works of God below the dignity of their philosophy; for the most inordinate vanity must look with respect on what formed the abstruse studies of so distingushed a person as Ray. His last letter to Dr. Derham, who had just been to visit him, is dated August 16, 1704. He speaks of having lately obtained Mr. Willughby's entomological papers, and describes himself as then entering on his History of Insects. How well he employed his time during the autumn, is evident from what we have related concerning this work, for he never saw another spring. He died at Black Notley, in a house of his own building, Jan. 17, 1705, in the 77th year of his age. His character is thus concisely given by Derham. "In his dealings, no man more strictly just; in his conversation, no man more humble, courteous, and affable; towards God, no man more devout; and towards the poor and distressed, no man more compassionate and charitable, according to his abilities," says the friend who wrote this eulogium, in his "Life of Mr. Ray," affrets, that he was buried, according to his own desire, in the church of Black Notley; but the authors of the Biographia Britannica are probably more correct, in saying, that he declined the offer made him by the rector, of a place of interment in the chancel, choosing rather to repose with his ancestors, in the church-yard. He perhaps thought, with bishop Hall, that "the house of God ought not to be made a repository for dead carcases." However this might be, the latter account is confirmed by the original situation of his monument, erected at the expense, in part at least, of bishop Compton. The long and elegant Latin epitaph has often been published. Its author was the Rev. William Coyte, M.A., father of the late Dr. Coyte of Ipswich, and the original manuscript is now before us, containing the information that Ray was interred in the churchyard. In 1737, the monument in question, which seems to have been a part of a altar tomb, being nearly ruined, was restored at the charge of Dr. Legge, and removed for shelter into the church; where therefore it became a cenotaph, as an inscription added on this occasion terms it. Forty-five years afterwards the tomb again underwent a repair, by the care of the present Sir Thomas Gery Cullum and others, who subjoined a third inscription, as follows:

Tumulum hunc, a nonnullis humanitatis, et scientiae naturalis, faventibus, olim conditum, et allorum bona diligentia poletis restauratum, 1737, nunc e vetustatis fitu et foribus pauci de novo revocatum, 1792.

A more lafting monument was dedicated to the memory of our great English naturalist, in the genus of plants which bears his name. (See THAELS.) The opinion we have there, in few words expressed, of his high rank in botanical science, it is hoped the present more diffuse account will justify. It must be lamented that he made, as far as we can learn, no collection of dried plants, which might serve to ascertain, in every case, what he described. The great Herbariums of Budde, Uvedale, &c. still kept in the British Museum, are indeed suppos'd to supply, in a great measure, this defect; they having been collected by persons who had frequent communication with Ray, and were well acquainted with his plants. Whatever he had preferred relative to any branch of natural history, he gave, a week before his death, to his neighbour Mr. Samuel Dale, author of the Pharmacologia. Nothing is said of his library, which was probably incon siderable. His pecuniary circumstances were very limited, for he merely conformed as a layman to the church of England, and was unwilling to publish what was requisite for receiving preferment. He is recorded nevertheless to have disapproved of separatis from the national church; justly disapproved, probably, by the contentions and fanaticism he had been throughout the greater part of his life. His principles and sentiments were far above the fastidious distinctions, which marked the orthodox or the heterodox of those times, and his mind was uncontaminated with their passions. His good sente might well lead him to regret, that those who had so lately escaped a most tremendous common enemy, should be so prone to quarrel amongst themselves. It is an honour to both these parties that they have been emulous to claim him as their ally.

In the preceding review of the literary productions of Ray, more numerous, as Haller says, than those of any other botanist, Linnaeus excepted, we have been obliged to pass over several things of less note; such as his lists of native British plants, for Gibson's edition of Camden's Britannia; and even a variety of communications to the Royal Society. Neither have we touched on the principles of his botanical system, that subject being explained at length by our predecessor, the late Rev. Mr. Wood, under the article Classification. Those who are anxious to peruse a more full and critical investigation of his works and studies, than it has been possible to give in this place, will do well to consult Dr. Pulleiney's "Sketches of the Progress of Botany in England." The "Philosophical Letters," collected and published in 1718, by Dr. Derham, containing 68 written by Ray, and many
many more by his correspondents, throw much light on his character and pursuits. We cannot help remarking that his hand-writing was peculiarly fair and elegant. A specimen of it exists among Sir Henry Spelman's vast and curious collection of manuscripts, now in the possession of John Patterson, esq., late M. P., for Norwich.

The portraits of Ray are not numerous. One in oil, taken at an advanced period of his life, remains in the British Museum, and Dr. John Sims is polished of a miniature, of an earlier date, of which its owner has given an engraving, by way of frontispiece to the first volume of the "Annals of Botany," published in 1805. The latter is rather deficient in that strength of character which appears in the more common prints, after a picture by Faithorne, often prefixed to the third edition of the Synoptes, and sometimes to the Histoire Plantarum. One of these prints was engraved by Elder; the other by Vertue. Neither of them is finely appropriated to any particular book. That in the German edition of his "Wisdom of God in the Creation," published at Leipsic in 1732, appears to be copied from one of these, and yet is so unlike them in execution, that if it were possible, one would suppose it taken from some other portrait of the same person. Ray's Works. His Life by Dr. Derham. Haller's Bibl. Bot. Pulteney's Sketches. Aikin's General Biogaphy. S.

RAY, in Geography, a town of France, in the department of the Upper Saone; 12 miles E. of Charnitte.

RAY, in Geometry. See RADIUS.

RAY, Radius, in Optics, a beam or line of light, propagated from a radiant point, through any medium.

Sir Isaac Newton defines rays to be the half parts of light, whether successive in the same line, or contemporary in several lines.

For, that light consists of parts of both kinds, appears hence, that one may stop what comes this moment in any point, and let pass what comes the next; and again, one may stop what comes in this point, and let pass that in the next. Now, the least light, or part of light, which may be thus stopped alone, he calls a ray of light.

A ray of light is, therefore, considered as an infinitely narrow portion, or an evanescent element of a stream of light; and a pencil, as a small detached stream, composed of a collection of such rays accompanying each other. As we cannot exhibit to the senses a single mathematical line, except as the boundary of two surfaces; in the same manner, we cannot exhibit a single ray of light, except as the confines between light and darknens, or as the lateral limit of a pencil of light.

If the parts of a ray of light do all lie straight between the radiant and the eye, which is the case when it moves through the same uniform substance or a vacuum, called a medium, the ray is said to be direct; the laws and properties of which make the subject of optics. If any of them be turned out of that direction, or bent in their passage, the ray is said to be refracted: and that branch of optics which treats of these refracted rays, is called dioptrics; which see. See also REFRACTION.

If it strike on the surface, or medium attached to the surface, of any body, and be driven back, it is said to be reflected: and that branch of optics which treats of these refracted rays, is called catoptrics; which see. See also REFLECTION.

In each case, the ray, as it falls either directly on the eye, or on the point of reflection, or of refraction, is said to be incident: and the angle which the incident ray makes with the perpendicular to the reflecting surface at the point of incidence, is called the angle of incidence; and the angle which the reflected ray makes with the same perpendicular, is called the angle of reflection; and also, the angle which the refracted ray makes with a perpendicular to the refracting surface produced, is called the angle of refraction.

Again, if several rays be propagated from the radiant equidistantly from one another, they are called parallel rays. If they come inclining towards each other, they are called converging rays. And if they go continually receding from each other, they are called diverging rays.

It is evident that the rays of light, which come from a luminous point, must fall divergingly upon any given surface; yet when the object is very distant, compared with the interval that separates these rays, the divergence of the rays becomes insensible; hence the rays of the sun, of the moon, of the stars, &c. are deemed parallel rays. When the luminous point is near, then the rays are feebly diverging.

It is from the various circumstances of rays, that the several kinds of bodies are distinguished in optics. A body, &c. that diffuses its own light, or emits rays of its own, is called a lucid, or luminous body. If it only reflect rays which it receives from another, it is called an illuminated body.

This distinction, however, is not always observed for a luminous body, in common language, means any visible object, whether it be visible by the emission of original light, like the sun, a candle, &c. or by reflected light, like the moon, or any other celestial or terrestrial object that has no native light, or that does not emit its own light.

If an object only transmit rays, it is called a transparent body. So that transparent bodies, such as water, glass, &c. are those through which light will pass, or through which our eyes can perceive objects situated on the other side, and all such bodies, as also a vacuum, are denominated mediums in optics.

If it intercept the rays, or refuse them passage, so that nothing can be seen through it, it is called an opaque body.

Hence no body radiates; i. e. emits rays, unless it be either luminous, or illuminated.

It is by means of rays reflected from the several points of illuminated objects to the eye, that they become visible, and that vision is performed; whence such rays are called visible rays.

When an eye views any object directly, some of the rays, which proceed from every perceivable point of the object, enter the eye, and the whole number of rays, or quantity of light, which thus enters the eye, is circumscribed by the rays which proceed from the extreme points of the object: and the angle which these extreme rays form at the eye is called the visual angle, from the magnitude of which we principally judge of the distance of a known object. Thus, if the same object is represented at different distances, it is evident that the farther the object is from the eye, the smaller will the visual angle be. Supposing also the distance between the eye and the object to remain the same, if by any means the rays of light are bent so as to enlarge the visual angle, then the object will appear larger, or it is said to be magnified; and on the contrary, if the visual angle be diminished, then the object will appear smaller, in which case it is said to be diminished.

In effect, we find that any point of an object is seen in all planes in which a right line may be drawn from that point: but it is allowed, nothing can be seen without light; therefore every point of an object diffuses innumerable rays every way. Again, from other experiments it appears, that the images of all objects, whence right lines may be drawn to
In passing by the edges and sides of bodies, he conceives that the rays may be bent several times backwards and forwards, with a motion like that of an eel; and that those rays which appear to fall on bodies are refracted or reflected before they arrive at the bodies: and adds, that they may be refracted, reflected, and inflected, all by the same principle acting in different circumstances. See Inflection and Light. See also Reflection and Refraction.

Again, do not the rays, falling on the bottom of the eye, excite vibrations in the retina; which, being propagated along the fibres of the optic nerve into the brain, cause vision? and do not several sorts of rays make vibrations of several bignesses, which excite sensations of several colours, much after the manner as the vibrations of the air, according to their several bignesses, excite sensations of several sounds?

Particularly, do not the most refrangible rays excite the shortest vibrations, to make a sensation of a deep violet; and the least refrangible the largest, to make a sensation of a deep red? and the several intermediate kinds of rays, vibrations of intermediate bignesses, to make sensations of the intermediate colours?

And may not the harmony and discord of colours arise from the proportion of these vibrations; as those of sound do upon the vibrations of the air; for some colours, if viewed together, are agreeable, as gold and indigo; others disagreeable. See Colour.

Again, have not the rays of light several sides ended with several original properties? It is certain we find, that every ray of light has two opposite sides, originally ended with a property, on which the unual refraction of island crystal depends, and other two opposite sides ended with that property.

Lastly, are not the rays of light very small bodies emitted from shining substances?

Such bodies may have all the conditions of light: and there is that action and re-action between transparent bodies and light, which very much resembles the attractive force between other bodies. Nothing more is required for the production of all the various colours, and all the degrees of refrangibility, but that the rays of light be bodies of different sizes; the leaf of which may make violet the weakest and darkest of the colours, and be the most easily diverted by refracting surfaces from its rectilinear course; and the red as they are bigger and bigger, may make the stronger and more hued colours, blue, green, yellow, and red. (See Colour and Light.) Nor is any thing more requisite for the putting of the rays into fits of easy reflection, and easy transmission, than that they may be small bodies, which, by attraction, or some other force, excite vibrations in the bodies they act upon; which vibrations, being swifter than the rays, overtake them successively, and agitate them so as by degrees to increase and diminish their velocity, and thereby put them into those fits. Lastly, the usual refraction of island crystal appears very much as if it were performed by some attractive virtue lodged in certain sides both of the rays, and of the crystal.

Rays of Heat denote separate portions of that emanation, which proceeds from an heated body, when placed in a colder temperature, and which expands itself in every direction, provided it be not prevented by the interposition of particular substanices. This appellation is adopted and thus applied, not because that emanation is certainly known to consist of separate streams, but merely for the convenience of explanation. The rays of heat are not the same with the rays of light. If this were the case, a certain quantity of

the eye, are painted in the eye, behind the crystalline, very small, but very distinct.

And lastly, from other experiments, that each ray produces an image of the radiating point: and that the several rays emitted from the same point are again united in one point, by the crystalline, and other humours of the eye, and thus thrown on the retina.

It is the spissitude or clofenes of the rays emitted from a luminous body, that constitutes the intenseness of the light. Yet the direction in which the rays strike the eye, has a considerable influence. In effect, a perpendicular ray, striking with more force than an oblique one, in the ratio of the whole line to the line of the angle of obliquity (as follows from the laws of reflexion, which lec,) a perpendicular ray will affect the eye more vividly than an oblique one, in that ratio.

If then the spissitude of the rays be equal, the intensity will be as the direction: if the direction be the same, the intensenes of will be as the spissitude: if both differ, the intensenes of will be in a ratio compounded of the direction and the spissitude.

Hence, first, if light be propagated in parallel rays through an unrefracting medium, its intensity will not be varied by distance.

Secondly, if light be propagated in diverging rays through an unrefracting medium, its intensity will decrease in a duplicate ratio of the distances from the radiant point, reciprocally.

Thirdly, if light be propagated in converging rays through an unrefracting medium; its intensity will increase in a duplicate ratio of the distances from the point of concurrence, reciprocally.

Fourthly, if the breadth of an illuminated plane be to the distance of the radiant point as 1 to 2,000,000, it is the same thing as if the ray struck upon it parallel: and hence, since the diameter of the pupil of the eye, when largest, scarcely exceeds 4th or 5th of an inch; the rays will fall upon it parallel as to sense, at the distance of 3860 English feet, which is nearly 6 furlongs. See Light.

The effect of concave lenses, and convex mirrors, is to make parallel rays diverge; converging rays become parallel; and diverging rays to become more divergent.

The effect of convex lenses, and concave mirrors, is to make diverging rays become parallel; parallel rays become convergent; and converging rays to converge the more. See Lens.

The rays of light are not homogeneous, or similar, but differ in all the properties with which we are acquainted; viz. refrangibility, refrangibility, and colour.

It is probable that from the different refrangibility the other differences have their rise; at least it appears, that those rays which agree or differ in this, do so in all the rest. Thus, from the different refractions the differently diffused rays excite in us, we call them red rays, yellow rays, &c.

The effect of the prism is to separate and sort the different kinds of rays, which come blended promiscuously from the sun; and to throw each kind by itself, according to its degree of refrangibility and colour, red to red, blue to blue, &c.

Besides refrangibility, and the other properties of the rays of light already ascertained by observation and experiment, Sir Isaac Newton supposes they may have many more: particularly, a power of being inflected, or bent, by the action of distant bodies; and those rays which differ in refrangibility, he conceives likewise to differ in this flexibility.
of heat ought to be accompanied with the same quantity of light; whereas it is found, that several substances emit a considerable quantity of light without any sensible heat, and others give out a considerable portion of heat without any light. But that these are two distinct powers of nature is a proposition, that has been amply illustrated, and most satisfactorily established by the discoveries and experiments of Dr. Herschel. This celebrated astronomer cautions thefe, who peruse the account of his experiments and observations upon them, from concluding, that in using the word rays, he means to oppose, much less to countenance, the opinion of those philosophers, who still believe, that light itself comes to us from the sun, not by rays, but by the supposed vibration of an ethereal ether, every where diffused through space: he merely claims the fame privilege for the rays that occur in heat, which they do not scruple to allow to those that illuminate objects. For in what manner ever this radiance may be effected, he undertakes to prove, that the evidence, either for rays, or for vibrations, which occasion heat, stands on the fame foundation on which the radiance of the illuminating principle, light, is built.

Proposing to give a comparative view of the operations that may be performed on the rays that occasion heat, and of those which are known to have been effected on the rays that occasion light, he selects such facts as are well known with regard to the latter. Light, he says, both polar and terrestrial, is a diffuence occasioned by rays emanating from luminous bodies, which have a power of illuminating objects; and, according to circumstances, of making them to appear of various colours. The rays of light are subject to the laws both of reflection and of refraction; but they are of different refrangibility. They are liable to be stopped in certain proportions, when transmitted through diaphanous bodies; and also to be scattered on rough surfaces. They are also suppos'd to have a power of heating bodies; but this is a subject "in dubio." The familar propositions, which it is his design to prove, and which by a variety of curious and well-conducted experiments he has confirmed, are such as follow. Heat, both polar and terrestrial, is a diffuence occasioned by rays emanating from centent substances, which have a power of heating bodies. These rays are subject to the laws of reflection and of refraction; and they are of different refrangibility. They are liable to be stopped, in certain proportions, when transmitted through diaphanous bodies; and to be scattered on rough surfaces: and in a certain state of energy, they may be suppos'd to have a power of illuminating objects, which latter property remains to be examined.

In the examination of the illuminating and heating power of the prismatic colours, our author observes, that the red-making rays are very far from having the former in an eminent degree; the orange predominates more of it than the red; and the yellow rays illuminate objects still more perfectly. The maximum of illumination lies in the brightest yellow, or palest green. The green itself is nearly equally bright with the yellow; but from the full deep green, the illuminating power decreases very sensibly; that of the blue is nearly upon a par with that of the red; the indigo has much less than the blue; and the violet is very deficient. Our author infers from other experiments, that the heating power of the prismatic colours is very far from being equally distributed; and that the red rays are chiefly eminent in this respect. Allowing that the power of heating is chiefly lodged in the red-making rays, it accounts for the comfortable warmth that is thrown out from a fire, when it is in the state of a red glow, and for the heat which is given by charcoal, coke, and halls of small coal mixed up with clay, used in hot-houses; all which throw out red light. It also explains the reason, why the yellow, green, blue, and purple flames of burning spirits mixed with salt, occasion so little heat that a hand is not materially injured, when palled through their combustions.

Having ascertained, that radiant heat is subject not only to the laws of refraction, but to those also of the different refrangibility of light, Dr. Herschel is led to form, that this heat consists of particles of light of a certain range of momenta, which range may extend a little farther, on each side of refrangibility, than that of light. In a gradual exposure of the thermometer to the rays of the prismatic spectrum, beginning from the violet, he found that he arrived at the maximum of light long before he came to that of heat, which lies at the other extreme. By several experiments it appears, that the maximum of illumination has little more than half the heat of the full red rays; and from other experiments our author concludes, that the full red falls still short of the maximum of heat, which perhaps lies even a little beyond visible refraction. In this case, radiant heat will at least partly, if not chiefly, consist, if the expression may be allowed, of invisible light; that is, of rays coming from the sun, that have such a momentum as to be unit for vision. Admitting it as highly probable, that the organs of sight are only adapted to receive impressions from particles of a certain momentum, this will explain why the maximum of illumination should be in the middle of the refrangible rays, as those which have greater or less momenta, are likely to become equally unit for impressions of light. Whereas, in radiant heat, there may be no such limitation to the momentum of its particles. From the powerful effects of a burning lens, however, we derive information, that the momentum of terrestrial radiant heat is not likely to exceed that of the sun; and that, consequently, the refrangibility of calorific rays cannot extend much beyond that of colourific light. Hence we may also infer, that the invisible heat of red-hot iron, gradually cooled till it ceases to shine, has the momentum of the invisible rays, which, in the solar spectrum viewed by daylight, go to the confines of red, and this will afford an easy solution of the refraction of invisible heat by concave mirrors.

Our author deduces from various experiments with the thermometer abundant evidence, that there are rays coming from the sun, which are less refrangible than any of those that affect the light. They are invested with a high power of heating bodies, but with none of illuminating objects; and on this account they have hitherto escaped notice. At the distance of fifty-two inches from the prism, there was felt a considerable heating power exerted by the invisible rays, an inch and a half beyond the red ones, measured upon their projection on a horizontal plane. Moreover, the power of heating is extended to the utmost limits of the visible violet rays, but not beyond them; and it is gradually impaired, as the rays become more refrangible. The maximum of the heating power is found to be vested among the invisible rays, and it is probably not less than half an inch beyond the last visible ones. It is also shown, that the sun's invisible rays, in their less refrangible state, and considerably beyond the maximum, still exert a heating power fully equal to that of red-coloured light; and consequently, if we may infer the quantity of the effluent from the effect produced, the invisible rays of the sun probably far exceed the visible ones in number. The general conclusion with which Dr. Herschel closes his account of one series
of experiments and his reasoning upon them, is in the following manner: "if," says he, "we call light those rays which illuminate objects, and radiant heat, those which heat bodies, it may be inquired whether light be essentially different from radiant heat? In answer to which I would suggest, that we are not allowed by the rules of philosophizing to admit two different canons to explain certain effects, if they may be accounted for by one. A beam of radiant heat emanating from the sun, consists of rays that are differently refrangible. The range of their extent, when dispersed by a prism, begins at violet-coloured light, where they are most refracted, and have the least efficacy. We have traced these caloriferous rays throughout the whole extent of the prismatic spectrum, and found their power increasing, while their refrangibility was decreased, as far as to the confines of red-coloured light. But their diminishing refrangibility, and increasing power, did not stop here; for we have pursued them a considerable way beyond the prismatic spectrum into an invisible state, still exercising their increasing energy, with a decrease of refrangibility, up to the maximum of their power; and have also traced them to that state, where, though still less refracted, their energy, on account, we may suppose, of their now falling density, decreased very little; after which the invisible thermometrical spectrum, if I may so call it, soon vanished."—"If this," continues our author, "be a true account of solar heat, for the support of which I appeal to my experiments, it remains only for us to admit, that each of the rays of the sun as have the refrangibility of those which are contained in the prismatic spectrum, by the construction of the organs of sight, are admitted, under the appearance of light and colour; and that the result, being flopped in the coats and humours of the eye, acts upon them, as they are known to do upon all other parts of our body, by occasioning a sensation of heat?"

Although, as we have above stated, the rays of light and those of heat poffeys many similar properties, yet Dr. Herschel has shewn, that there are some striking and substantial differences between them. The rays of heat are of a much more extensive refrangibility than those of light, as our author has clearly and incontrovertibly demonstrated both by reasoning and experiment; nor do those rays agree either in their mean refrangibility, nor in the situation of their maxima. Where we have mott light, there is but little heat, and where we have mott heat, we find no light at all. (See Refrangibility.) It is found, that the finess of refraction of the heat-making rays are in a constant ratio to the lines of incidence; but that the focus of the rays of heat in burning glases is different from the focus of the rays of light; that of heat being farther removed from the lens than the Focus of light, probably not less than a quarter of an inch: the heat at half an inch beyond the focus of light being still equal to that in the focus. Although light and heat are both refrangible, the ratio of the lines of incidence and refraction of the mean rays is not the same in both. Heat is evidently less refrangible than light. From experiments relating to the transmission of light and heat through diaphanous bodies it appears, that no kind of regularity takes place in the proportion of rays of one sort and of another, which are flopped in their passage. Heat and light seem to be entirely unconnected, and the rays that occasion them are different. We have several tables, formed from the author's experiments, and shewing the quantities of light and heat intercepted by different bodies. The blue and white and flint-glasses, r. gr. stop nearly three times as much heat as light, whereas the greenish crown glasses stops only about one-fourth more of the former than of the latter.

From a table exhibiting the effects of coloured glases, it appears, that a yellow glases stops only 333 rays of heat, but stops 819 of light; on the contrary, a pale blue stops 812 rays of heat, and but 684 of light. Again, a dark blue glases stops only 362 rays of heat, but intercepts 801 of light; and a dark red glases stops no more than 626 rays of heat, and yet intercepts nearly all the light, scarcely one ray out of 5000 being able to make its way through it. For the conclusions deduced from these tables, as they evince the non-identity of the rays of heat and those of light, and for the tables themselves, we must refer to the author's own paper, ubi infra. We are restrained by our limits from pursuing this curious subject, and from entering on a detail of Dr. Herschel's experiments, illustrating and confirming principles, the discovery of which must be allowed to be one of the greatest that has been made since the days of Newton; although the theories of some speculative philosophers might have led to it a few years earlier. Dr. Herschel was occupied in determining the properties of various kinds of coloured glases, which rendered them more or less fit for enabling the eye to view the sun through a telescope; and for this purpose it was necessary to inquire which of the rays would furnish the greatest quantity of light, without subjecting the eye to the inconvenience of unnecessary heat. He first observed that the heat became more and more considerable as the thermometer approached the extreme red rays in the prismatic spectrum; and pursuing the experiment, he found not only that the heat continued beyond the visible spectrum, but that it was even more intense, where the thermometer was at a little distance without the limits of the spectrum, than in any point within it; as we have already stated. For Dr. Herschel's communications to the Royal Society on this subject, we refer to the 90th volume of the Philosophical Transactions for the year 1802, part ii. p. 255; &c. p. 293; &c. part III. p. 437, &c.

Sir Henry Englefield has repeated Dr. Herschel's experiments with many precautions, and Mr. (Sir H.) Davy was a witness of their perfect accuracy. The excels of heat beyond the spectrum was even considerable enough to be ascertained by the sense of warmth occasioned by shining it on the hand.

It was first observed in Germany by Ritter, and soon after by Messrs. Le Chatelier, that the muriate of silver is blackened by invisible rays, which extend beyond the prismatic spectrum, on the violet side. It is therefore probable, that these black or invisible rays, the violet, blue, green, perhaps the yellow, and the red rays of light, and the rays of invisible heat, constitute seven different degrees of the same scale, distinguished from each other into this limited number, not by natural divisions, but by their effects on our senses, and we may also conclude that there is some similar relation between heated and luminous bodies of different kinds. See Young's Phil. Lect. vol. i. p. 639. See Heat and Refraction.

M. Delacroix has found, that the rays of invisible heat traverse glass with difficulty at a temperature below that of boiling water; but that they traverse it with a facility, always increasing with the temperature, as it approaches the point when bodies become luminous, and from these experiments it would appear, that the modification, whatever it be, which must be impressed upon the invisible rays to render them more and more capable of passing through glasses, makes them approach more and more to the state in which they must be when they penetrate our eyes, and occasion the sensation of vision. The same ingenious philosopher has likewise found, that the rays of heat which have passed through
through a plate of glass are proportionally more adapted to pass through a second plate; and from this circumstance we deduce a new proof of the peculiar state of these rays, and of the modification which they acquire. Miers. Gay-Lussac and Thenard have proved that all the changes of colour produced by light may be imitated and produced by heat, and by an elevation of temperature not exceeding 212°. Other phenomena previously observed indicated, that in the comparison of the actions of heat and light in heating bodies, or producing chemical changes in them, there is a great difference in the rays of different colours. M. Rochon announced the fact amply confirmed by Dr. Herschel, that the heat produced by the different rays of the prismatic spectrum was unequal. As Dr. Herschel fixed the maximum effect beyond the red rays, and showed, as we have already stated, that the most heating rays of the spectrum were entirely, or nearly, invisible; Dr. Wollaston, and Miers. Ritter and Beckmann, having examined the opposite, or violet end of the spectrum, found that this likewise possessed peculiar properties, and that, beyond the violet, there are invisible rays, which possess, in greatest perfection, the power of determining chemical combinations. It has been a subject of interesting research, whether the invisible, or almost invisible rays, situated beyond the extremities of the spectrum, possess any other properties of light. *E. gr. If the reflection of them from polished glass can give them that modification which Malus has distinguished by the name of "polarization." (See Light.) M. Berthollet engaged Miers. Malus and Berard to undertake this double object. M. Malus's death prevented his prosecution of the subject; but what he began M. Berard accomplished with the utmost possible exactness. By means of the heliostate, which Malus caused to be constructed for the philosophical cabinet of M. Berthollet, he obtained a ray of light, perfectly fixed, on which he could make experiments at pleasure. By decomposing this ray with a prism, he obtained an immovable coloured spectrum; and by placing very sensitive thermometers in the spaces occupied by the different colours, he was enabled to compare their caloric effects with the utmost certainty. He also ascertained their chemical properties by sublimating, in place of the thermometers, chemical compounds easily altered. He first of all observed the caloric power of the different rays, which, it is known, are in this respect unequal. M. Rochon, who is said to have first observed this inequality, placed the maximum of heat in the yellow ray, where the illuminating power is the greatest. Dr. Herschel, as we have before shewn, placed it out of the spectrum, and beyond the red ray. The experiments of Herschel have been confirmed by those of Berard, as far as they respect the progresive heating power of the rays from the violet to the red; but he found the greatest heating power at the extremity of the spectrum itself, and not beyond it. He fixed it at the point, where the bulb of the thermometer was still entirely covered with the red ray; and he found that the thermometer sunk progressively, in proportion as the distance of its bulb from the red ray increased. When he placed the thermometer quite beyond the visible spectrum, on the spot where Herschel fixed the maximum of heat, its elevation above that of the ambient air was only one-fifth of what it had been in the red ray itself. The absolute intensity of the heat produced was likewise less in the experiments of Berard than in those of Herschel.

M. Berard wished to know if these properties would exist in each of the pencils into which the ray divides itself in falling through a rhomboid of Iceland spar. In this case each of two spectrums exhibited the same properties. In both, the caloric power diminished from the violet to the red end; and it existed beyond the last visible red rays. In this operation the luminous molecules are polarized by the crystal. In order to determine whether the invisible rays of heat experience the same effect, M. Berard received the solar ray upon a polished and transparent glass, which polarized a portion of it by reflection. This reflected ray was then received upon a second glass, fixed in an apparatus, which permitted it to be turned round the ray under a constant incidence, and this incidence itself was determined in such a manner, that in a certain position of the glasses the reflection ceased to take place. We know, from the experiments of Malus, that a glass may be always disposed in such a manner that this condition is fulfilled. Things being thus disposed, by collecting with a mirror the caloric and luminous rays reflected from the second glass, and directing them upon a thermometer, M. Berard found, that as long as light was reflected the thermometer was elevated, and of course the heat was reflected likewise; but when, from the position of the second glass, the light was totally transmitted, the heat was transmitted at the same time, and the thermometer was not elevated. In this experiment, then, as well as the preceding, the caloric principle, whatever it may be, never separates from the luminous molecules.

To the ray of solar light employed in this experiment, M. Berard substituted a pencil of radiant heat proceeding from a body hot, but not red, and even not luminous. The effect was the same as before. The thermometer rose when the second glass was so situated as to reflect light, and it did not rise when the second could not reflect light. Therefore the particles of invisible radiant heat are modified by reflection, precisely like light.

After having studied the caloric properties of the different rays of the spectrum, M. Berard examined their chemical properties. When muriate of silver, or other white salts of silver, are exposed to light, they become dark coloured very speedily. Guaiac thus exposed to light pales from yellow to green, as Dr. Wollaston observed. Gay-Lussac and Thenard discovered another action of this light still more prompt and energetic. When a mixture of oxy-muriatic acid gas and hydrogen gas are exposed to the action of solar light, a detonation takes place, and water and muriatic acid are formed. These different phenomena enabled M. Berard to examine the chemical powers of the different rays of the spectrum. By exposing to the different coloured rays, pieces of card impregnated with muriate of silver, or small phials filled with the detonating mixture, he was enabled to judge of the energy of each by the intensity or rapidity of the chemical change which it produced. He found that the chemical intensity was greatest at the violet end of the spectrum, and that it extended, as Ritter and Wollaston had observed, a little beyond that extremity. When he left sublimates exposed for a certain time to the action of each ray, he observed sensible effects, though with an intensity continually decreasing in the indigo and blue rays. Hence we must consider it as extremely probable, that if he had been able to employ re-actives still more sensible, he would have observed analogous effects, but still more feeble, even in the other rays. 'To shew clearly the great disproportion which exists in this respect between the energies of the different rays, M. Berard concentrated, by means of a lens, all that part of the spectrum which extends from the green to the extreme violet; and he concentrated, by means of another lens, all that portion which extends from the green to the extremity of the red. This last pencil formed a white point so brilliant that the eyes were scarcely able to endure it; yet the muriate of silver remained more than two hours exposed to this brilliant light without undergoing any facili-
ble alteration. On the other hand, when exposed to the other pencil, which was much less bright, and left hot, it was blacked in less than six minutes. M. Berard concluded, from this experiment, that the chemical effects produced by light are not solely owing to the heat developed in the body by its combining with the substance of the body; because, on such a supposition, the faculty of producing chemical combinations ought to be greatest in those rays which poises the faculty of heating in the greatest perfection: but perhaps we should find less opposition between these two opinions, if we attended to the different refractions which may be produced by the same agent placed in different circumstances, and if we considered that agents of a nature quite different may determine the same combinations when they are employed.

Various hypotheses have been suggested in order to account for the properties above stated. If we wish to consider solar light as composed of three distinct substances, one of which occasions light, another heat, and the third chemical combinations; it will follow that each of these substances is separable by the prism into an infinity of different modifications, like light itself; since we find, by experiment, that each of the three properties, chemical, colorific, and calorific, is spread, though unequally, over a certain extent of the spectrum. Hence we must suppose, on that hypothesis, that there exist three spectrums one above another; namely, a calorific, a colorific, and a chemical spectrum. We must, likewise, admit that each of the substances which compose the three spectrums, and even each molecule of unequal refrangibility which constitutes these substances, is endowed, like the molecules of visible light, with the property of being polarized by reflection, and of escaping from reflection in the same positions as the luminous molecules, &c.

Instead of this complication of ideas, let us conceive simply, according to the phenomena, that light is composed of a collection of rays unequally refrangible, and of course unequally attracted by bodies. This supposes original differences in their size and velocity, or in their affinities. Why should those rays, which differ already in so many things, produce upon thermometers, or upon our organs, the same phenomena of heat or light? Why should they have the same energy to form or separate combinations? Would it not be quite natural that visibl should not operate on our eyes, except within certain limits of refrangibility; and that too little or too much refrangibility should render it equally incapable of producing that effect? Perhaps these rays may be visible to other eyes than ours, perhaps they are so to certain animals, which would account for certain actions that appear to us marvellous. In a word, we may conceive the calorific and chemical faculty to vary through the whole length of the spectrum, at the same time with the refrangibility, but according to different functions; so that the calorific faculty is at its minimum at the violet end of the spectrum, and at its maximum at the red end; while, on the other hand, the chemical faculty expressed by another function is at its minimum at the red end, and at its maximum at the violet end, or a little beyond it. This simple supposition, which is only the simple statement of the phenomena, equally agrees with all the facts hitherto observed, and accounts for those established by M. Berard, and even enables us to predict them. In fact, if all the rays, which produce the three orders of phenomena, are rays of light, they must of course be polarized in passing through Iceland crystal, or in being reflected from a polished glass with a determined incidence; and when they have received these modifications, they must be reflected by another glass, if it is properly placed, to exert its reflecting energy on the luminous molecules. On the other hand, if that force is null on the visible luminous molecules, the invisible light will not be any longer reflected: for the cause which occasions or prevents reflection appears to act equally upon all the molecules, whatever their refrangibility may be. It ought, therefore, to act upon the molecules of invisible light, the condition of visibility or invisibility relating merely to our eyes, and not to the nature of the molecules which produce these phenomena in us.

This mode of viewing the facts appeared to Mellef. Berthollet, Chaptal, and Biot, who made a report to the Institute on the Memoire de Berard, the most natural and simple; though the modést refcrice of Berard restrained him from deciding in a case, not sufficiently examined by the test of experiment. Annal. de Chimie, vol. xxxv. p. 309. or Thomson's Annals of Philosophy, No. 9.

Ray, Common, in Optics, is sometimes used for a right line drawn from the point of concourse of the two optical axes, through the middle of the right line which passes through the middle of the centres of the pupils of the two eyes.

Ray, Cone of. See Cone.
Ray, Deflection of. See Deflection.
Ray, Opic. See Optic.
Ray, Reflexibility of. See Reflexibility.
Ray, Principal, in Perspective, is the perpendicular distance between the eye and the vertical plane or table, as some call it. See Perspective.
Ray, Pencil of. See Pencil of Rays.
Ray, Pyramidal of. See Optic Pyramid.
Ray of Curvature, in Geometry, is used to signify the semi-diameter of the circle of curvature. See Radius and Curvature.

Ray, Clavated. See Raia Clavata, and Thornback.
Ray, Eagle. See Raia Aquila.
Ray, Electric or Smooth, a species of ray. See Raia, Torpedo, and Anatomy of Fish.
Ray, Fuller, Raia fullonica, a species of ray, deriving its name from the instrument which fullers use in smoothing cloth, the hack being rough and spiny. See Raia Fullonica.
Ray, Oblong. See Raia and Rhinobatos.
Ray, Osciulated. See Raia and Miraletus.
Ray, Rough. See Raia Rubra. At Scarborough, where it is common, it is called the white hams or gullet.
Ray, Shagreen, called at Scarborough the French ray, is about the size of the skate, but narrower in its form than the common kinds. The upper part of the body is covered closely with small shagreen-like tubercles, resembling the skin of the dog-fish; and from the nose to the beginning of the pectoral fins is a tuberculated space. Pendant.
Ray, Sharp-nosed. See Raia Oxynotus. This fish makes a noisy noise, and is supposed to be the bow of the ancients, which Oppian describes as the broadest among fishes, and fond of human flesh; adding, that the method it takes of destroying men is by overlaying and keeping them down by its vail weight till they are drowned. Pendant.

Ray, in our Old Writers, a word appropriated to cloth never coloured, or dyed, 11 Hen. IV. c. 6. Blount, Cowel.
Ray, in Botany, the spreading marginal flors of a compound flower; see Radius. The same term is applied to the sub-divisions of an umbel, more properly denominated
RAY

its general and partial flanks; unless we, like Linnaeus, consider the whole umbel as one aggregate flower. See Umbrella, and Inflorescence.

RAY-Gras, or Agriculture, an useful for of early gras that has long been, and ill is, much cultivated by the farmer in some districts. There are said to be different varieties of this gras, but that grown by Mr. Peacey, of Devonshire, has been found, on experience, much superior to the common for. This gras has sometimes the title of rye-gras. See Lolium Perenne.

It has been remarked by the Rev. Mr. Duncan, of Kilmarneick, in the fourth volume of Communications to the Board of Agriculture, that it has been found of late that there is an annual and perennial kind; that the latter should only be fown; but that the annual seed, he thinks, affords the greatest and most palatable crop of hay, and may be sown on those light fields which more readily tend to gras, at least a considerable proportion of it should be blended with the perennial seed. He adds, that the two kinds of seeds are readily distinguished by a careful observer, as the perennial is smaller, and fairer in colour, than the annual, and likewise much lighter. Good annual seed weighs from 21 to 24 lbs. avoirdupois weight per bushel, but the perennial only from 16 to 18 lbs. As no distinction of these forts was formerly made by farmers, he suggests it as probable that they have come to be known and distinguished, from the circumstance of no ray-gras disappearing wholly the first year, by which some persons have been tempted, from the high price of the seed, to allow what remained in the second year to advance to maturity, though to the great injury of the pasture. It is therefore from the seed of the second year's crop that he supposes the perennial gras has gradually originated; and its inferiority in point of substance seems, he thinks, to prove the supposition. By this means the farmer may, by allotting a small portion of good land for the purpose, supply himself with what is said to be the perennial seed, without submitting to the imposition of an extravagant price, and may probably ensure or improve upon the durability of it, by collecting feed from the third or fourth year's growth.

It is found to be an excellent gras for pasture as well as hay. It has an early, but not very abundant, foliage. It is highly relished by cattle and sheep. From its being apt to run up into flowering items, it should be kept well fed down. From its secreting and depositing much saccharine matter in the joints of the items, it affords a good proportion of nutritious matter for the support of animals, both in its green state and when made into hay. And it is said not to affect the wind of horses, which renders it particularly valuable for hunting and racing horses.

It has, however, been objected to by some, from the quantity of flower items which it feeds up; but this is affected by others to be only the cause when it grows in dry upland situations. It is found, of course, to vary much under different circumstances and situations.

The items that are most suitable for it are those of the loamy and sandy kinds, but it is capable of being grown on those of the clayey forts when not too stiff. On the two first forts, in mixture with other grasses, it frequently becomes permanent, and affords an useful spring food, especially for sheep flock.

As it is found to produce a thick well-connected sward in soils of the rich fertile kinds, it has been supposed only suited to them, though occasionally met with in those of the poorer descriptions.

In effect it is found very bad for the strong wet heavy lands.

But in other districts it is most found in stiff clayey soils, where clover is liable to fail in coming up well. Some, however, find that a light soil is quite as suitable for it as one of a clayey nature; and that though it may be most found in stiff heavy lands, it is not from the notion that lighter soils are less suited to it, but that such lands may be covered with this gras, should the clover crop not turn out well in consequence of the great infinities of the clayey soils.

On the stiff clayey soils the proportion of feed is usually from one bushel to one bushel and a half of ray-gras, with eight or ten pounds of red clover seed, to the acre. On other soils from six to ten gallons of ray-gras, with from five to eight pounds of red clover seed, and from two to four pounds of trefoil feed, are used to the acre; some adding to these, two, three, or more, pounds of white clover feed.

In Suffex, for a layer for one or two years, they employ of ray-gras feed three gallons, and of red clover and trefoil feed each one gallon, to the acre.

But for permanent pasture the proportion is this. Of ray-gras feed four gallons, Dutch clover and trefoil feed, of each two gallons to the acre. Other different proportions are made use of in different cases.

It has been well remarked by Dr. Campbell, in the third volume of Communications to the Board of Agriculture, that when land is in a proper state of manure, ray-gras united with white clover, will form a perfect sward the latter end of the second year after it is sown. A particular field, of about five acres, that was sown with these two grasses, was, he says, more perfectly grassed over than others, which had the addition of trefoil and rib-gras, and which were sown at the same time. A neighbour of his, the only man in the county that had tried ray-gras, told him it would not answer, and referred him to a particular field where some had been sown. The fact was, the doctor says, that he had cropped his field with oats until it was no longer worth ploughing, and then, with his last feed, he sowed ray-gras, which certainly did not flourish. But his argument would, he thinks, have been equally conclusive against any gras or grain whatever. The ray-gras languished, and finally died away, giving place to the vegetation suited to the state of the land. If it be expected that ray-gras, or any other good gras, should thrive and produce abundant crops on exhausted or poor land, it must not, he says, be in the soil which occurs here. And he adds the following useful remarks, on converting ray-gras into hay: it is necessary to cut it at a period previous to its being so ripe as to have perverted its feed, and changed to a yellow colour; for in this case a great part of the juice of the plant, which constitutes a principal part of the nutriment it is to afford, will be converted into a species of straw, and its nutritive properties be proportionally diminished. When it is made into hay, persons not acquainted with its qualities are apt to object to its apparent coarseness, which proceeds from its consisting almost entirely of flowering-items, the ray-gras having a comparatively smaller proportion of leaves than any other gras. Whether this be a defect or a merit will, he thinks, depend upon a solution of this question: Do the items and flowering parts of gras, or the leaves taken weight for weight, contain the greater proportion of nutriment? It does not appear, he says, that this has been determined by experiments instituted for the purpose; but it seems probable, from the items being so much sweeter than the leaves, (which is particularly perceptible upon chewing them when about half dry,) and from those vegetables which contain much saccharine matter being particularly nutritious, that the greater proportionate quantity of
Ray

Nutriment will be found to reside in the italks; and if so, the advantages of ray-grafs will be decisive. But, however this may be, it is certain that, supposing wet weather comes on during the process of hay-making, the flint part of the grasa that decays is the leaf, which soon becomes yellow, and then black, losing all pretensions to nutritive properties; in which case it is evident that almost the whole nutriment contained in the hay must reside, exclusively, in the flowering-itsalks. Ray-grafls then have, in unfavourable hay-features, an advantage, he thinks, over all others, inasmuch as from having fewer leaves it is not so apt to be injured by a continuance of rain; and it is, besides, when in the cokes, more accessible to the air and wind from lying open and light; and consequently not so apt to heat and mould as other grasa in similar situations and features. And he concludes it certainly polishes the following valuable properties.

1. That there are few grasa to early in the spring. 2. That there are none better relished by cattle, or more nutritive. 3. That it has the power of refilling the effects of bad weather, in ticklish features, in a greater degree than other grasa. 4. That there is a greater facility in collecting its feed than of any other grasa.

It is supposed that the prejudices against it have proceeded, 1. From its being known in land not capable of producing a full crop of any good vegetable. 2. From allowing it to shoot up so far, as to have formed the feed in the flowering-itsalk, before cattle have been turned into pastures; or that it has been cut for hay. Ray-grafts appears, he thinks, to partake more of the nature of grain than any other grasa. Hence, when it has perfected its feed, it shoots out no more italks, and but few leaves that fresh, as lord Kaimes has judiciously observed. Hence it is necessary to turn cattle into a field of this grasa early in the spring, and to keep it well under by a sufficient quantity of flock; in which case it will continue to put out fresh flowering-itsalks and leaves during the whole season. 3. The hay, for the reason just assigned, should be cut before it becomes a mere straw. Common ray-grafts, being composed of grasa in various stages of growth and ripeness, admits of greater latitude than a field of ray-grafts, because many of them will generally be in a proper state for cutting, although others may have passed their prime.

He adds the following facts in support of its nutritive properties. No hay, says he, could be better relished by my horses than this; not a particle of it was waited by them, or left in the rack; no animals could thrive, eat or do their work better, than they did, whilst they had this ray-graft to take to. Never was there a greater contrariety than when they were put to the natural hay-grafts of the country, after they had finished the other. They were literally starved into the eating of it; and in spite of an additional quantity of corn, they fell away (agreeable to his farming man's mode of expression) a limb a-piece. This year nothing can look better than his horses do upon this hay, (with which some red clover is mixed,) and this, with the addition of very little corn, and that mostly light, the tailings of oats and barley.

These facts place the utility of this grasa in a very striking point of view. And the following, given by Mr. Duncan, are of the same tendency, as he found in a comparative experiment of pieces of ground laid to pasture with it, and meadow soft-grafts alone and in mixture, that the ray-graft portion was not only more early ready for the feeders by nearly three weeks, but the hay of it always more greedily eaten by the horses and cattle, as well as the pasture in succeeding years, on the ray-graft division, Conanllyen eaten bare before the cattle flock would touch that of the soft-grafts.

In the county of Suffolk, farmers in many places pay, however, a very indifferent opinion of ray-grafts, believing it to do great injury to the land, especially when of the better kind. When turn, with red clover, it does not do so well or is so good as a preparation for wheat, but it answers well for pasture. In trying it mixed and unmixed with clover, some have found that without it, it is all the better for the wheat; and that the wire-worm after ray is sure to destroy the wheat.

Weaning calves it is found extremely useful and advantageous, as it agrees very well with them, far better than tares, which are liable to run through them, or scour.

In Suffolc this sort of grasa is employed in mixture with others, as a sheep-feed, with great benefit and success.

The farmers in the tillage parts of Oxfordshire also consider ray-grafts as preparing badly for wheat; they conceive that the wheat which follows will never be found so good where it is sown as where there is none. It is thought far from having any ameliorating effects on the land, as it draws too much. It is never sown alone by any. It makes the very work hay, unless cut at an early period, or very young, in the opinion of many.

In Berkshire this grasa is sown in the chalk district, and found to a certainty less nutritious than many other forst, as well as more exhausting in its nature. When intended for permanent pasture, it is found, in general, to fail in a very few years; and, unless the feed is changed, it will degenerate under any mode of management. It, however, possesses the advantage of being cheap, and of producing early feed, which are objects of no inconsiderable importance on a farm. Some find that the Peacey variety furnishes a forntnight or three weeks sooner than the common grasa. It is seldom sown finely, but in mixture with many other artificial grasa, in proportions to suit the difference of soil. In some places it is sown with different other artificial grasa in variety, every four years, on different parts of the land, so as to prevent it getting sick of the same kind of feeds.

In the intention of hay, it should be cut early, or its juices will be much exhausted. Horses fed on this for hay are found to prefer their wind better than on hay of other grasa.

In Chelshire the dairy farmers do not consider it a good grasa for producing milk, on which account it is not so much cultivated; its earliness, however, has made it esteemed by many; as on almost any soil, some suppose it will be a pasture a week or ten days sooner than any other kind. And its having the property of correcting the tendency of clover to produce flatulence, renders it also highly worthy of the farmer's attention.

When for hay, if not cut early, the produce is scarcely so nutritious as straw.

This grasa-feed is sometimes sown alone, and the quantity of feeds which the plants afford, and the facility of collecting it, are probably the reasons of its being very common; while the advantages of its earliness have led to its more frequent cultivation. It is suggested, however, that several grasa, as the vernal, the foxtail, the meadow pea, and some others, are equally as early as this grasa, and that the meadow fescue, the oat-grasa, and some others, seem to be as well deserving of the attention of the farmer.

According to the ingenious experiments on this grasa, made under the direction of the duke of Bedford, as stated in the appendix to Sir Humphry Davy's Agricultural Chemistry, the results were as follow.

The
The quantity of produce from a rich
brown loam, taken at the time of the
plant's flowering, was
Weight when dry
Weight of produce lost by drying
Quantity of nutritive matter
The quantity of produce taken at the time
when the feed was ripe
Weight when dry
Weight of produce lost in drying
Quantity of nutritive matter
Loaf of weight in nutritive matter by
taking the crop at the time of flower-
ing, nearly half its value
Proportional value of the flowering grains to that taken at the
time the feed is ripe, as 10 to 11.
The quantity of litter math produce
Quantity of nutritive matter
Proportional value of the litter math grains to that of the
quantity of flowering, as 4 to 10, and to that of the time
the feed is ripe, as 4.10 to 11. See Grass.
RAY, in Geography, a river on the W. coast of Java,
which runs into the sea. S. lat. 7° 27'. E. long. 107° 30'.
RAYEN, a town of the Rhenish palatinate; 11 miles
N.W. of Heilbronn.
RAYGEN, or Raymat, a town of Moravia, in the
circle of Brunn; 8 miles S. of Brunn.
RALPH. See Raleigh.
RAYMANGUR, a fortress of Hindoostan, in Myfory,
taken in 1791 by the British troops; 15 miles E. of
Nundydroog.
RAYMATLA, a river of Bengal, which runs into the
bay of Bengal, N. lat. 21° 35'. E. long. 88° 49'.
RAYMON, a town of France, in the department of the
Cher; 14 miles S.E. of Bourges.
RAYMOND DE PEGNAFORT, in Biography, a faint in
the Roman calendar, was a Spaniard by nation, and born
at the castle of Pequafort, in Catalonia, in the year 1175.
He received the early part of his education at Barcelona,
from whence he removed to the universitv of Bologna, where
he studied the law, took his degrees, and afterwards taught
the canon law for some time with great reputation. He was
afterwards called to Barcelona, by Berenger, bishop of that
city, who made him a canon, and provost of his cathedral
church. He held these polls in the year 1218, when he
established an institution which led the way to the foundation
of the Order of Mercy, (see that article.) In 1222 he re-
signed his dignities, and became a member of the Dominici-
Venian order of preaching friars at Barcelona. In 1230, pope
Gregory IX. sent for him to Rome, appointed him his
chaplain and confessor, and devolved on him the care of car-
rying on the compilation of the Decretals. The pontiff
would willingly have recompened him for his labours by pre-
senting him with very considerable church preferment, but
he chose rather the quiet of a monastery to the honours and
emoluments of the richest fees in Spain and Portugal, which
were offered to him. In 1238 he was called to assume the
pall of general of his order; but upon the plea of his inhuma-
ness, he was suffer'd, in about two years, to return to his
monastery, where he spent the remainder of his long life.
He died in 1275, having entered on the 100thd year of his
age. To his everlasting disgrace, he is said to have been
 principally instrumental in introducing the Inquisition in the
kingdom of Arragon, and into Languedoc, a circumstance
which probably was the means of his canonization in the
year 1601. He was author of "Summa de Calibus peni-
tentialibus, feu de Penitentia et Matrimonio," which was
long popular in the Catholic world, and went through nu-
erous impressions. The best edition of it is that published
by father Laget, at Lyons, in 1708. Raymond's chief
work is "Lib. VI. Decretalium," commencing with the pa-
pacy of Alexander III., where the decreals of Gratian
terminate, which was approved by pope Gregory IX.,
and constitutes the second volume of the papal canon law.
Moreri.
RAYMOND LULLY, a philosopher of much celebrity in
the dark ages, was born at Majorca in 1234. He was
brought up a soldier, and led the life of a man of pleasure.
Falling in love with a young woman, who was deaf to his
addresses, on account of a cancer with which she was afflicted,
and which she exhibited to his view, in order to make him
defect from his importunities, he was so much affec'd with the
fight, that he retired from the world, devoting himself
to pious pursuits, and in the search of a remedy for the dif-
card with which the object of his affection was afflicted; this
was the chief motive for the chemical studies for which he
became so famous. He undertook a course of travels into
the East, for the purpose of converting the Mahometans to
the Christian faith, and incurred very great hardships, and
the most furious dangers. So great was his zeal for this ob-
ject, that being unable to persuade certain Christian princes
to engage in it, he entered into the Franciscan order, and
returned to Africa, with the hope of obtaining the honour of
dying a martyr. He was accordingly thrown into pris-
on, and after suffering much torture, and long imprison-
ment, he was freed through the interest of some Genoese
traders, who took him on board their ship to convey him
home. He died jul when he had arrived within sight of
his native land, in the year 1315. As a chemist, his chief
object was the pursuit of the philosopher's stone, and the
universal remedy for all disorders. Boerhaave, who had pe-
rived the works of Lully, speaks highly of their merit; he
finds them, he says, "beyond all expectation, excellent, for
that he doubted whether they could be the work of that
age. So full are they of the experiments and observations
which occur in later writers, that either they must be suppo-
fitious, or the ancient chemists must have been acquainted
with many things which pass for modern discoveries." Lully
is suppos'd to have derived his chemical knowledge from his
travels in the East, particularly from the writings of Geber.
A complete edition of all the writings attributed to him,
was printed at Mentz. Raymond Lully is chiefly celebrated
for an invention by which he pretended to enable any one,
mechanically, to invent arguments and illustrations upon
any subject, and thus to reach the summum of science at a
small expence of time and labour. This "Great Art"
professes to furnish a general instrument for afflicting invention
in the study of every kind of science. For this purpose,
certain general terms, which are common to all sciences, are
collect'd and arranged, not according to any natural divi-

ingen, but merely according to the caprice of the inventor. An
alphabetical table of such terms was provided, and subjects
and predicates taken from them were inscrib'd in angular
spaces, upon circular papers. The effences, qualities, affec-
tions, and relations of things, being thus mechanically
brought together, the circular papers of subjects were fixed
in a frame, and those of predicates were so placed upon
them as to move freely, and in their revolutions to produce
various combinations of subjects and predicates; whence
would arise definitions, axioms, propositions, varying infi-

dently, according to the different application of general
terms to particular subjects. Such is the general idea of the
Lullian art, which, however applauded by certain writers of
that
that period, may be pronounced as unworthy of notice, except as a specimen of the artifice with which men frequently impose upon vulgar credulity. Enfield's History of Philosophy.

RAYMOND, in Geography, a township of America, in Rockingham county, New Hampshire, incorporated in 1764, containing 898 inhabitants; 12 or 14 miles W. of Exeter.

RAYMOND, or Raymond-town, a poll-town in Cumberland county, and district of Maine, containing 825 inhabitants; 142 miles N.N.E. of Bolton. The land is generally level, excepting one large hill, called Rattlesnake-hill, from its abounding with those reptiles. The greater part of the growth is pine and white oak, and the soil is difficult of culture.

RAYNAL, William-Francis, in Biography, a French writer of celebrity, was born at St. Genies, in the Rovegu, in 1713. He entered at a very early age among the Jesuits, and by his abilities excited high expectations of his future celebrity. His dislike of restraint induced him to quit the society in the year 1748, although he had made his profession, and had been ordained priest. He now entered his career of authorship, and distinguished himself as a political, historical, and miscellaneous writer. His first piece, published the same year in which he quitted the society, was entitled "Histoire du Stadhouderat;" he next published "Histoire du Parlement d'Angleterre," which gained him much reputation, though it had little claim to the dignified title of history, and was, moreover, tinged with many prejudices, religious and political. He also composed "Anecdotes Literaires," in three volumes, 12mo.; and "Mémoires de Ninon de l'Enclos," and was much employed in the "Mercure de France." The great work of the abbe Raynal was entitled "Histoire Philosophique et Politique des Establissements et du Commerce des Etrangers dans les deux Indes," to the composition of which he was led by his engaging in some commercial speculations, thinking them likely to turn out more profitably than literary pursuits. His history was published in 1770, and as it contained history, description, and calculation, intermixed with political and philosophical reflections, and was, through the whole, animated by an ardent spirit of philanthropy, and hatred of tyranny, civil and religious, it became popular, and the author was looked up to as one of the reformers of the age. Critics, however, soon found that, as a literary and philosophical work, it would not bear the test of examination. The style, though rich, was exceedingly declamatory; the images were frequently inflaming; and his principles vitiated by the licentiousness of his country; and the facts upon which the whole was founded were derived from incorrect or dubious documents. The author, it should seem, was soon made sensible of the imperfections of his work, and determined to improve it by travel; with this view he visited the principal commercial towns in France, and passed into England and Holland, at every place making inquiries among travellers and merchants with the most unerring facility. On his return, he published at Geneva an improved edition of his work, in 10 vols. 8vo., containing many additions and corrections. Its tone was unaltered, and its attacks upon existing authorities were so bold, that the parliament of Paris ordered it to be burnt, and issued a decree for apprehending the author. He retired to Spa, whence he travelled through Germany, and after having visited all the principal places, he returned to France, and lived some time quietly in the southern provinces. At the academies of Marfelles and Lyons he founded several prizes for essays on given subjects, of which the most remarkable was whether the discovery of America had been more useful or prejudicial to Europe.

America has now, owing to the quarrel and war subsisting between Great Britain and its colonies, become an object of peculiar interest; and the abbe Raynal, in 1781, published "Tableau et Révolutions des Colonies Anglois dans l'Amerique Septentrionale," which was commented upon and expounded by Thomas Paine, who was a zealous and able defender of the American cause, against the mother country.

The abbe came to Paris in the important year 1788, when the revolution was just ready to burst forth. He had not been long in the city, before the National Assembly was convoked, and one of its early acts annulled the decree passed against him; for this favour, he addressed a letter of thanks to the president, containing a retraction of certain principles contained in his work. Observing, afterwards, that the constitutional assembly were occupied in decrees which he thought were violent infringements on the rights of property, and in others calculated to augment the popular effervescence, he wrote, in May 1791, a long letter of advice and remonstrance. It was soon seen that the sentiments in this letter were very different from those which were generally expected from the author of the "Histoire Philosophique," their tendency being to repress popular licence, and to strengthen the hands of civil authority. Raynal, like many other philosophers of that day, had aided all in his power to produce the change, at which, when put into practice, he and they were greatly alarmed. But it was now too late to return: they had thrown the people their power, had taught them their rights, which it was in vain to expect they would be induced to abandon for any arguments he could produce. In the letter referred to, he says, "I have long dared to speak to kings of their duty, suffer me now to speak to the people of their errors, and to their representatives of the dangers which threaten us. I am, I own to you, deeply afflicted at the crimes which plunge this empire into mourning. It is true that I am to look back with horror at myself for being one of those who, by feeling a noble indignation against arbitrary power, may perhaps have furnished arms to licentious men. Do then religion, the laws, the royal authority, and public order, demand back from philosophy and reason the ties which united them to the grand society of the French nation, as, if, by expounding abuses, and reaching the rights of the people and the duties of princes, our criminal efforts had broken these ties? But no!—never have the bold conceptions of philosophy been represented to us as the strict rule for acts of legislation."

He next proves, that it was not the busines of the assembly to abolish every ancient institution; that the genius of the French people is such, that they can never be happy or prosperous but under a well regulated monarchical government; and that if they wished not the nation to fall under the work kind of despotism, they must increase the power of the king. Raynal was considered to be in his dotage, and himself and his writings were now disregarded. He retired in the midst of forms to Paffy, where, being reduced to a state of indigence, he died in March 1794, at the age of 85. Besides the works already mentioned, the abbe Raynal published "The History of the Divorce of Catharine of Aragon, by Henry VIII.," and "A History of the Revocation of the Edict of Nantes," in four volumes; but he committed many of his papers to the flames during the bloody reign of the monster Robespierre.

RAYNERIUS, a learned Italian monk, who flourished most probably in the 13th century, was a native of Pitia.
RAY

He acquired the character of a consummate divine and civilian, and was appointed professor of divinity, as well as raised to the most considerable offices of trust and honour belonging to his order. It is uncertain at what period he died. He left behind him many works, of which the chief is entitled "Pantheologia, seu, Summa univercele Theologiae." This is a dictionary of theology, with the subjects disposed of in alphabetical order; it has been held in high estimation among the members of the Catholic communion. It has gone through several editions in folio and quarto. The last edition was printed at Paris in 1655, in 3 vols. folio, with additions of father Nicolai.

RAYNHAM, in Geography, a township of Massachusetts, in Bristol county, taken from Taunton, and incorporated in 1731. It contains 1154 inhabitants. Besides the great river Taunton, this township is watered by several streams, upon which are six saw-mills, three grist-mills, a furnace, a forge, and fulling-mill. Here are also numerous ponds, of which Nipponuit, or Nippaunot, is two miles long and one broad. In this pond millions of alewives annually refort and leave their spawn in it. An excellent kind of ore, and various kinds of fish, are found in this township. Besides the usual occupations of husbandry and mechanics, many of the inhabitants are employed in the manufactories of bar-iron, hollow ware, nails, iron for vesseis, iron-hovels, potash, binnings, &c. The first forge set up in America was introduced into this town by James and Henry Leonard, natives of England, in 1652. The same family, in the 6th generation, now poss'is it. King Philip's hunting house stood on the northern side of Fowling pond, about one mile and a quarter from the pond. When the war broke out in 1675, which terminated in the death of the king and the ruin of his tribe, he left strict orders to all his Indians not to hurt the Leonards. Before Philip's time, Fowling pond was two miles long, and three miles and a quarter wide. But the water is now almost gone, and the large tract it once covered is grown up to a thick-fet swamp of cedar and pine. The vicinity has abounded with excellent ore, which has supplied the forge for 80 years; it is, however, incapable of being wrought into iron of the best quality.

RAYNOLEDS, or RAINOLDS, JOHN, in Biography, a learned English divine, was born at Pishoe, near Exeter, in the year 1549. In 1562 he was admitted a student at Merton college, Oxford, whence he was removed, in 1563, to a scholarship of Corpus Christi college. In 1572, having taken his degrees in the arts, he was appointed Greek lecturer in his college, in which department he acquitted himself with great applause. Fuller speaks of him in the highest terms as a commentator of Aristotle's Rhetoric. He had hitherto been zealously attached to the Papist religion, while his brother William was equally zealous for the Reformation. The difference in their sentiments leading them to frequent conferences and disputations, they made converts of each other, William becoming a determined Papist, and John a steady Protestant. He frequently appeared in the pulpit, and was greatly admired as a preacher. In the year 1588 he was admitted to the degree of doctor of divinity, and soon afterwards the fame of his great learning induced queen Elizabeth to appoint him professor extraordinary in that faculty at Oxford; after which he gave him the deanship of Lincoln, which he held only a short time, when he exchanged it for the presidencieship of Corpus Christi college, of which he was a fellow. He made this exchange from his attachment to an academical life, and his love of retirement and study. Similar motives led him afterwards to refuse a bishopric which queen Eliza-

beth offered him. He retrieved the finances of his colleges, which had been suffered to fall into dilapidation, and he reformed its decayed discipline, strictly obeying the statutes himself, and compelling all the other members to observe them. After the accession of James, he was appointed, with Dr. Sparks, Mr. Chaderton, and Mr. Knowles, to appear on behalf of the Puritans in the pretended conferences at Hampton Court; of which we have a full account in the second volume of Neal's "History of the Puritans," by Dr. Toulmin, p. 10—20. Dr. Raynolds did not on this occasion act according to his usual spirit, and, suffering himself to be browbeat by the royal tyrant, lost much of the respect which his character usually laid claim to. It was at the conclusion of this conference, that the king said to Dr. Raynolds and his friends, in answer to their arguments: "If this be all your party hath to say, I will make them conform themselves, or else I will harry them out of the land, or else do worse, only hang them, that's all." When James gave directions for undertaking a new and more correct translation of the bible, Dr. Raynolds was one of the Oxford divines who were commissioned to give a new version of the four greater prophets, the book of Lamentations, and the twelve minor prophets. While employed in this great work he was feized with the gout, under which he had been a sufferer many years, and which at length proved fatal to him. In the midst of the feverish pains, he perfervered in the task allotted to him, and once a-week his fellow-labourers at Oxford regularly assembled in his apartments, where they compared the fruits of their respective studies, determining what appeared to them to be the most faithful translation, till they had accomplished their task. Dr. Raynolds died in the year 1607, highly respected for his erudition, his piety, his modesty, and humility. Several of his biographers speak of him in the highest terms. Wooly says he was most prodigiously seen in all kind of learning, and had turned over all writers, profane, ecclesiastical, and divine, all the councils, fathers, and histories of the church. He was author of many theological works, of which we may mention "De Romana Ecclesia Idolotria, in Cultu Sanctorum, Reliquiarum, Imaginum," &c. 1596; and "Centura Librorum Apocryphorum Veteris Testamenti, aduersus Pontificios," which was a profligate work, and printed at Oppenheim, in Germany, 1611, in 2 vols. 4to.

RAYPOUR, in Geography, a town of Hindoostan, in Bahar; 40 miles N.W. of Chuprah.

RAYPOUR, a town of Bengal; 55 miles W.S.W. of Burdwan. N. lat. 22° 48'. E. long. 87° 5'.—Allo, a large and commercial town of Hindoostan, in the country of Ruttupour; 55 miles S. of Ruttupour. N. lat. 21° 24'. E. long. 82° 28'.

RAYPOUR, or Ray-Gaut, a remarkable pass on the Beyah river, about 17 or 18 miles from Noopour; situated a considerable way within the level country of the Panjab.

RAYTE, or RYCHE, in Ichthyology, a name given by Joannes Cuba, Albertus, and others, to the common rattle, or flaire. See Raia Baitis.

RAZANT. See RASANT.

RAZANT Line of Defence. See Defence.

RAZBOINIKOVA, in Geography, a town of Ruffia, in the government of Irkutsk, on the Angara; 56 miles N.W. of Balaganikai.

RAZBOINOI, a fort of Ruffia, on the Ural; 92 miles E. of Gnesenburg.

RAZE,
RAZI, in Biography, one of the surnames of the famous Muflihman Ben Omar Ben Khâtîb Râzî, Al Temânnî Al Bekrî, a native of the city of Rêîî, in the Perfian, Irak, of which the word Râzî is the apppellative. He was born in the year of the Hegira 543 correspondingly with 1148 of the Christian era, and became one of the most celebrated doctors. His knowledge was not confined to the learning usually taught in the Mohammedan schools, but it comprehended likewise the sciences imported into the East with the writings of the Grecian fages. He was, moreover, a very eloquent preacher both in the Arabic and Perfian languages. By these qualifications he acquired the favour of several princes, particularly of aultan of the Gaurid dynasty, who erected a college for him in the city of Herât in Chorafan. He was driven from this fitation by the intrigues of Cadi Abdâlamgîd, of the sect of Kera- mians, who contended that the deity was corporeal, and of human shape. Having challenged Râzî one day to a public difputation on the attributes of God, he was so confounded by the superior reasoning of the latter in defence of the divine spirituality, that he became his bitter enemy, and seized every opportunity of calumniating him to the sultan, as a man who, under the cloak of philosophy, concealed irreligious and impious notions. By his persuasions, the prince abanahed Râzî from the city, but he soon repented of his rash decrees, and recalled him. This happened in the year 12 of the Hegira. He was author of an “Introduction to the most sublime Mysteries for the Use of Men of Genius,” in which he explains the principles of the Mohammedan philosophy; and several other pieces. “Select Astronomical Researches” have been attributed to him, but perhaps on insufficient authority.

Râzî is also the surname of a celebrated philofopher, chemist, and alquimer, called Mohamed Ben Zakaria, a native of the same city as the preceding, who flourished under the caliphate of MoâŒîdd of the dynasty of the Abbasides. He died about the year 922 of the Christian era.

RAZIMIERZ, in Geography, a town of the duchy of Warfaw, situated between Slepceza and Pofen, where the unfortunate count Patkul was broken alive on the wheel, and impaled by order of Charles XII. of Sweden in 1708.

RAZINPAIJA, a fort of Ruffia, in the government of Upha, on the Ural; 36 miles S.W. of Orenburg.

RAZOIS, Port, a port at the S.W. extremity of the coast of Nova Scotia, and N.E. of cape Negro.

RAZOR, a well-known edged instrument used in shaving. Heat appears to give a partial increafe of tenacity to a razor’s edge, probably because the edge cools fastest, contracts, and is stretched.

RAZOR-BILL, in Ornithology, the common English name of the aea, a web-footed bird with no hinder toes, common on our sea-shores. See ALCA Torda.

RAZOR-FISH, in Ichthyology, the Coryphena novacula of Linnaeus, having the head and fins barred with bluish lines. See NOVACULA.

RAZOR ISLAND, in Geography, a small island on the coast of Brazil; 12 miles S. of Rio Janeiro.

RAZUDA, a town of Hindooftan, in Guzerat; 40 miles E.S.E. of Chitpour.

RÊ, an island in the Atlantic, near the west coast of France, about 16 miles long, and 3 broad: separated from the coast of Vendée by the straits of Breton, which are about 7 miles wide. The principal town is St. Martin de Rê. N. lat. 45° 13’. W. long. 1° 20’.

RÊ, in Commerce. See Rê.

RÊ, in Grammar, &c. an indepenable particle, or preposition, prefixed to the beginning of words, to vary, double, or otherwise modify their meaning.

The modificative re was first introduced by the Latins, from whom it is borrowed into most of the modern tongues. Præfian derives it from rétro, backwards; others rather derive rétro from re: others derive ré from the Greek ἀπ' : or from ἀ, I low.

The effect of the re is various: usually it signifies again, furcum, sur; as in re-join, re-sign, re-lame, re-course, re-bound, re-cite, re-hear, re-cognize, re-compare, re-double, re-linquiit, &c.

Sometimes it stands for contra, ad, against; as in re-lucent, re-umbent, re-cline, &c.

Sometimes for τὸν, super, over, as in re-dundant; sometimes for τὰ, long, far, as in re-moving, &c.

RÊ, in Mufic, the name of the second of the keys in the three hexachords of Guido, G, C, and F. See SOLMIZATION, GAMMUT, HEXACHORDS, and MUTATIONS.

Rê Alia Caccia, II, the Italian title of a comic opera, taken from our “Miller of Mansfield.” It was set to mufic for our opera-house in 1768, by Alfredri, a young com-poser of promising abilitie. He was husband of La Guidagni, the original “Buona Figliuola” in Italy, and feiter to Gaetano Guidagni, the celebrated singer. But the Miller of Mansfield was first formed into a comic opera for Paris, by Sedaine, and set by Monnigni, under the title of “Le Rê et le Fermier,” in 1762.

Rê Tedaro, II, a comic opera, founded on the adventures and vicissitudes of the unfortunate Theodore, king of Corfica. The mufic of this drama is one of the innumerable fources of the fertility of Pafelli's pen. It had been performed all over Italy and Germany with the greatest applauoe, previous to its being brought on our stage. The mufic, that was not changed, is extremely original and pleasing, particularly the finales. There was a mixture of airs by Corri, Mazzinchi, and Storace; but besides destroying the unity of style, the certainty of there being merit of some kind or other in every composition of Pafelli, inclines lovers of mufic to lament that any of his airs should be changed or omitted.

REA, in Geography, a river of England, which runs into the Tame, 3 miles N.E. of Birmingham.

REA, Lough, a lake of Ireland, in the county of Galway, on the border of which is the town of Loughrea. See LOUGHERE.

REACH, in Sea Language, the distance between any two points on the banks of a river, in which the current flows in a straight uninterrupted course.

RE-ACTION, in Physics, the action by which a body acted upon, returns the action by a reciprocal one upon the agent.

The Peripatetics define re-action to be that which a passive body returns upon the agent, by means of some quality contrary to that received from it, in the same part with which the agent acted, and at the same time; as if water, while it is heated by the fire, does at the same time cool the fire.

It was known, even in the schools, that there is no action in nature without re-action; and it was a maxim among them, omne agent, agens repatitur.

But the equality of the actions was not known. Sir Isaac Newton established it as one of the laws of nature, that
action and re-action are equal and contrary; or that the mutual actions of two bodies, striking one against another, are exactly equal, but in contrary directions; or, in other words, that by the action and re-action of bodies one on another, there are produced equal changes in each: and those changes are impelled towards directly contrary parts or ways. See Laws of Nature.

Some of the school-philosophers deny any such thing as re-action, properly so called, at all; urging, that action arises only from the ratio of the greater inequality; that is, we are only to account for action the excess of action, or what the agent does more than is returned by the patient. But the equality between action and re-action lets aside this exception.

READ, in Geography, a river of England, in the county of Northumberland, which runs into the Tyne, 10 miles N. of Hexham.

READ, Heads, a cape on the E. coast of Scotland. N. lat. 59° 35'; W. long. 2° 28'.

READFIELD, a poll-town of America, in Kennebec county, and district of Maine, bounded on the E. by Hol- lowell, and separated from Sterling on the W. by the eastern branch of the Androscoggin river; 8 miles W. of Hallowell, and 190 N.E. of Boston. It contains 1366 inhabitants.

READING, John, in Biography, organist, first at Lincoln, then at Hackney, and finally at St. Dunstan's church in Fleet-street, London. He was a scholar of Dr. Blow, and Stanley's first master. He published Hymns early in life, for pfalmodists in parochial congregations; and, lastly, he worked engraven upon copper, which he called "A Book of my Anthems, with a Thorough-bafe, for the Organ or Harpsichord." He died in 1766, far advanced in years.

Reading, in Geography, a borough and market-town in the hundred of Reading, and county of Berks, England, is 38 miles W. by S. from the metropolis. It is a town of considerable extent and importance, and contains, according to the parliamentary returns of 1811, 2332 houses, and 10,788 inhabitants.

Historical Events.—Reading is unquestionably of very great antiquity; but whether it is indebted for its origin to the Britons, the Romans, or the Saxons, is unknown. Conjectures, however, have been hazarded on the subject by various writers. Camden thinks its foundation ought to be referred to the Britons; Leland calls it the Pontes of Antoninus; and Dr. Beeke, the learned professor of modern history at Oxford, considers it the Calleva of Richard of Cireneccel. But the circumstances which are alleged in favour of these opinions, by their respective authors, are far from being satisfactory. This place is first mentioned in history, under its present appellation, in the year 871; at which time it is described by Asser as being a fortified town, belonging to the Saxon kings, but then occupied by the Danish invaders, who had retreated hither after their defeat at Englishfield. The victorious Saxons immediately invested the town; but their enemies, having received reinforcements, attacked the besiegers with such impetuosity, that, after an obstinate contest, they deemed it prudent to retire to Ab- down. Hither they were followed by the Danes, forces, which were again overthrown, and driven back to Reading. Here the latter remained un molested till the following year, when they marched to London. In the reign of Alfred, who mounted the throne of Wessex soon after this event, the Danes once more feized upon Reading, and they doubtless pillaged it occasionally during their incursions in the tenth century. Throughout that long period of incessant hostility and depredation, however, this town seems to have escaped any very serious disaster; but in 1066 it was reduced to ashes by Sweyne, king of Denmark, along with its famous munition, laid to have been founded by Elfirida, widow of king Edgar, as an atonement for the murder of Edward the Martyr. Reading soon recovered from this disfigure, and in the course of a century afterwards became a place of considerable importance. In 1121 king Henry I. laid the foundation of its magnificent abbey, in which his remains were sublimely interred, according to his own desire. Stephen, who usurped the throne after Henry's death, built a palace here, which was surrendered to his antagonist Henry Fitz-Empress, who obtained the crown, than he ordered it to be demolished, that the site of it is now uncertain. That monarch, however, otherwise evinced much partiality for Reading. Here he resided much of his time, and convened a parliament, as also an ecclesiastical congregation, in which Baldwin was elected archbishop of Canterbury. The abbey church was finished in this reign, and dedicated in presence of the king. In 1185 he came hither from London, to receive Heraclius, patriarch of Jerusalem, who presented him with the keys of the holy sepulchre, and the royal banners of Jerusalem, which Henry returned. In the reign of his successor, Richard I., a convention for the trial of Longchamp, chancellor and bishop of Ely, who had been appointed regent of the kingdom during the king's absence, was held here. King John also held a convention in this town, in 1206; and in 1212 a council was convened here by the pope's legate, for the purpose of effecting a reconciliation between that infatuated prince and the exiled bishops. In 1213 the king met the legate and barons at the abbey, and held a parliament. King Henry III. spent his Christmas at Reading in 1226; and twice during his reign summoned the laymen of the realm together, for the transaction of national business. He was the first monarch who granted a charter of incorporation to the town. In 1349, Edward III. held a great tournament here; and in 1359, the marriage of his son, John of Gaunt, with Blanche, daughter of Henry, duke of Lancaster, was solemnized in the abbey church. In 1384, Richard II. and his court, together with the mayor and aldermen of London, being assembled at Reading, John Northampton, the preceding mayor of that city, was convicted before them of sedition and heresy, and sentenced to perpetual imprisonment. In 1389 a great council was held at Reading, at which the king and his barons were reconciled by John of Gaunt. Parliaments were held here also in 1440 and 1451; in the former of which the order of nobles called viscounts was first established; and in the year following, the parliament adjourned hither from Westminster, on account of the plague. King Edward IV.'s marriage with Elizabeth, lady Grey, was first acknowledged at Reading, in 1464; on which occasion she made her public appearance at the abbey, conducted by the duke of Gloucester and the earl of Warwick. In 1466 parliament was a second time adjourned to Reading, to avoid the plague. King Henry VIII. frequently resided here, having converted the dissolved abbey into a palace. His son, king Edward VI., visited this town in 1552, when he was met by the mayor and aldermen at Coley-Crofts, and presented with two yokes of oxen; the mayor riding before him, uncovered, to the palace. The same ceremony was repeated, when Reading was visited by the bigotted Mary, and her husband, king Philip of Spain. Queen Elizabeth was a frequent visitor here, and had a seat in the church of St. Lawrence.

Early in the reign of Charles I., when the plague raged

with
with great violence at London, the courts of chancery, king's bench, and common pleas, were held here, as were likewise the court of exchequer, the court of wards and liveries, and the court of requels. In 1642, Reading was a parliamentary poll, but the garrison, being defective as to ordnance and ammunition, quitted the town, without resistance, on the approach of a party of the king's horfe. In consequence of this event it became a royal garrison, and continued to be fo till taken by the earl of Elysex in April 1643, after a siege of eight days. The king, however, again recovered it in September the same year, and held it till May following, when he ordered the works to be demolished, and evacuated the town. After this event Reading was frequently occupied as the head-quarters of the parliamentary army, and was consequently much impoverished by the contributions levied upon its inhabitants for the support of the military. In 1688 the army of king James II. was quartered in this town, but quitted it on the approach of the prince of Orange. On this occasion airmill took place in the market-place between two detachments of horfe, which terminated in favour of the Protestant interell, and is still commemorated, by bell-ringing, on the anniversary of its occurrence. Queen Anne visited Reading in 1700, when she was received by the corporation in plate, and presented with forty broad pieces of gold in an elegant purse made for the occasion.

Municipal Government.—Reading claims the honour of having been originally constituted a guild, by charter from Edward the Confessor. This claim, however, is extremely questionable; and at all events we feel convinced that the ancient guild was nothing more than an association of mechanics and trade-men for their individual benefit. The first monarch who conferred upon Reading the privilege of separate jurisdiction was Henry III., in the 37th year of his reign. His charter was subsequently confirmed by all his successors, but without any material alterations, till the reign of Henry VI., when the corporation is first mentioned by the title of the mayor and burgesses. Thus it continued to be designated till queen Elizabeth divided the burgesses into capital and secondary, and declared the mayor and them to be a common council for the borough. That principle further conferred upon the corporation considerable emoluments. Charles I. authorized aldermen to be elected, and invested the mayor and them with ample powers for the government of the town. This charter was confirmed, after the restoration, by his son Charles II., and is the one under which the corporation now acts. By it the officers are declared to be a mayor, twelve aldermen, and the name number of capital burgesses; the mayor, and his deputy, (the preceding mayor,) the senior alderman, the bishop of Salisbury, and his chancellor, being judges of the peace for the borough, and empowered to hold felions, and a court of record. The recorder is an officer added by Charles II., who likewise first acknowledged the town-clerk. Reading sent members to parliament from the time of the earliest records. Before 1716 the right of election was vested in the freemen not receiving shillings, and in the inhabitants paying shillings and half; but in that year it was limited, by a decision of the house of commons, to the inhabitants paying shillings and half only. The number of voters is estimated at 566, and the mayor is the returning officer. The spring assizes for the county are held at this town, as are likewise the Epiphany felions, but the summer assizes are held at Abingdon, and the Michaelmas, either there or at Reading, as the magistrates may judge most convenient.

Reading is a town of considerable extent, situated on both banks of the river Kennet, which separates itself into several branches in passiug through the town. It contains three parishes, St. Giles, St. Mary, and St. Lawrence, and is divided into five wards, called the High-ward, New-ward, Minster-ward, Old-ward, and London-ward, for each of which a constable is appointed. Formerly it was a place of great trade in woollens, but the manufacture fell to decay during the seventeenth century, and has never since revived. At present the chief manufactured products are, coarse linens, (such as flaxing, fail-cloth, floor-cloth, and facking goods,) gauze, crepes, mufflins, ribbons, hat-bands, shoe-thirlings, and other familiar articles. These afford employment to a great portion of the inhabitants among the lower orders; but the principal support of the town arises from its water communications with London, Bath, and Bristol. The articles exported are, flour, of which 20,000 sacks are sent annually to the metropolis, timber, brick, straight hoops, linnen, wood, check, beaver, and a variety of minor articles; in exchange are received groceries of every kind, iron, spirits, fir timber, dials, raves, Portland stone, bricks, hemp, flax, hides, leather, coals, Bath fine-flone, Birmingham goods, &c. For the convenience of trade, several wharfs are formed at Reading, and many improvements have been lately made in the internal navigation of the district at large.

This town, from time immemorial, has been noted for its markets, which are held weekly, on Wednesday and Saturday. The Wednesday's market is chiefly for fruit; but that of Saturday embraces corn and every article of provision. The spot on which the corn market is held, is a spacious piece of ground, of a triangular form, environed by commodious shops for the accommodation of people attending the market, who may be supplied here with colonial or manufactured goods cheaper than in any other town in the county. This market-place is kept in repair by the corporation, for which they are entitled to take one pint out of each sack of corn sold in the market, amounting to about 54,600 quarters annually. The provision market buildings adjoin to the corn market-place, and form a long square, containing, one-half of two ranges of butchers' shops, and the other half of apartments for the market-men, who bring butter, eggs, puppies, &c. for sale. At the southern end of this building is a square open area for fishmongers' and hucksteers' stalls, and next to this, and fronting a street called Fishers-street, is a large square gate-way, over which is the house occupied by the clerk of the market. Besides these market-places, there is another for the sale of hore pigs, conveniently situated between Friar-street and Broad-street. This is private property, but the corporation receive the toll. At Reading are four annual fairs, one on the 2d of February, another on the 11th of May, a third on the 25th of July, and a fourth on the 21st of September. The three first are chiefly for the sale of horses and cows; but the last is also a market fair for the hiring of servants, and is further remarkable for the quantity of cheese brought hither from the counties of Gloucester and Wilts. Hops are also plentiful at this fair.

The houses of Reading are mostly constructed of brick, and are generally disposed in regular streets, some of them very narrow, which have been paved under the authority of an act of parliament, passed in the year 1785.

The principal public buildings and institutions in the town are the three churches of St. Lawrence, St. Mary, and St. Giles, and several dissenting meeting-houses, the town-hall and free-school, the blue-coat school, the green school, the foundation school, the school of industry, the Lancastrian school, the school for national education, the theatre, and the county gaol.
The church of St. Lawrence was chiefly erected towards the close of the 16th century, and is partly constructed of materials taken from the buildings of the abbey. Among the parts of it, so pilfered from the monastery, is a large doorway, which is composed of a circular arch, ornamented with rich mouldings, from which were suspended on each side the arms of the abbey; but these are now nearly obliterated. This door-way is likewise ornamented with niches, in which statues formerly stood. The advowson of the church belongs to St. John's college, Oxford. St. Mary's church is somewhat more ancient than that of St. Lawrence, having been constructed about the year 1547, in the reign of a previous one, which had gone to decay. Some portions of this building have evidently belonged to an older edifice, particularly a window over the west door, which is in the early pointed style of architecture. St. Giles's church was probably constructed at the commencement of the 13th century. The tower only is modern, the ancient one having been demolished during the civil war. The livings of both the churches last mentioned are in the gift of the lord chancellor.

The principal meeting-houses for dissenters are the Calvinistic or Independent meeting-house in Broad-street, a Baptist meeting-house and a Quaker's meeting-house in Church-street, a Methodist chapel in Castle-street, and another in Minster-street, a Cudworthian and an Unitarian meeting-house in London-street, and a Catholic chapel in Vaferia-lane. Another meeting-house for Baptists has also been lately erected in Sievier-street.

The town-hall and free-school form one building; the free-school occupying the ground floor, and the hall, court-room, and offices, the floor above. The free-school was established in the reign of Henry VII., by John Thorne, abbot of Reading, with the funds of a suppressed almshouse. This school has two scholarships in St. John's college, Oxford, the gift of sir Thomas White, in 1557. Julius Palmer, one of the masters of this school, fell a martyr to his Protestant tenets in 1556. The blue-coat school, which is so named from the drees of the scholars, was founded in 1656, by Mr. Richard Aldworth, who bequeathed 4000l. for the support of a master, lecturer, and twenty boys. The present school-house is of late erection, and consists of a centre and two wings. Several donations and bequests having been made to this establishment by various persons, it now usually supports about 48 boys.

The green school is situated in Broad-street, and is appropriated for the education of the daughters of decayed tradesmen, residents in the town, and of orphans, who have been left unprovided for by their parents. The inhabitants of Reading are indebted for the institution of this school to the Rev. Charles Sturges, the Rev. Dr. Nicholls, and the Hon. and Rev. W. B. Cadogan, former vicars of the three parish churches belonging to the town. It is supported by annual subscription, and the proceeds of different donations and bequests. In the foundation school, founded in 1766, eight male and eighteen female children are taught to read. It was instituted with a legacy left for that purpose by Dr. Joseph Neale. The school of industry originated under the patronage of Mrs. Cadogan, for female children, and is supported by the voluntary contributions of ladies in the town. The Lancasterian school, established in 1810, is situated in Southampton-street, and is attended by about 320 boys, who are nominated by the subscribers individually. The school for national education was opened in September, 1813. It is founded on the plan of instruction recommended by Dr. Bell, and is chiefly supported by the clergy of the town and county. Both these institutions are calculated to be highly beneficial to the rising generation. Besides these leminaries of education, there are in Reading several Sunday schools, all the children attending which receive a suit of clothes annually, from a fund provided by the bequest of Mr. Edward Simeon, who clothed them in the same manner during his life-time. The theatre of Reading is a neat and convenient building, lately erected, under the act for regulating provincial theatres. The gaol was built in 1793, on the site of some of the abbey ruins. It is a large edifice, and contains commodious apartments for the keeper, a neat chapel, an infirmary, and a room for the reception of the magistrates, in the centre; and two wings, one for male, and the other for female prisoners, with yards, cells for refractory individuals, &c.

Besides the above public buildings and establishments, there is a public library lately established at Reading, under the name of the "Reading Institution," also a dispensary, which is attended by some of the medical gentleman of the town. The house is the property of the corporation, and the general expenses are defrayed by subscription. The Oracle may likewise be reckoned among the public buildings of Reading. This structure was erected by the mayor and burgesses, in conformity to the will of John Kendrick, who left 7500l. "to build a strong house of brick, fit and commodious to let the poor to work therein." The funds of this charity having been at different periods greatly abused and misapplied, the subject has been several times before the supreme courts of justice. The telsator's object, in bequeathing his large legacy, was the improvement of the woollen trade; but instead of this, it was perhaps the first occasion of the decay of that manufacture, by enabling such as could obtain its advantages to under-deal those who were not so fortunate. The same complaints are made against it, with respect to the manufactures now carried on in it, and, as we suspect, not without some show of reason.

Monastic Establishments.—As already mentioned, the earliest religious institution at Reading was a monastery for nuns, founded by Elfrida, the mother-in-law of Edward the Martyr. This nunnery was founded in 979, and was destroyed, in 1009, by the Danes. The precise site on which it stood is uncertain, but there can be no doubt of its existence. It appears from the Domesday-book, and also from Tanner's Notitia, that another nunnery was established here at a later period, but nothing of its history is known. The abbey, the ruins of which are still sufficient to attest its extent and importance, was founded by Henry I. in 1121. It occupied a spot of ground, equal, if not superior, to any in Berkshire for fertility of soil and beauty of situation. This spot comprehended about thirty acres, and was environed on three sides by a massive and lofty wall, and on the fourth by the river Kennet. Exterior to this wall was a piece of ground, about fifty yards wide, (like the pomerium that surrounded the Roman cities,) which it was not allowable either to cultivate or build upon. It had four entrances to it, defended by arched gateways, and having battlements on their tops similar to those on the walls. Within these was the outer court, whence another gate-way led into the inner court. Part of this building remains, and is composed of bricks, chalk, and flints; and, from the dissimilarity of styles which it exhibits, has evidently undergone many alterations and repairs. Some of it is probably as late as the reign of Henry VII., though other portions of it are, undoubtedly, of much higher antiquity. The inner court conducted to the principal entrance to the abbey, the situation of which, owing to the ground having been since built upon, and the confounding occasioned by throwing up the ramparts in the civil war, cannot now be accurately determined. The only entrance on this side at present is through an arched passageway, opening into the south-east corner of the cloisters, which is certainly...
certainly too mean to be supposed to have been the grand entrance to this superb monastery. The right-hand of the passage is a door-way, leading to a range of apartments, and within is a circular staircase, which conducts to the upper part of the building. This division of the abbey is conjectured to have been appropriated as offices for servants and others, as, under the arches, is a series of arched cellars, and at its southern extremity was the kitchen. The great hall, or confectionary, was entered from the cellars by three large entrance doors. It measured 80 feet in length, 40 in width, and the fame in height, to the centre of the ceiling, which was constructed of stone and supported by arches springing from four pillars, 20 feet high, placed against each of the side walls. These walls, and probably also the outer ones in every part of the building, measure twelve feet thick from the foundation to the fret-off, and fix feet thick from thence to the top, and are composed of flints and rubbish of various kinds, bedded in mortar, and indurated in the highest degree. The abbey-church appears to have extended 260 feet in length, and to have been built in the form of a crofs, with a tower and spire in the centre. The nave was 40 feet wide, and was divided from the side-sides by alternate piers and arches. From the malleable character of this structure, in general, and from the circular form of the windows in the dormitory, it is conjectured that those windows also had circular arches. In the ground to the east of the church, many skeletons have been discovered, a circumstance which points it out as the probable burial-place of the monks. The above-mentioned buildings constituted the body of the abbey, but there were likewise many others, both connected with and detached from them. Among these were the infirmary, the abbeys, and the mill. This hill is yet standing, and appropriated to its original purpose. It is a substantial edifice, built of flint and stone, and is probably coeval with the abbey-church.

Reading monastery was indubitably among the most distinguished in England. The monks were of the Benedictine order, and were endowed with many privileges and immunities, not only by the founder, but by several of his successors, and by some of the popes. They had the right of coming granted to them by king Edward III., also the right of holding three annual fairs, and a market every Sunday at Thatcham. The abbot was among those entitled to the precedence in the house of peers, next after the abbots of Glafburnbye and St. Alban's. He was lord of the manor of Reading, and possessed other wise much influence in the government of the borough. Many of the monks were distinguished for their talents and their acquirements in the learning of their respective ages. Robert of Reading, one of the first monks, was particularly famous, as being, with Adelard of Bath, the only Englishmen of their time who were masters of the Arabic language. The abbey-church was the place of sepulture of many royal and noble persons, among whom were Henry I., and his second queen, Adeliza, and probably also his first queen, Matilda; the emperors Huld, and William, eldest son of Henry II.; Constance, grand-daughter to Edward III.; Ann, countess of Warwick; Richard, earl of Cornwall, and king of the Romans; and Richard de Curtenez, natural son of Henry II.

At the dissolution, the revenues of this monastery were estimated at 2116l. 3s. 9d. annually, above 2000l. according to the present value of money. The lands, of course, were seized upon by king Henry, who parcelled them off, either in gifts or in lease, to different individuals; but the monastery itself was converted into a royal palace, and continued to be occasionally occupied by our kings till its destruction during the grand rebellion, in the reigns of Charles I. and II.

The other monastic institutions in Reading, besides those already noticed, were two convents for Franciscan or Grey friars, St. Edmond's chapel, and Colney chantry. One of the convents was founded about the middle of the thirteenth century, soon after the first appearance of the Franciscan order in this country. Its original situation was on a marshy ground adjoining the Caversham road, and still called the Friary Mead; but in 1285 the friars removed to their present residence, at the western extremity of Friars-Street. After the dissolution this house was appropriated as a work-house for the poor; and part of the church now forms the workhouse prison. This building is in the early pointed style, and has at its western end a very beautiful lancet window. The other convent flourished in Castle-Street, probably on the spot now occupied by the Methodist chapel. This institution seems to have been on a very small scale, though it is mentioned by Leland as "a large house of Grey freres." St. Edmond's chapel flourished on the rising ground, called Chapel Hill, near the borough prison. It was founded, in 1284, by Lawrence Burges, then bailiff of the town. In the civil war it was converted into a fort; and afterwards, about the year 1750, was demolished, and another chapel erected in its place on Broad-Friars. Colney chantry was instituted by one of that family in the reign of Richard II., for the souls of king Edward III., of Thomas Colney, John Colney, and William Cator. It had distinct incumbents of its own, and was under the patronage of the corporation.

Reading has given birth to several persons of eminence. Sir Thomas White, founder of St. John's college, Oxford, is said to have been born here; but Fuller affirms that he was a native of Rickmansworth. Archbishop Land was born in this town in 1573, having been the son of William Land, then a clothier in Broad-street, who, as the archbishop himself told lord Say, had borne all offices in the corporation, save the mayoralty. John Blagrave, the mathematician, is also commonly reputed to have been a native of Reading; as was Joseph Blagrave, a celebrated astrological writer, who does not seem to have been related to the mathematician. The other distinguished natives of Reading were, sir Thomas Holt; sir John Barnard, a noted alderman of London; James Merrick, the translator of the Psalms; William Baker, a learned printer; sir Constance Phipps, lord chancellor of Ireland; and Dr. Planck Bacon, author of several dramas, &c.

The vicinity of Reading presents several objects worthy of notice. A short distance to the southward, close to a place called Catherore-lane, may be seen a remarkable fratum of oyster-shells, imbedded in a vein of sea-faud, at least twenty fathoms beneath the surface of a hill. This fratum is from one to two feet in thickness, and extends through a circumference of five or six acres of ground. Mixed with the shells is a considerable quantity of small teeth, apparently of fish. Caverham, formerly a seat of the Craven family, and afterwards of the Cadogan, is situated nearly opposite the town, on the north bank of the river Thames. The house was built by the earl of Cadogan, in the reign of George I., but has since undergone material alterations. In the old mansion, Anne of Denmark, queen to James I., was friendly entertained by lord Knowles, when on her journey to Bath, in 1613. At the time Charles I. was a prisoner at Windor, the parliament, through the mediation of general Fairfax, permitted him to visit Caverham Lodge, where all his children who were in England, then resided, in the custody of the earl of Northumberland. In the hamlet of Woodley is a very pleasing seat, belonging to lord Sidmouth; and two miles to the westward
Weftward is another, the property of the Blagrave family. The park is very extensive, and is noted for fine venison. South-of, about the fame distance, is White-Knights, the seat of the marquis of Blandford. Sunning, celebrated in history as having been for some time the seat of the see of Wilfhiawe, and subsequently the seat of one of the palaces of the bishops of Salisbury, is a village three miles to the eafward, on the road to Maidenhead. Ireland mentions the bishop's palace fanding in his time. It was given by bishop Gheel, along with the manor, to queen Elizabeth, in exchange for estates in Dorfehawe. The antiquity of this place is strongly marked by the sepulchral monuments in the church. Close to Sunning is an elegant mansion, the seat of Charles Fyh Palmer, eq. Lyfons's Magna Britannia, 410. Berkshire. Beauties of England and Wales, vol. i. by John Britton and E. W. Brayley, 1801. The History and Antiquities of Reading, by John Mann, 1814.

From the latter work, the chief and most essential parts of this account have been obtained: and those who wish to poiffe the most copious and authentic history of Reading will procure this volume.

Reading, a township of America, in Fairfield county, Connecticut, S. of Danbury adjoining. It contains 1717 inhabitants. — Also, a large township of Middlesex county, in the flate of Massachusetts, incorporated in 1644, and containing 2285 inhabitants, many of whom are employed in the manufacture of shoes, from 2 to 300,000 pair being annually exported; 12 miles N. of Bolton. — Also, a township of Vermont, in Windfor county, W. of Windfor, adjoining. It contains 1565 inhabitants. — Also, a beautiful poll-town, and the capital of Berks county, Pennsylvania, situated on the N. E. side of Schuykill river; 54 miles N.W. of Philadelphia. This town is regularly laid out, and flourishes; its inhabitants are chiefly German: the borough and township contain 3462. The public buildings are a town hall, a court-house, an elegant church for German Lutherans, erected in 1793, a church for Calvinists, one for Roman Catholics, a meeting-house for Friends, and a large edifice for the public offices. In the township are 30 fulling mills, and several iron-works; and at the distance of 10 miles, on the road to Harrisburgh, is a spring, about 15 feet deep and 30 feet wide, from which issues a copious stream, containing some fine trout. In 1792 the sum of 12,000$ was voted by the county for building a stone arch bridge over the Schuykill, at this town, on the high road to Harrisburgh. N. lat. 40° 21'. W. long. 75° 55'. — Also, a township of Adams' county, in Pennsylvania, containing 732 inhabitants.

Reading. See Lectio. Reading of a Deed. See Deed.

Readings, in Criticism. Various readings, variae lectiones, are the different manners of reading the text of authors in ancient manuscripts; where a diversity has arisen from the corruption of time, or the ignorance of copyists.

A great part of the usefulness of the critics lies in settling the readings, by confronting the various readings of the several manuscripts, and considering the agreement of the words andsense. The various readings in the bible, (see Hebrew Bibles,) and in the classical authors, are almost innumerable.

Readings are also used for a fort of commentary or glosss on a law, text, passage, or the like; to shew the sense an author takes it in, and the application he conceives to be made of it.

Readington, or Riddexton, in Geography, a town of New Jersey, in Hunterdon county; 17 miles N.W. by W. of New Brunswick. It contains 1797 inhabitants.

Read's Bay, a road for ships on the W. coast of the island of Barbadoes, between Holkew and Speight's-town; half a mile broad. Ships may anchor here in safety, in six to twelve fathoms water, the ground being soft ooze, defended from all winds, except the west, which blows right into the bay. N. lat. 13° 47'. W. long 59° 47'.

Read's Borough, or Reed'sborough, a poll-town of America, in Bennington county and state of Vermont; 435 miles from Washington. It contains 420 inhabitants.

Re-afforested, is where a forest, having been defaflored, is again made a forest. As the forest of Dean was, by an act of parliament in the 20th of king Charles II. See Forest.

Re-aggravation, in the Romish Ecclesiastical Law, the last monitory, published after three admonitions, and before the last excommunication.

Before they proceed to fulfill the last excommunication, they publish an aggravation, and a re-aggravation. Peverel observes, that in France the minister is not allowed to come to re-aggravation, without the permission of the bishop or official, as well as that of the lay judge. See Excommunication.

Reah, in Geography, a town of Syria, in the pahaliche of Aleppo, situated in a country that abound with olives, of which considerable quantities are prepared, and sent to Peru and other parts. This is the residence of an Aga; 30 miles S.S.W. of Aleppo.

Real, Reale, is applied to a being that actually exists; in which sense it coincides with actual.

Real, in Law, is opposed to personal.

Real Action, that by which the plaintiff lays title to land, &c. See Action.

Customs are said to be real; that is, they determine all inheritances within their extent; and none may dispose of them, but according to the conditions allowed by the customs where they are situated.

Real altitude, aetts, character, chattels, covenant, distinction, dyzyrfs, estate, horizon, opitc placr, patronage, privilege, qualities, root, services, suit, and writs. See the several substantives.

Real, in Commerce, a Spanish money of account, of which there are four different forts. The real vellon is that which is most general; it consists of 8½ quarters, 17 ochoas, or 34 Maravedis vellon. Madrid, and the whole of Castile, with most of the adjacent provinces, and to Bilboa, Malaga, and Gallicia, keep accounts in reals and Maravedis vellon. The real of new plate (real de plata nueva, or provincial) is double the real vellon; it is worth 17 quarters, or 34 ochoas; and it is also reckoned at 34 Maravedis of new plate. This real is represented by an effective coin of base silver, but books are not kept in any part of Spain in this money.

The real of old plate (real de plata antigua), mostly called the real of plate, is chiefly used in foreign commerce and exchanges; it is worth 16 quarters, or 32 ochoas; and it is also reckoned at 34 Maravedis of old plate. Cadiz and Seville keep accounts in reals and Maravedis of old plate.

The real of Mexican plate (real de plata Mexicano) is used in transactions with Spanish America, where accounts are mostly kept in hard dollars, reals, and quarters, and sometimes in sixteenth: 8 Mexican reales make 1 hard dollar (pleno duro); this coin is worth 10 reals of new plate, 10½ reals of old plate, or 20 reals vellon. Thus, 1 real of new plate = 2 reals vellon: and 4 reals Mexican

REAL, or Reali, is also a name of account at Leghorn.
At Zante, and also Cefalonia and Corfu, accounts are kept in reali, of 10 lires, or 100 soldi, also called aspri.

REAL
is the name of a kind of boat in some places.
REAL el Novitas, in Geography. See Novita.
REAL Nuevo, a town of Mexico, in the province of New Biscay; 120 miles N.W. of Parral. N. lat. 29° 10'. W. long. 107° 20'.
REAL del Rosario, a town of Mexico, in the province of Chiaetlau, on the Spiritu Santo; 24 miles N. of Chiletlan.

REAL de Frayles, a town of New Mexico, in the province of Mayo; 60 miles from Santa Cruz. N. lat. 27° 44'. W. long. 110° 22'.

REAL de Minas, a town of New Navarre; 180 miles S. S.E. of Cafa Grande.

REAL de St. Juan, a town of New Navarre; 195 miles S. S.E. of Cafa Grande.

REAL, Knights of the, or Knights of the Lion, owed their institution to the following event. Laditraus, son of Charles Duras, having been proclaimed and crowned king of Naples at Gata, the Neapolitans set up Lewis II. duke of Anjou, and laid the foundation of the bloody wars that followed. These troubles divided the Neapolitan nobles into two factions; and of those who declared for the house of Anjou, some wore on their left arm a golden reale embroidered or on a red ground, by way of contempt to queen Margaret, widow of Charles III. who wanted to hold the reins of government during the minority of Laditraus, and called themselves "knight of the Reale;" whilst others wore on their breast the figure of a "lion, with her feet tied," pendant to a ribbon which paffed round their necks, indicating by it, that they looked upon queen Margaret as tied by the leg; and then styled themselves "knight of the Lion." The same.

REALICO, in Geography, a town of Mexico, in the province of Nicaragua, situated on a bay of the Pacific ocean, at the mouth of a river, both of the same name. The river is so deep and capacious as to be capable of receiving 200 fall of ships. The town is defended by large intrenchments, and very fine docks for building and repairing ships; but the place suffered considerably from the Buccaneers. The town is large, has three churches, and a hospital; but the place is unhealthy, on account of the creeks and flinking swamps in its vicinity. Its chief trade consists in pitch, tar, and cordage. At the mouth of the harbour is an islet, which intercepts the sea, and renders it safe and commodious; it forms two channels, but that on the N.W. side is much the best; 18 miles N.W. of Leon. N. lat. 12° 45'. W. long. 87° 30'.

REALGAR, in Mineralogy, sometimes called red orpiment, an ore of arsenic, consisting, according to Theronas, of 75 parts arsenic, 25 sulphur. The colour of realgar is a bright deep red, paffing into scarlet and orange; it occurs both massive, and crysallized in prisms, which have either 4, 6, 8, 10, or 12 fides, terminated by four-sided sumsits. The primitive form of the crysall is an octahedron, with faceal triangles. The fulce of realgar is between vitreous and waxy; it is semi-pellucid, soft, fragile, and easily fusible, burning in the air with a blue flame, and giving out arsenical and philphurous vapours. By friction it becomes negatively electrical. Realgar is found in the vicinity of volcanos, and accompanying other metallic ores, both in primitive and secondary mountains. This fulce is used as a pigment; and is formed by the Chinese into toys. See Sulphated Arsenic under Arsene.

In the history of the French Academy, we have an account of a cup brought to Paris by the ambassadors of Siam, and presented there, as a remedy used by that people against all diseases.

Upon an examination, which had like to have cost M. Homberg dear, he found it to be a kind of realgar, or red arsenic, much more caucic than our's.

Its use among the Siamese, he takes to have been the same with that of regulus of antimony; viz. to give an emetic quality to the wine drank out of it.

As the dofe of medicines is much stronger in the torrid zone than among us (the quantity of specie cania, e. g. ordinarily taken by the Indians, being twenty times as great as that among us), it is very poifible a cup of realgar, thoughe enough to poison a European, may prove a gentle medicine to a Siamese.

REALIJO, in Geography, a small island in the Pacific ocean, near the coast of Popayan. N. lat. 4° 16'.

REALIZE, in Commerce, a term little known in trade before the year 1719, when those immense fortunes began to be made in France and England, by the business of actions or stock.

By realising is meant the precaution many of those who had gained a fortune, took, to convert their paper into real effects: as lands, houses, rich moveables, jewels, plate, but, above all, into current species. A precaution capable of ruining the late; but the French regency had the wisdom to frustrate it, by taking proper measures to have the money, thus ready to be hoarded up, returned to the public.

REALISTS, REALISTE, a sect of school-philosophers who followed the doctrine of Ariflotle with respect to universal ideas, formed in opposition to the Nominalists, (see that article,) who embraced the hypothesis of Zeno and the Stoics upon that perplexed and intricate subject.

Aristotle held, against Plato, that, previous to, and independent on, matter, there were no universal ideas or effects, and that the ideas or exemplars which the latter supposed to have existed in the divine Mind, and to have been the models of all created things, had been eternally impressed upon matter, and were coeval with, and inherent in, their objects. Zeno and his followers, departing both from the Platonic and Aristoteliam systems, maintained, that these pretended universals had neither form nor essence, and were no more than mere terms and nominal representations of their particular objects.

Under the Realists are included the Scotists, Thomists, and all excepting the followers of Occam.

Their distinguishing tenet is, that universals are realities, and have an actual existence, out of an idea and an imagination; or, as they express it in the school-language, a porte rei; whereas the Nominalists contend, that they exist only in the mind, and are only ideas, or manners of conceiving things.

Doctor Odo, or Ourdard, a native of Orleans, afterwards abbot of St. Martin de Tournay, was the chief of the sect of the Realists. He wrote three books of dialectics; where, on the principles of Boethius and the ancients, he maintained that the object of that art is things, not words; whence the sect took its rite and name.

REALITY, REALITAS, in the Schools, a diminutive of res, thing, first used by the Scotists to denote a thing which may exist of itself, or which it a full and absolute being of itself, and is not considered as a part of any other.

Yet, a reality is conceived as something less than res; and accordingly every res is supposed to contain a number of realities, which they otherwise call formalities.

Thus, e. g. in a man, according to the doctrine of the Scotists, are a number of realities; viz. a substance, life, animal, and reason.

Some
Some distinguish reality into subjective and objective.

REALM, Renown, Kingdom, a country which gives its head or governor the denomination of king.

The word is formed of the French royaume, which denotes the name.

REALMONT, in Geography, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Alby; 9 miles S. of Alby. The place contains 22,477, and the canton 83,497 inhabitants, on a territory of 247½ square miles, in 19 communes.

REALVILLE, a town of France, in the department of the Lot; 8 miles N.E. of Montauban. N. lat. 44° 0'. E. long. 1° 34'.

REALM, a town of the Arabian Irak; 10 miles W. of Baffora.

REAMO, a town of Naples, in Abruzzi Ultra; 6 miles W.N.W. of Teramo.

REAMUR, a town of France, in the department of the Vendée; 18 miles N. of Fontenay le Comte.

REAMNG, a town of Bengal; 45 miles S. of Silhet.

REAPER, a person whose business is to reap or cut grain.

REAPING, the operation of cutting crops by means of the fickle. It is a very laborious sort of field-work, and one which requires considerable attention and care to perform it in a neat and exact manner. Reaping is performed with some other sorts of crops, besides those of the grain kind; as occasionally for peas, beans, flax, and others of a similar nature. Work of this nature is executed in many different ways, according to the differences in the customs of different districts; as by fets of men hired by the month, for this particular purpose, called harvet-men; by perfons taking it by the piece, or by the acre, and by the fheaf or fhouk of eight sheaves.

In some methods, by the piece or the quantity is unquestionably the bell, in most cases, on account of the very high prices which are exacted at this very busy season, and the very small extent of labour which is performed in working by the day, which cannot be controlled by the farmer at such hurried times. Besides, the work is, for the most part, the bell and most expeditiously performed in these ways; which are objects of very great importance, and deserving of much consideration in this sort of business. The eye of the farmer is, however, constantly necessary to see that all goes on in a right manner.

In the northern parts of Lancashire, this sort of labour is mostly performed by the day, or the hattock of ten sheaves, or the fhouk of twelve sheaves; three-pence being often paid for the former, and four-pence or five-pence for the latter, in these places.

In some districts, the reaping of the crops commences before they are quite ripe; but in others, not until this has fully taken place.

Reaping of Corn, the practice of cutting it with the fickle, or otherwise, by persons employed for the purpose. It may be observed, that the bushefs of reaping or cutting grain crops differs much in the manner of performing the work, in different districts of the kingdom, and kinds of crops. In the more southern parts of the island, the crops of this sort are mostly cut by means of short stiff fectyes, made for the purpose, having bows formed of bent ficks, or what in some places are termed cradles, fixed upon the lower parts of the handles, for the more readily depositing the ears or heads of the corn in one uniform direction, as much as possible, in order that it may be afterwards bound up into sheaves. But in other cases, the naked fectye is made ufe of; the corn being feldom bound up, being simply raked together into small heaps, in a similar manner to hay.

In the more northern parts of England, and in Scotland, the reaping of grain crops is, however, in general performed by the fickle, or reaping hook; the different handles, as soon as cut, being deposited upon boards, formed by twirling together a few fliks of the corn at the end, next the ears, and afterwards bound up into sheaves, in order to their being set up into flocks or hallocks. This method is, in most instances, adapted with the wheat and rye crops, in every part of the island; as in cutting them with the fectye, it is difficult to be performed without much loss being sustained by the shedding of the grain. And, in addition, it is of great advantage to have these sorts of crops bound up regularly into sheaves, the straw being much better.

Besides these, there is another mode sometimes practised, which is by means of a hook with a sharp edge, without any teeth; the labourer, in executing the work, hooking up the corn towards him. It is mostly made use of in the southern districts, where it is known by the name of lagging, the grain in this way being cut very low.

In this way the reaper collects enough for one sheaf at a time, binds it, and sets it up in tens, called a shock in Middlesex. This lagging (or fagging) practice is, to all intents and purposes, mowing with one hand against the standing corn. The toothles hook, employed in doing it, is of nearly twice the weight of the common fickle. It is sharpened occasionally, when necessary, in the manner of the fectye; and the operation of cutting the crop down is by a succession of blows made upon the flack of the standing grain, very nearly in the direction down towards the surface of the ground. Reaping in Middlesex is mostly all done in this way, as the proper ufe of the fectye is but little known.

This method has the advantage of being done closer, and with equal or more expedition than the hand reaping mode, besides the saving in flack, which is here supposéd worth 7s. the acre.

In Essex wheat crops are generally reaped or cut with the fickle, though in the vicinity of the metropolis it is not uncommon to have it mown with the fectye, as close to the ground as other sorts of grain crops, in the view of increasing the quantity of flack, which is there very valuable. It is thrown, in these cases, with great skill and dexterity into swaths. When perfectly ripe, it is soon bound up into sheaves of fix or eight inches diameter, with bands of wheat-straw of single or double lengths; but when not in this ripe or dry state, it is allowed to remain in the swaths two or three days, as necessary. However, in more than three quarters of the county, it is reaped or cut with the fickle; and indeed in almost all places, when beaten down by the wind and rain.

In regard to the time of reaping the grain, there is considerable difference in different districts; some not reaping it until it is quite ripe, while others cut it when something short of this state. This, however, should probably be regulated by the nature of the season, and the kind or quality of the crop, as well as the ufe to which the grain is to be put.

In respect to the manner of reaping grain crops, whether the fickle or fectye be employed for the purpose, there is much difference in the height at which the crops are cut in different places. In some it is the practice to have the bushefs performed in as close a manner as possible; while in others a flubble of eight, ten, and fifteen inches, or more,
is left. These different practices have their advocates; one party supposing that the work proceeds more slowly, where it is executed in so close a manner; while the other contend that the contrary is the case. But as the fluff which is left is not only useless to the land, but in many cafes very troublesome in its succedding culture, being frequently under the necessity of being removed, it would seem to be the best as well as cheapest practice, to have the bufnesses constantly executed in a close manner. It has been observed by a late practical writer, that by this means the agriculturist will not only have more litter at command, for the bedding of his yards, flails, and other places, and consequently an increase of manure, but have the buffetness more expeditiously performed, with much less waste of grain, and at the same time be freed from the trouble and expense of removing the fluff. It has indeed been fully shewn, by a careful trial, made with the view of ascertaining the difference between high and low reaping, that the advantage is considerably in favour of the close method.

And the result of the trial is thus stated by the writer of the Agricultural Survey of the West Riding of Yorkshire, who observes that the experiment was made upon part of a field of wheat, two ridges of which were cut close by the ground, and the other two considerably higher, though not so high as the general run of the Yorkshire fluffles. Each of the divisions was apparently of equal quality, and measured a traverse of about a quarter of a Scotch acre, which is about one-fifth larger than the English statute acre. The crop was flacked separately, and the time taken to the part cut low was one hour and forty minutes, of eight hourers; while the high cutting was performed by the same number of hands in forty-eight minutes. The wages paid that week were 18d. per day, and the supposed expense of maintenance 6d. or 2s. per day together. When threshed, the grain and straw were carefully measured and weighed, and the result of the experiment was as follows:

\[
\begin{align*}
\text{Reel} & \quad 8 \text{ hourers}, 1 \text{ hour } 24 \text{ minutes, at } 2s. \quad \text{per day, or } 23\frac{1}{4} \text{ d. per hour} \\
& \quad \text{The same hands in } 48 \text{ minutes} \\
\text{Difference of expense} & \quad 0 \quad 1 \quad 0
\end{align*}
\]

In favour of high cutting one shilling, or four shillings per acre.

\[
\begin{align*}
\text{1} & \quad \text{ peck of wheat more upon the low cut} \\
& \quad \text{ridges than those cut high, at } 1\text{ peck.} \\
& \quad 1 \text{ bushel }(22 \text{ avoirdupois pounds}) \text{ of straw, at } 2 \text{ d. per bushel} \\
& \quad \text{Or six shillings per Scotch acre.}
\end{align*}
\]

From which deduct the increased expence of cutting, there remains a benefit of twelve shillings per acre in favour of low cutting.

It is noticed farther, that in the above trial, according to the boat of the reporter's judgment, was fairly made; and the reason which urged him to make it, was to shun the objections of some neighbours, who alleged low reaping was not profitable. It is also proper to observe, that the field of wheat, on which the trial was made, was not broken down or straggled, so was in a favourable condition for high cutting. We have seen wheat-fields, where three times the quantity might have been left, unless great pains were used.

But the methods of reaping grain crops, both with the sickle and the fythe, have each their advantages and disadvantages. In the first manner, the crops are deposited with more regularity and exactness, and consequently bound into sheaves with greater facility and dispatch. Besides, in many cafes lefs loss is incurred by shedding, in the time the work is in performing; but the labour is executed with greater difficulty and trouble. The latter polishes the superiority of being more expeditious, and of being performed to any degree of cleannesses that may be required; while it has the evident disadvantage of leaving the cut grain in a more irregular and uneven situation, by which it is rendered lefs fit for being bound up into sheaves, which in many cafes is an inconvenience of great consequence. When the grain has attained a high degree of ripeness, there may likewise be great loss suffered, by its being siled during the operation, in this way of reaping and cutting the crop. Where this method is practised, it is, however, not unfrequently the cafe to have it bound into sheaves; though the most common custom is to let it remain in the rows or swaths, till fit for being put into the stack. When bound, it is generally the practice to cut it inwards against the crop on which it rests: in the other cafe, it is cut in the manner of grass for hay.

It is obvious, therefore, that when labourers are procured with difficulty, this mode of reaping is the most advisable; while, under the contrary circumstances, the former may be had recourse to with more advantage, as the work may be executed in a neater and more exact way. See Harvesting and Sickle.

It may be remarked, that this is a sort of work that is often let by the acre to perfons that go about for harvest work; and it may, in many cafes, be the belt performed in this manner. But great attention should be paid by the farmer, to see that the grain is cut and bound up in a proper method, and that the work be not performed in improper weather. The prices vary according to the nature of the crops, the season, and other circumstances, sometimes rising as high as eleven or twelve shillings the acre, and sometimes much higher.

Reaping Fork, a tool of the fork kind, invented for the purpose of raking and collecting the mown grain into sheaves, so that it may be bound up. It is constructed with two, rather long, prongs below, slightly curving upward, somewhat in the manner of the common large hay fork, to which are attached, at the upper part, near the insertion into the handle, two other upright prongs, which bend a little forward towards their tops or ends; by means of these, with the under prongs running along the ground, the tool being pushed forward by the labourer, the grain in the straw is raked up, brought togethet, held in a firm manner, and removed from the swathe so as to be bound into sheaves. In this way, the lower prongs perform the work of picking the strawy material from the land, while the higher upright ones prevent it from falling backwards, and determine the quantity which is necessary for a sheaf. In this manner, by this simple contrivance, the mown grain can be brought together and bound up with much greater regularity, and in a much more expeditious method than is possible to be done by mere hand labour.

Reaping Hook, an implement of the sickle kind, with which the buffness of reaping is performed in some districts. These hooks are sometimes formed with teeth, or in a toothed manner, and sometimes with a cutting edge. In Devonshire, and some other counties, those with smooth edges are generally preferred to sickles with fawed ones:
these sorts of hooks are used occasionally with either hand, the operator shifting hands, chopping the straw low down, and gathering about half a sheaf at a time, which, when put together, is bound with reed, combed from former wheat-straw, or with a double length of the wheat which is reaping. See Sickle.

Reaping Machine, a contrivance for the purpose of reaping grain by means of animal labour. With this view, and to facilitate an operation of such importance to the farmer, different attempts have been made to construct machines, so as to dispatch the work in a rapid manner by the assistance of horse labour, but the success with which they have been attended, has hitherto been far from complete. An implement of this sort has lately been made by Mr. Plunkett; it is upon a somewhat new principle, the horse drawing the machine instead of pushing it forward, as was the old mode of applying the power.

In this machine, the horse works from the front side of it, which is seen at once by the appearance of the implement, so as to be clear of the crop, and the two large wheels, by means of the axle, drive another wheel, which communicates with the other two wheels, the latter of which is found in the axis of the cutter; a man at the handles regulates the direction, &c. This machine may be seen fully represented in the second volume of the Farmer's Dictionary; and a reaping machine for clover may be seen in the same work in the same plate.

Other machines of this kind have still more lately been invented by other persons, but without answering the purpose in that full and complete manner which is necessary in this sort of work.

What appears to be chiefly wanting in these sorts of machines, to render them complete and effectual, as tools for the purpose of reaping, is that of having more power or velocity in the cutting parts, so that the work may be performed in a perfectly clean manner, without the straw being drove or forced down in an improper manner before the instruments which are to cut it; their cutting it out fully in the whole of its breadth; their being capable of being regulated to cut at different heights, and to different breadths; their being made capable of directing the cut straw grain all in one even regular direction, so that it may be bound up with facility; the horses, or other animals, being so attached to them as to permit of their walking along on the side of the standing grain, where the former cut was made, or where they put the implements before them, the having them so conveniently fixed in them as to admit of no sort of interruption to the labour in any way; their being made light and of ready application, as well as at a cheap rate; and their keeping the fethes or cutting parts in a perfectly sharp state, without their being taken out, and undergoing the operation of whetting. There are, besides these, some other points, which should be attended to, but these are, probably, the most material.

Reaps, small parcels of corn, laid along on the flubble, in reaping, to be afterwards gathered into sheaves by the binder. This is most commonly the case, when the weather is moist, as in dry times the reaps of corn are usually laid in the bands, and tied up, as soon as they are in sufficient quantity, into sheaves.

Rear, a term frequently used in composition, to denote something behind or backward in respect of another; in opposition to one, or another, before.

It is formed by corruption of the French arriere, signifying the same.

Rear, in a Military Sense, is used for the hind-part of an army, &c. in opposition to the front, or face of it.

Rear, in Naval Language, is a name given to the hind division of a squadron, or the half squadron of a fleet, and which is accordingly commanded by a rear-admiral, or the third officer of the said fleet or squadron.

Rear-admiral. See Admiral.

Rear-guard. See Guard.

Rear-half-sheets, are the three hindmost ranks of a battalion, when it is drawn up fix deep. See File-leaders.

Rear-line of an army encamped, is always twelve hundred feet at least from the centre line, both of which run parallel to the front line, and also to the rear.

Rear-rank, is the hind rank of a battalion, or squadron, when drawn up, and generally sixteen or eighteen feet from the centre line, when drawn up in open order.

Rear-up, in the Manege, called in French caber, is the action of a horse, when he raises himself upon his houghs or hinder legs, as if he would fall quite over in a backward direction, to the great danger of his rider. This is often caused by his having too much of the curb.

Rear, in Rural Economy, to raise the roof part of any fort of field or other building for containing some kind of live-stock.

Rear'd, or Wake-reared. See Wake-reared.

Rearing Animals, in Agriculture and Rural Economy, the business of breeding and bringing them up to the most suitable rates for the purposes of the farmer. The principles of this art depend upon a variety of different circumstances and kinds of knowledge, as has been already explained. See Breeding, and Live-stock.

Animals of the horse kind should invariably be brought up in the bell manner, without any sort of linting in their food, according to the uses they are designed to serve, in order that they may have their full growth and power. In the labouring cattle kinds of animals, attention should, in some degree, be paid to hardiness, both in their food and their exposure, by having recourse to the more coarse sorts of feeding in the left sheltered situations, but nothing of linting should ever be allowed, as by these means they become large, and capable of sustaining a greater degree of exertion. There is, likewise, much utility in good training, in rearing all sorts of animals in this intention; and it requires careful, steady, mild performers to be employed in it, as they, for the most part, acquire the habits and dispositions of those about them, in some measure; and the more early they are obtained the better. This point deserves much more attention from farmers and others than it has hitherto met with, as most of the bad habits of working animals arise from the neglect of it. Besides, good training and mild dispositions are highly favourable to fattening animals. See Horse.

In rearing poultry, pigeons, rabbits, and fish, much care, management, and circumspection, are constantly necessary, in order to their perfect success. Too little attention is for the most part bestowed on the nature of the birds, in some sorts of the more wild poultry kinds, as those which are of the game description, for instance, the galena, the pheasant, the fwan, and some others. These cannot be so readily reared, or with so much facility, under hens of the domestic kind, as other sorts are, such as the turkey, peacock, &c. This circumstance should therefore be always kept in mind in rearing such birds. See Poultry, Pigeons, Rabbit, &c.

A very nice attention and management is also requisite in the rearing and perfecting of fish. See Fish, Pond-Fisheries, and Salmon Fishery.

In rearing birds of the game kind, such as the above, in the way of ornament about a residence, Mr. Loudon has remarked, much depends upon encouraging them, when allowed
Abundance often (land, finds such garden as, tho' of the cerea trels, chervil, parsley, thyme, and some other kinds. They have likewise a tendency to encourage and domesticate labors. Abundance of feral land is a great part of the office of reason; and that about which it is usually employed; yet the principal act of reflection is the finding the agreement or disgression of two ideas, one with another, by the intervention of a third. As a man, by a yard, finds two houses to be of the same length, which could not be brought together to measure their equality by just proportion. Words have their consequences as the signs of such ideas, and things agree or disagree with what they really are; but we observe it only by our ideas.

Hence we may be able to form an idea of that ordinary disillusion of things, into such as are according to, those that are above, and those contrary to reason.

Those according to reason are such propositions, whole truth we can discover by examining and tracing those ideas we have from sensation and reflection, and by natural deduction find to be true or probable.

Those above reason are such propositions, whole truth or probability we cannot by reason derive from those principles.

Those contrary to reason are such propositions as are inconsistent with, or irreconcileable to, our clear and distinct ideas.

Thus the existence of one God, is according to reason; the existence of more than one God, is contrary to reason; and the resurrection of the body after death, above reason. Above reason may be also taken in a double sense; or above probability or above certainty.

They who dispute most against the power and privileges of human reason, do it because their own reason persuades them to that belief; and so, whether the victory be on their or our side, they are equally defeated.

They seek to terrify us with the example of many great wits, who, by following this ignis fatius (so they call the only polestar God has given us to direct our course by), have fallen into wild and ridiculous opinions, and incited the catalogue of heresies to so great a number; but these men either followed not their reason, but made it follow their will; or else they first hoodwinked it by interest and prejudice, and then made it shew them the way; or were wanting in those necessary diligences required for so doubtful a passage: or if, without any of these, the weaknesses of their understanding had deceived them, the error is neither hurtful to themselves, nor would be to others, if this doctrine of governing ourselves by our own reason, and not by authority and example, were generally establisht. Dif. Concern. Hum. Reaf.

It is not the use of such liberty, but the appropriating it to ourselves, that is the cause of all the disorders charged upon it. For those who lay a restraints on other men's reason, have first made use of their own to fetle them, and to make use of it in this very restraining of others. Ibid.

Reason, in Matters of Religion, is used in opposition to faith.

This use of the word, Mr. Locke takes to be itself very improper; for faith is nothing but a firm assent of the mind; which, if it be regulated, as it is our duty, cannot be afforded to any thing but upon good reason, and so cannot be opposite to it.

He that believes without having any reason for believing, may be in love with his own fancies; but he neither seeks truth as he ought, nor pays the proper obedience due to his Maker, who would have him use those discerning faculties he has given him, to keep him out of mistake and error.
But since reason and faith are by some men opposed to one another, it may be necessary to consider them together.

Reason, as contrariwise to faith, is the discovery of the certainty or probability of such propositions, or truths, which it has got by the use of its natural faculties; viz., by sensation, or reflection.

Faith, on the other hand, is the assent to any proposition upon the credit of the proposer, as coming immediately from God; which we call revelation, which see.

Reason, in Logic and Rhetoric, denotes a necessary or probable argument; or an answer to the question, cu? cef? why is it?

As if it be inquired, why do the subject and predicate agree? and it is answered, because they are spoken of the same thing: this last enumeration is a reason. Hence, say the schoolmen, because qua is the sign or character of a reason, as non, no, of a negation, and et, of an affirmation.

They make three kinds of reasons, rationes; viz. ratio ut, that; no, left; and qua, because. For, answering to a question, cu, why, we begin with because, qua; as, why do you study? that I may become learned; which is the ratio ut. Again, why do you study? left I should be ignorant; which is the ratio re. Lastly, why is a body tangible? because matter is impenetrable; which is the ratio quae.

The reason ut properly denotes the end, or final cause; and reason re the beginning; accordingly the one is called the reason, the other end; so that the reason qua is left the only reason, properly so called.

Reason, among Metaphysicians, is used in the same sense with effence; or that by which any thing is what it is.

This is sometimes also called formal reason, as representing the thing under that form or nature under which it is conceived.

Reason, in Mathematics. See Ratio.

Reason of State, Ratio Status, in Maters of Policy, denotes a rule or maxim, whether it be good or evil, which may be of service to the state.

The phrase is borrowed from the Italians, who first used ragione di fato in this sense.

Reason of state is properly understood of something that is necessary and expedient for the interest of the government, but contrary to moral honesty, or justice.

Politicians have a long time disputed about the ratio flatus; whether states and governments are tied down to the same laws of morality with individual persons; or whether things, otherwise immoral and unlawful, may not be practiced on urgent occasions, by way of reason of state?

The question is, whether any thing be unlawful, or prohibited a state, that is necessary to the preservation of that state, or whether it be allowed to preserve itself on any terms?

Reason, Challenge upon. See Challenge.

Reason sufficient of Leibnitz. See Leibnizian Philosophy.

Reasonable Aid, a duty which the lord of the fee anciently claimed of his tenants, holding in knight's service, or on foggage, towards the marrying his daughter, or the making his eldest son knight.

This is taken away by Stat. 2 Car. II. See Aid.

Reasoning, Ratification, the exercise of that faculty of the mind called reason: or, it is reason deduced into discourse; which see.

The agreement or disagreement of two ideas does not appear from the bare consideration of the ideas themselves, unless some third be called in, and compared, either severally, or conjointly with it: the act, then, by which, from ideas thus deduced and compared, we judge this or that to be so, or not so, is called reasoning. Or, it is that operation of the mind, by which we infer one thing, i.e., one proposition from two or more propositions premised. Or, again, it is the drawing of a conclusion, which before was either unknown, or dark, or doubtful, from some propositions which are more known and evident. It is the narrowths of the human mind which introduces the necessity of reasoning; for if the mere perception and comparison of two ideas would always show us whether they agree or disagree, then all rational propositions would be matters of intelligence, or first principles, and there would be no use of reasoning, or drawing any consequences. But when we are unable to judge of the truth or falsehood of a proposition in an immediate manner, by the mere contemplation of its subject and predicate, we are then constrained to use a medium, and to compare each of them with some third idea, that by seeing how far they agree or disagree with it, we may be able to judge how far they agree or disagree among themselves. Watt's Logic, part iii. chap. 1.

Rehault defines reasoning to be a judgment depending on some antecedent judgment; thus, having judged that no even number can be composed of five uneven numbers, and that ten is an even number; to conclude, that ten cannot be divided into five uneven parts, is a ratiocination, or reasoning.

This agrees with Father Malebranche's doctrine, one of the great points of which is, that reasoning, on the part of the underliner, is only a mere perceiving.

That ingenious author endeavours to shew, that, as to the underliner, there is no difference between a simple perception, a judgment, and a reasoning, except in this, that the underliner perceives a simple thing without any relation to any thing else, by a simple perception; that it perceives the relations between two or more things in a judgment; and, lastly, that it perceives the relations that are between the relations of things, in a reasoning. So that all the operations of the underliner are no more than mere perceptions.

Thus, e.g. when we conclude, that 4 being less than 6, twice 2 being equal to 4, are of consequence less than 6, we do no more than perceive the relation of the inequality between the relation of twice 2 and 4, and the relation of 4 and 6.

The manner of proceeding justly in reasoning; so as to arrive with the greater safety at the knowledge of truth, makes what we call method.

For the real benefit of logic to reasoning, see Logic and Syllogism.

Re-attachment, in Law, a second attachment of him who was formerly attached, and dismissed the court without day, by not coming of the justices, or the like customary.

Brook makes re-attachment either general or special. General is where a man is re-attached for his appearance on all writs of affize lying against him: special, for one or more certain writs.

Reau, in Geography, a town of Germany, in the principality of Culmbach; 9 miles S.E. of Hof.

Reave, in Rural Economy, a provincial term, used to signify the unroofing or disturbing the thatch or other covering of a building by winds, &c.

Reaumar, Rene Antonoine Ferchaud, Sieur de, in Biography, was born in 1683 at Rochelle. He was brought up to the study of the law, which he quitted for that
that of the mathematics, natural history, and natural philosophy. In 1703 he went to Paris, and to distinguish himself in a few years, that in 1708 he was admitted into the Academy of Sciences. From that time he entirely gave himself up to the pursuits of natural history in all its branches, and few men have puffed a life more actively and usefully employed. Utility was the constant aim in all his enquiries, even to the most minute parts of nature; and experiment and observation were his perpetual guides. No one surpassed him in the patient industry with which he observed natural phenomena, or followed the proceedings of art. The Memoirs of the Academy of Sciences, from 1709 to 1756, are enriched with his communications. The improvement of manufactures was a great object of his attention. In 1722 he published a work, entitled "L’Art de convertir le Fer forgé en Acier, et L’Art d’adoucir le fer fondus," which contained a minute and scientific account of the processes employed in that branch of manufacture, with hints for their improvement. He introduced into France the manufacture of tinned iron, which article had before been imported from abroad; and he made a great many experiments in the manufacture of porcelain, which contributed to its perfection in France. He also performed numerous experiments relative to the art of hatching chickens by artificial heat, as practised in Egypt, an account of which he published in two vols. 1752. M. Reaumur rendered his name celebrated by his peculiar method of graduation on the thermometer, which is still the one only used in France and many parts of the continent. In this thermometer the freezing point is marked zero, and the boiling point at 80°. (See Thermometer.) Some of the most valuable of Reaumur's physiological experiments were those relating to the concussive powers of the flambe in granivorous and carnivorous birds, in which he clearly establishes the different modes of action in these two classes, viz. by trituration, and by solution. In natural history, he acquired the greatest fame as an entomologist. Besides a number of curious papers on this subject in the Memoirs of the Academy, he published a very elaborate work, entitled "Memoires pour servir à Histoire Naturelle des Insectes," in five vols. 4to. 1734—1742. This work was the labour of many years, and the result of innumerable observations made in his garden, in which he kept insects of all kinds, that he might examine their generation, changes, and mode of life. Reaumur was a man of much private worth, of mild and amiable manners, and correct morals. He died in 1757; at the age of 75. He bequeathed his manuscripts, and cabinet of national philosophy, to the Academy of Sciences.

REAUMURIA, in Botany, so called in honour of the great French naturalist, Rene Antoine Ferchault de Reaumur, principally known, as a botanist, by his examination of the fructification of Fuci, but chiefly celebrated as a philosophical inquirer into the history of insects, and their transformations, to which the specific name of the original species, vermiculata, evidently alludes. Linnaeus mentions Hadlequin as the author of the name Reaumuria; of which we can find no traces in his book, though the specimen of the plant in the Linnean herbarium, has some appearance of having been gathered by this distinguished Oriental traveller. Is it possible, that the Anonyma dubia, n. 15, of his Iter Palaezinum, 465, which his editor Linneaus could not make out, can be the Reaumuria? The description is not inapplicable, except what concerns the ilamens and style. Yet this does not make him the author of the name, though it may possibly account for Linneaus's mention of him in conjunction therewith. The latter appears, by his manuscripts, to have once defined Vermicularis for the generic appellation.—Linn. Gen. 276. Schreb. 371. Willd. Sp. Pl. v. 2. 1249. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 327. Juff. 316. Lamarck Illust. t. 489. Dict. v. 6. 84. Clas. & ord. Polyandria Pentagynia. Nat. Ord. Succulentia. Linn. Ficoidae. Juss. Gen. Ch. Cal. Perianth inferior, of five prominent, ovate, pointed, permanent leaves. Cor. Petals five, oblong, equal, spathulate, rather longer than the calyx, oblique, or lobed, at the extremity. Nectary of five double, fringed scales, at the meeting of the petals, attached to their lower part. Stam. Filaments numerous, capillary, the length of the calyx, inserted into the receptacle; Desfont. anthers roundish, incumbent. Pij. German superior, roundish; styles five, thread-shaped, erect, approaching each other, on a level with the filaments; stigma filiform. Peric. Capsule ovate, of five cells, with five flat, at length reflexed, valves; the partitions membranous, unconnected, deciduous. Seeds several, erect, oblong, entirely clothed with numerous, fleshy, simple hairs, twice their own length.

Eff. Ch. Calyx of five leaves. Petals five, with ten fringed scales at their base. Capsule of five cells, with five valves, and five deciduous partitions. Seeds several, oblong, hairy.

Obi. Specimens in seed, from professor Desfontaines, have enabled us to reconcile his account, and that of Linneaus, with the observation of Forfalk, that "the capsule has only one cell," the partitions being deciduous, and concealed among the hairy seeds. Not having examined the nectariferous scales, we have, inadvertent to Labillardiere's and Hooker's plates of the second species, made the description so general as to accord with both.

1. R. vermiculata. Saltwort-leaved Reaumuria. Linn. Sp. Pl. 754. Willd. n. 1. Forsk. Egypt. Arab. 101. Desfont. Atlant. v. 1. 431. Lamarck Illust. t. 489. f. 1. (Sedum ficulnum maritimum vermiculatum, flore Saxifraga alba, femine villoso; Bosc. Sic. 6. t. 4. f. 5. G. S. minimum arborecens vermiculatum; Lab. Ic. 380. Cali vermiculatum albo et amplio fede rote flore; Barrel. Ic. t. 588. Vermicularis frutescens minor; Ger. Em. 523; at least the figure, which is that of Lobel. The description accords rather with Solfada fimbriata, as cited by Hudson.)—Leaves linear-awl-shaped, convex beneath. Calyx entire.—Native of barren sandy ground towards the sea, in Sicily, Barbary, Egypt, and Syria, flowering in summer. The habit of the plant is like a Tamaria, or Solfada. Stem shrubby, bushy, much branched, round, smooth, whitish, leafy. Leaves numerous, scattered, sessile, from a quarter to three quarters of an inch long, spreading, linear-awl-shaped, acute, fleshy, smooth, glaucous; convex beneath; flat above; dotted on both sides with minute depressions. Desfontaines compares the leaves to those of Sedum reflexum. Flowers terminal, solitary, white, not unlike those of Saxifraga Gygosperma, each accompanied with a number of imbricated floral leaves, like those of the stem or branch, but longer. Calyx-leaves ovate, with a narrow, entire, membranous edge, and awl-shaped leaf-like point. Petals terminating in three fleshy lobes, well represented by Barrelier. Capsule brown, very smooth, and somewhat shining; its valves rigid, reflexed after the seeds are discharged, and permanent. Seeds clothed with long, tawny, shining hairs. Forfalk says this plant is used at Alexandria as a cure for the itch, being applied bruised externally, and taken internally in the form of a decoction. It is an elegant little shrub, well worthy of a place in our gardens, or green-houses, to which it is as yet a stranger.

rebate, or rabat, is usually regulated on the footing of 8 per cent. per annum.

The reason of this expedient is, that the merchants hav- ing not always wherewithal to pay for their goods in hand, by means of the rebate, such as have, will find their account in it; and such as have not will be engaged to dischar ge themselves as soon as possible, for the sake of the discount.

REBATEMENT, in Heraldry, a diminution or abate ment of the dignity of the figures or bearing in a coat of arms. See A BATEMENT.

REBEFE, in Commerce, a measure of corn in Egypt, particularly at Alexandria, equal to about 46 bushels; as kilos, another measure is equal to 46 bushels. English measure: 17.94 rebecs is equal to 10 English quarters, and each of them contains 9587 cubic inches; and 16,51 kilos are equal to 10 English quarters, and each contains 10418 cubic inches.

REBEC, a musical instrument resembling a fiddle, with a neck, finger-board, three strings tuned 5ths, and played with a bow.

Etymologists have tortured themselves to find a derivation for the name of a vulgar instrument, no longer in use. Some trace it from the Arabic, some from the Celtic, the Welsh, the Spanish, Italian, and old French. Indeed, so numerous, discordant, and unsatisfactory are their opinions, as neither to be worth writing, nor perusal, if we could give them a place.

Rebec and ribble seem to be the same instrument, and are often indiscriminately used by Gower, Chaucer, and the still more ancient bards of Normandy, and our own country.

As the head, or scroll-work, of old viol and violins was to be curiously carved, so seems to have been that of the rebece. Chaucer compares the face of an old woman, an old trot, to the head of a rebece. Revelais does the same.

A tel mineliérier tel rebec
Tenant toujours le verre au bec
Car elle avoit vilage de rebec."

REBECO, in Geography, a town of Italy, in the department of the Panaro; 29 miles S.W. of Modena.

REBEL, JEAN-FERRY, En, in Biography, one of the 24 violins of the king of France's band, and chamber compos er to his majesty. He beat time for many years at the opera, and, in his day, passed for a great composer. His music for dances is still heard with pleasure. His capricios, froux, and dancing characters, have enjoyed great reputation, in 1703 he set the opera of Ulysses, written by Guichard.
Rebel left two children: Francis, who died in 1775, and Anne, the wife of the celebrated Lalande, master of the king's band.

Rebel, FRANCOIS, knight of St. Michael, master, like his father, of the king's band, and director of the opera, born 1702, and died in 1775. He was the son of Jean-Ferry Rebel, director of the orchestra at the opera, and one of the twenty-four violinists of the king's band. His son had obtained the reward, in 1717, of chamber musician to the king, and in 1703, that of composer; having given proofs of his abilities by many different works, but, above all, by his "Pyramus and Thisbe," composed in partnership with Franccur.

He was successively appointed to all the musical posts of honour and profit under the royal patronage and that of the public. The close and uninterrupted friendship between this musician and Franccur, does honour to the memory of both; having composed jointly, for 50 years, successful pieces, without discovering to which of them the greatest honour was due. Laborde. See Franccur.

REBELLION originally signified a second resistance or rising of such as had been formerly overcome in battle by the Romans, and had yielded themselves to their subjection.

It is now generally used for a traitorous taking up of arms against the king, either by his own natural subjects, or by those formerly subdued; whether their view be to deprive him of the supreme authority, or whether they intend to repel his commands in some particular affairs, in order to impose conditions on him. Popular commotion is a conglomeration of people, tumultuously assembled, and revolting the voice of their superiors, whether their designs be against those inferiors themselves, or only some private persons. Such violent commotions are common when the people think themselves aggrieved, and are occasioned by no order of men so frequently as the tax-gatherers. (See the next article.) If the rage of the malcontents be particularly kvelled at the magistrates, or others veiled with the public authority, and they proceed to a formal disobedience or violent proceedings, it is called a "sedition." When the evil spreads, infecting great numbers in the city or provinces, and subsists in such a manner, that the sovereign is no longer obeyed, such a disorder custom has more especially distinguished by the name of "insurrection." All these violations disturb the public order, and are crimes of state, even when arising from just causes of complaint. For violent measures are interdicted in civil society; the injured party should have recourse to the magistrates, to whom they may apply for redress; and if justice be not obtained from them, their complaints may then be laid at the foot of the throne. Every citizen should even patiently suffer supportable evils, rather than disturb the public peace. Nothing less than a denial of justice from the sovereign, or affected delays, can excite the furious commotions of a provoked people; they in some measure justify themselves, if the evils be intolerable, and the oppressions great and manifest. But, it may be asked, what conduct shall the sovereign observe towards the insurgents? The reply in general is, that which shall at the same time be most consonant to justice, and most salutary to the state. If he is to repress those who unnecessarily disturb the public peace; he is, by the same reasoning, to swerve clemency towards unfortunate persons, to whom just cause of complaint has been given, and who are guilty only in having undertaken to do themselves justice; so that they have been wanting in patience rather than fidelity. The sovereign should consider that his rights are derived from those of civil society, from the trust reposed in him, from the obligation devolved upon him of watching over the welfare of the nation, of procuring its greatest happiness, and of maintaining in it order, justice, and peace. He will also duly distinguish the nature and degree of the different disorders which may disturb the state, oblig him to take arms, or substitute the means of force instead of those of authority. By considerations of this kind he will regulate his behaviour towards revolted subjects. It cannot be questioned, that subjects rising against their prince without cause deserve severe punishment; yet in this case the number of delinquents calls for the sovereign's clemency; shall he depopulate a city, or defolate a province, in punishing their rebellion? Such a chivalry, however just in itself, becomes a cruelty when extended to so great a number of persons. Had the insurrection of the Netherlands against Spain been totally unwarrantable, every man of virtue would still exacerbrate the memory of the duke of Alva, who made it his boast that he had caused above 20,000 heads to be struck off by the hands of the common executioner. Let not his fantastic imitators (says the excellent Vattel) expect to justify their enormities by necessity. Who was ever more unhesitatingly insulted by his subjects than Henry the Great of France? His conquests were ever accompanied by an uniform clemency, and at length that excellent prince obtained the success he desired: he thereby gained over faithful subjects; whereas the duke of Alva loft his matter the United Provinces. Tyrants alone will treat, as seditiously, those brave and resolute citizens, who exhort the people to preserve themselves from oppression in the vindication of their rights and privileges; a good prince will commend such virtuous patriots, provided their zeal be tempered with moderation and prudence. If he has justice and his duty at heart; if he aspires to that immortal and unfailing glory of being the father of his people; let him mistrust the selfish suggestions of a minster, who represents to him as rebels all those citizens who do not hold out their hands to chains, who refuse tamely to suffer the strokes of arbitrary power.

The safest, and the most just way thoroughly to appease sedition, is to give the people satisfaction; and if the insurrection has been without cause, which perhaps has never been the case, still an amnesty is to be granted where the offenders are numerous. When this amnesty is once published and accepted, whatever has been must be buried in oblivion. A prince who makes any confidence of his word, is faithfully to keep what he has promised to rebels themselves; i.e. to those subjects who have revolted without reason or necessity. If his promises are not inviolable, what security have the rebels in treating with him? When they have once drawn the sword, they have nothing to do but, as one of the ancients expresses it, to throw away the feaboard. The prince will then want the mild and salutary means of appeasing a revolt: to exterminate the rebels will be the only expedient remaining. These will become formidable through despair: compulsion will bow success on them; their party will increase, and the state will be in danger. Vattel's Law of Nations, b. iii. See Great War.

Rebels is sometimes also used, in our ancient statutes, for a person who wilfully breaks a law; and sometimes for a villain defying his lord.

REBELLION, Commission of. See Commission.

REBELLIOUS Assembly, a gathering of twelve persons, or more, intending, going about, or practising, unlawfully, and of their own authority, to change any laws of the realm, or to destroy the inclosure of any park or ground inclosed, banks of fish-ponds, pools, conduits, &c. to the intent the same shall remain void, or that they shall have way in any of the said grounds; or to destroy the deer in any park, fish in ponds, cones in any warren, dovehouses,
houses, &c. or to burn loads of corn, or to shake rents, or prices of victuals. See Riot, Rout, and UNLAWFUL Assembly.

REBENSOE, in Geography, a small island in the North sea, near the coast of Norway. N. lat. 70°.

REBHIANG, one of the Hebrew accents, answering to our comma, and enumerated among their kings and prophets. It is marked by a dot over the middle of a letter. See Ati-nach, Syllok, &c. See also Accents.

REBINARE, was to give a second stirring or ploughing to arable land that lay fallow, to prepare it for fowing wheat, &c. or to plough the ground a third time for that purpose. "Tempus rebinandi erit post feelim Nativitatis Iacti Johannis Baptifi cum terra pullulaverit post caru-
can." Fleta, lib. ii. cap. 73.

REBNITZ, in Geography. See RIBNITZ.

REBORDAOS, a town of Portugal, in the province of Tras los Montes; two miles S. of Bragança.

REBOUND. See REDOIl.

REBOUX, in Geography, a town of France, in the department of Mont Blanc; 9 miles N.W. of Chambery.

REBTOF, a town of Bavaria, in the principality of Aichittat; 3 miles W. of Aichittat.

REBUS, a name-device, as Camden enlights it; or an enigmatical representation of some name, &c. by using figures or pictures, instead of words, or parts of words. Such is that of the gannet mentioned by Camden, who expressed his love to Rofc Hill, by painting in the border of his gown a rofe, a hill, an eye, a loaf, and a well; which, in the rebus style, is read, Rofe Hill I love well.

The Picards have the honour of the invention of this notable kind of wit; whence the French, to this day, call it "rebuses de Picardie." Camden adds, that the English first learnt it of them in the reign of our Henry III. by means of the garrisons we then had in Calais, Guenee, and other places bordering on Picardy.

Its origin is by Menage, &c. ascribed to the priests of Picardy, who, it seems, anciently, in carnival time, used every year to make certain libels, entitled de rebus que geruntur, being ralleries on the intrigues and transactions that had passed about the city; in which they made great use of such fort of equivoces and allusions, breaking and joining words, andsupplying them with paintings.

Camden tells us, the rebus was in wonderful esteem among our forefathers; and that he was nobody who could not hammer out of his name an invention by this wit-craft, and picture it accordingly.

The Sieur des Accords has made an ample collection of the most famous rebuses de Picardie. And Mr. Camden has done something of the same kind in his Remains.

Abel Drukker's device in Ben Johnfons Alchemifl, and Jack of Newbury, in the Spectator, are known to every body. But the rebus, being once raised to fign-polls, grew out of fashion at court.

Yet has rebus antiquity on its side, as having been in use in the pure Augustan age; Cicero, in a dedication to the gods, inscribed Marcus Tulius, with a little pea, called by the Latins cicer, by us a chiek pea. And Julius Caesar, in fome of his coins, ufed an elephant, called Cefar in the Mauritian tongue. Add to thefe, that the two mint-masters in that age, L. Aquilus Florus, and Voconas Viti-
ulus, ufed, the first a flower, the second a calf, on the reverfe of their coins.

REBUS, in Heraldry, a coat of arms which bears an allu-
sion to the name of the person: as three cailles, for Caffle-
ton; three cups, for Butler; three cones, for Conifby; a kind of bearings which are of great antiquity.

Rebus is also ufed by the chemical writers, sometimes to signify four milk, and sometimes for what they call the ultimate matter of which all bodies are composed.

REBUTTER, from re, and the French bouter, to repel, or bar, in Law, the anwer of the defendant in a caufe to the plaintiff's fur-rejoinder.

The plaintiff's anwer to the defendant's rebutter, is called a fur-rebutter.

Rebutter is also when a man warrants any land or here-
ditament to another, and the perfon making the warranty, or his heir, fues him to whom the warranty is made, or his heir or allignty, for the fame thing: if his, who is fo fixed, pleads the deed or fine with warranty, and pray judgment, if the plaintiff shall be received to demand the thing which he ought to warrant to the party, against the warranty in the deed, &c. this is called a rebutter.

Again, if I grant to the tenant to hold fine impetitione vaffi, and afterwards implad him for walle, he may debar me of the action, by flowing my grant; which is likewise a rebutter.

REC, in Geography, a river of France, which runs into the Sarre, at Sarre Alb.

RECANATI, a town of the marquisate of Ancona; near which towards Macerata are seen the ruins of Helvia Ricina; a town built by the emperor Sept. Severus, and destroyed by the Goths; 8 miles N.N.E. of Macerata. N. lat. 43° 25’. E. long. 13° 39’.

RECANGED, in Rural Economy, a term provincially ufed to signify lifed or deficoloured in stripes.

RECAPITULATION. See PALINODY, or Retraction.

RECAPITULATION, in Oratory, &c. a part of the peroration, or conclusion; called also anæphaphaœsis.

Recapitulation is a summary of the preceding discourse; or a concise, tranfient enumeration of the principal things infifted on at large in it; by which the memory of the hearer is refrehed, and the force of the whole collected into one view.

An inftance of this may be given in the peroration of Cicero's Manilian; "Quæ, cum bellum ita necellarium fit, ut negligi non petit: its magna, ut accuratissime fit ad-
miniſtrandum; eum ei imperatorem praeficere popifitis, in quo fit eximia bellii scientia, singularis virtus, clariflimi auclitorum, egregia fortuna; dubitatibus, Quirites, quin, &c."

In order to constitute a good repetition or recapitulation, it must be short and concise; it is also convenient to recite things in the same order in which they were at first laid down; but sometimes a repetition is made, by running a comparison between the speaker's own argument, and those of the ad-
verse party, and placing them in opposition to each other; and this method Cicero takes in the conclusion of his third oration upon the Agrarian law. In some cases, when the dis-
cours is very long, and the arguments infifted on have been many, the orator only mentions such things which he thinks of least consequence, by laying that he omits or paffes over them, till he comes to what is of greater moment, which he repreffes more fully. Ward's Orat. vol. i. sect. 18. See Preferiion.

RECAPTION, RECAPIT, or Refpisil, in Law, is a remedy given to the party himself for an injury to his own property. This happens, when any one hath deprived another of his property in goods or chattels personal, or wrongfully detains one's wife, child, or servant; in which case the owner of the goods, and the husband, parent, or matter, may lawfully claim and retake them, wherever he happens to find them, so it be not in a riotous manner,
or attended with a breach of the peace. Thus, e.g., if my horse is taken away, and I find him in a common, a fair, or a public inn, I may lawfully seize him to my own use; but I cannot justify breaking open a private stable, or entering on the grounds of a third person to take him, except he be feloniously taken, but must have recourse to an action at law. Receptation is unlawful, if it be done with intention to frustration or compound a larceny. See Restitution of Stolen Goods.

Receptation also is the taking a second dilivery of one formerly delivered in the same cause, and also during the plea grounded on the former dilivery. Receptation is also the name of a writ lying for the party thus delivered to recover damages. See Replevin.

Recapture, in Naval Insurance, denotes the recovery of a ship, or its cargo wholly or in part, after having been taken by an enemy. For every loss occasioned by capture, whether lawful, i.e., when made by a declared enemy, according to the laws of war, or unlawful, i.e., when it is against the rules established by the laws of nations, whether by friends or enemies, the insurer is liable, agreeably to the comprehensive and express words of the policy: and in every case of capture the insurer is answerable, to the extent of the sum injured, for the loss actually sustained. This may be either total, as where the ship and goods injured are not recovered; or partial, as where the ship is recaptured or restored before abandonment; in which case the insurer is bound to pay the salvage, and any other necessary expense incurred may be incurred by the recovery of his property. The insurer is liable for a loss by capture, whether the property in the thing injured be changed by the capture or not. As to the length of possession by an enemy, which is deemed sufficient to divest the property out of the original owner, or the effect of a recapture in revesting it; these are matters which can never now come directly in question between the insurer and insured, in any case of insurance upon real interest. In gaming insurances, or insurances without interest, indeed, when there was a recapture, the claim, as for a total loss, seems formerly to have involved the question, whether the property in the thing injured had, by the capture, or any proceeding founded on it, been divested out of the original owner, or not, before the recapture. Nevertheless, when a ship is injured “interet or no interet,” it has been repeatedly determined, that if the ship be taken, it is a total loss, however illegal the capture may be, and though the ship may be retaken and restored to the owner. But though no question can now arise between the injured and the insurer, as to the effect of a capture or recapture, in divesting or revesting the property; it may not be deemed unimportant to inquire when a capture shall be deemed to transfer the property to an enemy, and what shall be the effect of a recapture in revesting it in the original owner. The general opinion seems to be, that by the law of nations, the property of things captured in war is changed when all reasonable hope of recovering them is gone; and, with respect to things movable, all reasonable hope of recovering them is presumed to be gone when they are brought within the protection of the enemy’s forts. Grotius says, that ships or goods, taken at sea, become the property of the captors, when they are brought into the enemy’s harbours, or to the place where his whole fleet is stationed; for then all hopes of recovering them may be said to vanish. But, he adds, that by the law of nations, as introduced among European states in more modern times, things are considered as captured, when they have been 24 hours in the power of the enemy. Others deny this rule of the law of nations, and infin on the rule of the Roman law, that the prize must be carried

“infra praefidium” before it can become the property of the captors; and by “infra praefidium” Byssnerhoekoek understands the camps, the ports, the towns, and the fleets, of the enemy. In our courts of admiralty, however, it has always been held, by the marine law of England, independent of the statute which commands restitution, and fixes the rate of salvage, the property is not changed in favour of a vendee or recaptor, so as to bar the original owner, till there has been a regular sentence of condemnation: and in the reign of king Charles II., a solemn judgment was given upon this point; and restitution of a ship taken by a privateer was decreed, after she had been fourteen weeks in the enemy’s possession, because the ship had not been condemned. The same doctrine has, in several instances, prevailed in our courts of common law. In one case it was held that nine days’ possession by the capror, and in another, that four years’ possession, and several voyages performed, will not change the property, without a sentence of condemnation.

In general, whenever a ship is taken by the enemy, the injured may abandon, and demand as for a total loss; and he is not bound to make any claim or appeal in the enemy’s courts of admiralty, or to litigate there the validity of the capture.

But the injured is in no case bound to abandon; and, as the law now stands, no capture by the enemy can be so total a loss as to leave no possibility of recovery, for the jus possittymunii continues for ever, except in the case of a captured ship converted into a ship of war. (Stat. 33 G. III. c. 66. § 42.) If the owner himself should retake his ship or goods, he will be fully intitled to them; and if they be retaken at any time, whether before or after condemnation, he will be intitled to restitution, upon payment of a settled salvage. Stat. 29 G. I. c. 34. § 24; and 33 G. III. c. 66. § 42.

The chance of the owner’s recovering his property, does not, however, supplant the demand of the injured, as for a total loss; but in the case of a recapture, justice is done to the injured by putting him in the place of the injured. In questions upon policies of insurance, the nature of the contract as an indemnity, and nothing else, is always liberally considered.

When there has been a capture, whether legal or not, and the ship has been recaptured or restored, the insurer is bound to defray all necessary expenses which the injured has been put to for the recovery of his property. He is therefore liable for a sum of money paid by the injured to the captors, as a compromise made bona fide, to prevent the ship being condemned as prize. See Kansom.

It often happens that a recaptured ship is in a flate to prosecute her original voyage; and, in that case, it is the interest of the recaptors, as well as of the other parties concerned, that she should be permitted to do so. The last prize act (Stat. 33 Geo. III. c. 66. § 44) has therefore very properly provided, “That if a ship be retaken before she has been carried into an enemy’s port, it shall be lawful for her, if the recaptors consent thereto, to prosecute her voyage; and it shall not be necessary for the recaptors to proceed to adjudication till six months after the recapture, or till the return of the ship to the port from whence she failed; and the master, owners, or agents, with the consent of the recaptor, may dispose of their cargoes before adjudication: and in case the vessel shall not return to the port from whence she failed, or the recaptors shall have had no opportunity of proceeding regularly to adjudication within the six months, on account of the absence of the said vessel, the court of admiralty shall, at the instance of the recaptors, decree restitution to the former owners, they paying salvage, upon such evidence as to the court shall, under all the cir-

3 T
cumstances
cumstances of the cafe, appear reasonable; the expense of such proceeding not to exceed fourteen pounds."

We shall here observe, that there is an obvious difference between capture and arrest of princes; the object of the one is prize, that of the other detention, with a design to restore the ship or goods detained, or to pay the value to the owner. When a ship is detained in a port after a declaration of war, or the issuing of letters of reprisal, this more resembles a capture than a detention, and gives the injured an immediate right to abandon, as for a loss by capture, even though no condemnation be pronounced, and though the ship be afterwards reflored. The most frequent cause of detention is an embargo, which is a proclamation or order of state, usually issued in time of war or threatened hostilities, prohibiting the departure of ships or goods from some or all of the ports of such state until further order. An embargo laid on ships and merchandise in the ports of this kingdom by virtue of the king's proclamation, is strictly legal, when the proclamation does not contravene the ancient laws, or tend to establish new ones; but only to enforce the execution of such laws as are already in being, in such manner as the king shall judge necessary. But whether an embargo be legally or illegally laid, the injury to the owner, by the detention of his ship or goods, is the same; and the insurer is equally liable for the loss occasioned by it. If a ship be seized after a cessation of arms and preliminary articles of peace are signed, this shall not be deemed a capture, but only an arrest of princes. For the regulation of salvage upon a recapture, we refer to the article Salvage.

Capture by an enemy or a pirate, or an arrest of princes, or even an embargo, is prima facie a total loss; and immediately upon the capture, or upon a mere arrest, or at any time while the ship continues under detention, the injured may elect to abandon, and give notice to the insurer of his intention to do so; and thus entitle himself to claim as for a total loss from the insurer. For, from the moment of the capture, the owners lose their power over the ship and cargo, and are deprived of the free disposal of them; and, in the opinion of the merchant, his right of disposal being suspended or rendered uncertain, is equivalent to a total deprivation. It would therefore be unreasonable to oblige the insured to wait the event of capture, detention, or embargo.

There is this difference between a policy upon interest, and a wager policy, that in the one case the injured may, if he thinks proper, abandon the moment he has notice of a capture or detention, and this will bind the underwriters, whatever may be the ultimate fate of the ship; but in the case of a wager policy there can be no abandonment, because the injured has nothing to abandon.

But a capture or arrest does not necessarily, and at all events, terminate in a total loss, for as he cannot abandon till he has received advice of the loss; if, at the time he receives such advice, or before he has elected to abandon, he receive advice that the ship or goods insured are recovered, or are in safety, he cannot then abandon; because he can only abandon while it is a total loss, and he knows it to be so; not after he knows of the recovery. Therefore, if a captured ship be retaken and permitted to proceed on her voyage, so that she suffers but a small temporary inconvenience; this would only be a partial, and not a total, loss.

On the other hand, a title to retribution upon a recapture does not necessarily, and at all events, deprive the injured of the right to abandon; for if, in consequence of the capture, the voyage be lost, or not worth pursuing; if the salvage be very high; if farther expense be necessary; and the insurer will not undertake at all events to pay it, he may abandon. The rule is, that, if the thing injured be recovered before any loss is paid, the injured is entitled to claim as for a total, or a partial loss, according to the final event; that is, according to the state of the case at the time he makes his claim. There is no vested right to a total loss, till the injured, having a right to abandon, elects to do so; for he is only entitled to an indemnity for his loss as it stands at the time of the action brought, or offer to abandon.

But if, after a total loss has been actually paid, the thing injured be recovered, the insurer cannot oblige the injured to refund the money he has received; but he shall stand in the place of the injured, and so no injustice is done.

Cafes are mentioned by Mr. Serjeant Marshall, which serve as examples to show, that though a captured ship be recaptured, yet if the voyage be lost, the loss will be total, and the injured will have a right to abandon.

By the marine law, the property was not changed by the capture, till after condemnation; and since the 29 Geo. II. c. 34, the "jus poollinimii" continues for ever. A recapture does not in all cases prevent the loss being total. If the voyage be absolutely lost, or be not worth pursuing; if the salvage be very high; if further expense be necessary; if the insurer will not engage, at all events, to bear that expense, though it should exceed the value, or fail of successes; under these, and many other similar circumstances, the injured may disentangle himself and abandon, notwithstanding there was a recapture. Upon a recapture the property returns to the original owner, pledged to the underwriters for the amount of the salvage: upon the payment of which he is intitled to retribution. If upon a recapture the captain, finding that the voyage cannot be pursued, and, acting fairly for the benefit of all concerned, sells the ship and cargo to pay the salvage, and thereby put an end to the voyage, the injured may abandon and recover as for a total loss. However, a capture does not necessarily amount to a total loss, nor does a recapture prevent its being total. If the captain purchase the ship from the captors for account of his owners, the money paid, being in the nature of salvage, is only partial loss.

To this article we shall subjoin two or three remarks on the subject of abandonment, which do not elsewhere occur. A time should be fixed when the degree of the insurer's responsibility should be ascertained. In several maritime states on the continent, positive regulations have been established, limiting the time, after a loss has happened, within which the injured may abandon. In England we have no such positive regulation, nor any time limited by law for abandoning. But the courts have laid down a rule, better adapted to the purpose; and the rule is, that as soon as the injured receives advice of a total loss, he must make his election whether he will abandon or not. If he determines to abandon, he must give the underwriters notice of this within a reasonable time after the intelligence arrives; and any unnecessary delay in giving this notice will amount to a waiver of his right to abandon; for unless the owner does some act, signifying his intention to abandon, it will be only a partial loss, whatever may be the nature of the loss, or the extent of the damage. If the insurers in any manner prevent the abandonment, they shall pay the whole loss, to the amount of the sum injured. If no intelligence be received of a ship within a reasonable time, it shall be presumed that she foundered at sea; when the time has elapsed which affords that presumption, the injured may abandon, and claim as for a total loss. Marshall on Insurance, vol. ii.
RECARDAINS, in Geography, a town of Portugal, in the province of Beira; 6 miles E. of Bragança Nova.
RECCAN. See Arracan.
RECCO, a town of the Ligurian republic, near the sea-coast; 11 miles S.E. of Genoa.
RECEIF, a fort and harbour on the coast of Brazil. S. lat. 8° 10'.
RECEIT, or Receipt, in Commerce, an acquittance or discharge; or a written acknowledgment of having received a sum of money.
Where the receipt is on the back of a bill, &c. it is usually called an endorsement.
Among tradesmen the receipt usually makes the second of the three articles of an account; the receipt contains the monies received; the two others the expense, and the return or balance.
By the 44 Geo. III. c. 98, the former flamp duties were repealed, and others imposed; by the 48 Geo. III. c. 149, these last were repealed, and the following were imposed; viz.

<table>

And all receipts, discharges, and acknowledgments of the description aforesaid, which shall be given for or upon payments made by or with any bills of exchange, drafts, promissory notes, or other securities for money, shall be deemed and taken to be receipts given upon the payment of money within the intent and meaning of this schedule and of the foregoing act.

Exemptions from the preceding Duties on Receipts.
Receipts exempted from flamp duty by any act or acts of the present session, relating to the aforesaid taxes.
Receipts or discharges given by the treasurer of the navy for any money imprest to or received by him for the service of the navy.
Receipts or discharges given by any agent for money imprest to him on account of the pay of the army or ordnance.
Receipts or discharges given by any officer, seaman, marine or soldier, or their representatives respectively, for or on account of any wages, pay, or pension due from the navy-office, army pay-office, or ordnance-office.
Receipts or discharges given for the consideration money, for the purchase of any share in any of the government or parliamentary stocks or funds, or in the stocks and funds of the governor and company of the bank of England, or of the East India company, or South Sea company, and for any dividend paid on any share of the said stocks or funds respectively.
Receipts given for money deposited in the bank of England, or in the bank of Scotland, or royal bank of Scotland, or in the bank of the British linen company in Scotland, or in the hands of any banker or bankers, to be accounted for on demand, provided the same be not expressed to be received or by the hands of any other than the person or persons to whom the same is to be accounted for; but if with interest, see Promissory Notes.
Receipts or discharges written upon promissory notes, bills of exchange, drafts or orders for the payment of money duly flamped according to the laws in force at the date thereof, or upon bills of exchange drawn out of, but payable in Great Britain.
Receipts or discharges given upon bills or notes of the governor and company of the bank of England; letters by the general post acknowledging the safe arrival of any bills of exchange, promissory notes, or other securities for money.
Receipts or discharges indorsed or otherwise written upon, or contained in any bond, mortgage, or other security, in any conveyance, deed, or instrument whatever, duly flamped according to the laws in force at the date thereof, acknowledging the receipt of the consideration money therein expressed, or the receipt of any principal money, interest, or annuity thereby secured.
Receipts or discharges for money by deeds duly flamped according to the laws in force at the date thereof.
Receipts or discharges given for drawbacks or bounties upon the exportation of any goods or merchandise from Great Britain.
Receipts or discharges for the return of any duties of customs upon certificates of over entry.
Receipts or acknowledgments of payments indorsed upon any bills, orders, remittance bills, or remittance certificates, drawn by commissioned officers, masters, and surgeons in the navy, or by any commissioner or commissioners of the navy, under the authority of the act passed in the 35th year of his majesty's reign, for the more expeditious payment of the wages and pay of certain officers belonging to the navy.

3 T 2

Receipts
Receipts or acknowledgments of payments indorsed upon any bills drawn pursuant to any former act or acts of parliament, by the commissioners of the navy, or by the commissioners for managing the transport service, and taking care of sick and wounded seamen, upon and payable by the treasurer of the navy.

If any person shall write or sign any receipt liable to any stamp duty, without being first duly flamped as aforesaid, or with a flamp of a lower value than is herein directed; he shall forfeit 10s. if the sum paid or expressed therein shall not amount to 10s. and 2s. if the sum amount to 10s. or upwards. 31 Geo. III. c. 27. f. 17. 35 Geo. III. c. 55. f. 8.

Every person who shall give any receipt or writing acknowledging the payment of money, in which a less sum shall be expressed than the sum actually paid or received, or who shall separate or divide the sum actually paid or received into divers sums, or shall write off any part of any debt, or demand, or be guilty of or concerned in any contrivance with intent to defraud his majesty, shall forfeit 50l. 35 Geo. III. c. 55. f. 9.

And the persons, or their agent, from whom any sum shall be due or payable, and who shall have paid such sum, may provide a flamp of the proper duty, or of some higher rate of duty than required, and demand of the person entitled to such sum, or any agent to whom the same shall have been paid, a receipt for such sum, and also the amount of the duty thereon as aforesaid; and if such person refuse to give such receipt upon demand thereof, or to pay the amount thereof, every such person shall forfeit for each offence 10l. 43 Geo. III. c. 126. f. 5.

Stamps denoting the duties under former acts may be used, provided they be applied to receipts of the like amount as required by this act. f. 8.

And all vellum, parchment, and paper liable to any stamp duty as aforesaid, shall be flamped before the same be written or printed upon; or may be brought to the said commissioners or their officers to be flamped within 14 days after such receipts shall be given or bear date, and shall be flamped on payment of 5l. over and above the duty; and if brought after 14 days within one calendar month, on payment of 5l. over and above the duty. 31 Geo. III. c. 25. f. 19. 20. 35 Geo. III. c. 55. f. 10. 11.

All penalties by this act incurred may be sued for in the courts at Westminster; or any neighbouring justice may hear and determine any offence which subjects the offender to any pecuniary penalty; who may, on complaint made within three calendar months, summon the party accused, and the witnesses, and examine into the matter of fact; and on confession, or the oath of one witness, may give judgment therein, and levy such penalty by distress on the goods of the offender, which, if not redeemed within six days, may be sold; and such penalty shall be divided half to the king, and half to the informer; and for want of sufficient distress, the offender shall be committed to prison for three calendar months, unless such penalty shall be sooner paid. 31 Geo. III. c. 25. f. 24. 25. 35 Geo. III. c. 55. f. 13. 14.

If any person shall find himself aggrieved by the judgment of such justice, he may, upon giving security to the amount of such penalty and costs, appeal to the next sessions, which shall happen 14 days next after such conviction, on giving reasonable notice; and in such case judgment be affirmed, they may award the person appealing such costs as to them shall seem meet. 1d.

Provided, nevertheless, that such justice may, where he shall see cause, mitigate any such penalty, so as not to reduce the same to less than one moiety thereof over and above the costs. 31 Geo. III. c. 25. f. 26. 35 Geo. III. c. 55. f. 14.

Witnieses not appearing, having been duly summoned, without reasonable cause to be allowed by such justice, or refusing to give evidence, shall forfeit 40l. to be recovered in like manner. 31 Geo. III. c. 25. f. 27. 35 Geo. III. c. 55. f. 15.

Perfons counterfeiting or forging any stamp hereby directed to be made use of shall be guilty of felony without benefit of clergy. 31 Geo. III. c. 25. f. 29. 35 Geo. III. c. 55. f. 17. 43 Geo. III. c. 126. f. 11.

All powers given by any former act relating to the stamp duties shall extend to this act. 31 Geo. III. c. 25. f. 30. 35 Geo. III. c. 55. f. 18. 43 Geo. III. c. 126. f. 12.

Perfons sued or prosecuted on account of any thing done in pursuance of this act may plead the general issue and give the special matter in evidence; and if a verdict be for the defendant, or the plaintiff be nonsuited, treble damages shall be awarded against such plaintiff. f. 15.

By the 44 Geo. III. c. 58, the former duties on legacies under the care of the commissioners for stamp duties were repealed, and new duties were imposed. By the 45 Geo. III. c. 28, additional duties were imposed, and by the 48 Geo. III. c. 149, the following were imposed (being by f. 3. of this last act placed under the provisions of former acts relating to such duties, and those imposed by former acts were repealed).

Schedule, Part III.

Legacies and succession to personal or moveable estate upon intestacy.

1. Where the testator, testatrix, or intestate, died before or upon the 5th of April 1805.

For every legacy, specific or pecuniary, or of any other description, of the amount or value of 20l. or upwards, given by any will or testamentary instrument of any person who died before or upon the 5th of April 1805, out of his or her personal or moveable estate, and which shall be paid, delivered, retained, satisfied, or discharged, after the 10th of October 1808.

Also for the clear residue (when devolving to one person), and for every share of the clear residue (when devolving to two or more persons), of the personal or moveable estate of any person who died before or upon the 5th of April 1805 (after deducting debts, funeral expenses, legacies, and other charges first payable thereout), whether the title to such residue, or any share thereof, shall accrue by virtue of any testamentary disposition, or upon a partial or total intestacy; where such residue, or share of such residue, shall be of the amount or value of 20l. or upwards, and where the same shall be paid, delivered, retained, satisfied, or discharged, after the 10th of October 1808.

Where any such legacy, or residue, or share of such residue, shall have been given, or devolved, to or for the benefit of a brother or sister of the deceas'd, or any descendant of a brother or sister of the deceased; a duty at and after the rate of 2l. 10s. per cent. on the amount of the value thereof. 2 10 0.

Where to or for the benefit of a brother or sister of the father or mother of the deceased; or any descendant of a brother or sister of the father or mother of the deceased; a duty at and after the rate of 4l. per cent. on the amount or value thereof. 4 0 0.

Where
Where to or for the benefit of a brother or sister of a grandfather or grandmother of the deceased, or any descendant of a brother or sister of a grandfather or grandmother of the deceased; a duty at and after the rate of 5l. per cent. on the amount or value thereof

Where to or for the benefit of any person in any other degree of collateral consanguinity to the deceased, than is above described; or to or for the benefit of any stranger in blood to the deceased; a duty at and after the rate of 8l. per cent. on the amount or value thereof

11. Where the testator, testatrix, or intestate, shall have died after the 5th of April 1805.

For every legacy, specific or pecuniary, or of any other description, of the amount or value of 20l. or upwards, given by any will or testamentary instrument, of any person who shall have died after the 5th of April 1805; either out of his or her personal or moveable estate, or out of or charged upon his or her real or heritable estate, or out of any monies to arise by the sale, mortgage, or other disposition of his or her real or heritable estate, or any part thereof, and which shall be paid, delivered, retained, satisfied, or discharged after the 10th of October 1808.

Also for the clear residue, (when devolving to one person), and for every share of the clear residue (when devolving to two or more persons), of the personal or moveable estate of any person who shall have died after the 5th of April 1805, (after deducting debts, funeral expenses, legacies, and other charges first payable thereout), whether the title to such residue, or any share thereof, accrue by virtue of any testamentary disposition thereof, or upon a partial or total intestacy, whereby such residue, or share of residue, shall be of the amount or value of 20l. or upwards, and where the same shall be paid, delivered, retained, satisfied, or discharged after the 10th of October 1808.

And also for the clear residue (when given to one person), and for every share of the clear residue (when given to two or more persons), of the monies to arise from the sale, mortgage, or other disposition of any real or heritable estate, directed to be sold, mortgaged, or otherwise disposed of, by any will or testamentary instrument of any person who shall have died after the 5th of April 1805, (after deducting debts, funeral expenses, legacies, and other charges, first made payable thereout, if any), where such residue, or share of residue, shall amount to 20l. or upwards, and where the same shall be paid, delivered, retained, or discharged, after the 10th of October 1808.

Where any such legacy or residue, or any share of such residue, shall have been given, or have devolved, to or for the benefit of a child of the deceased, or any descendant of a child of the deceased; a duty at and after the rate of 1l. per cent. on the amount or value thereof

Where to or for the benefit of a brother or sister of the deceased, or any descendant of a brother or sister of the deceased; a duty at and after the rate of 2l. 10s. per cent. on the amount or value thereof

Where to or for the benefit of a brother or sister of the father or mother of the deceased, or any descendant of a brother or sister of the father or mother of the deceased; a duty at and after the rate of 4l. per cent. on the amount or value thereof

Where to or for the benefit of a brother or sister of a grandfather or grandmother of the deceased, or any descendant of a brother or sister of a grandfather or grandmother of the deceased; a duty at and after the rate of 5l. per cent. on the amount or value thereof

Where to or for the benefit of any person in any other degree of collateral consanguinity to the deceased, than is above described; or to or for the benefit of any stranger in blood to the deceased; a duty at and after the rate of 8l. per cent. on the amount or value thereof

And all gifts of annuities, or by way of annuity, or any other partial benefit, or interest, out of any such estate or effects as aforesaid, shall be deemed legacies within the intent and meaning of this schedule.

Exceptions.

Legacies and residues, or shares of residue, of any such estate or effects as aforesaid, given or devolving to or for the benefit of the husband or wife of the deceased, or to or for the benefit of any of the royal family.

And all legacies which were exempted from duty by the 39 Geo. III. c. 73, for exempting certain specific legacies, given to bodies corporate or other public bodies, from the payment of duty.

By f. 43. of 48 Geo. III. c. 149, the commissioners are authorized to remit penalties incurred before passing this act by non-payment of the duty on legacies, if the duty in arrear shall be paid on or before the 31st Jan. 1809.

By f. 44, in all cases not provided for by f. 43, where any receipt for any of the above matters shall be brought to the head office to be stamped after the expiration of three calendar months from the date thereof, it may be stamped on payment of the duty, together with the penalty incurred for not stamping the same in due time; and if the receipt have been signed out of Great Britain, and be brought to be stamped within 21 days after being received in Great Britain, and no penalty to be incurred.

The said duties to be under the management of the commissioners of the stamp duties. 35 Geo. III. c. 52. f. 3.

And in case of specific legacies, where the residue of any personal estate shall consist of property not reduced into money, the person taking admistration of such effects, or by whom the duty ought to be paid, may set a value thereon, and offer the duty accordingly; and may, at his own expense, require the stamp commissioners to appoint a person to test such value, and such commissioners may accept the duty by such person with an appraisement, but if they shall not be satisfied with the value so set, they may appoint a person to appraise such effects, and to set a value thereof, and require the duty to be paid accordingly; but if the person who ought to pay such duty shall not be satisfied with such valuation, he may cause the same to be reviewed by the commissioners of the land-tax of the district where such effects shall be, at their next meeting, if fourteen days have elapsed before such meeting, and if not, at the next succeeding meeting, of which appeal six days notice shall be given to the stamp commissioners; and the said commissioners of the land-tax may appoint a person to appraise such effects, and to set a value thereon, and may hear and determine such appeal in like manner as appeals to them in other cases, and their judgment shall be final; and if the valuation made under the authority of such stamp commissioners shall not be appealed from within the time aforesaid, or shall be affirmed upon appeal, the duty shall be paid accordingly; and if any variation shall be made on such appeal,
appeal, the duty shall be paid according to such variation; and if the duty assessed in manner aforesaid shall exceed the duty offered to and refused by such flamp officers, the expenses shall be borne by the person liable to pay such duty. If any dispute shall arise between persons entitled to any such legacy, or residue, or taking administration aforesaid, respecting the value thereof, or duty to be paid thereon, the duty shall be assessed by such flamp commissioners on reference to them by either party; and if the value of such property shall be in dispute, such flamp commissioners shall cause an appraisement to be made thereof, at the expense of the person liable to pay the duty, in manner aforesaid; and if such person shall be dissatisfied with such valuation, the same shall be reviewed and finally determined by the said commissioners of the land-tax, upon appeal to them within the time and in the manner aforesaid. And if the effects whereon such duty is payable shall be more than ten miles from London, such persons shall be depoited by the said flamp commissioners shall act in their stead. f. 22, 36 Geo. III. c. 52.

And if it shall appear to the said flamp commissioners, upon oath, to be administered by a justice, or matter extraordinary in chancery, that a duty has been paid than ought to have been, by mistake, without intention of fraud, such mistake may be rectified by such commissioners, who may accept the duty really due within three calendar months, if no suit hath been instituted, and on payment of 10l. per cent. thereon by way of penalty. f. 30.

Every person paying or receiving money contrary to this act, who shall within twelve calendar months discover the other party offending, so as he be convicted thereof, shall be indemnified and discharged from all penalties against this act. f. 31.

And all powers of forming acts relating to the flamp duties, not hereby altered, shall be in force, in the execution of this act. f. 42.

Wherever any executor or administrator shall not have paid the said duties within time, the court of exchequer may, on application from the flamp office on satisfactory affidavit, grant a rule for such executor to shew cause why he should not deliver to the commissioners an account on oath of all legacies, or of the personal property paid or payable by him, and why the duties thereon have not been, or should not be forthwith paid, and may make such rule absolute where it appears proper. And regillars of ecclesiastical courts shall, within a month of requisition, deliver to the flamp office an account of wills and letters of administration in their custody, with particulars relating thereto, and extracts from any wills deemed necessary by the commissioners, on payment of fees agreed on or allowed by the ecclesiastical court, on pain of 50l. recoverable by information by the attorney-general. 42 Geo. III. c. 90. f. 2, 3.

And by the 5 W. c. 21, the probable of the will or letters of administration of any common soldier or seaman, slain or dying in the service, shall be exempt from the flamp duties. f. 6.

RECEIVET. or RECEIPT. in Law. See RECEIPT.
RECEIPT of Homage. See RECEIPT.
RECEIPT of the Exchequer. See RECEIPT.
RECEIPT, in Medicine. See RECEIPT.
RECEIPTS, Auditor of. See AUDITOR.
RECEIVER, or RECEIPT, in Chemistry, a globe-shaped vessel, which is adapted to the neck or beak of an alembic, retort, or other distillatory vessel, in order to collect, receive, and contain the products of distillations. Receivers should be made of glass, not only because this matter refits the action of the strongest and most corrosive substances, but also because being transparent, it allows the operator to see through it, and to judge by the frequency of the drops, if the distillation be too quick or too slow, and also if the quantity and nature of the substances that come over be such as are required. Almost all receivers are kinds of bottles of different sizes, of a spherical form, the necks of which are cut short, and each of which is pierced with a small hole in its lateral or upper part, to give vent to the air or vapours, which are too expansive. Receivers of this form are called balloons; which see. Some receivers are mattrate with long necks. These are generally adapted to the beaks of flabs alembics. The long neck serves to keep the belly of the receiver, where the liquor is collected, at a proper distance from the fire.

Receivers have different forms for particular operations. Such are those which have two or three beaks, either to be adapted to other receivers, or to admit at the same time the necks of several distillatory vessels, when the intention of the operator is, that the vapours of different substances should meet in the same receiver. Such also are receivers for essential oils, obtained from aromatic plants distilled with water, which are to make, that they are never full, but that the water runs out, and leaves the oil behind. These are a kind of glass cucurbits, which contract as they rise higher; so that their neck or upper opening is but nearly of a convenient size to receive the beak of the worm. These receivers have another opening about the middle of the swelling or belly; and to this opening is joined a glass tube, which bends and rises vertically along the outer part of the receiver, so as to be within two inches and a half as high as the upper opening. At this height the tube bends again towards the side opposite to the body of the receiver, to pour into another vessel the liquor which arises there. It forms the figure of an S.

When this receiver is to be used, it is to be placed vertically under the beak of the worm. During the distillation, the liquor rises to an equal height in the body of the receiver, and in the crooked tube; when, therefore, the height of the liquor in the receiver becomes greater than the height of the tube, it must begin to flow from the mouth of this tube into another vessel placed on purpose to receive it; but as essential oils are either lighter or heavier than water, and as they are, therefore, always collected either above or under the water, and as the liquor which discharges itself through the tube is taken from the middle part of the receiver, nothing but water can be evacuated at the mouth of the pipe, while the oil always remains in the receiver. With such a receiver distillation may be performed without the trouble of changing the vessels. Macquer's Chem. Dict. See Distillation and Laboratory.

RECEIVER of an Air-Pump. is part of its apparatus; being a glass vessel placed on the top of the plate, out of which the air is to be exhausted. To an air-pump belong various receivers, of various forms and sizes, and serving for various purposes. See Air-Pump.

RECEIVER, Exhausted, in Pneumatics. See EXHAUSTED. And for the method of repairing those that are cracked, see CEMENT.

RECEIVER, Receptor, or Receptator, in Law, is used commonly in the bad sense, for such as knowingly receive stolen goods from thieves, and conceal them. This offence is only a misdemeanor at common law: however, by the statutes 3 & 4 W. & M. c. 9. and 5 Ann. c. 31. the offender is made accessory to the theft and felony. But because the accessory cannot in general be tried, unless with the principal, or after the principal is convicted, the receivers
receivers by that means frequently eluded justice; to remedy which it is enacted by statute 1 Ann. c. 9, and 5 Ann. c. 31, that such receivers may be still prosecuted for a misdemeanor, and punished by fine and imprisonment, though the principal felon be not before taken, fo as to be prosecuted and convicted. And in case of receiving stolen lead, iron, and certain other metals, such offence is, by statute 29 Geo. II. c. 30, punishable by transportation for fourteen years. So that now the prosecutor has two methods in his choice: either to punish the receivers for the misdemeanor immediately, before the thief is taken (Fellor, 373); or to wait till the felon is convicted, and then punish them as accessories to the felony. But it is provided by the same statute, that he shall only make use of one, and not of both these methods of punishment.

By the same statute also (29 Geo. II. c. 30,) persons having lead, iron, or other metals in their custody, and not giving a satisfactory account how they came by the same, are guilty of a misdemeanor, and punishable by fine and imprisonment. And by statute 10 Geo. III. c. 48, all knowing receivers of stolen plate or jewels, taken by robbery on the highway, or when a burglary accompanies the stealing, may be tried as well before as after the conviction of the principal, and whether he be in or out of custody; and, if convicted, shall be adjudged guilty of felony, and transported for fourteen years. By Stat. 21 Geo. III. c. 68, the receiving of any stolen copper, brass, bell-metal, or utensil fixed to any building, or any iron-irons or fencing set up in any court or other place, is made transportation for seven years, or three years' imprisonment to be kept to hard labour. By Stat. 21 Geo. III. c. 60, the receiving of stolen pewter of any kind is subjected to the like penalty, although the principal has not been convicted. By Stat. 22 Geo. III. c. 58, the receiving of any stolen goods, (except lead, iron, copper, brass, bell-metal, and folder,) is made a misdemeanor, punishable by fine and imprisonment, or whipping, as the court shall appoint; which shall exempt the offender from being convicted as accessory, although the principal be afterwards convicted, and the offence shall appear to be grand larceny, or some greater offence. (See Larceny.) For the punishment of receivers of goods stolen by hum-boats, &c. on the river Thames, see Stat. 2 Geo. III. c. 28. § 12. Receivers of linen goods stolen from the bleaching-grounds are, by Stat. 18 Geo. II. c. 27, declared felons without benefit of clergy. In France, receivers are punished with death; and the Gothic constitutions distinguished also three sorts of thieves: "unum qui conflitum dare, alterum qui contrahet, tertium qui receptaret et occulteret; pari pena singulos obnoxios." Receivers also denotes an officer, of which there are various kinds, separated from the particular matters they receive, the places where, or the persons for whom, &c.

As receiver of rents; receiver-general of the customs; receiver of the fines, upon original writs in chancery, &c.

Receiver-General of the duchy of Lancaster, is he who gathers all the revenues and fines of the lands of the said duchy, all forfeitures, alienations, &c.

Receiver-General of the pubic revenue is an officer appointed in every county, to receive the taxes granted by parliament and remit the money to the treasury.

Receiver's Office. See Greenwich Hospital.

RECENT Fruits. See Fruit.

RECEPTACLE of Stall Manure, in Agriculture, the place where the various matters from the stalls, and other places where animals are kept, are deposited and laid up.

Some suppose that these places should be a little hollow or excavated; while others are of quite a different opinion, and think that they should be even, or a little raised. A very slight hollowing is, however, probably the best. An experienced writer on this subject urges, that it is not to be inferred that, because they should be hollow, they should also be deep; as one principal use of them is to bring the rain waters, which fall within the yards or inclosed parts, into a stagnant state, and to let them off superficially, so as to prevent any thing of the ground current kind from carrying away the dung, either in a bodily manner, or in a thick fluid state; they may, in this way, suffer the more watery particles only to pass away into reseriores, prepared to preserve and keep them for future use. It is believed that two feet on the lower side, or deepest parts, may be taken as a mean depth; but less may often be quite sufficient; and the bottoms of the waste-water channels being laid six or eight inches lower than the rim of the basons, the depth of water which they can contain is, it is concluded, not more than sixteen or eighteen inches, when empty of manure. But it is suggested, as necessary to good farm management, that, soon after the winter's manure has been removed and cleared away, floors of marie, or some other earthy fertilizing material, mixed with lime, to the thickness of ten or twelve inches, should be spread out over the bottoms of the basons or hollowed parts; by which means a rich compost for grass lands may be formed at small expense, on which all the official materials of manure which can be collected, free from seeds of weeds, during the summer and autumn, should be deposited. In this manner the receptacles should be filled to the brims, even though no ample manure were put into them during the above two seasons; so that the winter's manure may have firm platforms to rest upon, out of the way of water, the great evil which antiquated prejudice so much fears in these manure receptacles, as the prevention of the due maturation of their different contents.

With these receptacles of manure there should be connected drains from the cattle-houses, stals, and farm-offices, for receiving and conveying the urine, and other liquid matters, from them to these basons or receptacles; and the mouths of their outlet channels should be well guarded, in order to prevent their being choked up by the manure, when piled up to considerable height above them. The receptors, pits, or wells, which are made before them, are always to be kept free, for the superficial water, or other liquid matters of the receptacles, to drain or filtrate into; and thence to pass away in moist weather; or be pent up in them, in dry warm seasons, for the purpose of being thrown over the piled-up manures, for the promotion of their decay and maturation.

Where there are grass lands lying conveniently below these receptacles and receptors for receiving their overflows, all the different parts of the places, where they are situated, may be made to serve gently towards them; but where land cannot be commanded for favouring this intention, the receptacles or basons should receive no other waters than what are supplied to them by the atmosphere. This regulation may easily be accomplished, simply by raising their rims a few inches higher than the surrounding surfaces, which should be frequently cleared from the manure and litter dropped upon them, depositing all such substances within their rims. The rain-water which falls, in these cases, is to be conveyed to the catch-pools, or the most contiguous common drains. In all cases, that which falls upon the buildings should be conveyed away, without being suffered to pass through the receptacles or basons.
unlefs where liquid manure is more in demand than that of
the bulky kind.

From the flow progres made by manures of this fort to
maturity, in the winter season, in the open air, even when
piled up in the driest situations, on account of its being con-
stantly foaked or faturated with moisture, and exposed to
the effect of the cold atmosphere, the plan of giving recep-
tacles of this fort a long oval square form, and covering
them with roofs, to free them wholly from rain, as well as
to defend them from cold, has been hit upon, and recom-
meend from authority. As by thus affording the articles
of manure the means of paling into the state of fermenta-
tion, in the winter months, their putrefaçion and decay
would be beneficially promoted, for the use of the more
early crops of the spring. But how far the advantage,
gained in this way, may equal or be superior to the expense
of building, and extra labour in the removals of the manure,
is a point which is by no means yet fully decided. And the
superior benefits, which have lately been derived from the
use of manure in its more raw or fresh state, render all new
schemes perhaps of less importance than would otherwise be
the case.

As it is a matter of great consequence to prevent the ex-
cessive waste of this fort of manure, which at present fre-
quently takes place in most parts of the country, it has been
suggested by an experienced writer, who has attended much
to the subject, and thought a great deal upon it, that piling
it in shallow receptacles or basins, and conducting the
liquor, when not wanted for moistening the piles of manure,
which overflows from them, to reservoirs or catch-pools, in
order to stop, deposit, and arrest the heavier and more grogs
particles in the liquor may be conveyed in it, and to provide a
valuable collection of liquid manure in particular situations,
and of rich muddy matters in other parts, are the most appro-
prate practical means of accomplishing the matter, in an easy and
cheap way, that can be adopted or had recourse to. See
Dung, Farm-Yard, Homestead, Manure, Reservoir,
and Yard Manure.

RECEPTACULUM, Receptacle, in Botany and Vege-
table Phytology, is the seventh, or last, part of fructifica-
tion distinguished by Linnaeus, being the common basis, or
point of connection, of the others. (See FRUCTIFICATION.)
It is evident that such a part must exist, under some shape
or other; yet the receptacle is not always distinguished by
any particular figure. In simple flowers it is often little
more than a mere point; in compound ones it is very remark-
able and important, serving, by its difference of
structure, to afford very good general distinctions. The
receptacle of the Daily, Bellis, is conical; that of Crys-
ifiantemum convex. In Spharanthis this part is very nearly
globular, while in some species of Centaurea and Cardina
it is either flat, or slightly concave. In Seneck it is naked;
deftitute of hairs or scales between the florets or seeds;
while in Cardua it is hairy, and in Antemis variously fealy.
This last genus differs, by the character in question alone,
from Crysifiantemum, whose receptacle is naked; but the
character is not so much natural, in this case, as could be
wished. Mr. Brown has observed to us, that it affords not
even a certain artificial distinction, in the Crysifiantemum
indicium of the gardens, Curt. Mag. t. 327; which Willde-
now, like M. de Ramatuelle and professor Desfontaines,
had referred to Antemis, because they found the recep-
tacle to be fealy. We are convinced they are in the right,
and yet this appears to be the very same plant with Crys-
ifiantemum indicium, the scales of the receptacle being
variable, and sometimes almost, if not altogether, evanecent.
Some genera of this class have a cellular, or honeycomb-
like receptacle, as Onopordum, and Tolpis (Crepis barbara of
Linnaeus). In that case the edges of the cells are variously
jagged, toothed, or fringed, and they now and then are
fearfully distinguishtable from the reticulations or rugosities
of some naked receptacles.

The receptacle of the flower, in Linnaean language, means
the area or space between the lamens and styles, in cer-
tain genera whose germen is inferior; as the whole umbel-
liferous order, in which the part in question is more or
less timid, often coloured, and assumes a glandular af-
pect. The receptacle of the seed is not unfigurantly a dis-
inft part from the capsule or its valves, serving to con-
nect the seeds therewith. (See an example of it in Recep-
talum.) The racbis, or common stalk of a spike, or spikelet,
in Grass, is also termed a receptacle.

In some plants the receptacle undergoes great changes,
acquiring a different texture in the fruit, from what it
had in the flower. Thus, the whole fruit, as we call it,
of the Fig, (see Ficus,) is a common receptacle, at first
coriceous, and, like the rest of the plant, containing a
milky, somewhat acrid, juice. It forms a bag, lined with
flowers or florets, and having a small aperture at the top.
After the flowers are palt, this bag becomes pulpy, co-
oured, and full of sweet aromatic juice. So the fruit of
the Strawberry, (see Fragaria,) is but an originally
small dry receptacle, subsequently enlarged, and become
pulpy, whose outside is fluid with naked seeds. In
Broussonetia, described under our article Papyrius, the
separate stalk of each germen becomes the enlarged and
pulpy supporter of a naked feed. In Polichcha, (see that
article,) the common receptacle of the flowers, minute
scaly, and hardly discernible, in its earlier state, changes to
a congeries of white, juicy, sweet, tooth-like scales, elev-
ing the seeds in their appropriate withered perianths, and
altogether constituting one of the most extraordinary pulpy
fruits that we have ever met with. A similar change of
substance is observable in the calyx of the Mulberry, as
well as in Commelina Zanonia; a change common and na-
tural in the germen of pulpy fruits, though rare in the par-
ticular parts of which we have been speaking.

RECEPTACULUM Chyli, in Anatomy, that portion of
the trunk of the absorbing vessels, into which the lacteal
abords pour the fluids which they have taken up in the
alimentary canal: it is usually rather larger than the neigh-
bouring portions of the vessel, and sometimes very con-
fiderably so. See Absorbsents.

RECEPTARI, a term of reproach used for such phy-
cicians as wrote pompous receipts for loads of medicines,
more consulting the good of the apothecary than the pa-
tient; as also for such as gave receipts for general medi-
cines, to be used at the discretion of people wholly unac-
quainted with the nature of dyes.

RECEPTION, Receptio, in Philosophy, denotes the
fame with passion, considered as opposed to action.

Reception is also properly used for the manner of treat-
ing or entertaining a person; and the solemnities and cere-
mones practiced on that occasion. See Entry.

The reception of ambassadors is usually performed with
a great deal of pomp.

Reception is sometimes also used for the act of ap-
proving, accepting, and admitting a thing. See Ac-
ceptance.

The canons law only binds where it is received: the civil
law is received in some countries, and not in others.

The French would never receive the council of Trent, the
Spanish inquisition, nor the dogmatists of the ultramontane
canonists.

Reception,
RECEPTION, in Astronomy, is a dignity befalling two planets when they exchange houses; 2. gr. when the sun arrives in Cancer, the house of the moon; and the moon, in her return, arrives in the sun’s house.

The same term is also used when two planets exchange exaltation.

RECEPTITIOUS GOODS. See Goods.

RECESSION of the Equinoxes. See RECESSION of the Equinoxes.

RECESSUS, a word used by some medical writers to express an abscess, or apophasmia.

RECESSUS Imperi, RECESSION of the Empire, a phrase used in speaking of the affairs of Germany, signifying a collection of the voices or determinations of a diet.

At the end of each diet, before it breaks up, they gather together all their resolutions, and reduce them into writing; the act which contains them they call the recessus imperii, because made when on the point of retiring.

RECEY fur Ouse, in Geography, a town of France, in the department of the Côte d’Or, and chief place of a canton, in the diocesis of Chatillon; 15 miles S.E. of Chatillon. The place contains 880, and the canton 5913 inhabitants, on a territory of 260 kilometres, in 17 communes.

RECHABITES, a kind of religious order among the ancient Jews, instituted by Jonadab the son of Rechab; and comprehending his family and posterity.

Their founder prescribed them three things: first, Not to drink any wine. Secondly, Not to build any houses, but to dwell under tents. Thirdly, Not to sow any corn, or plant any vines.

The Rechabites observed these rules with great strictness, as appears from Jerem. xxxvi. 6, &c. Whence St. Jerome, in his thirteenth epistle to Paulinus, calls them sacrifici, montis. Jonadab, their founder, lived under Jehoshaph, king of Judah, contemporary with Jehu, king of Israel; his father Rechab, from whom his posterity were denominated, descended from Raguel or Jethro, father-in-law to Moses, who was a Kenite, or of the race of Ken; whence Kenite and Rechabite are used as synonymous in scripture.

The Kenites entered the promised land with the Hebrews, and dwelt in the tribe of Judah, about the Dead sea. They were distinguished from the Israelites by their retired and austere mode of life, and by their contempt of cities and houses. Serrurius distinguishes the ancient Rechabites, and the new Rechabites of Jonadab. The injuctions of Jonadab laid no obligation on the other Kenites, nor on the other descendants of Jethro. This they continued to observe above 300 years. Jehu began to reign A.M. 3122, and Jehoiakim, king of Judah, was put to death A.M. 3405, B.C. 599; but in the first year of Jehoiakim, king of Judah, Nebuchadnezzar coming to besiege Jerusalem, the Rechabites were forced to take refuge in the city, fill, however, lodging in tents. During this siege, Jeremiah received orders from the Lord to converse with the disciples of Rechab, to invite them into the temple, and to offer them wine to drink. But the Rechabites would not accept the offer.

The Rechabites were, probably, led captive, after the taking of Jerusalem by the Chaldeans. (See Pslam lxix.) They returned from their captivity, and settled in the city of Jabez beyond Jordan. (See 1 Chron. ii. 55.) Some have suggested, that the Alidaees of the Maccabees, (1 Macc. ii. 42. vii. 13. and 2 Macc. xiv. 6.) were succeceors and followers of the Rechabites. Others have cont. founded them with the Ephesians. But it is certain, that the manner of life of the Ephesians was very different from that of the Rechabites, as appears from Josephus. Antiq. lib. xvin. cap. 2, who informs us, that the Ephesians had fields, and inhabited houses, but had neither wives nor children; and did not perform their religious ceremonies with the other Jews at Jerusalem: all which was contrary to the practice of the Rechabites.

RECHACING, in Hunting, the driving back of the deer, or other beasts, into the forests, chases, &c. which had straggled out into the copes or thickets, &c.

Anciently there were offices of rechachers of the deer belowed by the king on gentlemen, or old hunters, with salaries for the keeping of running dogs to drive the deer into the forests, and then to beat the dogs off, without pursuing any farther.

RECHANGE, in Commerce. See RE-EXCHANGE.

Rechange is also used at sea for such tackle as is kept in reserve aboard the ship, to serve in case of failure of that already in use. See Tackle.

The Levantines use the word rechange or refulit in the same sense.

RECHARGE of a Fire Arm, is a second loading, or charge. The rechange should never be no deep as the first charge, lest the piece, being over heated, should burst.

RECHBERG, in Geography, a town of Austria; eight miles N.W. of Grein.

RECHE, a river of France, which runs into the Amblave, near Malmedy. — Also, a town of England, in the county of Cambridge, on the river Cam, formerly a place of great trade, and before the draining of the fens, a port for vessels of considerable burthen; five miles W. of Newmarket.

RECHEAT, in Hunting, a leaf on the horns, by which the huntsman winds the horn, when the hounds have lost their game, to call them back from pursing a counter-feint.

RECHENBURG, in Geography, a town of Saxony, in the circle of Erzgebirge; four miles S.E. of Frauenfeld.

RECHIA, a town of Servia; 100 miles W. of Niagara; N. lat. 43° 12', E. long. 109° 4'.

RECHICOURT, a town of France, in the department of the Meurthe, and chief place of a canton, in the diocesis of Sarrebourg; five miles N. of Blomont. The place contains 992, and the canton 8316 inhabitants, on a territory of 217¾ kilometres, in 18 communes.

RECHNITZ, a town of Hungary; six miles S.S.W. of Gunz.

RECHPERG, a town of Austria; two miles N. of Stain.

RECLUSUS, among the Romans, a kind of square mantle, or veil, worn by women on the head. Salamis will have it to have been a sort of gown used by the Roman ladies, and tuckered up before with a square pin, of a purple colour.

RECEINA, in Geography, a town of the marquisate of Anczio; three miles N.W. of Macerata.

RECIPE, in Medicine, a prescription, or formula, of a remedy, appointed to be administered to a patient. See PRESCRIPTION.

It is thus called, because always beginning with the word receipe, take; ordinarily expressed by the abbreviation R.

RECIPIANGLE, or RECEIPT-ANGLES, a mathematical instrument, serving to take the quantity of angles; used especially in the drawing plans of fortifications.

The receipiangle was formerly a popular instrument among the French, but little known among us; it is usually very simple,
ample, in form of a square, or rather a bevel (which see); confining of two arms, or branches, riveted together, and yet moveable, like a factor, on the centre or rivet. To take an angle with it, they lay the centre of a protractor to the joint, and the degrees cut by the edge shew the quantity of the angle; otherwise the angle made by the two rulers is drawn on paper, and then measured with a protractor.

Sometimes there is a circle divided into degrees added over the centre or rivet, with an index to shew the degrees without a protractor. At other times the under branch is divided.

To measure a fiant angle with any of the reciprocals, apply the insides to the lines that form the angle; for a re-entering angle, apply the outsides, &c.

RECIPIENDO Excommunicatus. See Excommunicato.

RECIPIENDO et faciendo attornato. See Attornato.

RECIPIENT, in Chemistry. See Receiver.

RECIPIENT, Italian, a vessel like a tea-pot, intended for the separation of essential oils from the watery liquor on which they float.

RECIPIENT of an Air-pump. See Receiver.

RECIPROCAL, Reciprocus, something that is mutual, or which is returned equally on both sides, or affects both parties alike.

The end of human society is to afford each other reciprocal aid; there are reciprocal duties between the prince and his subjects, the husband and wife, &c. There is a reciprocal action between the agent and patient.

The lex talionis establishes a kind of reciprocation of justice.

If two similar triangles be cut by parallel lines, the sections of the sides will be proportional; and reciprocally, if the sides be cut proportionally, the triangles are similar.

RECIPROCAL, in Logic, is applied to terms which have the fame signification, or are convertible; as, reasonable animal and man.

Schoolmen define reciprocation a conversion of the several terms in an enunciation. And terms are said to be converted in an enunciation, when the predicate is put in the place of the subject, and reciprocally, the subject in that of the predicate.

Thus, rationality and relibility are said to reciprocate; for we say equally, a rational is reliable, and a reliable is rational.

RECIPROCAL, in Grammar, is applied to certain verbs and pronouns in some of the modern languages; in regard of their turning or reflecting the noun, or person, upon himself.

Thus the pronoun relative, himself, refers Cato to Cato’s self.

The abbé de Dangeau defines reciprocal verbs to be those whose nominative is plural, and denotes persons acting mutually on one another: as, Ces quatre hommes s’entraubaient, these four men fought together; Pierre et toi vous vous battez, Peter and you fight one another, &c.

Reciprocal verbs are a species of those which that author calls pronomininals, and which he distinguishes into reciprocal and identical.

RECIPROCAL, in Poetry, is applied to verses which run the fame both backwards and forwards; called also recurrents. See Retrograde.

RECIPROCAL, in Arithmetic and Algebra, is the quotient arising from the division of unity by any number or quantity. Thus, the reciprocal of \( a = \frac{1}{a} \), the reciprocal of \( \frac{x}{y} = \frac{y}{x} \), and so on.

RECIPROCAL Equations, in Algebra, are those equations which contain several pairs of roots which are the reciprocals of each other. Thus, an equation whose roots are \( a = \frac{1}{a} \); \( b = \frac{1}{b} \); &c. is called a reciprocal equation. Some authors define reciprocal equations, to be those equations whose coefficients proceed in the same order from both extremes, and respectively equal to each other; thus, \( x + a x + b x^2 + c x + 1 = 0 \) is a reciprocal equation; but this form ought rather to be considered as a necessary property of these equations, by which they may be readily distinguished, than to be employed in the definition of them; it being doublts the reciprocity of the roots from which they have received their peculiar appellation.

The solution of these equations may always be made to depend upon others of half the original degree, when the equation is of even dimensions; or upon half the dimension minus 1, when it is odd.

Thus far, in fact, this property is not exclusively due to reciprocal equations, as the same may be done in all cases where any similar relation is known to have place between the roots of an equation, whether by multiplication, division, addition, or subtraction; but in those cases there is nothing in the form of the equation by which such relations may be known to have place, whereas in reciprocal equations their reciprocity becomes immediately obvious by the peculiar order of their coefficient, these being the same from both extremes, both with regard to sign and magnitude. Hence any equation of the form

\[ x^n + a x^{n-1} + b x^{n-2} + \ldots + b x^2 + a x + 1 = 0 \]

is immediately known to be reciprocal, and we may proceed in its solution as follows.

First, if the equation be of odd dimensions, as

\[ x^{n+1} + a x^n + b x^{n-1} + \ldots + b x^2 + a x + 1 = 0 \]

then it is obvious that either \( + 1 \), or \( - 1 \), is one of its roots, for either \( + 1 \), or \( - 1 \), substituted for \( x \), according as the signs of the coefficients may require, will obviously render the whole expression equal to zero, and is therefore a root of the equation. The equation may, therefore, be immediately reduced to another of lower dimensions by division, according to the known theory of equations; thus, let the proposed equation be

\[ x^5 - 5 x^4 + 7 x^3 + 7 x^2 - 5 x + 1 = 0 \]

Here \( x = - 1 \) is obviously one of the roots, as this substituted for \( x \) renders the whole equal to zero; and consequently the whole equation is divisible by \( x + 1 \), according to the known theory of equation, which division being made, we have, for our reduced equation,

\[ x^4 - 6 x^3 + 13 x^2 - 6 x + 1 = 0 \]

which is now of even dimension one degree less than the original equation, and still reciprocal. We need, therefore, only consider equations of the latter form; viz. those of which the index of the highest power is an even number.

Let \( x^n + p x^{n-1} + q x^{n-2} + \ldots + g x^2 + p x + 1 = 0 \) be any reciprocal equation, whose roots are \( a, \frac{1}{a}; b, \frac{1}{b}; \ldots \);
RECI PROCAL EQUATIONS.

If, therefore, we really perform this multiplication, and equate the co-efficients, it is obvious, since the multiplication is reduced to half the number of factors, the equation by which the values of $m, n, r, &c.$ are obtained, will be of only half the dimension of the original equation; and having found these, since

$$x^2 + mx + 1 = 0$$

we shall have

$$x = -\frac{m}{2} \pm \sqrt{\left(\frac{m^2}{4} - 1\right)}$$

Thus, for example, let there be the proposed equation

$$x^3 + 5x^2 + 7x + 5 = 0$$

Multiply together $x^3 + mx + 1$ and $x^2 + nx + 1$ to get

$$x^5 + mx^4 + nx^3 + 2x + 1$$

Comparing the co-efficients, we have $m + n = 5$, and $m + n + 2 = 7$.

Hence, $m = \frac{5 + \sqrt{5}}{2}$, and $n = \frac{5 - \sqrt{5}}{2}$

therefore, $x = \frac{5 + \sqrt{5}}{2} \pm \sqrt{\left(\frac{50 + 10\sqrt{5}}{16} - 1\right)}$ and

$$x = \frac{5 - \sqrt{5}}{2} \pm \sqrt{\left(\frac{50 - 10\sqrt{5}}{16} - 1\right)}$$

which are the four roots of the proposed equation.

From the preceding principles are readily deduced the solution of all reciprocal equations under the 10th power.

3d degree. $x^3 + px^2 + rx + 1 = 0$.

Find $z$ in the simple equation $z^3 + p - 1 = 0$, and call it $r$; then

$$x = -1, x = \frac{1}{2} r \pm \sqrt{\left(\frac{1}{2} r^2 - 1\right)}$$

4th degree. $x^4 + px^3 + qx^2 + rx + 1 = 0$.

Find the two values of $z$ in the equation $z^4 + p z^2 + q - 2 = 0$, and call them $r, r'$; then

$$x = \frac{1}{2} r \pm \sqrt{\left(\frac{1}{2} r^2 - 1\right)}, x = \frac{1}{2} r' \pm \sqrt{\left(\frac{1}{2} r'^2 - 1\right)}$$

5th degree. $x^5 + px^4 + qx^3 + rx^2 + px + 1 = 0$.
are contained in the general formula
\[ x^n - 2 \text{ cof.} \frac{2k\pi}{n} x + 1 = 0; \]

\(k\) being any integer not divisible by \(n\), and \(\pi\) representing the semi-circumference. For it is a known trigonometrical property, that if

\[ 2 \text{ cof.} \ y = x + \frac{1}{x}, \]

then \(2 \text{ cof.} \ n y = x^n + \frac{1}{x^n}; \)

from which two equations we readily draw the two following; viz.

\[ x' - 2 \text{ cof.} \ y \cdot x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \ n y \cdot x^n + 1 = 0 \]

which have necessarily one common root, being both derived from the same value of \(x\); and since these are both reciprocal equations, if \(x\) be one root, \(\frac{1}{x}\) will be another; they have therefore two roots common, and consequently, from the known theory of equations, the former is a divisor of the latter. If, now, we make \(y = \frac{2k\pi}{n}\), or \(ny = 2k\pi\), these equations become

\[ x'^2 - 2 \text{ cof.} \frac{2k\pi}{n} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} 2k\pi x^n + 1 = 0 \]

But the cof. \(2k\pi = 1\), \(2\pi\) representing the whole circumference; therefore the latter equation is the same as

\[ x^n - 2x^n + 1 = 0; \]

having still for its divisor

\[ x' - 2 \text{ cof.} \frac{2\pi}{n} x + 1 = 0; \]

that is, the roots of the equation

\((x^n - 1)^2 = 0, \text{ or } x^n - 1 = 0,\)

are all contained in the general formula

\[ x^n - 2 \text{ cof.} \frac{2\pi}{n} x + 1 = 0; \]

and, therefore, by giving to \(k\) the successive values \(1, 2, 3 \ldots \frac{1}{2}(n - 1)\), the following formulae will be obtained; viz.

\[ x^n - 2 \text{ cof.} \frac{2\pi}{n} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{4\pi}{n} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{6\pi}{n} x + 1 = 0 \]
\[ \vdots \]
\[ x^n - 2 \text{ cof.} \frac{(n - 1)\pi}{n} x + 1 = 0 \]

which contain among them all the imaginary roots of the equation \(x^n - 1 = 0\).

And if, instead of making \(y = \frac{2k\pi}{n}\), as above, we make \(y = \frac{(2k + 1)\pi}{n}\), our second formula becomes

\[ x^n + 2x^n + 1 = 0, \text{ or } (x^n + 1)^2 = 0; \]

because cof. \((2k\pi + \pi) = -1\). Consequently, the equation \(x^n + 1 = 0, \text{ or } x^n = -1, \) will have for its general factor

\[ x^n - 2 \text{ cof.} \frac{(2k + 1)\pi}{n} x + 1 = 0; \]

which, by substituting for \(k\) as above, becomes

\[ x^n - 2 \text{ cof.} \frac{1\pi}{n} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{3\pi}{n} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{5\pi}{n} x + 1 = 0 \]
&c. &c. &c.

which formulae contain all the imaginary roots of the binomial equation \(x^n + 1 = 0\).

Suppose, for example, all the imaginary roots of the binomial equation \(x'^i - 1 = 0\) were required. Here we should have

\[ x^n - 2 \text{ cof.} \frac{360^\circ}{11} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{720^\circ}{11} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{720^\circ}{11} x + 1 = 0 \]

whence,

\[ x = \text{ cof.} \frac{360^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{360^\circ}{11} - 1\right)} \]
\[ x = \text{ cof.} \frac{720^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{720^\circ}{11} - 1\right)} \]
\[ x = \text{ cof.} \ &c. &c. &c. \]

And if the roots of \(x^n + 1 = 0\) were required, we should have from the second general formula

\[ x^n - 2 \text{ cof.} \frac{180^\circ}{11} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{540^\circ}{11} x + 1 = 0 \]
\[ x^n - 2 \text{ cof.} \frac{540^\circ}{11} x + 1 = 0 \]
&c. &c. &c.

Whence,

\[ x = \text{ cof.} \frac{180^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{180^\circ}{11} - 1\right)} \]
\[ x = \text{ cof.} \frac{540^\circ}{11} \pm \sqrt{\left(\text{cof.}^2 \frac{540^\circ}{11} - 1\right)} \]
\[ x = \text{ cof.} &c. &c. &c. \]

For more on this subject, see Barlow's Theory of Numbers, Bonneycastle's Algebra, and our article Polygon.

Reciprocal Figures, in Geometry, are such as have the antecedents and consequents of the same ratio in both figures. See Plate XII. Geom. fig. 2. Here

\[ A : B :: C : D, \text{ or, } 12 : 4 :: 9 : 3 \]

That
That is, as much longer as the side A, in the first rectangle, is than the side B of the second rectangle; so much deeper is the side C in the second rectangle, than the side D in the first; and, consequently, the length of one is compensated by the depth of the other.

Also, as the side A is \(\frac{1}{2}\) longer than the side C, so the side D is \(\frac{1}{2}\) longer than D: wherefore the rectangles must be equal.

This is the foundation of that Catholic theorem; that the rectangle of the extremes must always be equal to that of the means; and, consequently, the reason of the rule of three, or golden rule.

For, suppose there were given any three numbers, or quantities, geometrically proportional, as A, B, and C; and, that it were required to find a fourth, D, proportional to them: since \(A : B :: C : D\), therefore \(A \cdot D = B \cdot C\), and, consequently, \(D = \frac{B \cdot C}{A}\); that is, the fourth term is equal to the quotient of the second, multiplied by the third term, divided by the first.

Or, thus in numbers: suppose given \(12, 4\), and 9, required a fourth proportional. Now as \(12 : 4 :: 9 : Q\).

But \(12 \cdot Q = 4 \cdot 9 = 36\). Therefore \(Q = \frac{4 \cdot 9}{12} = 3\), by dividing both sides by 12.

And hence it follows, that if any two triangles, parallelograms, prisms, parallelepipedons, pyramids, cones, or cylinders, have their bases and altitudes reciprocally proportional, those two figures or solids are equal to one another, and, vice versa, if they are equal, their bases and altitudes are reciprocally proportional.

Reciprocal Proportion, is when in four numbers the fourth is less than the second by so much as the third is greater than the first; and vice versa. See Proportion.

This is the foundation of the inverse, or indirect rule of three. Thus, \(4 : 12 :: 8 : 6\).

Great use is made of this reciprocal proportion, by Sir Isaac Newton, and others, in demonstrating the laws of motion.

Reciprocal Theorem. See Theorem.

Reciprocally, the property of being reciprocal; thus we say, that in bodies of the same weight, the density is reciprocally as the magnitude; viz., the greater the magnitude the less the density; and the less the magnitude the greater the density; so again, the space being the same, the velocity is reciprocally as the time, and the contrary.

Reciprocity. The law of reciprocity is a term used by Legendre, in his "Theorie des Nombres," to denote a reciprocal law, which has place between prime numbers of different forms; which is this; that \(m\) and \(n\) being prime odd numbers,

\[
\text{the remainder of } m^2 \div n = \frac{n-1}{2} \text{; the remainder of } n \div m = \frac{n-1}{2} \text{;}
\]

provided \(m\) and \(n\) are not both of the form \(4 \cdot k - 1\), and if they are both of this form, then

\[
\text{the remainder of } m^2 \div n = -\frac{n-1}{2} \text{; the remainder of } n \div m = \frac{n-1}{2} m,
\]
or they will have only contrary signs.

Recission, in Law. See Redemption.

Recit, Fr, a general term in music, for what is sung by a single voice. It is likewise applicable to instruments; as, recit de basse, recit de hautbois, a solo part for the violoncello or hautbois. Indeed recit, in French, seems synonymous with the word soliloquy in Italian, to whatever vocal or instrumental part it is applied, in opposition to tutti, or chorus, in which the whole band is employed.

Recit in France is not only a technical term in music, but in the drama, where, at the opening of a tragedy, or subsequent to an event, it implies an account, a narration, the recital of an event. In the French and Italian tragedies, in imitation of the Greeks, battles and murders are always recited, but never transcribed on the stage.

Recital, in Law, the rehearsal, or making mention, in a deed or writing, of something which has been done before.

A recital is not conclusive, because it is no direct affirmation; and by feigned recitals in a true deed, men might make what titles they pleased, since false recitals are not punishable. If a person, by deed of alienation, recite that he is possessed of an interest in certain lands, and assign it over by the deed, and become bound by bond to perform all the agreements in the deed; if he is not possessed of such interest, the condition is broken; and though a recital of itself is nothing, yet being joined and considered with the rest of the deed, it is material. And where it is but a recital, that before the indenture the parties agreed to do such a thing, it is a covenant, and the deed itself confirms it. The recital of one lease in another, is not a sufficient proof that there was such a lease as is recited. But the recital of a lease in a deed of release, is good evidence of a lease against the recovee, and those who claim under him. A new reversionary lease shall commence from the delivery, where an old lease is recited, and there is none, &c. A. recites that he hath nothing in such lands, and in truth he has an estate there, and makes a lease to B. for years; the recital is void, and the lease good.

In this case, if the recital were true, the lease would not bind.

Recitation, the act of reciting, or delivering a discourse, either in the way of narration, rehearsal, declamation, or the like.

Recitativo, Ital., Recitative. The Credenza Dictionary gives no more early authority for the use of this word, as a musical term, than that of Battista Doni, de Precl. Mus. Vetera, published in 1647; who defines it, "a musical composition in an andante or plain style, different from air; it is used in narrative poetry, in imitation of reciting on the stage."

Rouilly's definition is more full and clear. He terms it "a discourse, or speech, in musical and harmonical tones. It is a melody nearly approaching to common speech; a musical declamation, in which the music ought to imitate, as much as possible, the inclusions of voice in declaiming. This melody is called recitative, because it resembles a narration, a recital; and is used in the dialogue of musical dramas."

We have presented our readers, under the article Opéra, with extracts from the prefaces of the poets and composers by whom recitative was invented, as well as from contemporary writers, who thought its origin of sufficient importance to be recorded.

Giovanni Battista Doni, about the middle of the 17th century, (Op. Om or. tom. ii. in Firenze, 1762, folio,) a learned and elegant writer on music, though extremely warped in his judgment by a predilection for the music of the ancients, in a dissertation on the Origin of Stage-singing, during his own time, gives to curious and instructive an account of the first operas that were performed at Florence, that we shall translate a part of it.

"Some kind of cantilena, or melody, has been introduced in
in dramatic representations, at all times, either in the form of intermezzi (interludes), between the acts; or, occasionally, in the body and business of the piece. But it is still fresh in the memory of every one, when the whole drama was first set to music, and sung from the beginning to the end.

The revival of theatrical music was brought about by the invention of recitative, as we have already stated in our article Opera.

The beginning of this century (1600) was the era of musical recitation on the public stage at Florence, though it had been used there in several private exhibitions before. There reposed in that city, during these times, Signor Gio. Bardi dei Conti di Verano, who was afterwards called to the service of pope Clement VIII., by whom he was tenderly beloved, and made his maestro di camera. This noble accomplished nobleman was particularly attached to the study of antiquity, and to the theory and practice of music, to which he had applied himself for many years so closely, that he became, for the time in which he lived, a correct and good composer. His house was the constant rendezvous of all persons of genius, and a kind of flourishing academy, where the young nobility often assembled to pass their leisure hours in laudable exercises and learned discourse; but particularly on musical subjects, when it was the wish of all the company to recover that art of which the ancients related such wonders, as well as other noble inventions, which had been ruined by the irruptions of barbarians.

"During these discussions, it was universally allowed that as modern music was extremely deficient in grace, and the expression of words, it became necessary, in order to obviate these objections, that some other species of cantilena, or melody, should be tried, by which the words should not be rendered unintelligible, nor the verse destroyed."

Euridice was the first musical drama after the invention of recitative. It was written by Ottavio Rinuccini, set by Jacopo Peri, and performed at Florence in 1600, on occasion of the marriage of Mary of Medicis with Henry IV. of France. The poem and the music were published separately the same year. The poet, in his dedication to the queen of France, says, "It is generally imagined that the tragedies of the ancient Greeks and Romans were entirely sung; but this noble kind of singing had not till now been revived, or even attempted, to my knowledge, by any one; and I used to think, that the superiority of our music to that of the ancient was the cause; till hearing the compositions of Jacopo Peri to the fable of Daphne, I wholly changed my opinion. This drama, written merely as an experiment, pleased to such a degree, that I was encouraged to produce Euridice, which was honoured with still more applause, when sung to the music of the famous composer Jacopo Peri, who with wonderful art, unknown before, had merited the favour and protection of the grand duke our sovereign, it was exhibited in a most magnificent manner at the nuptials of your majesty, in the presence of the cardinal legate, and innumerable princes and nobles of Italy and France."

Such is the abridged history of recitative. The only printed copy of the music to this primitive opera was in the library of the marchese Rinuccini, a descendant of the poet at Florence; in examining and making extracts from which, we observed that it was printed in score, and barred; two very uncommon circumstances at the time of its publication; that the recitative seemed to have been not only the model of subsequent composers of early Italian operas, but of the French operas composed by Lulli, a native of Florence; and that the time was as frequently changed as in the old French operas.

The confusion arising from all the parts singing different words at the same time, together with some other circumstances, mentioned under Opera, account for the necessity of a recitative, or a musica parlante, a speaking music, and for solo singing in general on the stage; besides, poetry was injured, and rendered unintelligible in fugues, canons, and in choruses, full of imitations and contrivances, all unfit for narration and dialogue.

To describe the characteristic difference of recitative from air, and common speech; it is not air, as no time is kept; it is not speech, as every inflexion of voice is in tune with some one note of the instrument by which it is accompanied; and as to the length or shortness of the notes that are written, the accompanist watches for the accents or termination of phrases, or lines in the verse, to give the chord to which the note that is sung belongs.

It is sometimes accompanied by the orchestra with ritornelli, or interludial harmonies; but then a regular time must be kept. This only happens in solemn scenes of dignity or dirge, and in folemnes.

No slurs or sharps are placed at the clef in recitative; these are all regarded as accidental; nor is Italian recitative ever confided to any one key.

After recitative was found, it was long ere any thing like an air appeared in these musical dramas. (See Opera, Air, Motivo, and Measure.) Rouillard has treated the article recitative at large, with great intelligence and good taste.

Reccitative Style, is the way of writing accommodated to this sort of music.

RECIV, LA, in Geography, a well-fortified town of Brfft, in the jurisdiction of Fernambuco.

RECKENITZ, a river which separates the duchy of Mecklenburg from Pomerania, and runs into a lake, which communicates with the Baltic near Ribnitz.

RECKHEIM, or REKUM, a town of France, in the department of the Lower Meuse, which gives name to a county, situated on the W. side of the Meuse, and surrounded by the bishopric of Liége; 7 miles N. of Miétrich.

RECKLING, in Rural Economy, a provincial word, signifying the left of the farrow or brood of pigs, poultry, or other sorts of domestic birds.

RECKLINGHAUSEN, in Geography, a town of Germany, fortified by a castle, and capital of a county of the name, which is situated between the bishopric of Munster, the duchy of Cleves, and the county of Mark; 16 miles S.S.W. of Munster.

RECKON, in Rural Economy, a term sometimes applied to a pair of pot-hooks of a certain make, occasionally employed in dragging wells, ponds, &c.

RECKONING, in Navigation, the act of estimating the quantity of a ship's way; or of the distance run between one place and another.

Or, more generally, a ship's reckoning is that account, by which at any time it may be known where the ship is, and on what course or courses she is to steer to gain her port. See Log-Board, Log-Book, and Journal.

This is usually performed by means of the log-line; the manner of applying which, see under its proper article, Log-Line.

Yet this is liable to great irregularities. Vitruvius ad

vives an axis to be passed through the fide of the ship, with two large heads projecting out of the ship, in which are to be included wheels touching the water, by whose revolution the space passed over in any given time may be measured. The fame has since been recommended by Snellius; but
but there are few who have written of navigation, that have not deemed the insufficiencies of this method.

**RECKONING,** Dead. See Dead Reckoning.

**RECKSON,** in Geography, a town of Bengal; 6 miles E. of Calcutta.

**RECLAIMING,** or Reclaiming, in our Ancient Customs, the action of a lord purifying, proscribing, and reclaiming his vallay, who had gone to live in another place, without his permission.

Reclaiming is also used in a similar sense, for the demanding of a person or thing to be delivered up, or surrendered, to the prince or state it properly belongs to; when, by any irregular means, it has come into the possession of another.

Reclaiming, in Falconry, is the calling of a hawk, or bird of prey, back to the fill.

The sparrow-hawk, geo-hawk, &c. are reclaimed with the voice; the falcon only by shaking the lure. So that the term luring, with regard to the falcon, is more proper than reclaiming.

The partridge is also said to reclaim her young ones, when she calls them together upon their scattering too much from her.

Reclaiming is also used for taming animals that are wild by nature.

**RECLAIMING,** in a monastic sense. See Religious.

**RECLAIMING Lands,** in Agriculture, the business of re-flouring and bringing them into a state of cultivation and improvement. There are various kinds and states of land, which admit of this form of amelioration and improvement; as among the wet forts, all those of the bay or estuary description, which are waffled and occasionally covered by the sea or other waters; different descriptions of fea lands, and those of the more firm marshy nature, and those in more inferior situations, which are of a lowe swampy or watery quality, as marshals and boggy grounds. And among those of the more dry, hard, wales, and wild descriptions; all the varieties of the rough fea of unimproved lands; the many different kinds of rough woody grounds; and the numerous forts of moorly lands, as well as other varieties, which are now and then to be met with in particular circumstances and situations.

The first of the wet or watery forts of land, noticed above, are far from being always ready, or in a ripe state for admitting improvement of this nature; yet in different situations and circumstances, they occasionally permit of its being accomplished, without any great difficulty or trouble. See Embankment, and Embanking against the Sea.

The fenny and marshy lands, where, in the former, they are wholly or only in a partial manner overflowed by ufeless aquatic plants; and in the latter, become so firm as to bear palfuring flock, and to afford nutritious herbage for their growth and support, but are notwithstanding fall liable to be overflowed by high tides, or land floods; are, of course, capable of very great improvement in the above ways, as well as by many other means. See Fen, Fenny Land, Marsh Land, and Salt Marsh.

These forts of watery lands are not incident to the flat bays and inlets of the sea-coafts, or the mouths of the large rivers, in a particular manner; but are met with in the more inland situations of the country, accompanying the larger rivers and waters in the more central parts of the kingdom: consequently such forts of improvement must be very extensive in their nature, and of very great importance to the nation.

The other kinds of swampy watery lands, which are liable to be covered with that fluid during wet seasons; those on the sides of lakes and ponds; the marshals which are choked and grown up with aquatic vegetables, to as to have some fort of hardisf curf formed upon them; and the soft boggy lands, formed in somewhat similar ways, are all capable of allowing great improvement, by suitable draining, and other methods of management. See Spring and Surface Draining, Swamps, Bogs, and Marshes.

The lands of the above kinds are mostly met with on the lower slopes, or at the feet of hilly grounds; being caused by the flagration of water in their internal parts, which has the effect of chilling and rendering them too moist for the production of a nutritious and useful herbage, as well as of promoting the growth of coarse plants of the aquatic nature, though their situations may occasionally have some degree of relative height.

There are many valuable tracts of land of these kinds, in many different parts of the island, which have been already reclaimed by these methods of proceeding; which should have the effect of stimulating the owners of such lands in other places, where they still remain unimproved, to exert themselves in getting them reclaimed.

Among the more dry kinds of unimproved lands, the first, or those of a rough, fony, walle quality, are all those in the valleys of hilly or mountainous tracts, on the skirts or lower parts of mountainous heights, and the rough fony lands, fit for cultivation, in other situations. They are the most readily reclaimed and improved, in the less hilly forts of lands and situations. In some cases, where the surfaces of the ground were in a great measure covered by large rocks and fones of great sizes, very hard in their qualities, and of scarcely any value, the lands have been reclaimed, and brought into an arable state, and let for high rents: the fones which were removed paying, in a great degree, the expences of the labour; they being exported and sold as paving-fones, and for other ufe to the metropolis. And though this cannot always be done, it shews what is capable of being performed by industry and perseverance; and that, where surface fones can be turned to useful purpofes, the most rugged and barren lands may be reclaimed with advantage, under proper modes of management. In fuch instances, instead of leaving the surfaces of the grounds in worfe flates than they were before, by being taken up with pits, and heaps of ufeless rubbish, which buried the better moulds, as is common in working superficial quarries, the pits and other hollows were levelled, and filled up to some height, with the coarse and rubbish materials produced in the course of the works, and the finer mould from other parts thrown back upon the above sub-foil materials, so as to form an even top-foil; the larger spaces of the ground being trenched over to a good depth, leaving the bed foil on the surface. It is suggested, that by following similar easy methods of management, in carrying on under undertakings of the fame kind, lands of a value in proportion to that of the materials which are removed, may commonly be created, without incurring any very great expence. Hence it is thought to behave those who have the direction and management of landed estates, that comprehend grounds of these forts, to examine and confider well whether the fony materials which they contain, and encumber their surfaces, cannot be turned or converted to some profitable purpofe, by the means of roads, iron railways, canals, or some other easy mode of conveyance for such heavy flubstances.

It must be noticed, however, that the method of levelling and trenching over the lands by the spade, in fuch circumstances, can only be practifed in a very few cafes, where labour is particularly cheap.

There is another description of fony lands, of a much less
lems formidable nature, which frequently stands in need of being reclaimed, and in which the surface is less encumbered than the interior parts of the soil. In these cases, the interrupting materials are rather large stones than rocks, though the latter may sometimes in part form them. The means which are best suited to the bringing of these into a profitable state of cultivation, are to be found in the more northern parts of the island, in the practice and exertions of particular spirited individuals. The plan of the improvement is perfectly simple, but it is expeditious in its performance; the whole of the lands being broken over, by means of the spade, to a proper depth, as from one to two feet. The stones which are not wanted for use are thrown into pits, and the hollow parts, to contribute to their being made level, and sometimes into the deep trenches formed in digging, being filled covered with the woof of the earthy materials, upon which the better moulds and turfy substancc, which are thrice in the work, are spread out as a foil, by which the whole is rendered very suitable for agricultural purposes.

The soil of reclaiming lands in this way depends, in some measure, on the call of surface in the lands, the nature of the interrupting matters, and the depth of the earthy substanccs to be removed, in raising a sufficiency of mould for forming the surface foil: but from five to twenty pounds the acre may be considered as the limits of the charges.

And this, it is supposed, leaves an ample profit in the sale of such lands, or otherwise, in those situations where tythes are not taken, and where the rates and taxes are so very few and trifling, and where labour and living is so cheap. It can now, however, be done in this manner in but few instances, as has been already noticed.

It is, notwithstanding, believed that there are very many lands, not only in these northern parts, but in England and Wales, that would more than repay the expenses of this spirited mode of improvement. It may be remarked, that where the stones are very large, or where fragments of rocks are met with, in these undertakings, they may be got rid of either by blasting, or rending their upper parts, or by sinking them in the foil, so as to allow the plough to pass over them with safety.

The former method is more suited to the less forts of stones; the latter to those of the harder kinds.

Such rocky grounds as are common in hilly and mountaneous situations, which, on account of their climate, and the compact nature of the rocky materials, as well as their quantity, are incapable of being cleared as corn-lands, or fo as to admit the plough, may often be reclaimed and improved as pasture lands for sheep, &c. or sometimes as hay lands. The plan of proceeding, in these cases, is that of removing the flaky matter from the surface, and allowing it entirely to the growth of grasy herbage; the means of accomplishing which are similar to those already noticed, but the soil considerably less: the main intention here being merely the smoothing of the surface ground, for the purposes of pasturing or mowing; but the more the flaky substanccs are covered with good earthly mould, the better and greater will be the quantity of produce. See Til-lage.

There are many rough woody tracts of ground, of the shrubby or other kinds, which may be cleared and reclaimed with ival advantage to their proprietors, as well as the community in general, as corn-lands, or for other ues. The most useful method of accomplishing this fort of improvement has been to dig out the whole of the roots, whether of low woods or timber woods, at the time of removing the tops, so as to admit the plough immediately. In perform-

ing this in this way, however, where the floors are of the timber kind, numerous and large, deep breaking of the ground is often necessary, which is laborious and expensive; and rotten wood, mould, leaves, and other surface matters, are apt to be left in mixture with the inferible or poisonous sub-flora. As lands, cleared and reclaimed in this manner, have been known to remain in a rare unprofitable condition, for several years, although hindered, dangered, and raised in sharp ridges, in order to its amelioration.

This improper practice has consequently been highly disadvantageous, injurious, and ruinous, and thrown much difficulty and interruption in the way of clearing and reclaiming such wakle lands for the growth of corn, however fustable they may be for the purpoce in the nature of their soils and situations, thereby tending to propagate and support the notion, that such forts of land will not repay the expenses and trouble of being improved.

But from attending to what has naturally happened to the cleared parts of wood-lands, it will be seen that a depth of fertile mould, rearing on lads fertile substanccs, form a regular foil and sub-foil, which are free from the roots of trees, ready to receive the plough, and afford corn crops in due succession. It is supposed to take place somewhat in this way. The trees having been suffered to become decayed, or more properly cut down in due season, and the brush or underwood cut and cleared away from time to time by the occupiers, while such commons or other places were fully or too much flocked with cattle and sheep, the young shoots were of course browned off and nibbled away quite to the stubs, conseqently weakened, and at length fially destroyed. The roots and other parts soon followed this course, and passed into a state of vegetable mould, increaing and enriching the soil at the same time. Nay, this may, in the natural state, it is supposed, be, in some measure, effected alone by the grazing animals, as it is essential to their existence.

This natural process, however allfified in this way, is flow, requiring a length of time for its completion; yet by proper means of art, well applied, it may be accomplished in a few years; the larger roots being extracted from the ground, instead of waiting for their reduction by a flow deelay, without any unnecessary disturbance of the sub-foil; and then filling in the pits by the roughnesses of the natural surface; by which means the cleared ground will be smoothed, and made fit in due time for being cultivated. Whereas the surface is much incumbered with leaves and rotten woody matters, they are to be raked up, and put into heaps to decay; or they may be burnt, and the ashes spread out over the surface of the land. Proper draining and further levelling mufl likewise take place, where necessary; as well as growing or hacking the surface forward, fo as to fow it with proper grafts seeds; again raking off any rubbith that may arise, and then rolling the whole quite smooth for mowing. It should be rocked hard, especially with sheep, mowing of occasionally any woody shoots that may be permitted to arise; keeping the whole in the state of close par-turage, until the smaller roots, which were left, be so decayed as to become obedient to the plough-share. At this period, but not before, such pasture ground may be broken up for grain crops in proper succession.

The process might be hastened by the use of lime, or other calcareous matters in union with the vegetable substanccs which were removed, as they would be sooner dissolved or reduced, and the compost more rich. And by spreading them out on the land a similar effect might be produced, and a finer fort of herbage be encouraged, which would cause a closer bite, and sooner bring the land into a mor
more thick set flate of sward, which is the prolific matrix for corn crops.

The really necessary expense of reclaiming and bringing these kinds of wooded lands into a state of cultivation, by these means, is inconsiderable, particularly where fuel is dear. Where the timber wood is properly cut down by the axe, and the underwood taken off rather below the surface, the larger roots, and the flubs which are left, will, in some instances, more than repay the cost of the clearing and levelling the surface. And the other expenses will be repaid by the immediate production of a pasturage ground, the value of which is constantly increasing without any further charge, until it may probably be worth two or three times what the lands were while they were in the woody condition.

In cafes where fuel is cheap, and particularly when the timber wood is rapidly fallen, as in the barking teafon, they may be cut off by the low level with the surface of the land; the flods and large superficial roots being after that carefully disbarked to some inches within the ground, so as to prevent their throwing out shoots to injure the surface and keep the roots alive. In this way the flods will be so decayed in a few years as to be capable of being removed with little trouble or expence. See Tillage.

In clearing and reclaiming moory lands where they are too wet, the first step is that of properly draining them; they are afterwards brought into cultivation and to their full value by other means, such as in large undertakings, by suitable divisions of the lands into fields proper for the farm or farms to which they are to be laid, and so ditched as that the surface water may be effectually taken off, without having deep, open, expensive troublesome drains in other parts; the surface of each field being adjusted in such a manner as to shoot off the rain water into the interjecting ditches, in order to prevent injury from happening, in that way, so as to impede the cultivation for any length of time.

As the surfaces of these kinds of land are mostly rugged and uneven, as well as of a looie spongy texture, which unfits them for the tillage procefses, without previous affilience from hand labour; where the moory earth, or vegetable mould, is deep, and rises to the surface uncovered by foulles matters, some length of time is requisite to bring it to that solidity and firmness of texture which is suited to the common arable purposes. Hence the general principle of improving deep moory lands, where there is no foulles covering, is supposed to be the same as that advised for bringing woodland into cultivation; namely, that of converting them to a profitable flate of herbage, before corn, crops are attempted to be produced.

The procefs must be guided and regulated by the nature and situation of the tract to be improved. Where the surface is very irregular, full of inequalities, and of an abrupt nature, it must first be adjusted so as to admit the means of tillage when they can be properly had recourse to, and for carrying away the surface water in the manner already noticed. Then to pare off the leffer hillocks and rifiings, as the tufts and hillocks which were formed during its wet state, and more or lefs of its general surface, so as to remove the coarse plants and flate mould which occupy it, and thereby produce a frequencs in the whole.

In dry teasons, when the surface has sufficient firmness to bear the tread of animals, the paring may be done by the rough for that purpose, but in other cafes by the breast-plough or paring-plod. When the surface has been cut over in this manner, and any part has the appearance of being too wet, as may be judged of by the colour of the mould, in some degree, covered flods are to be formed in such places, which may commonly be made in a cheap and durable manner by the firm fibrous tufts collected from the surface. The rill of the roots and mould which were pared off should be burnt, and their ashes spread evenly over the surface, being immediately raked or harrowed into the foil. At this period of the improvement almost any kind of foille material can be thrown over the ashes at a little expence; and a full quantity of different feeds be covered in with it; leaving the surface to take on a sward without any further trouble or outlay of money.

Afterwards the grassy herbage is to be kept closely fed down when the weather will permit, first by sheep and then by heavier forts of stock, until the surface becomes firm and the foil is well bound together by the fibrous roots of the herbage, so as to be capable of affording corn crops in proper incellion.

It has been objected to this summary mode of bringing the land into the state of herbage, that there are no immediate gross returns for the money laid out in reclaiming and bringing it into the cultivable state. But although corn cannot be raised on such raw looie-textured forts of land at first, potatoes are found to answer well, and rape with still more advantage in its culture, the labour attending it, and the profit which it affords. See Moor, Moory-Land, Spring and Surface Draining, &c. See also the Inverness-shire Agricultural Report.

The reclaiming and bringing lands of these several different descriptions into a state of cultivation and improvement is evidently a work of very great importance, particularly in a country where the population is getting too numerous for the produce, as by such means the extent of agricultural territory may be justly said to be increafed. Extensive improvements of these kinds have lately taken place in Cornwall, and some other southern districts.

Reclaiming Plantations and Timber Woods, in Rural Economy, the reflowing of such as have grown into a wild, neglected, and improper flate from some fort of mismanagement, or want of attention. The causes which have a tendency to produce this effect are very numerous, and have been the means of vast individual as well as national losfs. One material and very frequent caufe is the neglect of their boundary fences; another is the mistaken notion of its being the best practice to leave them entirely to nature after they are once properly planted; a third is the very absurd supposition, that nothing should be done to them for a length of time after planting, in the way of rendering the trees more thin among themselves, or in their branches; and lastly, an universal carelessness and disregard of them, frequently from the narrow conception of expence being incurred without the chance of any immediate return of profit. It is, on the whole, much too common to take great care in first forming the plantations, without ever thinking or taking any fort of interest in their after-management. But the bufnels is by no means accomplished in the simple act or operation of planting out the trees. Good examples of this kind of management are indeed few, but they occasionally exist, and much has been written on the matter, so that information may be readily obtained. And there is every inducement to get it; as well prepared, inclosed, planted, cultivated and managed plantations, will far outgrow others that have existed for a much longer time, but have been otherwise treated, often affording more than woods of three times their length of standing.

In directing the proper management in all cafes of this nature, some attention must be paid to the particular kinds of the plantation which they may be, in the first place; after which, the means of reducing them to their appropriate rates, or to some other in the most easy and convenient manner,

Vol. XXIX.
manner, may be taken into consideration. It may often happen that their proper originally intended states cannot be attempted, but that which has been gradually acquired must be promoted. With a view to the accomplishment of those intentions, plantations may be considered as consisting either of hard woods only, of evergreen or ruminous trees only, or of both these sorts of trees in mixture.

In the first of these kinds, or those which are composed solely of the hard-wooded sorts of trees and plants, where they are to be brought to the state of woods, as timber trees and undergrowths, and the latter to be used only as fuel, the good trees of such kinds as are suitable to the soil, and the probable demand of the vicinity and other parts, should be fixed upon, and left as standard trees; the whole of the others being cut over by the surface of the ground, so that they may become stools for supplying the undergrowths. When this has been performed, the ground, where necessary, should be dug, loosed, or trenched over, as circumstances may direct; but where the trees and underwoods have been much crowded, these kinds of work will seldom be required. However, if, instead of the common underwood, oak be required, then after itching upon the most proper and suitable standard trees for remaining, the whole of the rest are to be taken up by the roots, the land dug over, and acorns planted out upon it; which, when they are grown up, must be kept clean and free from weeds for some years, in order to promote their healthy growths and rising to the state of young trees.

Where the whole is to be reduced to the state of coppice wood for fuel only, the belt way is to cut over every part by the surface of the ground; and when for bark, to root out the whole, only referring the oaks, and planting with acorns, as already noticed.

In the grove forms to be produced, the most suitable and appropriate trees are to be left at proper distances, and the whole of the remainder taken out by the roots; after which the ground should have the proper culture, until the trees are incapable of being injured by cattle itch; at which time the whole may be laid down with natural grass feeds.

In the second sorts of plantations, where they have remained, after planting, without being in any way thinned, for a great many years, they are often, in a great measure, incapable of being remedied, as they are, for the most part, so overgrown by other trees, that their growth is suffering; wherever any thinning takes place, the trees all around are destroyed. In these cases it is the advice of some to have the whole grubbed up by the roots and replanted, after the ground has been properly prepared by following and repeated corn crops. But as there may sometimes be much loss in this way, it may be proper to try the cautious thinning of them, which should be done during the latter summer months in a careful manner, as success has occasionally attended this method.

With natural plantations of this kind under twenty years' growth, and artificial ones under ten, much advantage has been gained by suitable cautious thinning and retrenching. In all these cases there is no necessity whatever for the cultivation of the ground, as the trees suffer fewer or no plants to rise below them, and besides, injury may be done to their superficial roots.

The management in the laik or mixed kinds of plantations, where the evergreen woods are in such proportions as not to admit of either of the above modes, is to reduce them to the grove plan only, or to this in some parts and the wood kind in others; the modes of accomplishing both of which have been already laid down. However, in each of these methods, it will frequently happen that the tree or trees which are the most advantageous and definable in the parts where the plantations exist, are either very deficient, or wholly wanting. In all such instances it is probably the best and most beneficial practice to grub up nearly the whole of such trees, and replant the ground with the proper fort or forts; care being taken to leave such a number of the old trees, either in a scattered manner, or in narrow strips and few rows, for sheltering and protecting the young trees, plants, and seeds, which have been put in, planted, or sown. See Plantation and Wood.

It may be noticed that in reclaiming all kinds of wild and neglected plantations in lands which are inclined to the retention of moisture; the first thing which is necessary is invariably that of the removal of the flagrant wetness, as where this is not properly performed, the other operations will be of but little avail, however well they may be executed. In many extensive tracts of this nature, the injury which is sustained by this fort of neglect is scarcely to be calculated. There are many thousands of acres, in different situations in this country, which would by this means alone be brought to twenty times and more their present value. And as this fort of work in such cafes can, for the most part, be accomplished by open cuts or gutters alone, at a very trifling expense in comparison of that for arable and some other forts of land, it should never be neglected where good management is in the least degree attended to. See Spring and Surface Draining.

It is a material point in reclaiming all these sorts of plantations and timber woods, to keep the surrounding ditches and fences well up and in a proper state; as large tracts are often completely ruined in a very short time by attention in this respect, from the cropping, rubbing, and destruction in other ways produced by the entrance of cattle of different kinds into them. There is hardly anything so injurious to the more young timber plantations as cattle being suffered to get into them. See Fence.

The retrenching of old ill-managed plantations of these kinds should confinantly be done in a very gradual manner, having due regard to their length of standing, the nature of the trees, the quality of the land, the situation and exposure, as well as some other points. Their outside parts are in general to be left more thick and close, than those which are more in the interior, and the parts of the foil which are of a bad thin quality, should be left less thick of trees and plants than where it is of greater depth and richness. And open exposures should be kept more thick and close than where they are more warm and sheltered.

In retrenching the branches of the different trees, the work should be performed according to the length of time the trees have been growing, their particular growths and sizes, the difference of kind, and the uses, purposes, and intentions for which their wood or other parts are designed. It is always proper to flop rather short, than to carry it to an extreme, as there is sometimes danger in the latter cafe. See Pruning.

It is always necessary and essential to reclaim these old wild sorts of plantations as soon as possible, as the forming of new tracts of this kind chiefly benefit posterity, while the ameliorating and improving of the other, by these means, are an immediate and direct gain to the present proprietors, of very great national importance at the present time, and which would otherwise be complete loss to both.

No sorts of woods of the timber kind should indeed ever be suffered to remain any great length of time without being properly looked over and put into such states as that they may go on in the most beneficial and profitable manner, as
where they are in any way or by any means restricted or impeded in their growths, there is a constant and continual loss taking place, and the ultimate disadvantage is pro
digiously great, as the timber never becomes either so good or in such quantity; of course it is of inferior value in both respects, which makes a difference of much conformance to the proprietors as well as to the nation at large. See Wood.

RECLINATION of a Plane, in Dialling, the number of degrees which a dial-plane leans backwards, from an exactly upright or vertical plane, i.e. from the zenith. The reclination is easily found, by means of a ruler, and a quadrant; for having drawn an horizontal line on the plane by a level or quadrant, and to it another line at right angles, apply a ruler, so that one end of it may hang over, or reach beyond the plane; then will a quadrant, applied to the under edge of the ruler, shew the degrees and minutes of the plane’s reclination; counting from that side of the quadrant that is contiguous to the edge of the ruler. See LEAF.

RECLINATUS CAULIS, a reclined item, is bent towards the earth, as in many species of Ficus, Saliis, Rubus, &c.

RECLINER, or RECLINING Dial, is a dial whose whole plane reclines from the perpendicular; i.e. leans from you when you stand before it.

When this reclination is equal to the height of the pole, the dial is said to be equinoctial. See DIAL.

RECLINER, Declining, or Declining reclining dial, is a dial which neither stands perpendicularly, nor opposite to one of the cardinal points. See DIAL.

RECLUSE, among Religious, a person close shut up in a very narrow cell of a hermitage, or other religious house; and cut off, not only from all conversation with the world, but even with the house. The word is chiefly used for such as thus imprison themselves out of devotion, to do penance. It is sometimes also applied to incontinent wives, whom their husbands procure to be thus kept in a perpetual prison in some convent.

Recluses were anciently very numerous; they were then a kind of solitaries who shut themselves up in some little cell, with a vow never to stir out of it.

None were admitted to this oath until they had given sufficient proofs of their abstinence, and had leave from the bishop, or the abbot of the monastery where they were shut up; for the cells of the recluses were always to join to some monastery.

The prelate’s permission being obtained, they were tried for a year in the monastery; out of which, during that time, they never stirred.

They were then admitted to their vow of stability in the church before the bishop; which being done, and the recluse having entered his little cell, the bishop fet his seal on the door.

The cell was to be very small, and very exactly closed.

The recluse was to have every thing within it necessary to life; and even, if he were a priest, an oratory consecrated by the bishop, with a window which looked into the church, through which he might make his offerings at the mafs, bear the finging, sing himself with the community, and answer those who talked to him. But this window was to have curtains before it, both within and without; so that the recluse might neither see, nor be seen.

Indeed he was allowed a little garden in his reclosure, to plant a few herbs, and take fresh air; adjoining to his cell was that of his disciples, which he was very rarely without; with a window, through which they served him with necessaries, and received his instructions.

When it was judged proper to have two or three recluses together, their cells were made contiguous to each other with windows of communication; if any woman would consult them, or confess to them, it was to be in the church, and in the presence of all the world.

Where there were two or three recluses together, they were never to hold any conference, but on spiritual matters, and to confess to each other; where there was but one, he was to confess and examine himself.

If the recluse fell sick, his door was opened for people to come in and afflict him; but he was not allowed to stir out on any pretence whatever.

These articles are extracted from the rule, compiled for the recluses, by Grimaldi, a priest in the ninth century.

There were also women recluses, who led the same life, in proportion. St. Viborade lived a recluse at St. Gall, and was there martyred by the Hungarians in 825.

RECLUSION, the state of a recluse; or the cell and other appurtenances of it.

F. Heliot gives a particular account of the ceremonies practised in the reclusion of a woman, in that of mother de Cambry, in the monastery of Notre Dame. A cell being built for her in 1625, adjoining to the church of St. Andrew, in Turnay, the bishop waited for her early in the morning at the church-door. Upon her arrival, prostrating herself at the feet of that prelate, he gave her his benediction; conducted her to the grand altar; and there blessing a mantle, veil, and fcapular, he put them on her, and gave her a new name.

Having here made her vow, and the bishop having arranged the people in praise of the new recluse, he conducted her processionally to her reclusion; the clergy all the way finging Veni, sponsa Christi, &c.

Here the bishop, blessing her abreast, consecrated the reclusion, and shut her up in perpetual confinement.

RECOGNISANCE. See Recognizance.

RECOGNITION, recognition, denotes an acknowledgment. The word is particularly used in our law-books, for the title of the first chapter of the flat. 1 Jac. I. by which the parliament acknowledged the crown of England, after the death of queen Elizabeth, to have rightfully descended to king James.

RECOGNITIONS of CLement, in Ecclesiastical History, a supplication or apocryphal book, ascribed to St. Clement, but really composed by some learned and eloquent man in the second century. Rubius, who translated the ten books of Recognitions out of Greek into Latin, in whose translation only we now have them, plainly supposes them to have been written by Clement of Rome; but that the copies, in his time, had been corrupted in some places. The first ecclesiastical writer who has mentioned this work is Origen, by whom it is cited twice; but he does not seem to have held it in high estimation. Eusebius, who is supposed to mention the Recognitions under the title of “The Acts of Peter,” which made a part of them, rejects them, and owns no work for St. Clement, but his epistle to the Corinthians. Epiphanius mentions “The Travels of Peter” as written by Clement, but corrupted by the Ebonites, fo that little was left that is genuine. St. Jerome’s opinion of the works of Clement coincides with that of Eusebius. This book is, for a large part of it at least, says the learned Dr. Lardner, a fiction or romance, in which divers things concerning the Christian religion are representate in a philosophical manner, in order to render them more agreeable to the Greeks.
is called the "Circuits," or "Travels and Acts of Peter," from its subject; as it contains an account of the apostle Peter's disputes with Simon Magnus, and his discourses to other people, and his miracles. It is called the "Recognitions," from Clement's recognizing his father, and mother, and brethren, who had been long separated from each other.

Mr. Whifton, though he allows that this work was not written by Clement himself, supposes that it was the production of some of the hearers of Clement, and other companions of the apostles; but Dr. Lardner is of opinion, that it must be reckoned to be Clement's, or to be so purportive. With regard to the age of this work, Lardner farther adds, that the arguments here urged against Heathens seem to imply, that the Christian was not yet the prevailing established religion. And the author often speaks of the power of Christians to heal diseases, and to expel demons, as if it was common in his time. That such gifts were enjoyed by many Christians in the second, and in the beginning of the third, century, we are assured by Ireneus, Tertullian, Origen, and others; after which time, or however after the end of the third century, they were not so common, if they did not quite cease. Mr. Whilton's opinion of this book is, that if it be not, in some sense or other, itself a sacred book, yet it ought certainly to be esteemed in the next degree to that of the really sacred books of the New Testament. But in the opinion of many other learned men, it is a worthies piece, of little or no use. It contains, however, as Dr. Lardner suggests, some excellent sentiments, and fine passages, intermixed with very great faults, for which no excuse can be made. This book contains passages of our four gospels, though it has been doubted whether he used the four, or some one gospel containing in it all these. Its author seems to own the first epistle of St. John, and the book of the Revelation. He was also well acquainted with the book of the Acts of the Apostles; but it is not certain how far he owned it. The passages from St. Paul's epistles are not sufficient to prove, that they were esteemed by this writer to be of authority. The author does not seem, indeed, to have any great kind of esteem for the apostle Paul, and on this account he made little use of his epistles, and of the Acts of the Apostles. From his fly imputations, and injurious reflections upon St. Paul, it may be supposed that he was a mere Ebionite; the ancients assuring us, that this sect of Christians rejected the authority of that apostle and his epistles. The author bears testimony to many principal facts of the New Testament. He gives an account of our Lord's temptation; he mentions the choice of the 12 apostles, and afterwards of other 72 disciples. In one place he speaks of the 12 apostles in such a manner as if he intended to exclude Paul from the honour of the apostleship, and even to deny him the character of a sufficient and faithful "preacher of Christ's word." We have also, in this book, relations of the miracles of our blessed Lord's ministry, and of his death and resurrection, and the extraordinary signs attending these events. Grabe's Preface to the Writings of St. Clement in his "Spicilegium." Coteler apud Patr. Apol. tom. i. p. 344. &c. See Clementine Homilies.

Recognition, in the Dramas. See Discovery.

Recognition, in the Ablution per vim et duritiem fatio, in Law, is a writ to the justices of the common bench for granting a record touching a recognition, which the recognizor fugitives to have been acknowledged by force and hard dealing, that if it appear, it may be annulled. Transfertion Recognitionis facta coram justitiariis iterantibus. See Transcriptio.
among the cylinder, is to the length of the cannon diminished by the space behind the ball, as the weight of the ball is to the weight of the cannon. Let a twenty-four pounder of ten feet be 6400 pounds weight, and when the ball quits the piece, the cannon will have recoiled \( \frac{1}{16} \times 10 = \frac{1}{16} \) of a foot, less than half an inch.

The greater the charge, \( \text{ceteris paribus} \), the greater the rebound. By an experiment made before the Royal Society, and related in the Philosophical Transactions, it was found, that cannons, charged to a certain degree, throw the ball from right to left of their own direction; but that the can-
nons themselves recoil from left to right.

Some of the gentlemen of the French academy doubting the julluctions of the observation, M. Caflini, the younger, under-
took to repeat the experiment; which he did by means of a machine, as like that used in England as he could: and that tried over and over again.

The result was, that the ball, when the gun had liberty to recoil, was always thrown to the right of the point to which it was thrown when the gun was fixed without a possi-
ibility of rebounding; but then the recoil was always made the same way, \( \text{viz.} \) to the right; and he never found that contrariety of directions between the ball and the rebound, observed in the English experiment. See Hill. Acad. R. Scienc. A. 1703: p. 120, &c.

The cause of the phenomenon seems very difficult to aflign; for supposing the guns of a common make, with the hole on the top, we cannot so much as guess what cause should constantly determine the ball from right to left; unless some very material circunstances be omitted in the re-
 continual they have given us in the experiment.

Guns whose vents are a little forward in the chasse recoil more. To lessen the recoil of a gun, the platforms are gene-
 rally made floping towards the embrasures of the battery. See Projectiles.

RECOLATION, a method of finding the decoctions of vegetables, &c. by repeated percolation, or draining them several times succesively through a linen or woollen-

RECOLLECTION, a mode of thinking, by which those ideas, fought after by the mind, are with pain and endeavour found, and brought again to view. See Memory and Imagi-

RECOLLET S, a congregation of reformed Franciscans, called also friers minor of St. Francis, of the strict ob-

servation. They were eftablifhed about the year 1532, when some religious of the order of St. Francis being willing to keep his rule to the letter, Clement VII. gave them honours, whether they might retire, and receive such as were disposed to follow them. The same year he approved the riform; and in 1584 it was carried from Italy into France, where these religious had already been eftablifhed, in the towns of Tulles in Limousin, and Murat in Auvergne. They had a convent at Paris in 1603; and since they have erected no less than a hundred and fifty in the whole kingdom, where they are divided into feven provinces.

RECOLENE, in Geography, a town of France, in the department of the Doubs; eight miles W. of Be-

fancon.

RECOMMENDATI. See AFFIDAVIT.

RECOMMENDATION, in a Military Sense, denotes a certificate, flatting an individual to be properly qualified for a situation in the army. This certificate must be signed by a field-officer in the regulars, addressed to the commanding

officer of the regiment, by whom it is forwarded to the commander-in-chief, who lays the name of the perfon recommended before the king.

RECOMPOSITION, in Chemistry, the compounding of bodies from their separated parts, or principles, so as to compose the original whole again. This is extremely diffi-
cult to effect univerfally, but in fome fases it may be done, and that so perfectly, that the recomposed body shall not be diiltinguishable by the fenses from that which had never been separated by the fire. If the art of chemistry were perfect, we fould thus be able, at leaft in fome degree, to recompose all the bodies we divide; but this is far from being the cafe at prefent. We can by no means do this in vegetable and animal bodies, where there is a vefcular structure, and therefore we are carefully to diftinguish be-
tween the regeneration of organized, and that of unorgan-
ized bodies.

RECONCILIATION, in our Laws, Books, &c. A church is said reconciliari, to be reconciled, when it is confeffed, after having been polluted or profaned; as by the poliflion of pagans, heretics, &c.

RECONCILIATION of Penitents, in Church History, See POENITENTES.

RECONNOITRE, in War, implies to view and examine the state of things, in order to make a report of them.

The word is French, signifying, literally, to know, re-
colled.

We fay to reconnoitre the coasts, to reconnoitre a port, &c. A body of horfe was fent to reconnoitre their camp, the ground, the condition of the roads, rivers, &c.

Parties ordered to reconnoitre, are to observe the country and the enemy; to remark the routes, conveniences, and inconveniences of the fift; the poftion, march, or forces of the fecond. In either cafe, they should have an expert geographer, capable of taking plans ready; he fhould be the beft mounted of the whole, that in cafe the enemy happen to fatter the effort, he may fave his works and ideas.

All parties that go for reconnoitring only, fhould be but few in number; never more than twelve or twenty men. An officer, be his rank what it will, cannot decline going with to few under his command: the honour is amply made up by the importance of the expedition, frequently of the moft interefling confequence, and the propererl to recom-

mend the prudence, bravery, and address of any officer that has the fortune to fucceed.

It is preciffely neceffary that the officer ordered on this duty fhould be well acquainted with the country, the roads, and the diftance of the enemy. His party must confift of men of approved fidelity, part of whom fhould be difguifed. This detachment muft march off in the night. The men muft have ftrict orders neither to fmoke tobacco, make a noise, nor fpeak. The officer muft be provided with two guides, who are to be strictly interrogated, but are to re-

main ignorant of the route you intend to take. A detach-

ment of this kind fhould be furnished with fufficient for two or three days. The horfe are to be fed every two or three leagues, for it is absolutely neceffary that they shouid be always freth and fit for duty. The officer will take care never to halt, but at a diftance from any road, and also take every precaution to prevent his being furprifed, whilst his horses are feeding, &c.

RECONNOITRE is also used at sea. To reconnoitre a veftel, a fleet, &c. is to approach near enough to examine the rate and burden of a veftel, &c. the force it may have aboard, what nation it is of, &c.

To reconnoitre a land, or shore, is to obferve its situation, in order to find what land it is.

RECORD, RECORDIUM, in Law, an authentic testimony of any thing in writing, contained in rolls of parchment, and preferred in a court of record. See COURT, and CUSTO.

Records
Records are said to be *veritas et veritas vestigia*. So early as the Conquest we find the "preteritorum memoria eventorum" reckoned up as one of the chief qualifications of those who were held to be "eagbus patria opinem instituti." For it is an established rule to abide by former precedents, where the same points come again in litigation; as well to keep the scale of justice even and ready, and not liable to waver with every new judge's opinion, as also because the law in that case being solemnly declared and determined, what before was uncertain, and perhaps indifferent, is now become a permanent rule, which it is not in the breath of any infrequent judge to alter or vary from, according to his private sentiments: he being sworn to determine not according to his own private judgment, but according to the known law and custom of the land; not delegated to pronounce a new law, but to maintain and expound the old one. Yet this rule admits of exception, where the former determination is more evidently contrary to reason; much more if it be clearly contrary to the divine law. But even in such cases the infrequent judges generally pretend to make a new law, but to vindicate the old one from misrepresentation. For if it be found that the former decision is manifestly absurd or unjust, it is declared, not that such a sentence was bad law, but that it was not law, that is, that it is not the established custom of the realm, as has been erroneously determined. An act committed to writing in any of the king's courts, during the term in which it is written, is alterable, being no record; but that term once ended, and the act enrolled, it is a record, and of such credit as admits no alteration, or proof to the contrary.

It is a settled rule and maxim that nothing shall be averred against a record (see Court,) nor shall any plea, or even proof, be admitted to the contrary. (Co. Litt. 260.) And if the existence of a record be denied, it shall be tried by nothing but itself; that is, upon bare inspection whether there be any such record or no; else there would be no end of disputes. But if there appears any mistake of the clerk in making up such record, the court will direct him to amend it. Courts of record, or repositories for the public records of the kingdom, were first established by Edward I., our English Justinian, some of which are more ancient than the reign of his father, and those were by him collected.

Lawyers reckon three sorts of records; viz. a judicial record, as attainer, &c.; a ministerial record upon oath, as an office of inquisition found; and a record made by conveyance and content, as a fine, or deed inrolled, and the like.

Records, Affurances by matter of, are such as do not entirely depend on the act or content of the parties themselves; but the function of a court of record is called in, to subfintiate, preserve, and be a perpetual testimony of the transfer of property from one man to another; or of its establishment, when already transferred; of this nature are private acts of parliament, the king's grants, fines, and common recoveries.

Record, Court of. See Record, supra, and Court.

Record, Debit of, is a sum of money, which appears to be due by the evidence of a court of record. Thus, when a specific sum is adjudged to be due from the defendant to the plaintiff, on an action or suit at law, this is a contract of the highest nature, being established by the sentence of a court of judicature. Debts upon recognizances, together with flattus merchant, and flatsus staple, &c. if forfeited by non-performance of the condition, are also debts of record; the contract, on which they are founded, being witnessed by the highest kind of evidence, viz. by record of record.

Records, Imbezzling of. See IMBEZZLE.

Record, matter, mayer,oyer, or payer, priser upon matter of, fee matter, Muster, Oyer, and PRISONER, &c.

Record, Trial by, is used only in one particular influence; where a matter of record is pleaded in any action, as a fine, a judgment, or the like; and the opposite party pleads "nulli record," that is, there is no such matter of record existing: upon this, issue is tendered and joined in the following form, "and this he prays may be enquired of by the record, and the other doth the like;" and hereupon the party pleading the record has a day given him to bring it in, and proclamation is made in court for him "to bring forth his record, or he shall be condemned:" and, on his failure, his antagonist shall have judgment to recover. The trial of this issue is, therefore, merely by the record; for, as far Edward Coke observes (1 Inst. 117. 260.), a record or enrolment is a monument of to high a nature, and impudent in itself such absolute verity, that if it be pleaded there is no such record, it shall not receive any trial by witnesses, jury, or otherwise, but only by itself. Thus, titles of nobility shall be tried by the king's writ or patent only, which is matter of record. (6 Rep. 53.) Also in case of an alien, whether alien, friend, or enemy, shall be tried by the league or treaty between his sovereign and our; for every league or treaty is of record. (9 Rep. 31.) And also whether a manor be held in ancient demene or not, shall be tried by the record of Domeday in the king's exchequer. Blackft. Com. book iii.

Record, among Fowlers. A bird is said to record, when it begins to tune or sing within itself; or to form its notes and dispoife its organs for singing.

Thecock thrush is distinguished from the hen in recording; the first being more loud and frequent in it than the second.

Influences have been known of birds beginning to record when they were not a month old. This first effay does not seem to have the least rudiments of the future song; but as the bird grows older and stronger, one may perceive what the neitling is aiming at. A young bird commonly continues to record for ten or eleven months, when he is able to execute every part of his song, which afterwards continues fixed, and is scarcely ever altered. The term record is probably derived from a musical instrument, formerly used in England, called a recordor, which seems to have been a species of flute, and was probably used to teach young birds to pipe tunes. Lord Bacon describes this instrument (in his second Century of Experiments) to have been straight, to have had a fitter and greater bore, both above and below, to have required very little breath from the blower, and to have had what he calls a fipple or flopper.

RECORDARI facias legatum, in Law, a writ directed to the sheriff to remove a caufe depending in an inferior court, as hundred-court, county-court, court of ancient demene, &c. to the king's bench, or common pleas, &c.

It is thus called, because it commands the sheriff to make a record of the proceedings either by himself, or others; and then to fend up the caufe.

RECORDE, Robert, in Biography, an early English physician, of Welsh origin, commenced his education at Oxford about the year 1535; and in 1531 was elected fellow of All-Souls' College. Directing his studies to physic, but where, or under what matters, we are not told, he was created doctor in that faculty at Cambridge in 1545. Both before and after this period he is said to have taught arithmetic at Oxford, and to have excelled all his predeces-
fors in rendering this branch of knowledge clear and familiar. He is likewise mentioned as remarkably skilled in rhetoric, astronomy, geometry, music, mineralogy, and every part of natural history. He was well acquainted with the Saxon language, and made large collections of historical and other ancient manuscripts. To these various studies he joined that of divinity, and was attached to the principles of the Reformers. But notwithstanding he was justly deemed a prodigy of learning and talents, it does not appear that he met with encouragement at all adequate to his merits; since all that we know further of him is, that he died in the king's bench prison, where he was confined for debt, in the year 1558.

He was author of several works, some of which were several times reprinted, on the following subjects:

“The Ground of Arts, teaching the Work and Practice of Arithmetic, both in whole Numbers and Fractions,” 1540. This was dedicated to king Edward VI. “The Whetstone of Wit,” a second part of the former. “The Path-way to Knowledge, containing the first Principles of Geometry.” “The Cattle of Knowledge, containing the Explanation of the Sphere.” “The Urinal of Physick,” 1547, which was reprinted in London in 1582, 1599, and 1665; and in the last mentioned year, the title of “The Judicial of Urines” was given to it. This book contains a description of urinary vesicles with figures. It is a short, but very methodical treatise, full of divisions and subdivisions relative to the different kinds of urines, and the prognostics to be deduced from them. Nevertheless he candidly acknowledges at the beginning, that the judgment to be formed in diseases of the urine is not so certain as some have represented; and indeed the perplexity and variety of opinions concerning this subject are sufficiently apparent from his treatise. His other works were, “Of Anatomy”; “Of Auricular Confellion”; “Of the Eucharist”; and “The Image of a true Commonwealth.”

Akin's Biog. Memoirs of Medicine.

RECORER, RECORDATOR, a person whom the mayor, or other chief magistrate of any city, or town corporate, having jurisdiction, and a court of record, within their precincts, does associate with him, for his better direction in matters of justice, and proceedings according to law. He is usually a counsellor, or other person, verified and experienced in the law. In some towns, which have their particular affiliates within themselves, and no mayor, the recorder is the judge.

The recorder of London is one of the justices of oyer and terminer, and a justice of peace of the quorum, for putting the laws in execution for preserving the peace and government of the city; and being the mouth of the city, he delivers the sentences and judgments of the courts therein, and also certifies and records the city customs, &c. He is chosen by the lord mayor and aldermen, and attends the business of the city, on any warning by the lord mayor, &c.

RECORER, in Music. See Record, supra.

RECORDO & processa mittendis, in Law, is a writ to call a record, together with the proceedings in the cause, out of an inferior court into the king's court.

RECOVERY, in a legal sense, an obtaining of any thing by judgment, or trial at law; answering to civilitio among the civilians.

There is a true and a feigned recovery.

RECOVERY, True, is an actual or real recovery of any thing, or of the value of it, by judgment. As if a man sue for any land, or other thing, and have a verdict or judgment for him.

RECOVERY, Figned or Common, is a sort of fictio juris, being for a certain form or course prescribed by law to be observed for the better asuring of lands and tenements to us; the end and effect of which is, to discontinue and destroy entail's, tail, remainders, and reversions, and to bar the intails of them.

These common recoveries were invented by the ecclesiastics to clade the statutes of mortmain; and afterwards encouraged by the fines of the courts of law in 12 Edw. IV. in order to put an end to all fettered inheritances, and bar not only entail's, tail, but also all remainders and reversions expectant thereon.

A common recovery is so far like a fine (which fee), that it is a suit or action, either actual or fictitious; and in it the lands are recovered against the tenant of the freehold; which recovery, being a supposéd adjudication of the right, binds all persons, and veils a free and absolute fee-simpie in the recoveror.

This recovery is either with a single or double voucher; and sometimes a treble or farther voucher, as the exigency of the case may require.

As a recovery is in the nature of an action at law, not immediately compromised like a fine, but carried through every regular stage of proceeding, its form and method are not easily understood by those who are unacquainted with the course of judicial proceedings. Judge Blackstone has, therefore, stated its nature and progresses as clearly and concisely as possible; avoiding, to the utmost of his power, all technical terms and phrases not before interpreted. Of his luminous statement we shall avail ourselves in the sequel of this article.

Let us (says he), in the fifth place, supposè David Edwards to be tenant of the freehold, and deferous to suffer a common recovery, in order to bar all entail's, remainders, and reversions, and to convey the fame in fee-simpie to Francis Golding. To effect this, Golding is to bring an action against him for the lands; and he accordingly files out a writ, called a precipe quad reddat, because those were its initial and most operative words, when the law proceedings were in Latin. In this writ the defendant, Golding, alleges, that the defendant, Edwards, (here called the tenant) has no legal title to the land; but that he came into possession of it after one Hugh Hunt had turned the demandant out of it. The subsequent proceedings are made up into a record or recovery roll, in which the writ and complaint of the demandant are first recited; whereupon the tenant appears, and calls upon one Jacob Morland, who is supposèd, at the original purchase, to have warranted the title to the tenant; and thereupon he prays, that the said Jacob Morland may be called in to defend the title, which he so warranted. This is called the voucher, vocatius, or calling of Jacob Morland to warranty; and Morland is called the vouchee. Upon this, Jacob Morland, the vouchee, appears, is impleaded, and defends the title. Whereupon Golding, the demandant, desires leave of the court to imparl, or confer with the vouchee in private; which is (as usual) allowed him. And soon afterwards the demandant, Golding, returns to court, but Morland the vouchee disappears, or makes the default. Whereupon judgment is given for the demandant, Golding, now called the recoveror, to recover the lands in question against the tenant, Edwards, who is now the recoveror; and Edwards has judgment to recover of Jacob Morland lands of equal value, in recompense for the lands so warranted by him, and now lost by his default; which is agreeable to the doctrine of warranty. This is called the recompense, or recovery in value. But Jacob Morland having no lands of his own, being usually the cryer of the court
of setting them at liberty are apparent; it hath often been wifhed, that the procfs of this conveyance was shortened, and rendered less fubjeft to niceties, by either totally repealing the statute de donis; which perhaps, by reviving the old doctrine of conditional fees, might give birth to many litigations: or by veiling in every tenant in tail of full age the fame absolute fee-simple at once, which now he may obtain whenever he pleafes, by the col- luive fiction of a common recovery; though this might poifibly bear hard upon thofe in remainder or reversion, by abridging the chances they would otherwife frequently have, as no recovery can be fuffered in the intervals between term and term, which fonetimes continue for near five months togerher; or, laftly, by empowering the tenant in tail to bar the eftate-tail by a folemn deed, to be made in term time and enrolled in fome court of record; which is liable to neither of the other objections, and is warranted not only by the usage of our American colonies, and the de- cisions of our own courts of juflice, which allow a tenant in tail (without fine or recovery) to appoint his eftate to any charitable ufe, but also by the precedents of the statute 21 Jac. I. c. 19, which, in cafe of a bankrupt tenant in tail, empowers his commissioner to fettle the eftate at any time, by deed indented and enrolled. And if, in no national concern, the emoluments of the officers, concerned in pafling recoveries, are thought to be worthy attention, thofe might be provided for in the fees to be paid upon each enrolment.

The force and effet of common recoveries may appear, from what has been faid, to be an abfolute bar not only of all eftates-tail, but of remainders and reversions expextant on the determination of fuch eftates. So that a tenant in tail may, by this method of affurance, convey the lands held in tail to the recoveror, his heirs and affigns, abfolutely free and discharged of all conditions and limitations in tail, and of all remainders and recoveries. But, by statute 34 and 35 Hen. VIII. c. 20, no recovery had againft tenant in tail, of the king's gift, whereof the remainder or reversion is in the king, shall bar fuch eftate-tail, or the remain- der or reversion of the crown. And by the statute 11 Hen. VII. c. 20, no woman, after her husband's death, shall fuffer a recovery of lands fettled on her by her husband, or fettled on her husband and her by any of his an- cellors. And by statute 14 Eliz. c. 8, no tenant for life, of any fort, can fuffer a recovery, fo as to bind them in remainder or reversion. For which reafon, if there be tenant for life, with remainder in tail, and other remainders over, and the tenant for life is defirous to fuffer a valid re- covery; either he, or the tenant to the precife by him made, must vouch the remainder-man in tail, otherwise the recovery is void: but if he does vouch fuch remainder-man, and he appears and vouches the common vouchee, it is then good; for if a man be vouched and appears, and fuffers the recovery to be had againft the tenant to the precife, it is as efetual to bar the eftate-tail as if he himfelf were the recoveror. Salk. 571.

In all recoveries it is neceffary that the recoveror, or tenant to the precife, as he is ufually called, be actually feized of the freehold, elfe the recovery is void. (Pigott. 28.) For all actions to recover the feifin of lands, muft be brought againft the actual tenant of the freehold, elfe the fuit will lofe its effet; fince the freehold cannot be recovered of him who has it not. And, though these recoveries are in themselves fabulous and fictitious, yet it is nece- fary that there be alfores fabulœ, properly qualified. But the nietty thought by fome modern practitioners to be requisite in conveying the legal freehold, in order to
to make a good tenant to the *precipes* is removed by the provisions of the Statute 14 Geo. II. c. 20. which enacts, with a retrospect and conformity to the ancient rule of law, that, though the legal freehold be vested in lessees, yet those who are entitled to the next freehold estate in remainder or reversion may make a good tenant to the *precipis*—that, though the deed or fine which creates such tenant be subsequent to the judgment of recovery, yet, if it be in the same term, the recovery shall be valid in law; and that, though the recovery itself do not appear to be entered, or be not regularly entered, on record, yet the deed to make a tenant to the *precipis*, and declare the uses of the recovery, shall after a pollution of twenty years be sufficient evidence, on behalf of a purchaser for valuable consideration, that such recovery was duly suffered. And this may suffice to give the student a general idea of common recoveries, the last species of assurances by matter of record.

For an account of deeds to lead, or declare, the uses of fines, and recoveries; see Uses.

In some manors, by special custom, recoveries may be suffered of copyhold (Moor, 637.); but as these differ in nothing material from recoveries of free land, excepting only that they are not suffered in the king's courts, but in the court baron of the manor, we shall refer this subject to the article Surrender. In this place we shall observe, however, that a fine or recovery had of copyhold lands in the king's court may, if not duly served, after the tenure of the lands, and convert them into frank-fee, which is defined in the old book of tenures to be "land pleadable at the common law:" but upon an action on the case, in the nature of a writ of "decem," brought by the lord in the king's court, such fine or recovery will be reverted, the lord will recover his jurisdiction, and the lands will be restored to their former state of copyhold. Blackitt. Com. 2. ii.

**Clerk of Involvements of Recoveries and Fines.** See Clerk.

Recovery, Fort, in Geography, a fort of America, in the Indiana territory, situated on a branch of the Wabash river, about 23 miles from Greenville. It contains of two block-houses, and barracks with curtiens, sufficient for 60 men.

**ReCoupe**, French; formed of *rec* and *couper*, to cut again, in Law, to rebate, or discount.

Thus, if a man have ten pounds ________ out of certain lands, and he suffers the tenant of the land; in an affize brought by the defendant, if he recover the land and damages, the defendant shall recoup the rent due in the damages.

**ReCoupe** also denotes a quick, sharp reply, to a peremptory demand. See Repartee.

**ReCreant**, in our old Law-Books, implies cowardly, faint-hearted.

Hence _recranton._ See Craven and Champion.

Recount was so reproachful a word, that Glanville would not describe it. *Recreantes equi* is used by Fleta, lib. ii. cap. 2. for dull, jaded horses.

**Recreation Island**, in Geography, a fertile island in the Southern Pacific ocean, discovered by Roggewin in the year 1722. Some of the ship's company obtained a quantity of antifcorbutic herbs; but upon venturing into the country, they were assaulted by the natives, who, by casting stones at them, killed some, and wounded almost all. Many of the indians were killed by the fire-arms in return. The soil produces sugar-canes, cocoa-nuts, pomegranates, Indian figs, &c. The inhabitants were well made, robust, and very lively: their bodies were painted, and they were armed.

S. lat. 16°. W. long. 148°.

**Recrement, Recrementum**, in Medicine, some

*superfluous* matter separated from some other that is useless.

In which sense, it amounts to much the same with fines, or excrement.

Recrements of vegetables are useful as manure.

Recurrent is sometimes used to denote such secrete medicaments which, as are afterwards of use in the economy; as the lympha, gall, &c. which are thus called, in contradistinction to excrements, which are expelled out of the body, as of no farther use.

**Recrimination**, a posterior accumlation brought by the accused against his accuser, upon the same fact.

When two parties have made their mutual complaint at the same time; the business is, first, to determine who shall be the accuser, and who the accused, i.e. on whom shall fall the recrimination.

By the French laws, recrimination is of no force till the criminal hath been pursed legally.

**Recrudescence, Recrudescentia**, in Medicine, is a relapse, when a disease that has gone off returns again.

**Recruits, in the Military Art**, new men raised to supply the places of such as have loit their lives in the service, or are rendered unserviceable by age or wounds. See Listing.

**Recruit-Horses**, are the horses brought up for completing the regiments of horse or dragoons every year.

**Rectangle**, in Geometry, called also oblong, and

**Long Square**, a quadrilateral rectangular figure (Plate XII. Geometrical, fig. 3.) whose opposite sides, M L, and L K, as well as M I and L K, are equal.

Or, a rectangle is a parallelogram, whose sides are unequal, but its angles right.

To _find the area of a rectangle_, see _Parallelogram_.

If from the same point A, (fig. 4.) be drawn two lines, one of which, A D, is a tangent to a circle, the other a secant A B; the square of the tangent A D will be equal to the rectangle under the secant A B, and that part of it without the circle A C. If two or more secants, A a, A B, &c. be drawn from the same point A; the rectangles, under their wholes, and their parts without the circle, will be equal. If two chords intersect each other, the rectangles under their segments will be equal. The rectangles under equal lines are equal. The sum of all the rectangles contained under a given line, and all the parts of another any how divided, is equal to the rectangle contained under the two whole lines. If from any point, within a rectangle, to the angles of a rectangle, four lines be drawn, the sums of the squares of those drawn to the opposite angles will be equal. The rectangles contained under the corresponding sides of equiangular triangles, taken alternately, are equal. The rectangle under the two sides of any triangle is equal to the rectangle under the perpendicular to its base, and the diameter of the circumscribing circle. The square of a line bisecting any angle of a triangle, and terminating in the opposite side, together with the rectangle under the two segments of that side, is equal to the rectangle of the two sides, including the propaded angle. The rectangle of the two diagonals of any quadrilateral inscribed in a circle, is equal to the sum of the two rectangles contained under the opposite sides.

**Rectangles, Similar, See Similar.**

**Rectangle, in Arithmetic**, is the fame with product or factum.

**Rectangled, Right-angled, Triangle**, is a triangle, one of whose angles is right, or equal to 90°. See Triangle.
There can be but one right angle in a plain triangle; therefore a rectangled triangle cannot be equilateral.

**RECTANGULAR**, in Geometry, is applied to figures and solids which have one or more angles right.

Such are squares, rectangles, and rectangled triangles, among plain figures; cubes, parallelepipedes, &c. among solids.

Solids are also said to be rectangled with respect to their situation: thus, if a cone, cylinder, &c. be perpendicular to the plane of the horizon, it is called a rectangled or right cone, cylinder, &c.

The ancients used the phrase *rectangular section* of a cone, to denote a parabola; that is, a cone section, before Apollonius, being only considered in a cone, whose section by the axis would be a triangle, right-angled at the vertex. See Conic Sections.

Hence it was that Archimedes entitled his book of the quadrature of the parabola, by the name of "Rectanguli Coni Sectio."

**RECTANGULAR Boreometer.** See Boreometer.

**RECTANGULAR Windmills.** See Windmills.

**RECTIFICATION**, compound of rectus, right, direct, and &c. became the act of rectifying, i.e. of correcting, remedying, or reddressing, some defect or error, in respect either of nature, art, or morality.

**Rectification,** in Chemistry, is the repeating of a distillation or sublimation several times, and generally with a less degree of heat than at first, in order to render the substance purer, finer, and freer from aqueous and earthy parts.

Rectification is a reiterated depuration of a distilled matter, e. g. brandy, spirits, or oils, by distilling them over again, to render them more subtil, and exalt their virtues.

That the rectification of spirits may, in all cases, proceed with the greatest exactness, a due regard to it must be had even from the first fermenting the substance from which they are to be made, and continued through all the stages of distillation, the low wines, proof spirit, and alcohol. The management of the fermented liquor, to this purpose, is principally the letting it stand to subside after the fermentation is over, and the drawing it off clear and thin, not too rich for the still. The still is not to be overfilled with this.

Great care must be taken to prevent its burning, and the fains that run last must be kept separate, not mixed with the rest of the liquor distilled, which is now called the low wines. In the rectifying of these into proof spirit, great caution must be used that the fire be kept regular, not railed by sudden spirits, which always throw up the oil in large quantities, which is to be left behind. In the succeeding rectification of the proof spirit into alcohol, the same cautious management of the fire is necessary; and, in both this and the last, the fains are not to be suffered to run in among the spirit, but to be faved separately. They may be all mixed together at last, and reduced to a spirit fit for burning in lamps; but the keeping out of the rectified liquor will keep away the coarser and most flinking part of the oil of the ingredients.

By these cufy means, without any additional trouble or charge, we might be furnished with a spirit greatly exceeding what we commonly meet with. And in general, the art and mystery of our fellers of the several forts of English brandies, seem to consist in this prudent management; and in the adding a little of the *alem wini*, or oil of wine-lees, to the spirits thus procured pure; this gives the flavour of foreign brandies, and is so extensive in its use, that half an ounce of it is sufficient for a hoghead of pure spirit.

Malt spirit is that which principally requires all this care in the rectification, because its oil is more nauseous and offensive than that of any other spirit; but all others will be greatly the better for being treated in the same manner; and it is indeed necessary that they should for some particular uses.

It is remarkable, that no one method of combinatorial rectification, that is, of the rectification performed by means of falt, and other additions, is suited to all the several kinds of spirits; scarcely indeed will any one way serve for any two spirits; but this method, by simple and careful distillation, is equally suited to all. Molasses-spirit, cyder-spirit, wine-spirit, or brandy, rum, and arrack, are all improved by it; and all of them are then known to be perfectly rectified, when, in the state of alcohol, they not only prove totally inflammable in a little vessel floating upon cold waters, but when poured into the purest spring water they have not the least power of making any change in it, nor leave any marks of oiliness, or that unctuous which, on the mixture of the last pure spirits, floats on the top, and in certain lights gives the rainbow colours. Shaw's Essay on Distillery. See Alcohol and Distillation.

Fixed salts are rectified by calculation, dissolution, or filtra-

Metal are rectified, i.e. refined, by the coppel; and regulator by repeated fusions, &c.

In a word, all rectifications are founded upon the same principle; and consist in separating substances more volatile from substances less volatile; and the general method of effecting this is to apply only the degree of heat which is necessary to cause this separation.

**Rectification of vitriolic Acid.** See Concentration.

**Rectification,** in Geometry, is the finding of a right line equal to a proposed curve, or simply finding the length of a curve line; a problem which, even in the present advanced state of analysis, is attended in many cases with considerable difficulty; and was, in all, totally beyond the reach of the ancient geometers, who were not able to affign the length of any curve line whatever; though they could, in a few instances, determine the area of a curvilinear space. See Quadrature.

The first rectification of a curve line was effected by Mr. H. Neal, as we are informed by Dr. Wallis, at the conclusion of his Treatise on the Cilloid. This curve was the semicircular parabola, and Neal's rectification of it was published in July or August, 1657; and two years after, viz. in 1659, the fame was done by Van Haereat in Holland. See Schooten's Commentary on Descartes' Geometry.

It is, however, to the doctrine of fluxions that we owe the complete rectification of curve lines, in finite terms, when they admit of it; and in others by means of infinite series, circular arcs, logarithms, &c.; of which method we shall give a general view in the present article.

Let $\text{AMO}$ (Plate XIII. Analysis, fig. 10.) be a curve of any kind, whose ordinates are parallel to one another, and perpendicular to the axis $AH$; and let the fluxion of the abscissa $AP$ be denoted by $Pp$ or $MR$, and $RM$ be taken to represent the corresponding fluxion of the ordinate $PM$, then will the tangent $Mm$ be the line which the generating point of the curve would describe, if its motion were to become uniform at $M$; conforently this line will truly express the fluxion of the space $\text{AM}$. Hence putting $AP = x$, $PM = y$, and $AM = z$, we have $z = Mm = (MR + RM) = y(x'^2 + y^2)$; from which, and the equation of the curve, the value of $y$ may be determined.

But if all the ordinates of the proposed curve $AR$ (fig. 10.) be referred to a centre $C$; then, putting the tangent $R\overline{P}$, intercepted by the perpendicular $C\overline{P}$, $= t$, the arc $BN$, of a circle described about the centre $C; x$, the radius
radius $CN$ (or $CB$) $= a$, &c. (see Quadrature of Curves, Cof. 2.) we shall have $z = y : z = y _1 \left( CR \right) = t \left( KP \right)$; and consequently, $s = \frac{y}{t}$; whence the value of $s$ will be found, if the relation of $y$ and $t$ is given.

1. To find the length of the semi-cubical parabola, of which the equation is $a x^3 = y^2$, or $x = \frac{y^2}{a^3}$.

Here $s = \frac{3}{2} y \frac{y'}{a^3}$, or $s^2 = \frac{9}{2} y \frac{y'}{a^3}$; substituting, therefore, this value of $s^2$ in the general expression

$$z = \sqrt[3]{(3 y^2 \frac{y'}{a^3} + y)}$$

the fluent of which is

$$z = \frac{1}{27 a^3} \times (9 y + 4 a)^{\frac{3}{2}} + C$$

Now when the arc is $0$, then $y = 0$; therefore

$$\frac{4 a^3}{27} + C = 0$$

whence the complete fluent is

$$z = \frac{(9 y + 4 a)^{\frac{3}{2}} - 4 a}{27 a^3}$$

which is the length of the curve, answering to any length of the ordinate $y$.

II. To rectify the common parabola; or to find the length of any parabolic arc $AM$ (fig. 11.) Let the parameter $= a$, the abscissa $= AP = x$, &c. as above. From the well known property of this curve, $a x = y^2$; and $a \frac{x}{y} = 2 a y$; consequently $s = \frac{2 y}{a}$, and $s^2 = \frac{4 y^2}{a^2}$, which substituted for $s^2$ in the general expression for the length of the curve, makes $z = \left(\frac{4 y^2}{a^2} + y^2\right)^{\frac{3}{2}} = \frac{y}{a} \times (a^2 + 4 y^2)^{\frac{3}{2}}$;

which, thrown into an infinite series, becomes $z = \frac{y}{a} \times \left\{a + \frac{2 y}{a} - \frac{2 y}{a} \times \frac{4 y}{a} + \frac{4 y}{a} + \text{etc.}\right\}$; i.e. $z = \frac{y}{a} \times \left(\frac{2 y}{a} + \frac{4 y}{a} \right)$

The fluent of this series is $z = \frac{y}{a} \times (a^2 + 4 y^2)^{\frac{3}{2}}$.

Otherwise: the above $z = \frac{y}{a} \times (a^2 + 4 y^2)^{\frac{3}{2}}$ is

$$\frac{a^2 + 4 y^2}{a} \times (a^2 + 4 y^2)^{\frac{3}{2}} = \frac{a^2 y^2 + 4 y^2}{a} \times (a^2 y^2 + 4 y^2)^{\frac{3}{2}} = \frac{1}{2} a y^2 + 4 y^2 \times \left(\frac{a^2}{a} + 4 y^2\right)^{\frac{3}{2}}$$

But the fluent of the first of these

two terms is $= \frac{1}{2 a} \times (a^2 y^2 + 4 y^2)^{\frac{3}{2}} = \frac{y}{a} \times (\frac{1}{2} a y^2 + y^2)^{\frac{3}{2}}$; and the fluent of the last of the two terms is $= \frac{1}{2} a \times \text{hyp. log. of } y + (\frac{1}{2} a y^2 + y^2)$; therefore $z = \frac{y}{a} \times \left(\frac{1}{2} a y^2 + y^2\right)^{\frac{3}{2}} + \frac{1}{2} a \times \text{hyp. log. of } y + \left(\frac{1}{2} a y^2 + y^2\right)^{\frac{3}{2}}$.

But when $x$ and $y$ vanish, or become equal to $a$, as they do at the vertex, this fluent becomes $= \frac{1}{2} a \times \text{hyp. log. of } \frac{1}{2} a y + \text{and therefore, the said fluent being corrected, gives the true value of } x$, or the length of the curve $AM = \frac{y}{a} \times \left(\frac{1}{2} a y^2 + y^2\right)^{\frac{3}{2}} + \frac{1}{2} a \times \text{hyp. log. of } y + \left(\frac{1}{2} a y^2 + y^2\right)^{\frac{3}{2}}$.

Hence, if $AC$ and $DC$ (fig. 12.) be the conjugate semi-axes of an equilateral hyperbola; and $AC = a$, $MP = 2 y$, $QM = x$, then will $AP = x - a$; and $x = x^2 = a^3 = a^3$; consequently $s = \sqrt{(4 y^2 + a)}$. If then $q$ be supposed infinitely near $Q M$, we shall have $Q q = s$, and therefore the element of the area $C Q M A = \frac{q}{s} \times \sqrt{(a^3 + 4 y^2)}$. Whence it appears, that the rectification of the parabola depends on the quadrature of the hyperbolic space $C Q M A$.

III. To determine the length of an arc of the common hyperbola. Let the semi-transverse axis be represented by $b$, and the semi-conjugate by $c$, and we shall have $b^2 y^2 = 2 b x + x^2$, from the nature of the curve (see Hyperbola); and therefore $x = \frac{b y \sqrt{c^2 + y^2}}{c}$, and $z = \sqrt{(x^2 + x)} = \sqrt{\left(\frac{b^2 y^2}{c^2} + \frac{b^2 y^2}{c^2} + \frac{b^2 y^2}{c^2}\right)} = y \sqrt{(1 + \frac{b^2 y^2}{c^2} + \frac{b^2 y^2}{c^2})}$; which, by converting $\frac{b^2 y^2}{c^2}$ into an infinite series, becomes $y \sqrt{(1 + \frac{b^2 y^2}{c^2} + \frac{b^2 y^2}{c^2} + \frac{b^2 y^2}{c^2} + \text{etc.})}$. But still we have the square root to extract: in order which, let it be assumed

$$1 + 2 A y^2 + B y^4 + C y^6 + D y^8, \text{ &c.}$$

Then, by squaring, and transposing, there arises

$$1 + 2 A y^2 + 2 B y^4 + 2 C y^6 + 2 D y^8, \text{ &c.} + A^2 y^2 + 2 A B y^4 + 2 A C y^6, \text{ &c.} + B^2 y^4, \text{ &c.}$$

$$= \frac{b^2 y^2}{c^2} \times \frac{b^2 y^2}{c^2} + \frac{b^2 y^2}{c^2} \circ \frac{b^2 y^2}{c^2} + \text{etc.}$$

Hence $A = \frac{b^2}{2 c^2}$, $B = \frac{b^2}{2 c^2} - \frac{b^2}{2 c^2} = - \frac{b^2}{2 c^2} - \frac{b^2}{2 c^2}$, $C = \frac{b^2}{2 c^2}$.

Hence $A = \frac{b^2}{2 c^2}$, $B = - \frac{b^2}{2 c^2} - \frac{b^2}{2 c^2} = - \frac{b^2}{2 c^2} - \frac{b^2}{2 c^2}$, $C = \frac{b^2}{2 c^2} - A B = \frac{b^2}{2 c^2} + \frac{b^2}{4 c^2} + \frac{b^2}{16 c^2} \text{ &c. &c. &c.}$

Therefore $z = \frac{y}{a} \times \left(\frac{b^2 y^2}{c^2} + \text{etc.}\right) = \frac{y}{a} \times \left(1 + A y^2 + B y^4, \text{ &c.}\right)$

$$= \frac{y}{a} \times \left(1 + A y^2 + B y^4, \text{ &c.}\right)$$

$$= \frac{y}{a} \times \left(1 + A y^2 + B y^4, \text{ &c.}\right)$$

$$= \frac{y}{a} \times \left(1 + A y^2 + B y^4, \text{ &c.}\right)$$

$$= \frac{y}{a} \times \left(1 + A y^2 + B y^4, \text{ &c.}\right)$$

$$= \frac{y}{a} \times \left(1 + A y^2 + B y^4, \text{ &c.}\right)$$
RECTIFICATION.

\[
\begin{align*}
\frac{b}{4} + \frac{b^3}{16c^3} = x^3, \text{ &c.} \quad \text{And consequently } z &= y + \\
\frac{b^3}{6c} - \left( \frac{b}{c} + \frac{b^3}{4c^3} \right) &= x^2 + \left( \frac{b^3}{2c} + \frac{b^6}{8c^6} \right). 
\end{align*}
\]

By the very same way of proceeding, the arc of an ellipse may be found, the equations of the two curves differing in nothing but their signs.

IV. To rectify the spiral of Archimedes. The value of \( t \) (A T, fig. 13.) being denoted by \( \frac{b^2}{\sqrt{(b^2 + y^2)}} \) (see Tangent of the Spiral, &c.), we have

\[
\theta = \frac{b^2}{\left( b^2 + y^2 \right)^{1/2}}
\]

which fluxing being the same as that expressing the arc of the common parabola (Prob. II.), by inserting in the expression \( \dot{z} = \frac{y}{a} \times \left( a^2 + 4y^2 \right) \), \( b = \frac{1}{2}a \), its fluent will, therefore, be truly represented by the measure of the said arc, or by \( \frac{y}{a} \sqrt{\left( b^2 + y^2 \right)} + \frac{1}{2} y \times \text{hyp. log.} \)

or

\[
\frac{y}{a} \sqrt{\left( b^2 + y^2 \right)}
\]

the value there found, by making the proposed substitution.

V. To rectify the involute of a circle, whose nature is such, that the part P R (fig. 14.) of the tangent intercepted by the point of contact and the perpendicular C P, is every where equal to the radius C O of the generating circle.

In this case \( \dot{z} = \frac{y}{a} \times a = A C \), becomes

\[
\frac{y}{a} \times a = \frac{C P}{2 a C A}
\]

the true measure of the required arc A R.

VI. To find the length of a circular arc. — This may be expressed either in terms of the sine, cosine, verf sine, or any other trigonometrical line, as follows. First, let the verf sine \( x \), the sine \( y \), radius \( r \), and arc \( z \), then, by the property of the circle, \( y^2 = 2r - x^2 \)
or, putting tangent \( t = \frac{y}{r} \)

and secant \( s = \frac{r}{r} \)
as are readily deduced from the known properties of the circle.

Now, by means of these values of \( x \), or of \( 2r - x^2 \), and the general equation \( \dot{z} = \sqrt{(x^2 + y^2)} \), we readily draw the following values of \( \dot{z} \), viz.

\[
\dot{z} = \begin{cases} 
\frac{r}{\sqrt{x}} & \text{if } (2r - x^2) = r^2 \\
\frac{\sqrt{r^2 + t^2}}{t^2} & \text{if } (2r - x^2) = r^2 \\
\frac{\sqrt{r^2 - s^2}}{s^2} & \text{if } (2r - x^2) = r^2 
\end{cases}
\]

the fluents of which can only be found in series, which are as follows; making radius \( r = 1 \), viz.

Having
RECTIFICATION.

Having this laid down his plan of operation, by a few trials he fell upon a number well suited to his purpose, viz.
knowing the tangent of \( \frac{1}{4} \) of 45°, or \( 11^\circ 15' \), to be very nearly \( \frac{1}{5} \), radius being 1, he assumed for his first arc that
whose tangent is \( \frac{1}{5} \); then since \( \tan 2a = \frac{2 \tan a}{1 - \tan^2 a} \),
he had \( \frac{5}{12} \) for the tangent of his double arc, and \( \frac{120}{119} \) for the
double of this, or for four times the first, which being a little greater than 45°, was well adapted to his views; for
by a known trigonometrical property, \( \tan (a + 45) = \frac{\tan a + 1}{\tan a + 1} \); that is, the tangent of the small arc, which is
equal to the excess of his multiple above 45°, was

\[
\frac{120}{119} - 1
\]

He had, therefore, two arcs to compute, the one
having for its tangent \( \frac{1}{5} \), and the other \( \frac{1}{239} \); and then four
times the fifth of these arcs minus the latter, would evidently give the exact arc of 45°, and both these numbers being such as to converge very well in the general series, the difficulty attending the usual approximation was avoided.

Other approximations, however, have since been discovered, which, if not more rapid, their investigation is, at least, more simple, of which, perhaps, that of Euler's is the most deserving of notice. This celebrated geometer observes, that every arc whose tangent is commensurable with the radius, as, for instance, 45°, may be divided into two arcs, of which the tangents, though much smaller, are still commensurable with the radius; for since

\[
\tan (a + b) = \frac{\tan a + \tan b}{1 - \tan a \tan b},
\]

we have also

\[
\tan a = \frac{\tan (a + b) - \tan b}{\tan (a + b) \tan b},
\]

where it is obvious that if \( \tan (a + b) \) and \( b \) be rational, \( \tan a \) will also be rational; thus, if \( \tan (a + b) = \tan 45° = 1, \) and \( \tan b = \frac{1}{3}, \) we have \( \tan a = \frac{1}{3}, \) and we shall evidently have a similar result, whatever rational fraction we assign for \( b \).

We shall find, therefore, by the series which gives the arc in terms of the tangent, each of these arcs, the sum of which will evidently be the measure of the whole arc sought; whether the arcs themselves, which belong to these tangents, be rational or irrational, with respect to the whole arc of which they form the parts. These tangents, substituting in

\[
\frac{1}{3} - \frac{1}{3 \cdot 3^2} + \frac{1}{5 \cdot 3^3} - \frac{1}{7 \cdot 3^2} + \frac{1}{9 \cdot 3^4} - \&c.
\]

and arc to \( \tan \left( \frac{1}{3} \right) = \frac{1}{3} - \frac{1}{3 \cdot 3^2} + \frac{1}{5 \cdot 3^3} - \frac{1}{7 \cdot 3^2} + \frac{1}{9 \cdot 3^4} - \&c.
\]

In both which series, the terms diminish much more rapidly than in the original series, and may therefore be computed with tolerable ease.

But it is evident that we may proceed farther in this approximation, by dividing each of these into other two arcs, by which means the convergency will obviously be much more rapid; and though, generally speaking, for every subdivision we double the number of our series, yet the degree of convergency is so much the greater as amply to compensate for the additional number of series. Besides, we may always subdivide our greater arc, so that one of its subdivisions shall be the same as the smaller arc, in which case we do not increase the number of series. Thus; arc to \( \tan \left( \frac{1}{2} \right) = \)

decrease to \( \tan \left( \frac{1}{3} \right) + \) and to \( \tan \left( \frac{1}{4} \right) ; \) therefore arc to \( \tan \left( \frac{1}{2} \right) = \)

to \( \tan \left( \frac{1}{3} \right) + \) and to \( \tan \left( \frac{1}{4} \right) \); again; arc to \( \tan \left( \frac{1}{3} \right) + \) and to \( \tan \left( \frac{1}{4} \right) ; \) therefore arc to \( \tan \left( \frac{1}{2} \right) = \)

to \( \tan \left( \frac{1}{3} \right) + \) and to \( \tan \left( \frac{1}{4} \right) ; \) and so on to

\[
\tan \left( \frac{1}{n} \right) + \tan \left( \frac{1}{n} \right), \text{ and so on to any extent required, which might in course be pursued so far as to render the operation as simple and as little laborious as can be expected in such kind of computations. Even with these already mentioned, the circumference of the circle might undoubtedly be computed to 200 places of decimals, with less labour than it cost Vica to carry them to 10 places, or Romanus to 15.}

The reader will observe, that this approximation differs from Machin's in nothing except the simplicity and generality of the investigation; for if we make the successive subdivision of the greater arc, so as always to include in it the smaller one, we shall find in our results the identical formula of Machin.

Let us repeat our former expression

\[
\tan a = \frac{\tan (a + b) - \tan b}{1 - \tan a \tan b}
\]

Let \( \tan (a + b) = \frac{R}{T}, \tan a = \frac{R'}{T'}, \tan b = \frac{r}{t} \) and

we shall have generally \( \frac{R'}{T'} = \frac{R t - T r}{R t + T r} \).

Let now \( (a + b) = 1 \), answering to arc 45°, so that \( R = 1, \) and \( T = 1; \) assume also \( r = 1, \) then, by constantly substituting, in the general expression, the values found for \( R', R'', R''', \&c. \) and \( T', T'', T''', \&c. \) for \( R \) and \( T \) respectively, we shall have

\[
\begin{align*}
R' &= \frac{t - 1}{t + 1} \\
T' &= \frac{t^2 - 2 t - 1}{t^2 + 2 t - 1} \\
R'' &= \frac{t^3 - 3 t^2 - 3 t + 1}{t^3 + 3 t^2 - 3 t - 1} \\
T'' &= \frac{t^4 - 4 t^3 - 6 t^2 + 4 t + 1}{t^4 + 4 t^3 - 6 t^2 - 4 t + 1} \\
R''' &= \frac{t^5 - 5 t^4 + 10 t^3 + 10 t^2 + 5 t - 1}{t^5 + 5 t^4 - 10 t^3 - 10 t^2 + 5 t + 1}
\end{align*}
\]
It consists of two circles, either laid upon, or let into one another, and so fastened together in their centres, that they represent two compasses, the one fixed, the other moveable: each is divided into thirty-two points of the compasse, and three hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west in ninety degrees.

The fixed compasse represents the horizon, in which the north, and all the other points, are liable to variation.

In the centre of the moveable compasse is fastened a silk thread, long enough to reach the outside of the fixed compasse: but if the instrument be made of wood, an index is used instead of the thread.

**Rectifier**, in the Distillery, the person whose whole employment is to take the coarse malt-spirit of the malt-filler, and re-distill it to a finer and better liquor. The art of the rectifier might be entirely set aside, if the malt-filler could make his spirit perfect at a second operation; which seems very practicable, if the malt-fillers could be induced to forgo their old practice. The great things to be recommended for the improvement of their art, would be, first, the brewing in perfection; and secondly, the keeping of their wath after the manner of talle beer, till it has entirely lost its malt flavour, and acquired a pungent acid vinicity; and then, thirdly, leaving out the lees, to distil with a well-regulated fire. It is scarcely to be thought how pure a spirit is to be obtained from malt this way; but the great art would be, the finding of a method to make malt liquors artificially flat, bright, and flavourous, though otherwise vinos. Shaw's Lectures, p. 223.

**RECTIFYING of Curves.** See **Rectification**.

**RECTIFYING of the Globe or Sphere**, is a previous adjusting of the globe or sphere, to prepare it for the solution of problems. For the method of doing it, see *Usi of the Geographical Globe*.

**RECTILINEAR, Right-lined.** in *Geometry*, is applied to figures whose perimeter consists of right lines.

**RECTILINEAR Angle, Maps, and Superficies.** See the substantives.

**RECTITUDE, Rectitude, Reialm, in matters of philosophy, refers either to the act of judging, or of willing; and therefore whatever comes under the denomination of rectitude is either what is true, or what is good: these being the objects about which the mind exercises its two faculties of judging and willing.

**Rectitude of the mind, considered as it judges, i.e. rectitude of the faculty of judgment, consists in its agreement and conformity to the nature and reason of things, and in its determining and deciding about them according to what their constitutions, properties, uses, &c. really are.**

**Rectitude of the mind, considered as it wills, called also moral rectitude, or uprightness, consists in the choosing and pursuing of those things which the mind, upon due enquiry and attention, clearly perceives to be good; and avoiding those that are evil.**

**RECTITUDINES, in Law, rights, or legal duties, belonging either to God, or man.** See *Right*.

**RECTO,** a writ usually called a writ of right; of so high a nature, that whereas other writs in real action are only to recover the possession of the lands, &c. in question, lost by the plaintiff, or his ancestor; this aims to recover both the fein thus lost, and the property of the thing: so that both rights are here blended together; that of property, and that of possession.

If a man lose his cause upon this writ, he is without all remedy.

There are two kinds of this writ: breve magnum de rebus, or
or breve de reto patens, a writ of right patent; and recto
clauum, a writ of right clofe.

The writ is so called, because fent open. It lies only for
him that hath fee-fimple in the lands fued for, againft the
tenant of the freehold at leaf.

Indeed, the writ of right patent is extended, in praetice,
beyond its original intention; for a writ of right of dower,
which lies for the tenant in dower, is patent; and fo in fe-
veral other cafes. Fizherb.

The writ of right clofe, called alfo breve parvum de reto,
is directed to the lord of ancient demefne, or the bailliff
of the king's manors; and lies for thofe who hold lands
and tenements by charter, in fee-fimple, or in fee-tail, or for
term of life, or in dower, if they be ejected out of fuch
lands, or diffeited. In fuch cafe a man, or his heirs, may
fue out the writ of right clofe, directed to the lord of ancient
demefne, commanding him to do him right in his court.
This is called a writ fecundum confuetudinem manerii. See
Possession, Property, Title, and Writ.

Recto de advocatione ecceflae, a writ of right, lying where
a man has right of advowson in fee to him, and his heirs;
and, the incumbent dying, a ftranger prefents his clerk to
the church; and he, not having brought his action of quaere
impedit, nor darrenin prefentment, within fix months, has suf-
tered the ftranger to influff upon him. See Diffirnbance of
Patronage, Quaere impedit, and Assina darrenin prefent-
ment.

Recto de caffula terre & hereditis, a writ which lies for
him whom tenant dying in his nonage, a ftranger enters, and
takes the body of the heir.

This writ as to lands holden in capite, or by knight's fervice,
is become ufelefs by the Stat. 12 Car. II. but not where
there is a guardian in foance, or appointed by the laft will of
the ancestor. See Guardian.

Recto de dote, a writ of right of dower, which lies for a
woman that has received part of her dower, and proceeds
to demand the reftant in the fame town againft the heir, or
his guardian. This extends either to part of the whole, and
is a more general remedy than that mentioned in the next
article.

Recto de dote unde nihil habet, is a writ of right which lies in
cafe where the husband, having divers lands and tenements,
has aliened no dower to his wife; and he is thereby driven
to sue for her thirds againft the heir, or his guardian. See
Dower, and Writ of Entry.

Recto quando or quia dominus remittit, a writ of right,
which lies in cafe where lands or tenements in the fignory of
any lord, are in demand by a writ of right.

If the lord hold no court, or, at the prayer of the de-
mandant or tenant, fend his writ to the king's court, to put
the caufe thither for that time; this writ f ues for the other
party, and has its name from the words comprised, which is
the true occafion of it.

Recto de rationabili parte, a writ that lies between pri-
vies of blood, as brothers in gavel-kind, or fitters, or other
coparceners, as nephews and nieces, and for land in fe-
fimple.

If a man leafe his land for life, and afterwards dies, leav-
ing ifue two daughters, and, after, the tenant for life fikewife
dies; the one fitter entering on all the land, and fo deftreing
the other, the fitter fo deftefted fhall have this writ to recover
her part.

Recto fur disclaimer, a writ which lies where the lord, in
the court of common pleas, does ave upon his tenant, and
the tenant disclaims to hold of him; upon which dis-
claimer the lord fhall have this writ. This takes place
when the tenant upon a writ of allife for rent, or on a re-
plevin, disowns or disclaims his tenure; whereby the lord
lofe his veridict; in which cafe the lord may have this writ,
grounded on this denial of tenure, and that, upon proof of
the tenure, recover back the land itself fo holden, as a
punishment to the tenant for fuch hisfalse disclaimer. This
piece of retaliating juftice, whereby the tenant who endeav-
ours to defraud his lord is himself deprived of the estate,
as it evidently proceeds upon feudal principles, fo it is ex-
prefsly to be met with in the feudal constitutions; "vaffal-
lus, qui abnegavit feudum ejufve conditionem, expoli-
betur."

Recto folo. See Foho.

RECTOR of a parifh, the parfon, or he who has the
charge or cure of a parifh church. See Parfon.

If the predical tythes of the parifh be impriopriated, or ap-
propriated, i.e. either in lay lands, or in thofe of fome eccle-
fiatical community, then, instead of rector, the parfon is
called vicar, (which fee). In England are reckoned 3485
rectories.

The name rector denotes him governor or ruler, quia
tantum jus in ecclesia parochiali habeas, quantum predicat
in ecclesia collegiata.

RECTOR also denotes the chief elective officer in feveral
foreign universities, particularly in that of Paris.

RECTOR is also ued in feveral convents for the fuperior,
or officer who governs the house.

The Jefuits ued it for the fuperiors in fuch of their houfes
as were either feminaries, or colleges.

RECTORY, or Rectorate, Regoria, a parifh church,
parfonage, or spiritual living, with all its rights, glebes, and
tythes.

RECTRICES, in Ornithology, denote the strong feathers
of the tails of birds.

RECTUM Intestinum, in Anatomy; or in Enlish,
the rectum; is the laft portion of the large intestine,
and of the whole alimentary canal. It begins at the left
acroc-iliac lymphys, below the figmoid flexure of the colon,
and ends at the anus. See Intefine.

RECTUM, Ulcers in the Neighbourhood of. See Fis-
tula in Ano.

RECTUM, Concretions and extraneous Substances lodged in.
The concretions formed in the larger intelines, and espe-
cially in the rectum, by the accumulation and protracted
lodgment of the feces, may become the caufe of oblitinate
contipation, which can only be removed by their extrac-
tion. Sometimes these masses of indurated matter include
no extraneous subfance; in other infances, their nucleus
is a biliary calculus; in a vaft number of cafes, they are
merely compos'd of the feces in a dry hardened state. It is
remarked that women, and perfon's of advanced age, are
most fubject to the conftipation arising from the obstruction
thus occafioned in the large intelines. Children and adults
in the vigour of life are not, however, entirely exempt
from the disorder, though they seldom have it, except when
the formation of fuch concretions in the bowels has been
brought on by swallowing a large quantity of hard indig-
itable bodies, like cherry and plum-$,tones. Laitily, ex-
cellently hardened masses of fecal matter have been noticed
in patients who have for a long while been confined to bed
in the recumbent pofture by severe difeafes.

Whatever may be the caufe of the disorder, whether the
defect itfelf conflits in a mere accumulation of indurated
feces, with which the rectum is dilated, and behind which
the excrement is detained; or whether the conftipation
is not complete, the concretion allowing the liquid part of
the feces to pass out between it and the inside of the inti-
tine; the eXistence of the hardened mafs may be known
by
by the constipation which it produces; by the sefle of
weight which the patient feels about the fundament; and
also by the possibility of actually touching the inflamed
obstructing body, when a finger is introduced up the
rectum.

Oily emollient dlyters, and carminative draughts, will
serve for expelling such concretions as are not of too firm a
consistence; but the extraction of them is absolutely ne-
cessary when they are particularly hard. The operation is
to be done with a fpoo, or suitable forceps, properly oiled;
and, after the concretion has been removed, an emollient
dlyter is to be administered, in order to allay any irritation
which may have been caused by the introduction of the
requisite instruments. When the fpinthcr ani contracts too
forcibly, that the operation is attended with extreme pain
and difficulty, we are advised by surgical writers to make a
dilatation of the anus, by practising an incision at its po-
terior angle. A wound made in this direction cannot do
injury to any part of confequence, whilst there would be a
risk of wounding the urethra in the male, or the vagina in
the female subject, if the cut were made at the anterior
angle. An incision, carried laterally, would be apt to in-
jure the pudic vell's. A division of the fubes of the
fpinthcr ani does not produce any material permanent
weakness of its action, and a paralysis of this muscle, ac-
cording to Richerand, can never proceed from such a caufe.
Nofographic Chirurgica, tom. iii. p. 414. edit. 2.

The hard concretions which lodge in the rectum cannot
be reached with the finger when they are situated high,
and, in this circumstance, the surgeon must ufe a probe, or
found, in order to affure himfelf positively of their presence,
their moveableness, and their fize.

With regard to foreign bodies lodged in this interline,
tome have been swallowed, and have passed through the
whole extent of the alimentary canal, whilst others have
been pushed up the anus to a greater or leffer height.
The extraction of these laid is generally attended with a
great deal of difficulty, and even demands on the part of
the operator more than ordinary fagacity, in confequence
of the various shapes, the hardnefs, and the fragility of
them different bodies. Olafs phials, instrument cajas, flutes,
&c. have been introduced into the rectum by manicures.
One perfon of this defcription put into his rectum a flint-
stone, which did not admit either of being extracted, or
broken, owing to its hardnefs, and slippery furface, and
which in the end caufed the patient to die in the greatest
agonie, with fwallowing and gangerous mischief in the abdo-
men. Marchetti has recorded an instance, in which a pig's
tail, hardened by cold, was forcibly thruf up the rectum
of a girl of the town. This extraneous body could not
be withdrawn, as the short briffles, which all inclined out-
ward, immediately came into contact with and pierced the
inner part of the bowel. It remained in the part fix
days, and occasioned a train of alarming fymptoms, fuch as
fever, vomiting, fwallowing of the abdomen, and obfinate
conflipation. Marchetti falfened a ligature to the end of
the foreign body, which protruded at the anus, and then
pulled the ligature through a long piece of reed, which he
introduced up the rectum, in order that the foreign body
might be drawn through this tube without the interline
being lacerated. The experiment was completely success-

In another example a piece of wood, three inches long,
and two in width, was introduced into the rectum. Con-
flipation of the abdomen, fever, conftipation, and difficulty
of making water, came on, and lasted fix days. The im-
possibility of removing the extraneous fubftance with a
pair of forceps, led to the idea of using a horer, which,
having been palled up the rectum under the guidance of the
finger, was inferted deeply enough into the piece of wood
to draw it out. The extraction, however, could not be
effected without a great deal of pain. See Mclanges de
Chirurgie, par M. Saucourt, p. 484. Hmiton de l'Aca-
Chirurgicae, tom. ii. p. 569, edit. 2.

Rectum, Congenital and Syphilitic Contractions of its in-
ferior Portion. A contraction of the lower end of the
rectum is sometimes an original malformation; but more
frequently it arises from what has been confidered by various
surgical authors to be a venereal thickening of the parietes
of this fubflance. If this be really a syphilitic disorder, a
circumstance which is to be doubted, it is certainly as
grievous as any of the more common effects of the venereal
difeafe. Excreffences grow from the mucous membrane at
the rectum, and defcharge a purulent matter, which is con-
tinually oozing from the anus. When a finger is palled
within this aperture, the irregularities occasioned by the
tumour may be plainly felt. Such writers as believe in
the syphilitic nature of this complaint inform us, that the
truth of this may be known by the antecedent and co-exifen-
t symptoms of the venereal difeafe. They admit, however,
that the disorder almost always lafts after the cure of evry
other mark of typhillis, and they caution us not to perip-
ually in admifering mercury any longer for a difeafe
which cannot be further benefited by it. These circum-
fances are quite sufficient to prove that there is not much
reason for the doctrine, that this fort of contraction of the
lower end of the rectum is venereal.

Such writers as consider the complaint to be connected
with typhillis, of couffe recommend the exhibition of mer-
cury, and they further advise the frequent injection into
the rectum of a weak folution of the oxymurate of the fame
mineral. Tents, fmeared with mercurial ointment, are also
recommneded to be palled into the bowel. The latter
applications are flated to have the advantage; 1st, of op-
posing, by mechanical preface, the further increase of the
excreffences; 2dly, of dilating the contracted part; and,
3dly, of acting on the difeafe by their medicinal quality.

For our own part, we much doubt the mode of the
venereal nature of the foregoing complaint. The language
of the advocates for such a doctrine is full of fuppositions,
that they are influenced in their judgment more by pre-
judice than reason. "The venereal affection of the coats
of the rectum (fays one of these writers) almost always lafts
after the total extinction of the syphilitic virus. Then, we
ought to be content with the employment of dilating me-
chanical means, without perifling in the ufe of medicines,
which would ferve only to ruin the patient's constitution.
An elastic gum cannula is to be prefered, and it fhould be
of a conical shape, in order that it may be gradually intro-
duced further and further, in proportion as the dilatation
of the bowel is effected." Richerand, Nefographic Chirug.,
tom. iii. p. 418, edit. 2.

In cafes of congenital contraction of the rectum, the
only plan which can be adopted, is that of making an in-
cision through the posterior part of the intestine.

Rectum, Polypi of. Sometimes, though not often,
polypi grow from the mucous membrane of the rectum,
and by their size obftruct the paffage of the feces. Their
existence is at first manifefted by an uncan feffe of heav-
iness, and afterwards they are protruded outwardly in the
efforts which the patient makes at ftool. The anus con-
tracting after their expulsion, their roots become frangulated, so
that they cannot return, and excessive agony is produced.
In this circumstance, the surgeon should take the opportunity of removing them with a knife, after having tied their root, or even without this precaution. The lining of the rectum, freed from the weight of the tumour, immediately retracts, and if the polypus should have received a supply of blood from a large vessel, hemorrhage may ensue. Such accident may be remedied by completely detaching the wounded part of the rectum with a large piece of sponge, or with a compress of lint; but as it is easier to prevent the hemorrhage altogether, than to stop it after it has occurred, we would advise surgeons, whenever the excrecence is of any size, always to tie its root before removing the rest of it with a cutting instrument.

Rectum, Prolapsus of. See Prolapsus Ani.

Rectum, Scirrhous contracted. Scirrhus of the rectum is not uncommon at an advanced period of life. Sometimes it extends over a considerable length of the gut, but generally it is more circumscribed. The coats of the bowel become much thicker and harder than in the natural state. The muscular coat is subdivided by membranous septa, and the internal coat is sometimes formed into hard irregular folds. The surface of the inner membrane is occasionally ulcerated, so as to form a cancerous disease. Every vestige of the natural structure is occasioned lost, and the gut is changed into a gritty substance. The cavity of the bowel is always rendered narrow at the scirrhous part, and is sometimes almost obliterated. When the passage through the gut is much obstructed, the bowel is always a good deal enlarged just above the stoppage, or iritriture, from the accumulation of the feces there. As the disease advances, adhesions form between the rectum and adjacent parts, and ulcerations produce communications between them.

The disease is usually not much noticed till somewhat advanced, not being at first very painful. The patient only thinks that he is colitive, and that he voids his stools with a little difficulty. In time, a good deal of pain is felt in the part affected, especially at stool, after which some relief is experienced. Pus and blood may sometimes be noticed with the excrement, particularly when the disease has advanced to the ulcerated state. The patient at length becomes feble, the constitution suffers, and dissipation follows. Severe teneimentus attends the whole course of the disease.

Default has often seen the disease form a communication between the rectum and vagina, and the feces have passed through the latter part. In the latter stage of the affection, the rectum, bladder, vagina, uterus, and adjacent parts, are all involved in one common ulceration.

When the disease has attained the ulcerated state, it is probably always incurable. Palliatives can now only be resorted to, such as anodyne and emollient glyniers, the warm-bath, &c. with the exhibition of medicines like opium, cicuta, uva ursi, &c. Claudius added his remedies to the inside of the bowel by means of tents, and did not employ the latter as a mode of curing the disease, when least advanced. Valvafa used to introduce a cannula pierced with numerous holes, when his patient got into the bath, so as to let the fluid enter the intestine. Numerous practitioners, among them Morgagni, made mercurials the base of their treatment, from a fallacy that the complaint was of venereal origin.

When the disease is not attended with ulceration, the contraction and thickening of the gut may be diminished by introducing bougies, keeping them for a certain time, every day, i.e. introduced, and increasing their size gradually. The pressure of these instruments seems to loosen the disease, and stop its progress; a proof that its nature differs from that of what is usually understood by scirrhous. Default used to employ long tent-like, made of lint, lincered with ceruse, and passed into the bowel by means of a probe, with a forked end. This surgeon gradually increased the size of the tents, so as to continue the compression, to which he always referred all the good was owing. Their length was also augmented by degrees. Fresh ones were at first, introduced twice every day. When any hard stools were introduced on the outside of the anus, Default cured them on the same principle, viz. by making pressure on them with compresses and a bandage. This eminent surgeon effected a cure of a scirrho-contracted rectum by this method. The woman was taught to pass occasionally the tent her self, so as to prevent a relapse. The disease is laid to afflict women more frequently than men; from a comparative table kept at the Hotel-Dieu, this has been the case there in the proportion of ten to one. See Œuvres Chirurgicales de Default, tom. ii. p. 422.

Rectum, Hemorrhoidal Swelling of. See Hemorrhoids.

Rectum, in Law. See Recto.

Rectum, in our old Law Writers, is also used for a trial or accusation.

Rectum, Common, denotes a trial at law, or in the common course of law. Stare ad rectum, denotes to stand a trial. Rectum rogare, to petition the judge to do right.

Rectus, in Anatomy, a name applied to several muscles, generally, but not invariably, distinguished by the straightness of their fibres, or of their general direction.

Rectus abdominis. See Obliquus.

Rectus adductus, or externus, Rectus adductus, or internus, Rectus attellus, or superior, Rectus depriment, or inferior, muscles of the globe of the eye. See Eye.

Rectus anterior cruris, or femoris, Rectus cruris; Rectus extensor cruris, or femoris, which see.

Rectus capitis anterior major et minor. See Rectus internus.

Rectus capitis internus major, rectus anticus major, tra- chelio-fono-occipitius; a muscle of the head, flattened, broader and thicker than below, occupying the anterior and lateral part of the neck, and reaching from the tranverse processes of the sixth cervical vertebra, to the inferior surface of the balslear processes of the occiput. Its anterior surface is covered by the carotid artery, the internal jugular vein, the nerve of the eighth pair, the great sympathetic, and the pharynx. The longus colli, the rectus capitis internus minor, the articulations of the occiput and atlas, and of the latter bone, and the second vertebra, are covered by its posterior surface. The inner edge lies on the longus colli, and is connected to it by cellular substance; the outer is fixed to the front of the tranverse processes of the sixth, fifth, fourth, and third cervical vertebrae, and is attached above the latter. The lower end, very thin and pointed, is fixed to the tranverse processes of the sixth cervical vertebra; it ascends with a little obliquity from without inwards, increasing in breadth and thickness; it approaches the muscle of the opposite side, and is attached by its upper end to the balslear processes of the occipital bone, in front of the foramen magnum. At the upper part of this muscle is a broad and thin aponeurosis, which depends on the anterior and inner surface: the attachments to the tranverse processes are by small tendons terminating in muscular portions. The muscular fibres run obliquely between the half mentioned tendons and the aponeurosis.

This muscle bends the head forwards on the neck; and restores it after it has been carried backwards. The muscle of
of one side, acting singly, inclines the head towards its own side.

Rectus capitis internus minor, or rectus anticus minor, tracheo-facial-occipit: a small muscle of the head, lying under the larynx, short, narrow, and flattened, and extending from the atlas to the occiput. It is covered in front by the rectus internus major, the internal carotid artery, and the great sympathetic nerve; behind it covers the capsule of the articulation between the atlas and occiput. The outer and inner edges present nothing remarkable. Its lower extremity is fixed to the anterior surface of the lateral portion of the atlas, and to the neighbouring part of its transverse process. Thence it ascends, increasing somewhat in size, and inclines a little inwardly, and is fixed to the under surface of the basilar process of the occiput, behind and a little on the outside of the rectus internus major, and to the cartilaginous sail filling the space between the occipital and temporal bones. It has aponeuroses at its extremities, and very short muscular fibres between these.

Its action on the head is exactly the same with that of the rectus internus major.

Rectus capitis lateralis, le premier transverse antérieur Winslow, atlo-ido-mastoïden, petit droit lateral; a small muscle of the head, situated at the upper and lateral part of the neck, flattened and quadrilateral, reaching from the transverse processes of the atlas to the occiput. It is covered in front by the internal jugular vein; and it covers behind the vertebral artery. The two edges present nothing remarkable. Below it is fixed to the front of the upper surface of the transverse processes of the atlas; thence it ascends a little outwards, and is attached above to the rough impression behind the jugular foramen. It is muscular, except just at the attachments, which are tendinous. Its action, like that of the two last muscles, is to restore the head, when it has been bent backwards; to bend it forwards; and, when one muscle acts singly, to incline it laterally.

Rectus capitis posticus major, atlo-ido-occipit: a muscle of the head, of a triangular flattened figure, placed at the upper and back part of the neck, and extending from the spinosus processes of the second cervical vertebra to the occiput. Its posterior surface is covered by the complexus, and above by the obliquus superior capitis; the anterior surface covers the posterior arch of the atlas, the rectus posticus minor, and the occiput. The inferior extremity, narrow, and almost pointed, is attached to the spinosus processes of the second cervical vertebra, thence it ascends, directed outwards, and a little backwards, and gradually increasing in breadth, to be inserted in the inferior surface of the occiput, at about an equal distance from the great external transverse ridge, and the foramen magnum, between the complexus, the obliquus superior, and the rectus posticus minor. The extremities alone are tendinous; the rest being muscular. It restores the head, when it has been bent forwards; and carries it back on the vertebral column. When one muscle acts singly, it will have the power, from the oblique direction of its fibres, of rotating the head, so as to turn the face towards its own side.

Rectus capitis posticus minor, atlo-ido-occipit: a small flattened muscle with radiated fibres, and consequently a triangular figure, placed at the upper and back part of the neck, extending from the atlas to the occiput, and lying with its fellow in the interval between the two rectus majors. Its posterior surface is inclined downwards and covered by the complexus; the anterior surface corresponds to the occiput, and to the interval between it and the atlas. The lower extremity is the narrowest part, and is fixed to the rough impression in the middle of the posterior surface of the posterior arch of the atlas; it extends parallel to the opposite muscle and directed backwards, and is fixed to the external surface of the occipital bone at a short distance from the foramen magnum. It raises the head when bent forwards; and extends it or carries it back on the neck.

Rectus cervix, rectus extensor or anterior cervix, droit ou grele antérieur, ileo-rotulien; a muscle of the thigh, long and flat, broad in the middle, and narrow towards its extremities, occupying the middle and front part of the limb, and reaching from the anterior and inferior spine of the ilium to the patella. It is covered in front by the iliacus internus, the factitis lateralis, and the saphena lateralis; behind it covers the orbicular ligament of the hip, the great extensors of the knee, and the external or anterior circumflex vessels. The outer and inner margins of the muscle are unattached in their upper three-fourths; they are conflated, in their lower fourth, with the extensors of the knee.

The superior extremity of the rectus cervix presents two tendons, one of which is straight, the other curved. The former is fixed to the anterior and inferior spine of the os innominatum: the latter, curved from before backwards, and from above downwards, is fixed to the outer surface of the os innominatum for about an inch, immediately above the edge of the acetabulum. From this upper attachment the muscle descends vertically in front of the thigh, growing broader to the middle of the limb; it then becomes narrow towards the lower part, and is fixed to the bony of the patella.

The rectus is tendinous at its extremities, and fleshy in the middle. The upper tendon has been already described as divided into two portions; the anterior of these, attached to the anterior and inferior spine of the os innominatum, is the thickest and shortest, and has the same direction as the muscle; the other is longer and curved, and detaches some fibres to strengthen the orbicular ligament of the hip. The two portions join unite in a common tendon; this spreads out into a broad aponeurosis, which descends about four inches on the front of the muscle, and then dips into its substance. The inferior tendon is broad and flat, and arises from the bony of the patella; its posterior surface is united to the great extensors of the knee, and the edges are strongly connected to the vastus externus and internus. It is broad at the patella, grows a little narrower as it rises, then spreads out again, and forms a broad aponeurosis, covering the back of the muscle above its middle. The superficial fibres of this tendon descend over the front of the patella, to which they are strongly united, and are lost below in the tendon which unites this bone to the tibia. The muscular fibres are placed very obliquely between the superior and inferior tendons; they cover the back of the first up to the part where its two portions separate; and they descend on the front of the second to within two inches of the patella.

It extends the knee-joint, either by bringing the leg forwards upon the thigh, or the thigh upon the leg, according as the one or the other part is rendered a fixed point. If the knee be extended, or firmly retained in the bent position by its flexor muscles, the rectus may bend the thigh upon the pelvis; when the leg and thigh are fixed, it can bend the pelvis forwards upon the latter, as in the attitude of stooping to pick up any object from the ground. In the erect attitude it prevents the pelvis from inclining backwards; and refines it when it has been carried in that direction.

Rectus in cura, in Luxa, one who stands at the bar, and no man objects any thing against him.
When a man hath offended the outlawry, and can participate of the benefit of the law, he is said to be reduct in curia.

RECUVER, in Geography, a village and parish in the upper half-hundred of Blackgate, rape of St. Augustine, and county of Kent, England, is situated at the distance of 10 miles N.E. by N. from Canterbury. It is noted in history as the site of the Roman Regulbium, the station or castle which defended the northern entrance to the celebrated Portus Ruthepensis. It is remarkable, that while the ocean has receded from the southern entrance, leaving Richmond (Rutupium) considerably inland, it has gradually advanced upon Reculver. This is proved on the authority of several ancient writers, particularly Leland, who states, that in his time it stood about half a mile from the shore, whereas, at present, the tide washes the walls of many of the village houses, and threatens to overwhelm the whole at no distant period. Regulbium was a station of much importance, as it not only commanded an extensive view of the open sea, but likewise of the mouths of the Thames and the Medway. It was therefore used as a watch-post to discover the approach of an enemy; and also as a lighthouse to guide Nautes. In its perfect state the station was of a square form, with the angles rounded off, and was envirored by a ditch exterior to the walls, of which a considerable portion still remains. The extent of the inclosed area from east to west is about 100 yards, and from south to north about 158 yards. The ancient town was without the station, and is supposed to have stood towards the north, on that part of the coast long since swallowed up by the waves: and from the present shore, as far as a place called Black Rock, seen at low water mark, where, according to tradition, a church once stood, there have been found great quantities of tiles, bricks, fragments of walls, telfelled pavements, and other marks of a ruined town; and remains of the household furniture, drefs and equipment of the horbes belonging to its inhabitants, are continually met with among the sands; for after the fall of the cliffs, the earthen parts of them being washed away, these metaline substrances remain behind. When a part of the cliff here fell down about the conclusion of the seventeenth century, a number of small vaults, arched over, and several cisterns, were discovered. The latter were all of the same figure, namely, square, and measured from ten to twelve feet in length each side, and the same in depth. They were constructed of pols, driven deep into the ground, with planks two inches thick fixed to them. Their use was evidently the reception and preservation of rain water, which the Romans thought more wholesome than spring water. Vast quantities of Roman coins have been discovered both in the fields and along the shore here; and Du Frenne has produced many, which, from the markings upon them, appear to have been struck at a mint in this place. Britsh and Gaulish coins are likewise occasionally found here; also seals, keys, spoons, gold rings, bracelets, finger, bulbe, belts, bridles, harness, beans of seals or filibards, and many other articles of which the use has not yet been determined.

When Kent was subdued by the Saxons, Regulbium became a principal seat of the monarchs of that dynasty. It was then called Raculf and Raculf-leger; and hither king Ethelred retired with his court, after his conversion to Christianity by St. Augustine. In the next century it obtained the name of Raculf-mifer, from a Benedictine abbey founded here by Baffa, a priest and nobleman, to whom lands were granted for that purpose by king Egbert, as an atonement for the murder of his two nephews. This abbey was disolved previous to the Conquest, having probably been destroyed by the Danes. The town, however, continued in a flourishing condition for many years after that event, and had the privilege of a weekly market granted to it in 1313; but this right has been long discontinued. The church here is an ancient and spacious edifice, consisting of a nave, with three aisles, a chancel, and two lofty towers, surmounted by spires at the angles of the west front. The nave is separated from the aisles by five pointed arches, rising from short oblong piers; and from the chancel by three small semi-circular arches, springing from tall round columns, with very angular capitals. In this church kings Ethelbert 1. and II. are said to have been buried; and a monument erected to the memory of the first is described by Weever in his "Funeral Monuments," though it has now disappeared. On the floor of the chancel are several brasses of great antiquity. (See Richmond.) Beauties of England and Wales, vol. vii. by E. W. Brayley. History and Antiquities of Reculver and Herne, by W. Brayley, D. D. 8vo.

RECUMPADO, in Geography, a town of Hinderland, in the circuit of Rajamundry; 23 miles N.W. of Rajamundry.

RECUPERATORIES, among the Romans, were commissioners appointed to take cognizance of private matters in dispute, between the subjects of the state and foreigners, and to take care that the former had justice done them.

It came at last to be used for commissioners, to whom the prior referred the determination of any affair between one subject and another.

RECURRER, in Anatomy, a name under which the inferior laryngeal branch of the vagum is often described, from the circumstance of its arising in the chest below the point of its distribution to the larynx, and then going back into the neck in a retrograde course. See Nerve.

RECURRING SERIES, is a series so constituted, that each succeeding term is connected with a certain number of the terms immediately preceding it, by a certain and irrevocable law; as the sums or differences of some multiples of those terms. Thus the series

\[ \alpha, \beta, \gamma, \delta, \epsilon, \zeta, \&c. \]

is a recurring series; for these terms being respectively represented by \( \alpha, \beta, \gamma, \delta, \epsilon, \&c. \), we have

\[ \gamma = 2x\beta - x^3\alpha \]
\[ \delta = 2x\gamma - x^3\beta \]
\[ \epsilon = 2x\delta - x^3\gamma \]
\[ \zeta = \&c. \]

that is, each term is equal to \( 2x \) times that which precedes it, minus \( x^3 \) times the one preceding the last.

Or, generally, let

\[ \alpha, \beta, \gamma, \delta, \epsilon, \zeta, \&c. \]

be any series whose terms are denoted as above, by \( \alpha, \beta, \gamma, \delta, \epsilon, \&c. \). Also, let \( \mu, \nu, \pi, \&c. \), represent the successive multipliers by which the terms are connected, so that

\[ \alpha = x \]
\[ \beta = \beta \]
\[ \gamma = \mu x \beta + \nu x^3 = + \&c. \]
\[ \delta = \mu x \gamma + \nu x^3 = + \&c. \]
\[ \epsilon = \mu x \delta + \nu x^3 = + \&c. \]
\[ \zeta = \&c. \]

then this series is called a recurring series; and \( \mu + \nu + \&c. \) Du Moivre calls the scale of relation, which is said to be of one, two, three, \&c. terms, according to the number of multipliers
RECURRING SERIES.

Multiplier by which it is connected. In the above we have used only two, \( \mu \) and \( \nu \), whence \( \mu + \nu \) is called the scale of relation, which is here of two terms; and \( 1 - \mu - \nu \) is the scale of relation, as \( 1 - \mu - \nu \), is called by the same author the differential scale, which is always equal to the denominator of the fraction from which the series is produced.

If, in the above series, the terms had the relation
\[
\alpha = \alpha \\
\beta = \beta \\
\gamma = \gamma \\
\delta = \mu x \gamma + x^2 \beta + \xi x^3 \alpha \\
\epsilon = \mu x \gamma + x^2 \beta + \xi x^3 \gamma \\
\zeta = \mu x \gamma + x^2 \beta + \xi x^3 \gamma \\
\&c. \quad \&c. \\
\text{then the scale of relation would be } \mu + \nu + \xi, \text{ which is of three terms; and the differential scale, or the denominator of the fraction, is } 1 - \mu - \nu - \xi.
\]

The following problems are naturally connected with the doctrine of recurring series, viz.,

1. Any recurring series being proposed, to find the scale of relation, or the law of the series, which is not always obvious on inspection.

2. To find the sum of an infinite recurring series, or the sum of any number of its terms (n).

3. To find a general expression for any indefinite term of such a series, as \( \alpha \), for example, the \( n \)th term.

We shall consider each of these problems under their separate headings.

I. To find the scale of relation in any proposed recurring series.

Let \( \alpha, \beta, \gamma, \delta, \epsilon, \&c. \) be a recurring series, of which it is required to find the scale of relation.

Assume
\[
\delta = \mu \gamma + \nu \beta + \&c. \\
\epsilon = \mu \delta + \nu \gamma + \&c. \\
\beta = \&c. \\
\]

Where \( \beta, \gamma, \delta, \&c. \) are known, and \( \mu, \nu, \&c. \) unknown quantities, whose numerical values are required, and which are readily found by the usual method of elimination. Thus in the above, using only \( \mu \) and \( \nu \), we have
\[
\mu' = \frac{\delta - \gamma \beta}{\gamma - \nu \beta} \quad \&c. \\
\nu' = \frac{\delta - \gamma \beta}{\gamma - \nu \beta} \quad \&c. \\
\]

These values of \( \mu' \) and \( \nu' \) will obviously contain in them the powers of the indeterminate quantity \( x \), which being taken out, we shall have the required numerical values of \( \mu \) and \( \nu \).

Let it be required to ascertain the scale of relation in the series
\[
\alpha, \beta, \gamma, \delta, \epsilon, \&c. \\
1, 3, x, 5 x^2, 7 x^3, 9 x^4, 11 x^5, \&c. \\
\]

Here, by substituting the proper values of \( \beta, \gamma, \delta, \&c. \) in the above equation, we have
\[
\mu' = \frac{33 x^3 - 27 x^5}{20 x^3 - 21 x^4} = \frac{8 x}{4 x} = 2 x \\
\nu' = \frac{49 x^3 - 45 x^5}{21 x^3 - 25 x^4} = \frac{4 x}{-4 x} = -1 x^2 \\
\text{when } \mu = 3x, \text{ and } \nu = -1.
\]

The same method may obviously be employed in any other case; but in order to know whether or not we have assumed a scale of relation of a sufficient number of terms, we must repeat the same operation upon three other terms, of which one at least was not before employed; and if both give the same values, we may be assured of the truth of our results: or we may otherwise, instead of repeating the operation, examine the several terms, and see whether they agree with the law we have determined, and if not, we must increase the terms in our scale of relation; for it may be observed, that we can never fail of determining them in consequence of having assumed too many terms, as we shall, in that case, have one of our results zero.

Lagrange has formed a different rule for ascertaining whether a given series be recurring or not, which Mr. Bonycastle has given at p. 323 of his Algebra; but as it does not seem adapted for detecting the law of formation, we shall not hint it.

II. To find the sum of any recurring series, of which the scale of relation is known.

Let \[
\alpha, \beta, \gamma, \delta, \epsilon, \&c. \\
a, b, c, d, e, f, \&c. \\
\]

be a recurring series, of which the scale of relation is \( \mu + \nu \), so that
\[
\alpha = \alpha \\
\beta = \beta \\
\gamma = \mu x \gamma + \nu x^2 \beta + \xi x^3 \alpha \\
\delta = \mu x \gamma + \nu x^2 \beta + \xi x^3 \gamma \\
\epsilon = \mu x \gamma + \nu x^2 \beta + \xi x^3 \gamma \\
\&c. \quad \&c. \quad \&c. \\
\]

Here it is obvious, that the whole sum
\[
S = a + \beta + \gamma + \delta + \epsilon + \&c. \\
S = a + \beta + \mu x (\beta + \gamma + \delta + \epsilon + \&c.) + \nu x^2 (\alpha + \beta + \gamma + \&c.) \\
S = a + \beta + \mu x (S - \alpha) + \nu x^2 (S - \alpha) \\
\text{whence } S = \alpha + \beta - \mu x \alpha \\
\]

which is a general expression when the scale of relation is of two terms.

When the scale of relation is of three terms, so that
\[
\alpha = \alpha \\
\beta = \beta \\
\gamma = \gamma \\
\delta = \mu x \gamma + \nu x^2 \beta + \xi x^3 \alpha \\
\epsilon = \mu x \gamma + \nu x^2 \beta + \xi x^3 \gamma \\
\text{and } \xi x^3 \gamma \\
\&c. \quad \&c. \quad \&c. \\
\]

it is equally obvious that
\[
S = a + \beta + \gamma + \delta + \epsilon + \&c. \\
S = a + \beta + \gamma + \delta + \epsilon + \&c. \\
S = a + \beta + \gamma + \mu x (S - \alpha) + \nu x^2 (S - \alpha) + \xi x^3 + S \\
\text{whence we have } \\
S = a + \beta + \gamma - \mu x (\alpha + \beta) - \nu x^2 (\alpha + \beta) - \xi x^3 + S \\
\]

which is the general expression for the sum, when the scale of relation is of three terms.

In the same manner we have
\[
S = a + \beta + \gamma + \delta + \epsilon + \mu x (\alpha + \beta + \gamma) - \nu x^2 (\alpha + \beta + \gamma) + \xi x^3 + S \\
\text{for a scale of relation of four terms; and so on.}
\]

But as the terms \( \alpha, \beta, \gamma, \delta, \&c. \) contain in them certain powers of \( x \), we may reduce the above expressions to simpler forms.
RECURRING SERIES.

From the preceding part of this article it appears, that every recurring series may be considered as arising from the development or expansion of some rational fraction of the form

$$\frac{a + b x + c x^2 + dx^3 + \&c.}{1 - \alpha x - \beta x^2 - \gamma x^3 - \delta x^4 - \&c.}$$

Let us, therefore, suppose this fraction to be converted into the infinite recurring series $A + B x + C x^2 + D x^3 + E x^4 + \&c.$ of which we already know how to determine the co-efficients, and the law of their formation.

Now if this rational fraction be decomposed into its simple fractions by the method explained under the article RATIONAL FRACTIONS, and each of these simple fractions be then converted into a recurring series, it is evident that the sum of all these series ought to be equal to the original series $A + B x + C x^2 + D x^3 + E x^4 + \&c.$

Now each of these partial fractions being of the form

$$\frac{A'}{1 - r x},$$

the series hence arising will have the form

$$A' + A'r x + A'r^2 x^2 + A'r^3 x^3 \ldots A'r^n x^n$$

of which $A'r^n x^n$ is the general term. Hence, the several series arising from the partial fractions may be supposed to be

$$A' + A'r x + A'r^2 x^2 + A'r^3 x^3 \ldots A'r^n x^n$$

and since the sum of these series is equal to the original one proposed, we know that the co-efficients of the like powers of $x$ are also equal, whence we have

$$A = A' + A'' + A''' + A'''' + \&c. \quad B = A' r + A'' r^2 + A''' r^3 + A'''' r^4 + \&c.$$  

whence it appears that the co-efficient of any term $x^n$ of the recurring series is equal to the sum of the co-efficient of the same power of $x$, which arise from expanding the several simple fractions into which the given fraction is decomposed; and this co-efficient is always equal to the sum of each of the numerators of the several simple fractions, multiplied into the $n$th power of the corresponding value of $r$ in the denominator of the same fraction, at least while the denominator contains no equal factor. But if, among the partial fractions, there is any one of the form $\frac{A'}{(1 - r x)^n}$, the general term of this will be $(n + 1) A r^n x^n$; of $\frac{A}{(1 - r x)^n}$ the general term is $(n + 1) \frac{(n + 2)}{2} A r^n x^n$; and univerfally $\frac{A}{(1 - r x)^n}$, the general term is

$$(n + 1) \frac{(n + 2)}{2} (n + 3) \ldots (n + k - 1) \frac{A}{(1 - r x)^k},$$

we may, therefore, in all cases wherein the generating fraction of the original series admits of a rational decomposition, arrive very readily at the general term upon the principles above explained.

Thus,
RECURRING SERIES.

Thus, as an example, let there be proposed the recurring series

\[ 1 + 4 x + 14 x^2 + 46 x^3 + 146 x^4 + \&c. \]

to find the general term, or the co-efficient of \( x^n \).

The sum of this series is found by the preceding part of this article to be

\[ \frac{1 - x}{1 - 5 x + 6 x^2}. \]

This rational fraction is equal to \( \frac{1}{1 - 2 x} + \frac{2}{1 - 3 x} \). Now the general term of \( \frac{1}{1 - 2 x} \) is \( 2^n x^n \); and of \( \frac{2}{1 - 3 x} \) is \( 2 \cdot 3^n x^n \), as shown above, therefore the general term of the proposed series will be \((2 \cdot 3^n - 2^n) x^n\).

It may be observed, however, that this method is in some cases very laborious, and not always practicable; it will, therefore, frequently be better to make use of the multinomial theorem, which may be done by putting the generating fraction under the form

\[ (a + b x + c x^2 + \&c.) (1 - x) \beta x - \gamma x^2 - \&c. \)

See *Multinomial Theorem*.

V. To find the sum of any number \( (n) \) terms of a recurring series.

For this purpose it is only necessary to find the co-efficient of the \( n + 1 \)th term of the series. Then, from the sum of the entire series subtract the sum of the series beyond the \( n \)th term, and the difference will obviously be the sum of the first \( n \) terms sought.

Let there be proposed as an example to find the sum of \( n \) terms of the series

\[ 1 + 2 x + 3 x^2 + 4 x^3 + \ldots + n x^{n-1}. \]

The infinite sum of this series is readily found \( \frac{x}{(1 - x)^2} \).

In the second case, viz. of the terms beyond \( n x^{n-1} \), the series is

\[ (n + 1) x^n + (n + 2) x^{n+1} + (n + 3) x^{n+2} + \&c.; \]

and in the formula \( \frac{a + \beta - \alpha n x}{1 - \mu x - \nu x^2} \) we have only to substitute \( \alpha = (n + 1) x^n \) and \( \beta = (n + 2) x^{n+1} \), instead of \( \alpha = 1 \) and \( \beta = 2 x \), as in the former. Hence we have

\[ s = \frac{(n + 1) x^n + (n + 2) x^{n+1} + 2 (n + 1) x^{n+1}}{1 - 2 x + x^2}, \]

and, therefore, \( s - s' \), or the sum of the first \( n \) terms is equal to

\[ \frac{1 - (n + 1) x^n + n x^{n+1}}{(1 - x)^2}. \]

2. Required the sum of \( n \) terms in the series

\[ 1 + 3 x + 5 x^2 + \ldots + (2 n - 1) x^{n-1}. \]

Here, by trial, we find the scale of relation to be \( \mu = + 2 \), and \( \nu = - 1 \), as before, therefore the infinite sum is

\[ s = \frac{a + \beta - \alpha n x}{1 - \mu x - \nu x^2} = \frac{1 + 3 x - 2 x}{1 - 2 x + x^2} = \frac{1 + x}{(1 - x)^2}. \]

After \( n \) terms, the series becomes

\[ (2 n + 1) x^n + (2 n + 3) x^{n+1} + (2 n + 5) x^{n+2} + \&c. \]

which therefore arises from the fraction

\[ \frac{(2 n + 1) x^n + (2 n + 3) x^{n+1} - 2 (2 n + 1) x^{n+1}}{1 - 2 x + x^2} \]

\[ = \frac{(2 n + 1) x^n - (2 n - 1) x^{n+1}}{(1 - x)^2}. \]

whence the sum of \( n \) terms is

\[ \frac{1 + x - (2 n + 1) x^n + (2 n - 1) x^{n+1}}{(1 - x)^2}. \]

3. Required the sum of \( n \) terms of the series

\[ (n - 1) x + (n - 2) x^2 + (n - 3) x^3 + \&c. \]

Here again, the scale of relation is \( n = + 1 \), therefore the infinite sum is

\[ \frac{(n - 1) x + (n - 2) x^2 - 2 (n - 1) x^3}{(1 - x)^2}. \]

After \( n \) terms, it becomes \( x^{n+1} - 2 x^{n+2} + \&c. \), the sum of which is found in the same manner to be \( \frac{x^{n+1}}{(1 - x)^2} \); therefore \( n \) terms of the proposed series is

\[ \frac{(n - 1) x - n x^2 + x^{n+1}}{(1 - x)^2}. \]

Hence, also, \( n \) terms of the series

\[ \frac{(n - 1) x + (n - 2) x^2}{n} + \frac{(n - 3) x^3}{n} + \&c. \]

is found to be

\[ \frac{1 + x - (n + 1) x^2 + (2 n + 2) x^{n+1} - n x^{n+1}}{(1 - x)^2}. \]

the scale of relation being \( n = 3 n, 1 \).

In all the preceding examples we have determined the infinite sum of the series, as beginning at the first term, and at the \( (n + 1) \)th term a more easy method is as follows, which is due to Simpson. Ellias, p. 96.

Let \( A + B + C + D + \ldots + K + L + M + N \) be any finite recurring series, of which each term depends upon the three which precede it, the scale of relation being \( p, q, r \), so that

\[ p A + q B + r C = D \]

\[ p B + q C + r D = E \]

\[ &c. \]

or, which is the same,

\[ p A + q B + r C - D = 0 \]

\[ p B + q C + r D - E = 0 \]

\[ p C + q D + r E - F = 0 \]

\[ \ldots \]

\[ p K + q L + r M - N = 0 \]

whence,
whence, by addition
\[ p(A + B + C + \ldots + K) + q(B + C + D + L) + r(C + B + D + \ldots + M) = 0 \]
\[ r(C + B + D + \ldots + M) - (D + E + F + N) \]
\[ S = 0 \]

Or, representing the whole sum by \( S \),
\[ p(S - L - M - N) + q(S - A - M - N) + r(S - A - B - N) - (S - A - B - C) = 0 \]
which, by addition and division, gives
\[ p(L + M + N) + q(A + M + N) + r(A + B + N) - (A + B + C) \]

where the sum depends merely upon the three first and the three last terms of the series; and a similar expression, it is obvious, may be obtained for any other scale of relation.

It may not be amils to observe, that when the proposed series is wholly numeral, (the sum of which, as we have before observed, is to be found by making \( z = 1 \)); both this formula and the preceding one fail, in the case in which the denominator of the fraction becomes zero, and we must, therefore, in such cases, have recourse to other methods of summation, as given under the article Series.

On this subject the reader should consult De Moivre's Mise Analytique, and his Doctrine of Chances, and Euler's Analytique Infiniment, where he will find an explanation of its application to the approximation to the roots of equations. Colson's Comment on Newton's Fluxions. Suring's Methodus Differ. Cramer's Analyse des Lignes Courbes. Bernoulli de Serie. Inf. &c. See also a chapter on this subject, in vol. ii. of Bonnycastle's Algebra.

RECURVIROSTRA, the Avocet, in Ornithology, a genus of birds of the order Grallae, of which the generic character is; bill depressed, fuscate, recurved, pointed, flexible at the tip; the feet are palmate, four-toed, the hind toe not connected, very short, and placed high up; the nostrils are narrow, piercing; the tongue is short. There are only three species.

*AVOCETTA; Scooping Avocet; called also in different parts of this country, butter-flip, fooporter, yerler, crooked-bill, &c. This bird is variegated with white and black; the bill is three inches and a half long; iris hazel; crown black; a white spot behind and beneath the eyes; ruf of the head, neck, back, exterior part of the wings, lesser quill-feathers, tail, and under part of the body, white; inner capulars and greater quill-feathers without and at the tips black; legs blueish, and very long; membrane connecting the toes indented. It refines in the temperate parts of Europe, weighing thirteen ounces; and measuring, from the tip of the bill to the end of the tail, eighteen inches. It breeds in the fens of Lincolnshire, and Devonshire, in Kent. The female lays two white eggs, tinged with green, and marked with large black spots. In winter these birds assemble in small flocks of six or seven, and frequent the shores, particularly the mouths of large rivers, in search of worms and marine insects, which they scoop out of the mud or sand. They seem to be particularly fond of the cancer, pulex, or loculata. By means of their long legs, they run over shores that are covered five or six inches with water. In their movements they are lively, alert, volatile, and difficult to catch. When the female is frightened off her nest the counterparts lament; and when a flock is disturbed, they fly with their necks stretched out, and their legs extended behind, over the head of the spectator, making a shrill noise, and uttering a yelping cry of twit, twit, all the time.

AMERICAN; American Avocet. The head and neck are reddish; back black, beneath it is white. It inhabits North America and New Holland. Bill black; front dusky-white; neck above white; primary and tertial wing-coverts black, the middle ones, and some of the secondary quill-feathers, white.

ALBA; White Avocet. This species is white; the lower wing-coverts brownish; bill orange; legs brown. It inhabits Hudson's Bay; fourteen inches and a quarter long. Bill tufted with black; edge of the wings, greater quill-feathers, and tail, tinged with yellowish.

ALBA; White Avocet. This species is white; the lower wing-coverts brownish; bill orange; legs brown. It inhabits Hudson's Bay; fourteen inches and a quarter long. Bill tufted with black; edge of the wings, greater quill-feathers, and tail, tinged with yellowish.
There are two kinds of reds; the one in leaves, called Spanish red; the other a liquor, which is an extract of a fearlet dye.

Red, in Dying, is one of the five simple or mother colours of the dyers.

Some reckon seven kinds, or calls of red: viz. fearlet-red, crimfon-red, madder-red, half-grain-red, half-crimfon-red, lively orange-red, and scarlet of cochineal. But they may be all reduced to three, according to the three principal drugs which give the colours; which are kermes, cochineal, and madder.

The fine fearlet, called scarlet of the Gobelines, is given with agaric, bran-water, wood, and scarlet grain, or kermes. Some dyers add cochineal, and others fennugreek; brightening it with bran-water, agaric, tartar, and turmeric. See KERMES and SCARLET.

Crimfon-red is dyed with bran-water, tartar, and meuffle cochineal. See CRIMSON.

Madder-red is dyed with madder; to which some add realgar, or red arsenic: others, common salt, or other salts, with wheat-flour; or agaric with spirit of wine, with galls or turmeric. See MADDER.

The half-grain is made with agaric and bran-water, half fearlet grain, half madder, and sometimes turmeric.

The half-crimson is made of half madder, half cochineal. As to the lively orange-red, the fluff must be first put in yellow, then in a liquor made of goat's hair, (which has been boiled several times with madder,) dissolved over the fire with certain faltine liquors, as urine, tartar, &c.

The scarlet of cochineal, or Dutch scarlet, as the French call it, is made with flarch, tartar, and cochineal; after first boiling it with alum, tartar, sal gema, and aqua fortis in which pewter has been dissolved.

Befides these seven reds, which are good and allowed colours, there is also a Brazil red; which is discouraged, as fading easily.

Of the seven good reds, only four have particular casts, or shades; the madder-red, crimfon-red, lively orange-red, and scarlet of cochineal.

The casts or shades of crimfon are flesh colour, peach colour, carnation roe colour, and apple-tree flower colour. Those of madder are flesh colour, onion-peel colour, and flame colour. Those of orange are the fame with those of crimfon. Scarlet, besides the shades of all the rest, has some peculiar to itself, as cherry colour, fire colour, &c. See DYEING.

Red, in the Manufacture of Glass. See Red Glass.

To make a deep red in glass, the following method is that most practised by the glafs-men. Take crystal frit twenty pounds, broken pieces of white glass one pound, calcined tin two pounds; mix these well together, and put them into a pot to melt and purify. When these are melted, take lead calcined, scales of iron from the smith's anvil, both powdered very fine, of each an equal quantity; put leisurely an ounce of this mixed powder to the before mentioned metal; mix all well together, and let them stand fix or eight hours in fusion to incorporate; take out a proof after this, and if there be too little of the powder, it will appear of a dusky yellow; then more of the powder must be added, and then add three quarters of an ounce of calcined braüs, ground to a fine powder; mix them thoroughly together, and the mass will be of a blood red; continue stirring the whole together, and frequently taking out proofs of the colour, when it is right, work it immediately, otherwise it will lose its colour and become black. The mouth of the pot must in this process be left open, else the colour will be lost. Neri's Art. of Glafs, p. 100.

Red, in Heraldry. See Gules.

Red, in Painting. For painting in oil colours; they use a red called��metar, or vermilion; and another called lutea. See each in its place.

In limning and fresco, for a violet red, instead of lacoce they use burnt ochre, a natural earth found in England; for a brown red, they use burnt ochre, which is a native yellow earth, made red by calcination. It is chiefly brought from Oxfordshire; and burnt by those who prepare it in large ovens. The marks of its goodnes are brightness of colour, and a friable chalky texture, without manifesting any gritty roughness when rubbed between the fingers.

The common Indian red, which is of a hue verging to the scarlet, is much used, on account of its standing and warmth though not bright colour, in finer as well as coarser paintings in oil. It may be prepared by taking of the caput mortuum or ochre left in the iron pots after the distillation of aqua fortis from nitre and vitriol, two parts; and of the caput mortuum or coelothar left in the long necks after the distillation of oil of vitriol, one part; breaking the lumps found among them, and putting them into tubs with a good quantity of water; and having left them to stand for a day or two, frequently stirring them, then lading off as much water as can be obtained clear from them, and adding a fresh quantity; repeating the same treatment till all the faltes be washed out, and the water comes off nearly infipid. The red powder which remains must then be washed over, and, being freed from the water, laid out to dry. When this is designed for nicer purposes, it should again be washed over in bafons.

The true Indian red is a native ochreous earth of a purple colour, brought from the island of Ormus, in the Persian gulf; and called, among the authors on these subjects, terra Peucia. At present it is very rarely to be found; but it is certainly very valuable (there being no other uncompounded purple colour in use with oil) as well for the force of its effect, as for the certainty of its standing. In its genuine state, it needs no other preparation than grinding or washing over. It may be easily distinguished from any fictitious kind, by its being more bright than any other ochre which can be made so purple; and if it be rendered artificially purple by any addition, the fire will soon betray it; into which the genuine may be put without any hazard of change.

Venetian red is a native red ochre (see VENETIA SOLIS), not much different from the common Indian red, but fouler; and may be easily prepared, by mixing common red ochre with the coelothar or caput mortuum taken out of the aqua fortis pots, and washed over. As it is generally used by the house painters in imitation of mahogany, it requires no other preparation than to be well ground with the oil with which it is used; but when it is used in miniature painting, it should be carefully washed over.

Red, Blowen, in the Porcelain Manufacture, a name given to a peculiarly coloured china ware, of a spangled red, or to the colour alone that spangles it. It is an ornament easily introduced into use in our own manufactories of porcelain ware, and is done in the following manner. The colour is to be prepared of common copperas, calcined to a red colour in a charcoal fire, in a crucible, with another luted on the top of it inverted, and with a hole in its bottom. The signal of the calcination being finished, is, when the black clouds cease to come up through the hole, and a fine white thin vapour rises in their place. The vessels are to be then suffered to cool, and the red matter in them is to be reduced to a fine powder, while the vessels to be coloured with this
are yet wet. The operator is to provide a glass pipe, and covering one end of it with a piece of fine gaize, he is to dip this into the powder, and taking it carefully out, with what little is sticking to it, he is to blow again the veffel at some distance from it: thus the finest part of the powder only will reach the veffel, and will lie on in form

glittering triangles, very small, but all different. This is a fort of colouring much esteemed by the Chinese themselves, and they have a way of using the common blue in the same manner; but few of the veffels thus painted come over to us.

Red Clover, in Agriculture, an useful artificial grains for arable lands. It has this name in contradistinction to the white and some other forts. There were at first many and very great prejudices against and objections made to the introduction of this plant into cultivation by fanners, which were not surmounted without difficulty, and it prevailed for some length of time in particular districts, as Staffordshire and Worceftershire, before it was known in some other counties, where it is now very predominant and beneficial, as Cheshire, Lancashire, and many more.

In some arable counties red clover is found to fail as a crop when long cultivated, drying away in the winter and spring, which the farmers designate by saying that the land is sick of it. This is a severe inconvenience to them in many cafes; and renders such variations in the courses of cropping necessary, as may prevent the recurrence of it so frequently as has hitherto been the cafe. It is very liable to fail in every particular of the county of Eftex, but of the cafe of which there are different opinions, some thinking that the land becomes sick of the plant, while others do not attribute it to any fatuity of this nature, but alter their modes of cropping that it may not take place fo often. About the Belcamps and Bofley this is very much the cafe, some venturing it only once in seven years, and in that cafe it succeds well. In all the Tendring hundred it is found to decline little on the strong rich lands, but is felt on the lighter forts; on both the cropping is varied in regard to it. In the neighbourhood of Thorndon the lands are sick of it. And at Audley End the land is tired of it, but more in many cases from want of fufficient feed than any thing else. In the vicinity of Hal-lingbury it is very liable to fail, if fown oftener than once in seven or nine years, though the fytem thereabouts is crop and fallow.

In the county of Oxford some fow red clover twice in ten years, the land being new to it; of course it never fails. On the gravelly loamy soils about Henly it dies from repetition, fo that it is alternately omitted in cropping, others being substituted, as white clover, trefoil, and peas. Nothing of this fort was known forty years ago, but now they fow it only once in two rounds. The loams and bone-

brash lands around Wood Raton are not in general tired of this plant; fome however find it to fail on the latter fort of foil. About Great Tew, where the lands have been inclosed forty years, they are not yet tired of red clover. At Atterbury, where the lands have been inclosed more years, it does not now succeed quite so well as it did fifteen or twenty years ago. In these failures other crops are put in, as tares and early peas drilled.

Some fulfilp sheep's dung to be destructive to the red-
clover plant, but there are no proofs of the fact.

The mofl proper management of red clover as a prepara-
tion for wheat is a matter of great importance. Some think feeding it off wholly the belt practice; others mowing and feeding; and a few mowing altogether. The method of feeding off the crops altogether, when done in a close

even manner, is probably the most advantageous in this

intention, though there may be some immediate loss and

cconvenience; after which that of mowing the first crop

and feeding the second in a useful manner; the third mode,
or that of mowing twice, is moft to be feared, but upon some
forts of land it may be done and answer well for wheat.

These methods are all practifed and have their advocates in

different parts of Eftex; and some think that they get as

good wheat after white as red clover, as well as that feeding

the latter does no injury in this refpect.

The farmers in Oxfordshire follow nearly the same practices, and hold much the fame opinions in regard to the management of this crop as a preparation for wheat. And the custom of

moving and feeding off the first year, is thought the bet

practice in some other counties.

But in the county of Lancashire, and some others adjoining it, they know nothing of the land being ever fit or tired of this fort of crop, though they grow it in more frequent

fucceffion and in a more full manner than perhaps any where else in the kingdom. Ask the farmers about this, from one

end of the above county to the other, they are all of the

fame opinion, and appear much surprifed at the question, not

ever having any conception of fuch a circumstance. What

can be the reafon that red clover has been as long and as

frequently cultivated in fuch districts, as in thofe where it is

fo liable to fail? Does it depend upon the difference in the

nature or quality of the fols, or the management in regard

to the quantity of feed and other matters? The circumstance

is worthy of further and more clofe attention and in-

vigation, in confequence of its great importance to the

farmer.

There is one particular feature of management in the cul-
tivation of red clover in the county of Oxford, which is

that of hand-fowing over it from fourteen to fifteen bushels
of Newbury peat-alhes, that are brought into the Thames,
by the Reading canal, on the acre, about the end of Febru-
ary or the beginning of the following month; which has an
immediate effect upon it, seldom failing to produce a crop,
except where it naturally declines. The expence is estimated
at about ten shillings the acre. These alhes do not, how-

ever, seem to be employed in this way to the red clover crop in the
district where they are found and prepared.

Seeded red clover undergoes two or fucceffive threfhings, the

first, which only beats off the heads and chaffs containing
the feed from the stalks, is called cobbing in fome places; the

parts thus separated being denominated the red-clover cob.

The work is performed on a thick wooden plank frame for

the purpose, and requires much labour to separate the feed,
which, when done, is cleaned and passed through different
flexes, being ultimately divided into two forts, the primary and

secondary. The cult of these operations is very great,
amounting to from four to fix threflings the bushel, and some-
times much more. It has been concluded by Mr. Middleton,
that this plant grows a full crop in all the arable lands of this
country, from the lands of Norfolk to the clays of Cleve-
land and Suffolk. And that various fols that have been ex-
hibited by corn, and not much accustomed to red clover,
have been so much restored by it, as to produce a good crop
of wheat; but that to do this every means should be used to
secure a full crop, as that is an excellent preparation for

corn; and seldom fails of ensuring a considerable produce,
 arising from shade, froth, and putrefaction, the natural
and constant attendants of full-grown red clover. It is

supposed advifable, in fome cafes of poor land, to feed both

crops off on the land by sheep and other animals, in fome
way or other. And sometimes to mow the firft and feed

the fconde, or the contrary. In every point of view this is an

intercefling plant to the farmer. See Clover.
Red Gum, an infect disease on wheat, by which the ears of the grain are deprived of their nutrition, and thereby prevented from perfecting themselves. It is described by Mr. Middleton to be a collection of insects, which are visible to the unaided eye, and which, in the early part of their growth, are of a reddish colour, but become brown with age: the black spots on the straw, blades, and ears of the wheat, are supposed to be the excrement of the insects. The blighted ears are probably rendered fo, by the insects piercing the necks of the straw immediately below them, and sucking the farinaceous juice, otherwise defined for filling the corn. In those ears which have both perfect and imperfect grains, the insect has perhaps infected its probe at the connection between the corn and the straw, and by drinking up the food of the grains severally, has starved many of them in such a manner as to cause their destruction and decay. The exact nature of the disease is not, however, yet well ascertained.

Red Hay, a term used to signify such as is mow-burnt, in opposition to such as is green from a moderate heat, and winny hay, or such as is mouldy.

Red Land, a term used by husbandmen to express a sandy loam of a reddish hue, intermixed for the most part with pieces of sandstone of the same colour, or somewhat deeper.

It may be noticed that there are several varieties of this soil: one of which is almost entirely made up of sand; another with an admixture of loam with the sand, the whole making a loose loamy earth; and a third full of fragments of a poor sandy iron ore, and often containing thinning fpeculae of felenite. See Soil.

In some parts of the country, there is a rich red sandy loam, upon a red gritstone rock. In some places this land is of a more sandy quality than in others, and, in particular instances, a deep red loam, or red clay. The lands are mostly of an excellent quality, both for arable purposes and those of grains; but the sandy parts are poorer than those of the clayey kind, especially for the former use. The red soil tracts in this district are considered as the most suitable for the cultivation of the crops, being well suited to almost every kind of plant which can be entrusted to it, in the way of cultivation. Soils of this nature prevail more or less in a vast number of counties throughout the kingdom, even from the most southern ones to those far advanced towards the north.

Red Rown, a term signifying the red tinge in ripening barley, and sometimes other sorts of grain.

Red Rown, a provincial term, applied to the grains of barley, when in a ripening state, or fired, and with red. The crop is then said to be in the red row.

Red Antimony, in Mineralogy, an ore of that mineral, of a cherry-red colour, containing, according to Klaproth, 67.5 antimony, 10.8 oxygen, 19.7 sulphur.

It occurs most frequently in minute diverging capillary crystals. It melts and evaporates before the blowpipe, yielding a sulphureous odour. See Antimony.

Red Arsenic. See Arsenic.

Red Chalk. See Reddile, and Ores of Iron.

Red Cobalt, called cobalt crystal, and cobalt bloom or ochre, an ore of cobalt, of a peach blossom red colour. See Cobalt.

Red Copper, Ruby copper, an ore of copper, of a cochineal red colour, inclining to a lead-grey. It consists, according to Klaproth, of 91 parts copper and 9 of oxygen. See Copper.

Red Hamatite, Fer oligische concretionis of Haüy, an ore of iron, found in kidney-shaped and globular balls. The structure is fibrous, and divergingly radiated, but arranged in concentric curves; the colour is a blueish-grey, intermixed with red. By friction, it acquires a high metallic lustre. It yields from 60 to 70 per cent. of pure iron. (See Iron.) An excellent ore of this kind is procured near Ulverstone, in the north of Lancashire, much valued, as producing an iron of a peculiarly ductile quality, suitable for the purposes of the wire-drawers.

Red Lead. See Minium and Lead.

Red Scalp Iron Ore, Fer chilipeur infanti of Haüy. It consists of fey particles slightly cohering; it has an unctuous feel, and stains the fingers. It passes into micaceous iron ore.

Red School. See Ores of Titanium.

Red, or Ruby Silver Ore, Argent antimonii sulphur of Haüy. Werner divides this into two sub-species, dark red silver ore, and light red silver ore, distinguished from each other by their colour, and the situations in which they occur. The dark red ore is commonly accompanied by galena, antimonial sulphur of silver, quartz, calcareous spar, and pyrites. The colour is between cochineal red and lead-grey. It occurs massive, disseminated, and crystallized in equiangular six-fined prisms, frequently variously truncated. The form of the primitive crystal is an obtuse rhomboid, with flat planes of the faces 109° 28' and 75° 32'; the inclination of the faces 109° 28' and 70° 32'. The external lustre is sub-metallic, and in some specimens metallic; internally it is shining, and sometimes semi-metallic and metallic. The fracture is uneven, and in the crystallized varieties imperfectly small conchoidal. See Ores of Silver.

The massive varieties are opaque; the crystallized, semipellucid and pellucid. The colour of the free air is a cochineal red. This variety yields easily to the knife: before the blowpipe or charcoal it decrepitates, and melts with a slight effervescence, emitting a dense fume, which colours the charcoal yellow, and leaves a globule of silver. The specific gravity is 5.50 to 5.608.

The light red silver ore is usually accompanied by native arsenic, white cobalt ore, orpiment, and sulphate of barytes. The colour palles from a carmine red to a medium between cochineal red and lead-grey. In most of its characters it agrees nearly with the dark red silver ore; but when fused, it yields an arsenical vapour. Hence some chemists have conjectured that this ore differs from the dark red ore, by the former containing antimony, and the latter arsenic. According to Klaproth, red silver ore contains nearly

\[
\begin{align*}
60 \quad & \text{of silver}, \\
16.5 \quad & \text{of antimonial kines}, \\
5.2 \quad & \text{oxygen}, \\
5.9 \quad & \text{sulphur}.
\end{align*}
\]

A variety of red silver ore, probably the light red ore of Werner, analysed by Proust, gave

\[
\begin{align*}
74 \quad & \text{sulphuret of silver}, \\
25 \quad & \text{sulphuret of arsenic}, \\
6 \quad & \text{oxyd of iron}.
\end{align*}
\]

Red silver ore may be distinguished from cinnabar and red copper ore, by its specific gravity, which is considerably less than the former, and greater than the latter; the specific gravity of red silver ore being 5.6 to 5.8.

red cinnabar 7  to 7.5.
red copper 2.9.

Red Vitriol, a salt found at Neufohl, in Hungary, in the form
form of transparent crystals of a pale rose-red colour, and more or less transparent. It was discovered by Klaproth to be a fulphate of cobalt. Its solution affords a pale blue precipitate, with carbonate of potash, which tinges borax a pure blue colour.

Red Charr, in Ichthyology. See Charr.

Red Eye, Erithrophthalmus, the cyprinus erythrophthalmus of Linnaeus, called by some rothsaniis, or roasting, which, in the German language, signifies the same. It very much resembles the common river bream in shape, but that it is somewhat thicker. The fins are all red, and the whole body of the fish is stained with a very elegant red, but no part of it so much as the iris of the eyes. When the scales are off, the body is of a greenish hue; and it has a yellow spot under the tongue. It very much resembles the river mullet in some particulars, but it is of a more beautiful colour, and its eyes are more red. Its largest size feoms a foot in length. It is a well-tasted fish; and spawns in April, under cover of the roots of trees. Ray.

This fish is called rudd by some English authors; it is also called rotillus later, rubello flavissiliis, and fiscello. It is very common in many of the rivers of Germany and England, and is in season all the year, except in spawning time, when the male is subject to a great number of white spots on its head, and is more rough than at any other season. Willughby. See Cypinus Erithrophthalmus.

Red-Breast, in Ornithology, a well-known bird, for the characters of which, see Motacilla Rubacula.

The song of this bird is remarkably fine and soft, and continues through the greater part of the winter, spring, and summer. Many of the autumnal songsters seem to be the young cock red-breasted of that year. Pennant.

Thompson, in his Seaons, Winter, line 246, has admirably described the annual visits of this gueft: and the ancient ballad of 2The Babes in the Wood, recording the affection of this bird for mankind, is universally known.

Red Chatterer of Latham, Red-bird from Surnam of Edwards, and Aquila carniceps of Gmelin, a bird of red colours, with an ocular band, and the wing and tail-feathers black at their tips. It is found in New Spain, Guiana, and Surnam.

Red Game, an English name of a bird, common in the mountainous parts of Yorkshire, and some other of our northern counties. See Gob-cock, Grouse, and Tetrao Lagopus.

Red-Pole, or Linnets. See Fringilla and Linnet.

Red-Pole, Yellow, or Red-headed Warbler. See Motacilla Petechia.

Red-Back, the name of a water bird, called by authors gallinula erythrops, and calidris; the leucopus calidris of Linnaeus. It is about the size of the common plover. The back is of a greyish or brownish-green, usually spotted with black; its neck grey, and its throat variegated with black and white; the breast white, with a few loose streaks of black; the wing-feathers are variegated with black, brown, and white; the bill is two fingers breadth long, slender, and shaped like the beak of the woodcock; reddish at the base, and blackish lower down; its legs are of a fine beautiful red, and the hinder toe is very short and small. It breeds in the fens and marshes; is found on most of our shores; conceals itself in winter in the gutters, and is generally found single, or at most in pairs. When disturbed it flies round its nest, making a noise like a piping. It lays four eggs, of a whitish colour tinged with olive, and marked with irregular spots of black, chiefly on the thicker end. Ray and Pennant. See Scolopax.

Red-Start, the English name of the rubicilla, or motacilla phenicurus of Linnaeus, a very beautiful bird. The bill and legs of the male are black; the forehead white; the crown of the head, hind part of the neck, and the back, are of a deep blue-grey; the cheeks and throat black; the breast, rump, and fides are red; the two middle feathers of the tail brown, the others red; the wings brown. In the female, the top of the head and back are of a deep ash colour; the rump and tail of a duller red than those of the male; the chin white; the lower side of the neck cinereous; and the breast of a paler red.

This bird appears among us only in the spring and summer, and is observed to come over nearly at the same time with the Nightingale. It is so shy, that it will forsake its nest, formed with moss on the outside, and hair and feathers within, in hollow trees and the holes of buildings, if the eggs are only touched. It has a very soft note; and is remarkable for shaking its tail, and moving it horizontally, as a dog does when sawing. Pennant.

Red-Start, Greater. See Lanius Insanus. See also Turdus Saxatilis.

Red-Start, Indian or Bengal. See Lanius Emuria.

Red-Start, Small American. See Muscicapa Rubicula.

Red-Start, Grey. See Motacilla Gibraltanica and Erithacus.

Red-Stone Pipp. See Linnet.

Red-Tail. See Motacilla Erithacus and Guiaica.

Red-Wing, the name of a bird of the turdus, or thrush kind, called also in some places the wind thrush, or jawine pipe; and by Linnaeus and others the turdus ilicaris, or thas.

It is a little smaller than the common thrush, and is less spotted. Its back, neck, and head, are of the same colour with those of the common thrush; but its fides under the wings, and the feathers which line the wings, are of an orange colour, or duky red; its belly and breast are whitish, and its throat yellowish, with brown spots: the wings are of a sort of chestnut colour, a little variegated. It feeds on insects, as worms, and the like; and is a bird of passage, coming to us in large flocks about the same time with the fieldfare, and leaving us also when that bird does. When the red-wing appears on the coast in autumn, it is certain the woodcocks are near. It is not well known where they breed, though some have guessed it to be in the mountains of Germany and Bohemia. They have a bitterish taste, and are less valued than the fieldfare. With us they have a digestible piping note; but in Sweden, during the spring, they sing very finely, perching on the top of some tree among the forest of maples. They nest in hedges, and lay six blueish-green eggs spotted with black. Ray and Pennant.

Red Water, a disease in sheep. It has been suppos'd by farmers to be caused by taking too much watery food, such as turnips, clover, rape, eddih, &c., but it is not peculiar to sheep feeding on turnips or rape, as has been believed by some. Its removal has been attempted by the use of common salt, a tea-spoonful of mercurius muriaticus, and the frequent driving the animal about; and it is asserted, that the disease may be wholly prevented by having recourse to the use of dry food, in the night time, while the sheep are feeding upon these juicy kinds of food. See Sheep.

In Sussex the sheep are sometimes affected with this complaint on their being first turned into turnips, which is suppos'd to be caused by their eating too large a portion of them in wet seasons. The disease is also believed to originate in the sheep being let out of the fold, when the ground
is covered with hoar frost; and often from feeding in the
oat-cerfs about the beginning of the autumn, when the
young oats are strong. It is thought here to be readily
obviated by allowing a small quantity of hay to as to coun-
teract the great water-nets of the turnip; the quantity of
half a pound or even less in the course of the day is be-
lieved to be quite enough for each heaf in this intention.
It is likewise suspected, that clover, rubble, and folded
land, are productive of it in wet weather or moist feafons.

RED Weed, in Botany, a name given to a plant common
in the Bermudas, and some other places; and called by our
frit travellers to that part of the world, the Summer Island
red weed. Its berry is of a fine red colour, and affords a
tincture little inferior to that of cochineal, and poffeffing
all its virtues in medicine: the only misfortune of this,
and other very fine vegetable colours, is, that they
fade soon. The juice of the fruit of the opuntia, or
prickly pear, is as fine a dye as can be procured from the
cochineal, but it will not fand; the infect feeding on this,
however, we find affords a colour of the fame nature that
will fand. The fruit of the red weed is in the fame man-
ner liable to be eaten by infects as that of the prickly pear;
and it is worthy a trial, whether the colour obtained at
fend hand from thofe infects, will not fand as well as the
cochineal does, and whether the infects may not be pro-
pagated in a fufficient abundance to serve the markets in
the fame manner. Phil. Tran. N° 40.

RED Weed is also a provincial term, signifying the
round smooth-headed poppy, a pernicious weed in corn-
fields. See Weeds.

RED Worm, in Natural History, the name of an infect
very destructive to young corn crops. The following de-
cription of this worm has been given by Mr. W. Baker:
after observing, that he has often heard of the havoc
which red worms make in young wheat, barley, and oats;
and in fome few writers upon husbandry has read of them,
but never faw them till May 1764; when, to his great mor-
tification, in a few days they defroyed almost totally nine
acres of his wheat, for he did not reap above half a barrel
per acre; and that the ingenious M. de Chateauveaux fpeaks
of an infect, which is certainly of the fame kind, if it be
dot the very infect which he has now under confeideration;
and in noticing the lofs fuffered in wheat crops, fays, they
found in it many little white worms, which afterwards be-
came of a chefnut colour. They poft themselves between
the blades, and eat the ftems. They are ufually found be-
tween the firft joint and the roots; every fmall which they
attacked grew no more, but became yellow and withered.
And the fame misfortune happened to them in the year
1753. The infects appeared about the middle of May,
and made such havoc, that the crops were almoft defroyed;
Stillingfleif, afo, in the second edition of his Mifce-
laneous Tracts, fpeaks of an infect, which is probably the
fame as in Suffolk and in fome parts of Norfolk, where
the farmers find it their interest to encourage the breed of
rooks, as the only means to free their grounds from the
grub, from which the tree or blind-beetle comes, and which
in its grub flate defroys the roots of corn and grafs to fuch
degree, that he has been a piece of pature land where you
might turn up the turf with your feet: he adds, that Mr.
Matthews, a very obferving and excellent farmer of War-
grove, in Berkshire, told him, that the rooks one year,
whilst his men were hoeing a turnip field, sat down in a
part of it, where they were not at work, and that the crop
was very fine in that part, whereas in the other part there
were no turnips that year; though M. de Chateauveaux
defcribes this worm as being firft white, and afterwards be-
coming of a chefnut colour, he has carefully fought them
diffident periods during the past year, but always found
them of the fame chefnut colour, never varying in any par-
ticular except that of fize, which he finds to be the cafe at all
feafons in which he has feen them; and he obferves, that the
infect fpoken of by Stillingfleif as a grub, which, he fays,
defroys corn and grafs, induces him to believe that it is the
fame infect (though the report which he relates from Mr.
Matthews feems to contradict it), becaufe he has obferved
that the red or chefnut worm never appears voluntarily
upon the surface; but when the earth is turned up,
either with plough or fpade, the rooks or crows are very
bold in their approaeh to pick them up, a circumstance
which, he owns, has in fome degree abated its enmity to
thefe birds; he therefore never defroyes or frightens them
off his land till he is ploughing it; but when he fows,
when the corn rifes, and when it is ripe; he defroys or
banishes them as well as he can, becaufe the muffich which
they do at thofe times is intolerable; he has alfo obferved
his lacon to decay in its tops' soon after it has been up;
and upon examining the roots he has found the red worm
which had eat them off; and that, in this, this infect feems to
be everywhere in Ireland called the red worm, but by fome
of the English writers, who have fpoken of an infect which
defroys the corn in the manner already mentioned, which
he thinks undoubtedly the fame, it is called a grub or, by
others the large maggot, and the rook worm, becaufe the rooks eat it.

These worms are about half an inch long, and about
one-tenth of an inch in diameter; they are jointed in their
fkins, and are of a very firm texture; they have many
fhort legs, two small black fpcks, which appear to be
their eyes; and two small points springing from their heads,
with which, he believes, they eat the corn, and which in
that work, he apprehends, act like forces: and all that
he has fen of this fpicies are of a bright chefnut colour.
For this reafon, he fhould conceive it would be more de-
criptive to call them the chefnut-worms. When they are
exposed to the air, by turning up earth which is infected
with them, they will very soon cover themselves again in
the foil, which they are very capable of doing by the
strength which their make gives them, although they ap-
ppear to be a flagellum infect, and have not the advantage
of a dry furface upon their fkins, which the common large creeping
worm has, which enables that injdniouf worm to pen-
trate the earth, and get under timber and ftones with eafe.
The red worm, immediately endeavouring to cover itself from
the air, is certainly, he thinks, from natural infalit, as it will
foon die when exposed to the air, as will appear by the ex-
periment, N° 15, mentioned below.

It is further fiated, that thefe worms defroy wheat, bar-
ley, oats, and lucern, while in an infant fiate, in the months
of March, April, and May. Late fown barley and oats
they will defroy as late as June. He has not yet expe-
rienced that they defroy any other crops. The muffich
done by them is in dry weather. Rain fufficient to pen-
etrate the ground makes them defert from defroying the
corn; and he fuppofes every thing elfe which they at any
time injure. They eat wheat off, pur above the crown of
the roots; barley and oats in the fame place, and also
higher up, upon the part of the flem which is below the
surface of the earth. And thefe worms feem to abound
more in ground which is lightly tilled, than in fuch as
hath been well tilled; but in lay ground they feem to be
more numerous than any where elfe, and the fields upon
his farm in which he has fomen them, are better than
other fields where they are not; whether that circumfance
contributes to their increafe, he cannot fay; but the fol-
following
lowing experiments prove that they will live longer in water than they can when exposed to the open air.

**Experiments.**

N° 1. He put ten red worms into a wine glass with common salt in it. They were all dead in four hours.

N° 2. Into a glass with brine in it he put ten red worms. They were all dead in six hours.

N° 3. Into a glass with lime in it, which had been flaked for a long time, and exposed to the weather, he put the like number. They were all dead in forty-four hours.

N° 4. Into a glass with the above lime, and some water in it, he put the like number. They were dead in twenty hours.

N° 5. Into a glass with lime newly flaked, and when cold, he put the like number. They were dead in fourteen hours.

N° 6. Into lime water, made with cold water, he put the like number. They were dead in ten hours.

N° 7. Into a glass with foot in it, he put the like number. They were dead in four hours.

N° 8. Into foot and water he put the like number. They were dead in four hours.

N° 9. Into pure water he put the like number. They were dead in fifty-two hours.

N° 10. Into a glass, without any thing in it, he put the like number. They were dead in thirty-two hours.

It is slated that by these experiments it is seen that all the articles used will kill this worm in a short time, particularly the salt and foot. He thought it necessary to consider different articles, the better to suit different parts of the kingdom.

Where lime can be conveniently had, and that it is used as manure, he is apt to believe, from the experiments, that no injury can be sustained from these worms; but he is afraid a small quantity will not effectually destroy them; besides, he should fear, if it were not put on before the flooding of the corn, that it might stingle the blades of the corn; for, from these experiments, it appears that lime newly flaked is more suddenly destructive to them than old lime, and therefore it is to be preferred.

Where lime is used for no other purpose than to destroy this worm, he should conceive, that about eight barrels, regularly fown by hand on an acre of ground, might be sufficient; it must be first flaked and cold before a man can possibly call it upon the ground with his hand, lime being a very strong caustic; and even when it is cold the man should have a thick glove upon his hand.

Where salt may be used to destroy this worm, it must always be fown upon the ground before the intended crop; for although corn will vegetate, and receive benefit from salt as manure, when it is used antecedent to the sowing of the corn, yet if it be added after the corn is growing it will certainly destroy it: therefore it should never be used for this purpose, but before the corn is sown, or at least before it vegetates.

He conceives that where salt is used for this purpose only, about four hundred and a half to an acre will answer the purpose, which is a little more than one ounce to every square yard.

It is seen by the experiments, that foot kills this worm as soon as salt; and as in most places it is to be had at a much less price than salt, he thinks there can be no doubt about preferring it; besides which, it may be safely used after the corn is up.

He had some small parcels of barley under experiments, which these worms began to destroy; and in order to con-

"vey the foot as soon as possible to the roots of the plants, he mixed a little of it in water, and poured it on the plants with a garden watering-pot: the consequence was that he did not lose one plant afterwards.

It will hardly be imagined that he means that the same method is to be pursued upon a whole farm: no; the method he would recommend to the practice of the farmer is this: to spread, or call by hand, as he fows his corn, about six or eight barrels of foot on an acre, and let him be careful to choose a calm day for the work, otherwise the wind will carry away a great part of it; and as what remains cannot be regularly dispersed, let him be careful to do it early enough in the spring, that the rain may wash in the foot and convey it to the roots of the plants before the worm begins the mischief; if he does this, he is persuaded his crop will be preferred.

It is found by the experiments, that these worms will live longer in water, by twenty hours, than when exposed to the open air; but that, length, is that in fifty-two hours, they died in the water; perhaps this might be from the effect of drowning; but if so, he might have expected they would have been totally destroyed in his two fields in the winter of 1763 and 1764, by the immoderate rains which fell at that season for a long continuance, which often flooded the lands. But they survived that winter, as appeared by the great loss he afterwards sustained by their destroying his wheat; and therefore, whether water be an enemy to them or not, it seems not easy to determine: but if those which died in the glass of water were really drowned, he thinks he may conclude that water is necessary to their existence in the earth, and probably aids them in getting their food from it; and what seems to confirm this notion is, that when the land is wet, they do not touch the corn, but as soon as the land is dry, they begin their mischief. However, this speculation he must submit to the consideration of persons more capable of dis-
remedies, which must have arisen, he thinks, from their either having used too small a quantity, or not having observed the necessary precautions; if those which he has recommended shall be put in practice and found to answer, he shall think himself amply rewarded.

This worm undoubtedly does great injury to grain crops in many cases, in particular soils and sorts of land; but a great number of additional facts and experiments are wanting to fully prove its nature, and the ways in which its destructive effects on such crops are produced, as well as the best, most ready, convenient, and effectual ways in which it can be destroyed. See Wire-Worm.

Red Deer, fifth, eighth, florins, tartar. See the subjunctives.

Red Ink. See Ink and Printing.

Red Notes, in old Miseric, before the invention of printing, were used for diminution. In the MS. at Paris of the Latin and French poems of Guillaume Machaut set to music, chiefly motets for a single voice, some are written in black and red notes, with this indication to the singers; "In fine suntperfecte, et rubrae imperfectae," an admonition worth remembering by those who wish to decipher music of the fourteenth and fifteenth centuries, in which red notes frequently occur. It was an easy expedient of diminution till the invention of the press, when the use of different coloured inks on the same page occasioned the trouble and expense of double printing. See Machaut.

In the Pexyian collection at Cambridge, there are examples of the use of red notes for diminution in fragments of music by Joseph Gwinneth and Robert Davie, who flourished in the time of Edward IV. Morley has given some examples of the use of red notes in his annotations.

Red Bank, in Geography, a port of the United States, on the S.E. side of Delaware river, in the town of Woodbury, Gloucester county, New Jersey; seven miles S. of Philadelphia.

Red Bay, a bay on the N. coast of Spitzbergen. N. lat. 79° 44'. E. long. 10° 42'.—Alfo, a bay on the S.E. coast of Labrador. N. lat. 51° 50'. W. long. 56° 10'.—Alfo, a bay on the N. part of Buffalo's bay, on the S. coast of Maffachusetts, in America.

Red Crab Island, a small island in the East Indian sea, near the coast of Arracan. N. lat. 21° 30'. E. long. 91° 50'.

Red Deer Lake, a lake of North America. N. lat. 55° 10'. W. long. 112'.

Red Flaggy Bay, a bay on the N. coast of the island of St. Christopher, E. of Ragged Point.

Red Haven, a bay of Scotland, on the N. coast of the county of Banff; three miles E. of Cullen. N. lat. 57° 39'. W. long. 2° 28'.

Red Head, a cape of Scotland, on the E. coast of the county of Angus; six miles S. of Montrose. N. lat. 56° 53'. W. long. 2° 26'.—Alfo, the N. point of the island of Eda. N. lat. 59° 6'. W. long. 2° 40'.

Red Hills, rocks in the German sea, near the coast of Northumberland. N. lat. 55° 26'. W. long. 1° 57'.

Red Hoak, a town of America, in the township of Rhode- beck, and Dutchess county, New York, on the E. bank of Hudson's river; 21 miles S. of Hudson.

Red Hoofs, Vale of, a district of England, in the county of Warwick, which owes its name to a hoarse cut in a hill, the soil of which is reddish.

Red Island, an island near the E. coast of Labrador. N. lat. 43° 55'. W. long. 55° 50'.—Alfo, an island near the W. coast of Newfoundland. N. lat. 48° 35'. W. long. 59° 10'.

Red Lake, a comparatively small lake of North America, at the head of a branch of the Bourbon river, sometimes called "Red river;" its form is nearly round, and its extent is about 60 miles in circumference. It has on one side an island, close by which a river enters. It lies almost N.E. from the mouth of Willimantic, and from the lake of the Woods. N. lat. 51° 3'. W. long. 94° 10'.—Alfo, a lake of North America, in N. lat. 47° 40'. W. long. 92° 15'.

Red Lick, a salt spring of the state of Kentucky; 32 miles E. of Stamford.

Red Point, a cape on the E. coast of New Holland. N. lat. 34° 29'. W. long. 208° 45'.

Red River, a river of Louisiana, which rises in about N. lat. 35°, and W. long. 96°, and runs into the Mississippi, N. lat. 37° 15'. W. long. 91° 48'.—Alfo, a river of Upper Canada, which runs into lake Superior. N. lat. 45° 51'. W. long. 85° 48'.—Alfo, a river of Tennessee, which runs into Cumberland river, about two miles N.W. of Clarksviue. N. lat. 36° 18'. W. long. 87° 46'.—Alfo, a river of Kentucky, which runs into Kentucky river, about nine miles above Booneborough, N. lat. 37° 45'. W. long. 84° 18'. It is 60 yards wide at the mouth.—Alfo, a river of North America, which rises from Red lake, in N. lat. 47° 40', and runs into Winnipeg lake.—Alfo, a river of Canada, which runs into the Utwas; 60 miles W. of Montreal. See also Natchitoches.

Red Sea, called by the ancients the "Arabian gulph," forms the grand natural division between Asia and Africa, and extends about 21° or 1470 British miles from the straits of Babelmandeb to Suez; it terminates in two branches, the western being extensive, and the eastern affording a little beyond the parallel of mount Sinai.

This sea is called, in the Old Testament, the sea of Saph or Zuph, the sea of weeds, on account of the great quantity of alge and fuci, and perhaps the naupluses and coraline substances, anciently supposed to be of vegetable origin, found at its bottom, and near the shores. In scripture language it is also denominated "the tongue of the Egyptian sea;" in the Greek and Latin geography, it was called the gulph of Heropelis; and by the Arabian geographers, the western arm of the sea of Kolzum, (al Kol- zum, with the article,) which seems to have some affinity with "Clyfma," another name by which this gulph was formerly known; Kolzum in Arabic, and Clyfma in Greek, signifying destruction, in deference, as it is supposed, to the destruction of Plautus's boat. Don John de Cilfro, viceroy of the Indies for the king of Portugal, conjectures that it was called the Red sea from the great quantity of coral that is found in it. Pliny says that it obtained this name, in Greek "Erythrea," from a king called Erythros, who reigned in Arabia, and whose tomb was seen in the island Tyrine or Agrys. Several learned men believe, that this king Erythros is no other than Elyon, or Edom; Edom, in Hebrew, signifying red or ruddy, as Erythros does in Greek. But Calmet is of opinion, that Edom never dwelt, either on the shore of the Red sea, or on the Pharan gulph, which has been sometimes also called the Red sea. His habitation was east of the land of Canaan, towards Bozra; and he inclines to believe, that the name of the Red sea was not given to this gulph till after the Idumeans, descendened from Edom, had spread themselves from east to west as far as the Red sea. At that time it might receive the name of the sea of Edom, which the Greeks rendered by the Red sea, or "thalassa erythrea."

The famous miracle of the passage of the Red sea by 600,000 Israclites, besides old men, women, and children, recorded in the sacred writings, is well known. Those who have been defirous of explaining this passage, without
out admitting the miraculous part of the history, have had recourse to a variety of conjectures; both as to the place and the manner in which this passage was effected. As to the place of the passage, there has been a difference of opinion even among those who have not hesitated to acknowledge that it was miraculous. Till of late years it has been generally believed, that the passage of the Israelites was at Baideah, or Bedea, which, according to Niebuhr, is about six German miles from Suez, and where the sea, says Bruce, is something less than four leagues broad, by 50 feet deep. In support of this hypothesis, Dr. Shaw has traced the march of the Israelites to their third encampment before Pihahri-roth. Whilst they were removing from the edge of the wilderness of Etham towards this station, they had left the open country and were marching through a narrow pass, betwixt the mountains of Gewobee and Attackah. In these circumstances the Egyptians might well imagine, that they could have no possible way of escape, as the mountains of Gewobee would obstruct their progress towards the south, and those of Attackah would impede their advancing towards the land of the Philistines; the Red sea lay before them to the east; whilst Pharaoh closed up the valley behind them, with his chariots and horsemens. This valley terminates at the sea, in a small bay, made by the eastern extremities of the mountains above-mentioned; and is called "Tiah Beni Israel," i.e. the road of the Israelites, from a tradition still existing among the Arabs of their having passed through it; and it is also called "Baideah," from the new and unhallowed miracle that was wrought near it, by dividing the Red sea, and destroying it, Pharaoh, his chariots and his horsemens. The encampment of the Israelites, according to Dr. Shaw, was at this bay, before Pihahri-roth, betwixt Migdol and the sea, over against Baal-tzephon, Exod. xiv. 2. Baal-tzephon, as this learned geographer suggests, might have relation to the natural situation of the place itself, or to some watch-tower, or idol-temple that was erected upon it; or it may be taken for the extremity of the mountains of Suez, or Attackah, the most conspicuous of these defects, as it overlooks a great part of the Lower Thebais, as well as the wilderness that reaches towards, or rather which makes part of, the land of the Philistines. Migdol might lie to the south, as Baal-tzephon did to the north of Pihahri-roth. The marches of the Israelites, from the edge of the wildernesses, being towards the sea, i.e. towards the E., their encampment betwixt Migdol and the sea, or before Migdol, could not well have any other situation. Pihahri-roth, or the mouth of Hihroth, or a narrow gulph or defile, may denote the mouth, or the most advanced part of this valley towards the E., or towards the Red sea. But as the Israelites were delivered at this place from their captivity and fear of the Egyptians (Exod. xiv. 13) we may suppose that Hihroth denotes the place where they gained their liberty, harar and hiahrot being words of the like import in the Chaldee. It may be further urged in favour of this explanation, and also of the tradition still preferred, of the Israelites having passed through this valley, that the eastern extremity of the mountain, supposed to be Baal-tzephon, is called, even to this day, by the inhabitants of these defects, "Jibbel Attakah," or the mountain of deliverance; which appellation, together with those of Baideah and Tiah Beni Israel, could never have been given or imposed upon these inhabitants at first, or preferred by them afterwards, without some faithful tradition, that such places had been once the actual scene of these remarkable transactions. The sea likewise of Kolzum, i.e. destruction, as the correspondent part of the Red sea is called in the Arabian geography, is a further confirmation of this tradition. Moreover, the Ithlyophagi, who lived in this very neighbourhood, are reported by Diodorus Siculus (i. iii.) to have preferred the like traditionary account from their forefathers, of this miraculous division of the Red sea. There are likewise other circumstances that tend to prove, that the Israelites took their departure from this valley, in their passage through the Red sea; for an account of which we refer to Shaw's Travels, ch. v.

This hypothesis, however, says Geddes, (Crit. Remarks on Exod. xiv.) has been fairly given up by our best modern critics; and the "Sinus Hecropolitans," or gulph of Suez, pitched upon as the scene of action. The idea was first suggested by Le Clerc, and since adopted and defended by Michaelis, Niebuhr, and almost all the German commentators. But Mr. Bryant still contends for Bedea (Baideah), and calls the arguments of Niebuhr "prejudice and misconception." Dr. Geddes, whose sentiments concerning Moses and his whole history are singular, denies that there was any thing miraculous in the event; and strenuously maintains, that Suez or its vicinity was the place of passage; for here, he says, at this day, are shallows fordable at low water, and which might, in former times, have been frequently dry. We all know what changes happen in the bed of seas as well as that of rivers, especially where that bed is silt, which is the case with that of the gulph of Suez. The occurrence is thus described by Dr. Geddes. When Moses saw that the Egyptians had found out that the Israelites meant not to return, and were about to pursue him with a force which he could not resist, he wisely took the only course that was most likely to afford him an escape. Acquainted, as he must have been, during his long stay in Midian, with the nature of the Red sea, and its ebbs and flows, he deemed it better to take his chance of passing over some shallow which he knew to be fordable at low water, than to expose himself to be overtaken in a defile, where no stratagem could save him. If he got the start of the Egyptians but for a single day, he would have time to watch the tide, and begin his march as soon as the passage was fordable; and in the space of a few hours might be safe on the other side. The width of the sea at Suez is at present, according to Niebuhr's measurement, 757 double paces, or 3450 feet. It is common for the Arabs to pass on foot over this passage, although not always without danger, as the sea sometimes flows back unexpectedly. At Suez, according to Niebuhr, it is low water, at the full of the moon, at half past six; but the passage of the Israelites must have happened some days after the full of the moon, the ebb and flow must have been considerably later, and the former must have occurred in the night-time, during which the Israelites are said to have passed. Michaelis was of opinion, that, as a strong wind is said to have accompanied this event, it might have caused a double ebb, as it sometimes does on the coast of Holland and North Germany; but Niebuhr thinks that no such thing is likely to happen in the Red sea. Be this as it will, the wind might certainly have prolonged the ebb; and, if it happened at the time of the passage, might well be considered as a providential interference, and readily confirmed into a miracle. Josephus, in recording this transaction, puts a formal speech into the mouth of Moses to his terrified and discontented people, and a prayer to God before he strikes the sea with his rod; yet he tells us that all this he has related as he found it in the sacred books. But he seems not sure, whether to consider it as a miracle or a natural effect. "Let no one," says he, "wonder at this account of a way of safety being opened to thoes old-world innocent folks, even through the sea, whether by the will of God or naturally; since, of later days, the Pamphylian sea opened a way
way for Alexander's army, when God through him had decreed to overturn the Perian empire." (Antiq. l. ii. c. 16. n. 5.) For this he appeals to all Alexander's historians; and, indeed, both Appian and Arrian, who relate the event, seem to have considered it as a sort of divine intervention; but honest Strabo tells us, that Alexander only took the advantage of low water; and, trusting to his good fortune, paddled through the freight with his army; but not on dry land; for the water came up to the nave. (Strab. l. xiv.) The same was the case with Scipio's soldiers, who surprized New Carthage by taking the advantage of an ebb; although they waded sometimes up to the knee, at other times up to the nave, in water. (Liv. l. xxvi.) Here, says Geddes, the same two natural caues, the tide and a strong wind, concurred to make a passagge through the water, as concurred at the passagge of the Red sea; and in both cases they were converted into a miracle. Josephus concludes his narrative with these words. "Of such things, let every one think as he pleases;" and the author now cited adopts his language. It has been said, and thus the priests of Memphis explained the history (see Euseb. Prep. l. iv. c. 17.), that Moses taking advantage of the time of the ebb, led the Hebrews over in safety; but the Egyptians, not knowing the nature of the sea, and eaily entering it just before the return of the tide, were all swallowed up and drowned.

In opposition to all conjectures for explaining this history, without having recourse to miracle, we shall content ourselves with appealing to the history itself, Exod. xiv. 16, 17, &c. from which it appears that the Hebrews traversed the sea from thence to thence on a large space of dry ground, which was left by the retiring water; and that they were driven back to overwhelm the pursuing host of Pharaoh. See also Izaiah, lxxii. 11, &c. Habbakuk, iii. 15. Wisdom of Sol. xiv. 7. x. 17. 18.

It is thought, says Calmet, after Eusebius, that the place where the Hebrews passed the Red sea, is two or three leagues below its northern point, at the place called Kolfum, or Cylema. Niebuhr informs us that, every where on the coast of Arabia, we meet with indications, that the waters are withdrawn; e. g. Mufa, which ancient authors mention as a port of Arabia, is now at many leagues distance from the sea; near Loheia, and Gidda, we see great hills filled with the same kind of shells and corals, as are now found living in the sea; near Suez, are petrifications of all these things. From these and similar circumstances he infers, that some thousand years ago this Arabian gulf was much larger, and extended much farther north, especially that arm of it near Suez, for the shore of this extremity of the gulf is very low. The breadth of the arm of the sea at Suez, he adds, is about 5450 or 5500 feet (in its present state). Although it would much shorten the distance of their way, no caravan now crosses this arm, nor could the Israelites have crossed it, without a miracle. The attempt must have been much more difficult to the Israelites, some thousand years ago, the gulf being then probably larger, deeper, and longer toward the north, at the lowest time of the tide. Niebuhr crossed, when returning from mount Sinai, that arm of the sea, over to Kolfoum, upon his camel; and the Arabs, who accompanied him, were only immered to their thighs in water. The banks of the Red sea are pure sand from Suez to Girondol; but lower to the south are banks of coral. If the Israelites had crossed the sea upon such banks, they must have been greatly incommoded by them.

The Red sea, notwithstanding the difficulty and danger, and also the tediousness of its navigation, was, for many ages before the discovery of the passage by the Cape of Good Hope, the channel of communication between Egypt and other countries, bordering on the Mediterranean, and India. Accordingly, Dr. Robertson observes, in his "Historical Disquisition concerning Ancient India," that navigation made its first efforts in the Mediterranean and the Arabian gulf, and that in them the first active operations of commerce were carried on. Nor are the accounts of the earliest historians in this respect at all improbable, if we consider the position and form of the two great inland seas. They lay open the continents of Europe, Asia, and Africa, and spreading to a great extent along the coasts of the moist fertile and most early civilized countries in each, seem to have been defined by nature to facilitate their communication with one another. We find, accordingly, that the first voyages of the Egyptians and Phenicians, the most ancient navigators mentioned in history, were made in the Mediterranean, and, moreover, by acquiring early possession of ports on the Arabian gulf, they extended the sphere of their commerce, and are represented as the first people of the west who opened a communication by sea with India. Solstitials, in the course of his reign (if we may give credit to some historians), was able to fit out a fleet of 400 ships in the Arabian gulf, which conquered all the countries stretching along the Erythrean sea to India. The Phenicians, who, by their situation on the Mediterranean, and the imperfect state of navigation, could not attempt to open a direct communication with India by sea, were prompted by the enterprising spirit of commerce to wrest from the Idumeans some commodious harbours towards the bottom of the Arabian gulf. From these they held a regular intercourse with India on the one hand, and with the eastern and southern coasts of Africa on the other. The distance, however, from the Arabian gulf to Tyre was so considerable, that it became necessary for them to take possession of Rhinocolura, the nearest port in the Mediterranean to the Arabian gulf. Thither all the commodities brought from India were conveyed over land by a route much shorter, and more practicable, than that by which the productions of the East were carried at a subseuent period from the opposite shore of the Arabian gulf to the Nile. At Rhinocolura they were reshipped and transported by an early navigation to Tyre, and distributed through the world. For an account of the trade which the Jews carried on by the Red sea, we refer to the articles OPHIR and TYRE. For the manner in which the Egyptians carried on their trade with India by means of this gulf, see ALEXANDRIA and BERENICE.

All the commercial transactions of the ancients with the East were confined to the ports on the Malabar coast, or at the farthest extended to the island of Ceylon. To these staples, the natives of all the different regions in the eastern parts of Asia brought the commodities which were the growth of their several countries, or the product of their ingenuity, in their own vessels, and with them the ships from Tyre and from Egypt completed their invetments. While the operations of their Indian trade were carried on within a sphere so circumscribed, the conveyance of a cargo by the Arabian gulf, notwithstanding the expense of land-carriage, either from Elath to Rhinocolura, or across the desert to the Nile, was so safe and commodious, that the merchants of Tyre and Alexandria had little reason to be solicitous for the discovery of any other. During the period in which this mode of carrying on commerce was followed, the price of goods imported from India into Europe was very much enhanced by the various operations to which the conveyance of them was subject. In Ceylon, or the ports on the Malabar coast to which they were brought from the various countries of Asia by the natives, they were put
There and monopoly it standing harder and others another powder, Redoon. From reduced of India some See it painting, Rep. I short, for druggists, and others of our modern druggists, fold under the name of bole armenic.

It is found in many parts of the world; the best in England is that from several parts of Derbyshire, from whence the colour-shops and druggists of London are supplied; many of the latter thinking this a shorter method than the common use of our bole armenic makers, of preparing it from a mixture of tobacco-pipe clay, and the red ochre called Spanish brown.

This lof, or common redde, is a loofe ponderous earth, of a lax texture, and very friable; and of a pale, but tolerably bright red, of a somewhat smooth and glossy surface, soft to the touch, adhering firmly to the tongue, easily broken between the fingers, and flasing the hands. It is of a rough aalborger, very readily breaks, and falls to powder in water, and makes no effervescence with aqua fortis. Hill.

Some call reddle, lapis hematitae; but the real hematites is another thing.

REDEEMABLES, in Law, are lands, funds, &c. sold with a reservation of the equity of redemption. Crown lands are redeemable for ever; others only for a certain time.

RE-DELIVERY, an yielding or delivery back of a thing; if a person has committed a robbery, and stolen the goods of another, he cannot afterwards purges the offence by any re-delivery. Co. Litt. 69. H. P. C. 72.

RE-DEMISE. See DEMISE.

REDEMPTION, Redemprio, a faculty or right of re-entering upon lands, &c. that have been sold, and assigned; upon reimbursing the purchase-money, with legal costs.

Bargains in which the faculty, or, as some call it, the equity of redemption, is reserved, are only a kind of pignorative contracts.

A certain time is limited, within which the faculty of redemption shall be exercised; and beyond which it shall not extend.

Redemption, in Theology, denotes the recovery of man-
kind from sin and death, by the obedience and sacrifice of Christ, who on this account is called the Redeemer of the world. See COVENANT.

Redemptions, Redemptionen, in our old Law Writers, denote grievous multitudes imposed by way of commutation for the head or life of the delinquent.

Redemption of the National Debt. See Fund.

REDE, or Reden, in Geography, a town of Prussia, in the territory of Culm; 20 miles N.E. of Culm.

Redens, Redans, or Redant, in Fortification, a kind of work indented in form of the teeth of a saw, with faltant and re-entering angles; to the end that one part may flank or defend another.

It is also called jaw-work, and indented work. The faces in this flank one another.

Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expense of building battlements; as when they stand on the side of a river, a marsh, the sea, &c. But the fault of such fortification is, that the beleaguers from one battery may ruin both the sides of the tenaille or front of a place, and make an assault without fear of being ensnared, since the defences are mined.

The parapet of the corridor also is frequently redented, or carried on by way of redens.

Redes, in Geography, a river of South America, which runs into the gulf of Darien, N. lat. 7° 37'. W. long. 76° 42'.

Redenhiiion, Redhibicio, in the Civil Law, an action allowed a buyer, by which to annul the sale of some moveable, and obliges the buyer to take it back again, upon the buyer's finding it damaged, or that there was some personal cheat, &c.

The redhibition, or redhibitory action, has a place in several cafes, in the body of the civil law. If a horse was sold that had the glands, were broken-winded, or foundered, it was a redhibitory cafe; and the seller might be obliged to take him again within nine days.

Redi, Francis, in Biography, an Italian physician, was descended from a noble family, and born at Arezzo, in Tuscany, in the year 1626. He commenced his studies at Florence, and then removed to Pisa, for the prosecution of his philosophical and medical pursuits, where he received the degree of doctor in both those sciences. He had acquired great reputation both in science and literature, and was induced to settle at Florence, where he at length gained the favour of the court, and was appointed first physician to Ferdinand II. duke of Tuscany, and subsequently to Cosmo III. These appointments and his constant professional employment did not, however, prevent him from cultivating his favourite study of the belles lettres. He devoted much of his time to the language of his country, and contributed not a little to the perfection of the dictionary of the academy of La Crusca, of which, and of several other learned bodies, he was a member. Totally free from presumption, and attached to every cultivator of learning and science, he was always ready to give his assistance to them in every way he could, and was universally esteemed and beloved. He displayed both in his practice, and in the prosecution of his inquiries in natural history, a singular acuteness of observation, and a complete incredulity as to the marvellous, which was so prevalent in his time; and he cautioned his friends and pupils against the popular errors in this respect. Although he was afflicted with epileptic fits in his latter years, yet he appears neither to have abandoned his studies, nor his professional business, until his death, which took place in 1697, in his 71st year.

Redi was the author of several Italian poems, which are held in much estimation. His other works were all written in Italian, and his style was deemed so pure and elegant, that the authors of the dictionary of La Crusca have often cited it as a standard. Most of his writings on natural history have been translated into Latin; especially his "Experientia circa Generationem Insectorum, cum Figuris Accisis," his "Observationes de Viperis," his "Experientia circa diversas Res naturales, speciatus ilius quae ex Indiis adfuntur," and his "Observationes de Animalibus viventibus, quas intra Animalia viventia reperierunt." He also published a letter on the Ufe of Spectacles, and an Essay on Syphilis. Eloy Dufi. Hist. de la Med.

Redi, in the notes to his "Bacco in Toscana," a dithyrambic poem, published in 1685, has given many curious etymologies and explanations of the medical terms used by the Italians in early times.

REDIGOODÉM, in Geography, a town of Hindoostan, in the circar of Ellore; 25 miles W. of Ellore.

REDIMICULUM, among the Romans, a girdle, which going about the neck, divided on the breast, and falling down each side, went round, and kept the robe tight to the body.

REDINKA, in Geography, a town of Portugal, in the province of Beira; 14 miles S. of Coimbra.

REDINTEGRATED Medals. See Medal.

REDINTEGRATION, Redintegratio, in the Civil Law, the act of restoring a person to the enjoyment of a thing, of which he had been illegally dispossessed.

In France, where a person is despised of his property, he claims it again by reintegration, or act of restitution. But the reintegration must be demanded within a year and a day, otherwise it is precluded.

Redintegration, in Chemistry, the restoring of any mixed body, or matter, whose form has been destroyed by calcination, corrosion, sublimation, or the like, to its former nature and condition.

The redintegration of mercury is properly called revivification. Mr. Boyle has an express treatise on the redintegration of salt and nitre; where he shows, that after reducing it by fluxion into fixed nitre, which is next to kin to salt of tar in all its properties, he could presently redintegrate it, by pouring a sufficient quantity of spirits of nitre on it; i.e., he could re-produce true crystals of the usual form and virtue of salt and nitre.

It is a strong objection against the chemical principles, that we cannot redintegrate the body they were procured from, by re-mixing them.

This seems to argue, that the body did not properly consist of such elements, or that they were not originally contained in it, but were rather produced by the fire.

REDIPATAM, in Geography, a town of Hindoostan, in Marawa; 18 miles N. of Ramadnaporum.

REDIRE ad Patron, in Law, is applied to a perfon, whose outlawry is reversed, and who is restored to the king's peace.

REDISSEISIN, a diffifion made by him who once before was found and adjudged to have diffiged the fame man of his lands or tenements; for which there lies a special writ, called a writ of redissisin. See Assise of Novel Diffision, Dissesion, and Post-Diffision.

REDMANS, or RADMANS, in Doomsday and other ancient books, are probably the same with road, or road-knights; viz. men who, by the tenure or cullion of their lands, were to ride with, or for, the lord of the manor, about his business.

REDFITZ, in Geography, a river of Germany, formed by the union of the Upper and Unter Raffat, about 5 miles S. of Roth, in Franconia. After receiving in its course several
several streams, it discharges itself into the Maine, a little below Bamberg.

REDOLESCO, a town of Italy, in the department of the Mincio; 14 miles S.W. of Mantua.

REDON, a town of France, and principal place of a district, in the department of the Ille and Vilaine; 32 miles S.S.W. of Rennes. The place contains 3783, and the canton 11,620 inhabitants, on a territory of 187.2 kilometres, in 5 communes. N. lat. 45° 39', W. long. 2°.

REDONDA, an island in the W. Indies, about 10 miles in circumference, without ports, rivers, or towns. N. lat. 16° 55'. W. long. 62° 20'.

REDONDELA, or REDONDELLA, a town of Spain, in the province of Galicia, near the west coast, defended by a strong castle; 32 miles W.S.W. of Orense.

REDONDO, a rock, about three miles in circumference, between the islands of Montserrat and Nisis, in the W. Indies. N. lat. 17° 6'. W. long 61° 35'.

REDONDO Novo, a town of Benguela. S. lat. 11° 22'. E. long. 13° 45'.

REDONDO, 0, a town of Portugal, in Alentejo; 14 miles E.N.E. of Evora. N. lat. 38° 33'. W. long. 7° 22'.

REDONDOS, a town of Portugal, in the province of Beira; 17 miles S. of Coimbra.

REDOUBLE', Fr., in M Carolina, a doubled interval in the octave above a single interval. The octave of the octave, with us, is called the 15th. See INTERVAL.

REDOUTE, or REDOUTE, Redoute, in Fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach; as also for the lodging of corps de garde, and to defend passages. See FORT.

They are chiefly figures of three, four, five, or six sides, encompassed with a ditch, and a bank of earth, which consists of two parts, called rampart and parapet.

In marshy grounds, redoutts are often made of stone-work, for the security of the neighbourhood; their face consists of from ten to fifteen fathoms; the ditch round them from eight to nine feet broad and deep; and their parapets, which are cut into embasures and merlons, have the same thickness. See REDUNT.

The inner sides of square redoutts are usually between the limits of twelve and thirty-two yards; and when they are to be defended by musketry, the number of men necessary to the defence may be thus determined: half the square squared gives the number of troops; and twice the square root of a given number of men, shews the length in yards of the side of a square redoutt proper to contain them.

To construct a square redoutt.—Mark out a square, whose side is adapted to the number of troops allotted for the defence, as A B (Plate VII. Fortification, fig. 5.) for the inside of the rampart. About this square, at the distance of ten or twelve feet, describe another square, whose side, C D, is the inner boundary of the parapet; make a parapet of about nine or ten feet thick, whose outline is the line E F; leave a berm about three or four feet broad, whose side is G H; and dig a ditch about fifteen feet wide, and about six or seven feet deep, which should be rounded before the angles of the redoutt. Make the rampart from four feet to nine or ten feet high; let the parapet be six or seven feet higher, and let the foot-bank be four feet and a half lower than the crown of the parapet. On that side most secure from the enemy, make a bridge across the ditch, and a passage through the rampart, about four or five feet broad when the defence is musketry, about nine or ten feet broad when cannon are to be used; and that up the passage by a strong gate. If the redoutt is to be defended by cannon, both the rampart and parapet should be at least five or six feet thicker. In order to make the fire pretty nearly equal on all sides, and sufficient for defending the angles of the work, M. Clairac has contrived to cut the inside of the parapet into notches, whose two sides, of a yard each, are at right angles to one another, and make half-right angles with the sides of the work; the manner of which, and its defence, are plainly shown in the figure, where the lines with dots at the ends represent the fire three different ways from the same side.

For the method of constructing flanked redoutts, see FORT. A detached redoutt is a kind of work resembling a ravelin, with flanks placed beyond the glacis; such as B (Plate V. Fortification, fig. 6.) They are made in order to occupy some spot of ground which might be advantageous to the besiegers; and likewise to oblige the enemy to open their trenches farther off than they would otherwise do. Their distance from the covert-way ought not to exceed a hundred and twenty toises, that they may be defended by musketry from thence. The gorge, a b, is forty toises; the flanks, a c, b f, which are perpendicular to the gorge, ten; and the faces, e d, f d, thirty; the ditch before it is fix toises, ending in slopes at both ends; the covert-way, four; the branches of the covert-way about forty-two toises long; the faces of the places of arms, y, y, which are perpendicular to the branches, ten; and the other, which is parallel to them, fourteen. The communication from the covert-way to the redoutt is five or six toises wide; and there is a traverse made just at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis. Robertson's Marine Fortif. p. 20, &c. Muller's Fort. p. 45, &c. See ARROW.

Redoutts are also small works of the same form made in a ravelin.

Redoutt, Caftle, or Donjon. See REDOUTE.

Redoutts au Grenaille, differ from other redoutts by having the inside line of the parapet broken, so as to resemble a pot-hook, or the teeth of a saw; by which a greater fire can be brought to bear upon the defile than if only a simple face was opposed to it, and consequently the passage is rendered more difficult.

Redouttes de Terre, Fr. redoutts that are hastily thrown up, and made with earth, for the purpose of securing entrenchments, circumvallations, passages of rivers, &c.

Redouttes de Maconnerie, Fr. redoutts made of mason-work; generally constructed in places where an enemy might derive advantage from establishing himself; they are likewise built upon the foiliants angles of the glacis.

Redouttes Caffinieres, Fr. caftellated redoutts, or such as are arched over and made bomb-proof. Those constructed for the defence of Gibraltar, and for the security of Dover caftle, are of this description.

Redouttes a Masticoli, Fr. are those which are made of brick or stone-work several stories high. The highest story juts out about one foot beyond the wall that surrounds or fronts the redoutt.

REDRESSING, the rectifying or setting any thing straight again.

Trees and other plants have a natural faculty of redressing themselves, when, by any external cause, they are forced out of the perpendicular.

In the moral sense, to redress grievances, is to reform or remove them. The redress of injuries is the object with a view to which courts of justice are infituted in every civilized society; in order to protect the weak from the insults of the stronger, by expounding and enforcing those laws, which define rights and prohibit wrongs. This remedy is, therefore,
therefore, to be sought for by application to these courts; that is, by civil suit or action.

To redress a flag, among hunters, is to put him off his changes.

**REDRILL, To, in Military Language, is to put a folder through the first elements of military training.** Every folder, after his return from long absence, must be redrilled before he is permitted to sit in the ranks of a company.

**REDRUTH, in Geography, a considerable market-town in the east division of the hundred of Penwith, and county of Cornwall, England, is situated on the road from Launceston to the Land's-End, at the distance of 262 miles S.W. from London. It occupies the declivity of a fine hill in the very centre of the mining district, and derives its support entirely from the mines. Dr. Pryce supposes it to have been a town in Saxon times; but if so, the records of its history during that period have been totally lost. It is first mentioned in the year 1532, when William Baffet, the then proprietor of the manor, obtained for the inhabitants the privilege of fairs and markets. In 1502 a similar grant was made in favour of John Baffet, efq.; and in Oliver Cromwell's time, Mr. Buller of Morrall procured a charter for a market on Fridays, which was confirmed by king Charles II. At present there are two weekly markets, held on Tuesday and Friday; and three annual fairs, chiefly for cattle and oxier manufacturers. The tolls of two of these fairs and the markets belong to the Buller family; and the other fair to lord de Dunstanville, the defendant of the Baffets. The increase of this town, since the commencement of the copper mines in the last century, has been as fix to one, as appears by the average of baptisms. According to the population return of 1801, it contained 664 houses, and 4714 inhabitants; but in 1811 the houses were reduced to 6379, and the inhabitants to 4593 in number.

Redruth consists chiefly of one long street. The church, the living of which is a rectory, was built, in 1770, by lord de Dunstanville, in the head of a more ancient one. This building is situated about half a mile from the town. Here are the remains of a chapel of ease, dedicated to St. Rumon, which has been unroofed for many years. In Redruth are meeting-houses for Quakers and Abaptists, besides two for Methodists in the town, and a third in the north part of the parish. In 1809, a large school-house was built here by subscription, and a public house placed in it by the same means; but the subscription having been discontinued, the school is now kept open by the master on his own account.

Among the numerous mines in Redruth and the contiguous parishes of Gwennap, Kenwyn, and St. Agnes, those denominated the Gwennap mines are considered to be the principal. These lie to the south-east of Redruth, in a part of the country where the tin and copper lodes are peculiarly rich, and in some places interfet each other. The country of the united mines Huel-Gorland, Poldice, and Huel-Unity, is fertile; that of Huel-Jewell, Huel-Gorland, and Trufavan, is fertile; and it has been remarked, that the metallic veins mostly obey the course of the granite mountains, and run very nearly parallel with them. The united mines employ about 600 men, of whom 400 work under ground. The water is drawn off by four immense steam-engines, one of the cylinders of which is nearly seven feet in diameter. The Huel-Virgin mine is 160 fathoms deep, and is extremely productive; but the Huel-Unity and Poldice mines are still more rich, and are wrought to such advantage, that the proprietors usually drain from 16,000l. to 20,000l. per annum. The depth of the Poldce mine is 170 fathoms; but at present it is not worked at a lower depth than 140. This is one of the oldest mines in the county, and yields a yellowish copper ore, a robin tin, and a few flakes of galena. The Huel-Gorland mine is 120 fathoms below the surface, and is wrought at the expense of about 1000l. a month. The North Down mines, nine in number, occupy an extent of two miles in length, and one in breadth, and have their surplus water carried away by the same long adit which runs through the Gwennap mines to the Carnon-Stream works.

Besides the mines, there are several other objects in the vicinity of Redruth not deserving of notice. Portreath, about four miles to the north, is a small sea-port for the importation of coal and lime, and the exportation of copper ore to the works in Wales. It is defended by a fort, mounting four guns, and was erected by lord de Dunstanville in the year 1782, and is maintained at his expense. Tiddy park, the ancient seat of the Dunstanville family, adjoins Portreath on the south-west. This manor is first mentioned as being in their possession as early as the year 1102, about thirty years before the marriage of Cecilia de Dunstanville with William Baffet, who carried the Dunstanville estates to the Baffets. The present manor-house is of modern erection, consisting of a centre, and four detached pavilions at the angles, the whole constructed chiefly of Cornish freestone. The principal rooms are decorated with some good portraits by Vandyke, Kneller, and Sir Joshua Reynolds; and also with a few pieces by Rubens, Carlo Dolci, Bononi de Ferrari, Rembrandt, Borgognone, and others of less note. The park and pleasure grounds attached to this mansion are very extensive; containing about three hundred acres, finely varied by wood and lawn, and appearing like a well-cultivated garden in the midst of a defert.

Weitward from Redruth, about a mile and a half, is Cara-breach hill, which Dr. Borlafe and others contend ought to be regarded as the grand centre of Druidical worship in this county, almost every kind of monument commonly attributed to the Druids being found, as they allege, upon that eminence. How far this opinion is correct, we shall not pretend to decide; but we may observe, that several late writers maintain, that a part of the supposed monuments of religion, viz. the coves, are in fact the result of natural convection. No doubt, however, some of them are artificial, and probably belonged to the Druids; and what seems to corroborate this idea is, the circumstance of Redruth being a corruption for Dr-C-Druith, which signifies the Druids' town. On the summit of this hill is a circular fortification, called the Old Castle, which appears to have been formerly surrounded by a strong wall, and about 300 yards to the eastward, on a ledge of succedent rocks, stands Carn-breach castle, part of which lays claim to a very high antiquity; but the remainder is of comparatively modern date. The rocks upon which this structure is erected not lying at all contiguous to each other, are connected by malleable circular arches thrown over the cavities.

On the south-west side of Carn-breach hill is Pendarees, the feot of John Stackhouse, efq. It is a large handsome building, situated on an eminence commanding extensive views over the western parts of the county. In a field contiguous is a large cromlech, composed of three upright stones, and an import. Claymore, situated about three miles further to the south-west, has been for several centuries a feot of the family of St. Aubin. The house is deeply embossed in wood; and contains, besides several pictures of curiosity and value, a large collection of rare and choice prints, accumulated in the portfolios of its present possessor. Lyfons's Magna Britannia, vol. iii. London, 1814, 410. Beauties

REDSEAK. See Iron.

REDSTONE, in Geography, a town of Pennsylvania, on the Monongahela; 55 miles N.W. of Pittsburg.

REDDBORS, those who buy stolen clothes, &c. and, to the end they may not be known, turn them into some other fashion, &c. See FRIPPERY, and REGATOR.

REDUCE, in Chemistry. See REDUCT.

To Reduce a Place, in Military Language, is to oblige the governor to surrender it to the besiegers by capitulation.

To Reduce the Circle, is to reduce or bring back a battalion or company which has been formed in circle to its original position in line.

To Reduce the Square, is to reduce a battalion or battalions which have been formed in a hollow or oblong square to their natural situation in line or column.

REDUCED CHART. See Chart.

To be Reduced, in Military Language, is to be taken off the establishment, or cafe to receive pay as soldiers. When a regiment is reduced, the officers are generally sent upon half pay. Sometimes, as at the close of a war, the corps are reduced, and the officers remain upon full pay. Hence are derived the expressions in and out of the break. In the break denotes the liability of being reduced: out of the break signifies the certainty of being kept upon the establishment.

To be Reduced to the Ranks, is to be taken from a superior appointment in a regiment, and to be ordered to the duty of a common soldier. This sometimes happens by way of punishment, when a sergeant or corporal misbehaves. A sergeant, however, cannot, at present, be reduced, except by sentence of a regimental court-martial.

REDUCE, REDUCE, of REDUCE, a military term, signifying an advantageous piece of ground, intrenched and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire to, in case of a surprise. Reduces have been sometimes made for the purpose of securing different parts in a town independent of its citadel. They were proposed by the celebrated Vauban. See Duxion.

REDUCE, in Building, a kind of recess, or little place, taken out of a larger, to make it more uniform and regular; or for some other convenience, as a little cabinet a hive of a chimney, for alcoves, &c.

REDUCE, or REDUCE, among Chemists, is a powder by which calcined metals and minerals are reduced again to their regulars, or pure substance.

REDUCTION, REDUCTION, in the Schools, a manner of bringing a term or proposition, which before was opposite to some other, to be equivalent to it.

Reduction is effected by the addition or subtraction of a negative particle. Thus, to reduce this proposition, no man is an animal, to be equivalent to its opposite, every man is an animal, I drop the negative, and say, man is an animal. After the like manner might the term every man be reduced, by adding the negative and saying, there is no man.

Reduction of Propositions is useful in a more general sense, for any expression of one proposition, by another proposition equivalent to it.

To a reduction, therefore, there are two propositions required, the reduced, and the reducing; which are considered as the extremes of it, and to be connected in the reduction by means of the particle that is; which here has the effect of a copula.

As here, only animals think; that is, animals think, and nothing besides animals thinks. Where the proposition preceding the particle is reduced, and the subject of the reduction; that following the particle reduces, and has the effect of the predicate of the reduction, and the particle that is acts as a copula, importing, not barely that the proposition is expressed by another, but by another equivalent one, or, as it were, the same.

Reduction of Syllogism, is a regular changing or transforming of an imperfect syllogism into a perfect one. Or, it is a change of a syllogism in respect of form, by which the necessity of the illusion, or inference, is made more evident.

Reduction obtains in syllogisms of the second and third figure; as also in the indirect modes of the first. By it these are all brought to the first.

There are two kinds of this reduction; the one direct, or oftenwise, performed merely by a conversion of one or both the premises, or by a transposition of them; as when camefrees is reduced to colour: the other indirect, called per impossibile, or ad absurdum; by which the person who denies the goods and legitimacy of an imperfect syllogism, is reduced to affect or grant something absurd and impossible, or contradictory to some other thing maintained by him.

Suppose, e. g. a person granting the premises of the following syllogism, denies the conclusion: All fraud is prohibited; but some trading is not prohibited; therefore some trading is not fraud. We thus proceed against him if the syllogism be not good, the antecedent is NULL, but the consequent false; and, therefore, the contrary of the conclusion must be true: now I take the contrary of the conclusion, which you thus give, viz. all trading is fraud; and of that, with the other premise of the former syllogism, viz. the major, which you likewise grant, make a new syllogism; thus, All fraud is prohibited; all trading is fraud; therefore all trading is prohibited. But this proposition, all trading is prohibited, and the other, some trading is prohibited, which you granted me in the first syllogism, are contradictions.

Reduction, in Arithmetic, is the converting of monies, weights, or measures, into the same value in other denominations; e. g. pounds into shillings and pence; or shillings and pence into pounds.

The reductions of the principal monies, coins, weights, and measures, ancient and modern, foreign and domestic, are found under COIN, WEIGHT, MEASURE, POUND, FOOT, &c.

Reduction is of two kinds: 1. Descending, when a quantity is to be brought from a higher denomination to a lower.

This is done by considering how many of the next less denomination are contained in the next greater before, and by that number multiplying the greater.

Thus pounds are reduced into shillings, by multiplying by 20; shillings into pence, by multiplying by 12; and pence into farthings, by multiplying by 4.

Troy pounds are reduced into grains, by multiplying by 12, 20, and 24; and avoirdupois hundreds into ounces, by 4, 28, and 16.

2. Ascending, when a lower denomination is to be reduced to a higher.

In order to this, the business is to divide the least by so many of its denomination as are contained in the next greater: thus, 24,720 pence, divided by 12, and the quotient by 20, gives 103 pounds.

If there remain any thing in each division, it is respecti-
Reduction of Decimals. See Decimals.
Reduction of Fractions. See Fractions.
Reduction of Ratios. See Ratios, Reduction of.
Reduction of Surds. See Surds.
Reduction of Equations. Various algebraical operations are clasped under this head by different authors; some considering it to be the fame as is likewise, and more properly, called the solution of equations, or the finding of their roots: some define it to be the taking away or exterminating all the unknown quantities except one, otherwise called elimination: others again, under this head, treat of what is more usually termed the transformation of equations; and others again apply it to the depriving of an equation, or the reduction of it to another of lower dimensions, which latter seems to us the only operation that can properly be treated of under the above designation. See Resolution, and Transformation.

There are but few cases in which the reduction of an equation can be effected, viz. only when a known relation has place amongst any of its roots, in which case the equation will admit of being reduced as many degrees lower, as there are independent conditions known to have place. So that if the relation be only between two roots, which is one condition, the equation may be reduced two degrees; if the relation extend to three roots, it may be reduced three degrees; and so on.

The conditions or relations more commonly considered, are those in which the roots of an equation form an arithmetical or geometrical progression, and when an equation has any number of equal roots. The two former relations seem rather objects of curiosity than utility, as it is not probable that an equation should have such relations obtain between its roots; but with regard to equal roots they may frequently arise in the solution of various problems. When any geometrical or physical problem is proposed, the number of its possible solutions is generally limited, and therefore the ultimate result arising out of such investigation ought to be an equation, the number of whose roots agree with the limited number of solutions. But it may happen that the analyst, by not pursuing the belt mode of operation, is led to an equation of higher dimensions than is requisite, in which cases, upon investigation, it will always be found that his refuting equation has some number of equal roots, which being taken away, will reduce the equation to one of lower dimensions, which gives the proper number of solutions to the original problem. As to the cases in which the roots of an equation form a geometrical progression, they occur almost exclusively in the solution of binomial equations, having prime indices, a property which M. Gauß has turned to a good account in the solution of thefe equations. See Polygon, and Reciprocal Equations.

Nearly all other relations between the roots of equations are signified for the purposes of framing quations, and exercising the ingenuity of authors and their students.

1. To ascertain whether a proposed equation has any equal roots.

Let \( x^n + ax^{n-1} + bx^{n-2} + \ldots + \gamma x + \alpha = 0 \), be any equation whose roots are \( a, b, c, d, \&c. \). Then from the known theory of equations we have

\[
\begin{align*}
\alpha x^{n-1} + \beta x^{n-2} + \gamma x^{n-3} + \&c. &= (x - a)(x - b)(x - c)(x - d) + \&c. \\
\text{And it may be thewn also, that the equation } m x^{n-1} + (m - 1) x^{n-2} + (m - 2) x^{n-3} + \&c. &= (x - a)(x - b)(x - c)(x - d) + \&c. \\
\end{align*}
\]

that is, it is equal to the sum of all the \( m \) equations that can be formed by the different combinations of the \( m \) first roots, taking \( m - 1 \) at a time. (See Warings Meditationes Algebraicae, cap. 3.) Now if we suppute the first equation to have two equal roots, as, for example, \( a = b \), the above products will become

\[
\begin{align*}
x^n + ax^{n-1} + bx^{n-2} + \gamma x^{n-3} + \&c. &= (x - a)(x - a)(x - c)(x - d) + \&c. \\
m x^{n-1} + (m - 1) x^{n-2} + (m - 2) x^{n-3} + \&c. &= (x - a)(x - a)(x - c)(x - d) + \&c. \\
\end{align*}
\]

where it is obvious that both the one and the other of these equations have the same factor, viz. \( (x - a) \).

If the equation had three equal roots, it is equally obvious that both equations would have the common factor \( (x - a)^2 \); and generally, if the equation had \( p \) equal roots, they would both have the common factor \( (x - a)^{p-1} \).

Therefore, when it is proposed to find whether a given equation have equal roots, we must from the proposed equation draw the derived equation as above, (which, it will be observed, is the same as would arise from taking the fluxion of the first, leaving out of course the \( x^p \)), and find by the usual methods, whether these two functions have any common measure; which, if they have, will furnish us with the equal root fought; and consequently the original equation may then be reduced by division to another of two degrees lower dimension for two equal roots; of three degrees lower for three, and so on.

Exam. 1.—It is required to find the equal roots of the equation \( x^5 - 48x - 128 = 0 \).

Here the derived equation is \( 3x^4 - 48 = 0 \), and the common measure of these two functions is \( x^4 + 4 \); whence \( -4 \) and \( -4 \) are the equal roots; the third root being \( +8 \).

Exam. 2.—It is required to ascertain whether the equation

\[ x^3 + 3x^2 - 14x^2 - 12x + 40 = 0 \]

have equal roots, and what they are.

Here the derived equation is

\[ 4x^2 + 9x^2 - 28x - 12 = 0 \]

and the common divisor of the two is \( x - 2 \); whence \( x = 2, 2 \), which are two of the equal roots. Divide now the original equation by \( x^2 - 4x + 4 \), and we have

\[ x^3 + 7x + 10 = 0 \],

whose
whose roots are $-2$, and $-5$; therefore, the four roots of the proposed equation are $2, -2, -2, -5$.

If the roots of an equation be equal, but with contrary signs, the operation is more simple. For, in this case, we have only to change the signs of the roots in the proposed equation, by changing the alternate signs of its co-efficient; and we shall thus have two equations, having necessarily a common quadratic factor of the form $x^2 - a^2$, which may be found, and the equation depred as before.

Exam. 3.—Required the roots of the equation $x^2 + 3x^2 - 7x^2 + 27x - 18 = 0$, two of which are equal, but with contrary signs.

By changing the signs of the alternate terms, we have $x^2 - 3x^2 - 7x^2 + 27x - 18 = 0$, the common quadratic divisor of which is $x^2 = 9 = 0$; whence the equal roots with contrary signs are $+3$, and $-3$. Now dividing the proposed equation by $x^2 - 9$, we have $x^2 + 3x + 2 = 0$;

whence $x = \frac{-3 \pm \sqrt{1}}{2} = -2$, and $-1$, which are the other two roots.

On this subject the reader should consult Waring's Meditations Algebraice, cap. 3. See also Bonnycaile's Algebra, vol. i. and ii.

Reduction of Interest of the public Debt. See Fund.

Reduction of Curves. See Curve.

Reduction of a Figure, Design, or Draught, is the making a copy of it, either larger or smaller than the original, fulfilling the form and proportion.

The great use of the proportional compasses is in the reduction of figures, &c. whence they are also called compasses of reduction.

There are various methods of reducing figures, &c.; the most easy is by means of the perspective (which see), or parallelogram; but this has its defects. The best and most usual methods of reduction are as follow:

To reduce a figure, as ABCDE (Plate XII. Geometry, fig. 5.) into a less compasses.—About the middle of the figure, as $z$, pitch on a point; and from this point draw lines to its several angles, A, B, C, &c.; then drawing the line $ab$ parallel to $AB$, $bc$ parallel to $BC$, &c. you will have the figure $a b c d e$ similar to ABCDE.

If the figure $a b c d e$ had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as $z D, z C, &c.$ and to draw lines, viz. $D C, C B, &c.$ parallel to the sides $d e, e b, &c.$

To reduce a figure by the angle of proportion.—Suppose the figure ABCDE (fig. 6.) required to be diminished in the proportion of the line $A B$ to $a b$ (fig. 7.); draw the indefinite line $G H$ (fig. 8.), and, from $G$ to $H$, let off the line $A B$; on $G$ describe the arc $HI$; let off the line $a b$ as a chord on $H I$, and draw $G I$. Then with the angle $IGH$ you have all the measurements of the figure to be drawn. Thus to lay down the point $c$, take the interval $B C$, and upon the point $G$ describe the arc $K I$; also on the point $G$ describe $M N$; and upon $a$, with the distance $M N$, describe an arc cutting the preceding one in $c$, which will determine the side $b c$. And after the same manner are all the other sides and angles to be described. The same process will also serve to enlarge the figure.

To reduce a figure by a scale.—Measure all the sides of the figure, &c. as ABCDE, by a scale, and lay down the same measurements respectively, from a smaller scale in the proportion required.

To reduce a map, design, or figure, by squares.—Divide the original into little squares, and divide a fresh paper of the dimensions required, into the same number of squares; which are to be larger or less than the former, as the map is to be enlarged or diminished.

This done, in every square of the second figure, draw what you find in its correspondent one in the first.

Reduction to the Equations in Astronomy, is the difference between the argument of latitude, as N P (Plate XIX. Astronomy, fig. 10.) and an arc of the ecliptic N R, intercepted between the place of a planet and the node N.

To find the reduction.—The angle of inclination $P N R$, and the argument of latitude $N P$, being given, find, by the doctrine of spheric, the arc $N R$; subtract $N R$ and $N P$ from each other, the remainder is the reduction.

Reduction into first Matter, is a term which alchemists formerly used, when they found their substances putrefy, and grow black.

Reduction was more particularly used for the conversion of a dry matter into a liquid, particularly into water; which by the alchemists was held the principle of all things.

The reduction of metals into their first matter, or principles, according to these philosophers, can only be effected by mercury; nothing else being able to loosen the fixed sulphur of metallic bodies, which binds them together.

Reduction, in Metallurgy, is the decomposition of a metallic oxide, so as to leave the metal in a state of greater or less purity, and exhibiting the sulphur which is so eminent characteristic of metallic bodies.

Reduction is, for the most part, effected by charcoal and a high temperature, either with or without the assistance of fluxes. For the various modes of reduction in actual practice, see the articles of the different metals.

Reduction, in Surgery, denotes an operation by which a dilated, laxated, or fractured bone is restored to its former place. Reduction, or restoration, is always to be performed before any remedy be applied.

Reduit, in Military Affairs. See Reduct.

Redundancy, or Redundance, a fault in discourse, confuting in the use of a hyperlithy of words. Words perfectly synonymous are redundant, and ought to be retrenched. Redundancy neccessarily makes the style weak and languid. See Pleonasm.

Redundant Hyperbola, in Geometry, is a curve of the higher kind, thus called, because it exceeds the conic section of that name in the number of its hyperbolic legs; being a triple hyperbola, with fix hyperbolic legs.

Redundant Intervals, in Music, is used for an interval exceeding the truth by a comma.

Some apply redundant to an interval exceeding a diatonic interval by a feminine minor; but this is more usually called a superfluous interval. See Interval and Second.

Reduplication, in Rhetoric, a figure by which a verse begins with the same word as the preceding one ends with. See Anadiplosis.

Reduplication, in Logic, is a kind of condition expressed in a proposition, indicating or aflying the manner in which the predicate is attributed to the subject.

The usual reduplicative words are quatenus, as, so far as, considered as, inasmuch as, &c. Hence,

Reduplicative Propositions, are such in which the subject is repeated, with some circumstances or condition. Thus, Men, as men, are rational; Kings, as kings, are subject to none but God.

Redutea, in Botany, so called by the late M. Ventenat, in honour of his friend M. P. J. Redouté, one of the most accurate and intelligent botanical draughtsmen, and perhaps the finest botanical painter, ever known. He is the author of a splendid coloured work in folio, on the Lilaceous...
Redwood River, a river of America, which runs into the Washash, N. lat. 40° 16'. W. long. 87° 5'.

Red, or Rei, in Commerce. See Red.

Red, Lough, in Geography, an expansion of the waters of the river Lough, in Ireland, between the county of Rol-
common and the counties of Longford and Welfernath,
reaching from Loughborough nearly to Athlone, with sev-
eral islands, and in some places three miles broad.

Red, in Botany. See Anem.

The root of the arum dox a of Dioscorides, attracts
any matter lodged in wounds, if powdered and applied to
them with wine, or if it is taken fresh and reduced to
powder with an onion or mixed with honey. (Oribis de
Med. Car. lib. iii. cap. 32.) It also removes pains arising
from dilocation of limbs, and carries off pains in the hips.
The green leaves cut and applied, are said to cure the ery-
epilepsia. Poor people boil the flowers in water or in beer,
which they mix with honey, and drink, after being filtered,
to cure coughs, oppensions of the breath, and consump-
tions. The ancients made flutes and other musical instru-

Red, Indian flowering. See Canna.

Red Maze. See Tryple.

Red, in Agriculture, the name of an aquatic plant,
infesting boggy lowlands or meadows on the sides of
rivers.

The best method of destroying reeds, is by draining
the land; for if the drains be cut deeper than their roots it will
take away their nourishment, and, consequently, destroy
them. Ashes, or foot, will likewise sometimes kill them;
and if you plough up the land, and laying it in high
rises. They always indicate a deep good moor soil, as a
bad one will not nourish or support them. There are
many different sorts of reeds, but those of the more florid
and tall kinds are often of much use in thatching the different
sorts of farm buildings, where other better kinds of
coverings are scarce, and these abundant. There is also a sort
of reed found in Huntingdonshire, and some of the adjoining
counties, that is very valuable for the purpose of laying
platter floors with. In other situations, reeds of the other
kinds may be met with, that may be found useful for
different purposes either of the farmer or in the arts. In such
situations they may be cultivated with advantage as an article
of profit: and it may often be more beneficial than to have
them destroyed, especially where they are of a valuable nature,
and where the land is of too moor and boggy a quality to be
ever fully reclaimed and brought into either the state of good
arable or meadow ground. Slips on the sides of large rivers
or brooks are likewise, frequently, the most advantageously,
conveniently, and profitably kept under reed crops, as the
overflow of the waters prevent their being usefully managed
in any other manner. There are other situations, as those
about the borders of large ponds, lakes, and other waters,
where they may be preserved with far greater propriety than
having them destroyed, provided even that can be accom-
plished without difficulty, as not any thing more valuable
can in general be raised in such places. They are, however,
by no means to be continued wherever any better crop will
grow and succeed.

Red is also a term applied to fitch draw of the wheat
or rye kinds as has not been bruised by threshing or in any
other way.

Red Hedges, in Gardening, that fort of hedge fence which
is formed from reeds. They are a sort of temporary internal
fences made with these dried materials which may be had
deap, and be expeditiously formed into hedges by the affil-

lieaceous tribe, including some other beautiful plants allied
thereto, which has already extended to the seventeenth volume;
and it is to his pencil that the perfection of most botanical
works that have appeared in France, for near thirty years
past, particularly the publications of L'Heritier and Ven-
tenat, is owing.—Venent. Jard. de Cels, t. 11. Poiret in La-
marché Dict. v. 4. 87.—Clas and order, Monadelphia Poly-

Gen. Ch. Cal. Perianth inferior, double, permanent:
the outer of many minute leaflets: inner much larger, of
one leaf, in five very deep segments. Cor. Petals five,
roundish kidney-shaped, imbricated obliquely, united at
the base to each other, and to the column of the stamens. Stam.
filaments numerous, united below into a conical tube, sub-
divided and branched above; anthers kidney-shaped. Pip.
Germin superior, ovate, liripennis; stylo thread-shaped, swell-
ing upwards, about as long as the stamens; stigma three,
obtuse. Peric. Capsule ovate, of three cells and three valves,
the partitions from the middle of each valve. Receptacles
of the seeds three, inserted into the base of the capsule, alter-
nate with the valves, and nearly equal to them in length,
linear, bearing seeds on each edge. Seeds fix or eight in
each cell, obovate, minutely stalked, inserted in two rows
on the receptacle, each clothed with dense wool.

Eff. Ch. Calyx double; the outer of many minute
leaves; inner in five deep segments. Stigmas three. Capsule
of three cells and three valves. Seeds enveloped in wool.
Receptacles three, linear, unconnected with the valves.

Obf. Ventenat considers the three distinct receptacles, as
affording the most essential distinction, between this and
every other malaceous genus. The woody seeds, moreover,
distinguish it from all except Caffpyrum, whose large three-
leaved outer calyx is abundantly different from Reducca.

The only known species is

de Cels, t. 11.—Discovered by Riedlé in the island of St.
Thomas, and raised in M. Cels's garden at Paris. The
plant is herbaceous and annual, and M. Ventenat seemed to
think it might serve to decorate our flower-borders, like
other annuals of very hot climates, in the open air, being,
we presume, raised on a hot-bed in the spring. Every part
of the herbage is beprincled with small, whitish, fringed
feals, readily seen with a magnifying glas. The root is
spindle-shaped, yellowish. Stem erect, twelve or fifteen
inches high, about the size of a goose-quill, angular, pityh,
branched, leafy, dark green, many-flowered. Leaves alter-
nate, on longish stalks, spreading widely, ovate, undivided
or three-lobed, entire, an inch or less and half long; pale
beneath. Stipulae minute, awl-shaped, deciduous. Flowers
large, handmee, sulphur-coloured, with a dark purple radi-
ating spot at the base of each petal, solitary, erect, on
long, simple, axillary stalks. Segments of the inner calyx
nearly linear, half as long as the petals. Style hairy. Cap-
sule the size of a filber. Wool of the seeds of a dirty grey.

—We have not heard of this plant in any English collection.

REDUVIA, in Surgery, a word used by fome for a whit-
low, and by others for a painful crack, or other discomfort
about the nails, either of the fingers or toes.

REDUX, in Chemistry. See REDCUT.

REDWAETH BAY, or Treath Cohs, in Geography, a
bay on the N. coast of the island of Anglesey. N. lat. 55°
17'. W. long. 4° 25'.

REDWITZ, a town of Bavaria, in the diocese of
Bamberg; 4 miles N.W. of Kunftadt.

REDWITZ, a town of Germany, in the principality of
Culmbach; 4 miles N. of Bayreuth.
ance of pot and railing, being of great utility for occasional use in gardens, to inclose particular internal spaces of ground, so as to afford shelter to certain seedling plants, both in nurseries and large kitchen gardens; and in some nurseries, to form places of shelter for many sorts of seedling trees and shrubs, &c., which, being tender whilst young, require the shelter of a fence in winter to break off severe or cutting blasts two or three years, till they gradually gather strength and a greater degree of hardiness. They are also useful in training several sorts of wall-fruit trees again, to form them for rows, or what are called trained trees; admitting of planting trees against each side of them, fix, eight, or ten feet asunder. See Nursery.

And in large open kitchen-gardens they are occasionally made use of to inclose the melonary, or place for raising early melons and cucumbers in; and often as crosst internal fences, under which to form warm borders for the purposes of raising various early crops of vegetables.

The proper sort of reeds for these fences are the dried stems of the common marsh reed, which grows in great plenty by river sides, and in lakes, and marshy places, furnishing a crop of stems annually fit to cut in autumn, when they should be bound in bundles, and stacked up, or hove up, to remain for use.

These fences are sometimes erected in fixed ranges, and sometimes formed into moveable panels. In the first mode, some stout poles should be placed fix or eight feet asunder, and five or six high, and from pole to pole carry two or three ranges of flat thin railing, one range near the bottom, another near the top, and a third in the middle; against this railing, the reeds must be placed about two inches thick, having other railing fixed directly opposite; so that the reeds being all along between the double railing, the bottoms railing either upon a plate of wood, or let into the ground, but the former is preferable; and as soon as one panel is formed, the railing should be nailed as close as possible, driving some long spike-nails through each double railing, or binding them with strong withy bands, or tar rope-yarn, but nailing is the bet, in order to bring them as close as may be, to secure the reeds firmly in the proper position; the top should be cut even afterwards.

In the better method, a frame-work of railing should be prepared as above, each panel six or eight feet long, and the reeds fixed therein as before directed; then, where they are intended to be placed, poles must be ranged fix or eight feet distant to support the different panels. Or sometimes the panels may be placed inclining against the wall or other fence, in time of severe weather, when the borders are narrow. These sorts of fences are now however in much less use in gardening than formerly.

Reed, Ezekiel's. See Ezekiel's Reed.

Reed, Calamus, likewise denotes a Jewish measure, otherwise called canna.

Reed, in the Manufacture of Tapestry. See Tapestry.

Reed Sparrow, in Ornithology. See Emberiza Schoenicius.

Reed Point, in Geography, a cape on the W. coast of the island of Antigua. N. lat. 17° 12'. W. long 61° 36'.

Reedham. See Reepham.

Reeds, in a Fire-ship, are made up in small bundles of about twelve inches in circumference, cut even at both ends, and tied each with two bands. There are two kinds of them; the long, which are four feet; and the short, which are two feet five inches in length. Some of them are singly dipped, i.e. at one end, the rest are dipped at both ends, in a kettles of melted composition. After being immersed about seven or eight inches in this preparation, and then drained, they are sprinkled over with pulverized sulphur upon a tanned hide. See Fire-ship.

Reedsborough, in Geography. See Readsborough.

Reedstown. See Strong.

Reedy Creek, a river of New Jersey, which runs into the Atlantic, N. lat. 39° 55'. W. long. 74° 16'.

Reedy Island, an island of America, in the Delaware river, 50 miles below Philadelphia, and 20 miles from Bombay Hook, about three miles long and not more than one-fourth of a mile wide. This island was formerly banked in, but is now under cultivation, and overflowed in high tides. It is the rendezvous of outward-bound ships in autumn and spring, waiting for a fair wind. Here is a secure harbour at Port Penn, where piers have been erected by the state of Pennsylvania. On each side of the island is a channel; but vessels, especially of the larger kind, choose to keep the eastern side.

Reedy River. See Saluda.

Reedy River Shool, a post-town of America, in Greenfield county, South Carolina.

Reef (ref), Dutch, in Navigation, denotes a certain portion of a fall, comprehended between the top or bottom, and a row of eyelet-holes parallel to it. The intention of the reef is to reduce the surface of the fall in proportion to the increase of the wind; for which purpose there are several reefs parallel to each other in the superior falls, by which they may be still farther diminished, in order to correspond with the severer degrees of the gale. The top-falls of ships are usually furnished with four reefs, parallel to the yard; and there are always three or four reefs parallel to the foot of those main-falls and fore-falls which are extended upon booms; a circumstance common to many of the small vessels. Falconer.

A bag-reef is the fourth, or lower, reef of a top-fall. A balance-reef crosses boom-main-falls diagonally, from the foot to the end of the upper reef-band on the after-larch. This is used to contract the falls in a storm.

Reef also denotes a chain of rocks, lying near the surface of the water.

Reef-Band, in Sea Language, a piece of canvas, fewed across the fall, to strengthen it in the place where the eyelet-holes of the reefs are formed.

Reef-Hanks, short pieces of log-line or other small line, fastened at certain distances to form the reefs of boom-fails.

Reef-Tackle, is a rope which passes from the deck to a block at the top-mast head, and thence to another block at the top-fall-yard-arm, where it communicates with another rope, called its pendant, that runs downwards through a hole in the yard, and is afterwards attached to a cringle, a little below the lowest reef. It is used to pull the skirts of the reefs close up to the extremities of the top-fall yards, in order to lighten the fall, the weight of which would otherwise render it very difficult to perform this operation. Falconer.

Reef Island, in Geography, a small island in the East Indian sea, about 50 miles from the W. coast of Sumatra. 8. lat. 4°. E. long. 106° 3'. Also, a small island in the East Indian sea, near the N. coast of the island of Celebes, N. lat. 9° 8'. E. long. 122° 48'.

Reefing, in Sea Language, the operation of reducing the fall, by taking in one or more of the reefs, which is performed by lines, points, or knottles. The top-fails are always...
REEE, to reel rope on from a six-thread ratline to a two-much rope, have four ribs fixed at each end in a flat circular piece of wood; and round the edges are blades, or handles, to turn them: one of the circular pieces is called the head, and is made to slide off for taking the coil away. They turn on an iron spindle, and are from ten to thirty-six inches long, and from twelve to eighteen inches diameter. The Bench-lea used by sail-makers is similar to a spinning-wheel, and is used to expedite winding the twine from the skeins to the twine-ree. Log-reels have several ribs fixed in a circular piece of board at each end, and turn or run upon a spindle, having a handle at one end. (See Log.) Turn-reels, used by sail-makers, are short cylindrical pieces of wood, hollowed in the middle to receive the twine, with a hole through the middle for the spindle. Tho' used by rope-makers have four oak bars, about eighteen inches long, framed together at the ends on a wooden spindle; one of the bars slides, for the convenience of taking off the twine. The Turn-ree is a narrow board, with three or four holes at each end, in which pegs are fixed for reeling marble and other lines.

REEF, in Geography, a small navigable river of America, in Tennesse, which discharges itself into the river Missippis, about 35 miles S. of the Ohio. It is 50 yards wide seven miles from its mouth. One of its branches rives on the borders of Kentucky.

REELING, in the Manufactories, the winding of thread, silk, cotton, or the like, into a skain, or upon a bottom, to prevent its entangling.

It is also used for the charging or discharging of bobbins, or quills, to use them in the manufacture of different stuffs, as thread, silk, cotton, &c.

Reeling is performed different ways, and by different engines.

REEM, in Zoology. See Rhinoceros Unicornis.

REEMING, a term used by caulkers for opening the beams of the planks with reeming-irons, that the oakum may be more readily admitted. To make any hole larger is also termed reeming.

Reeming-Irons, are the largest irons used by caulkers in opening the beams.

REEMSTOWN, or Reamstown, in Geography, a small poiltown of America, in Lancaster county, Pennsylvania, situated on a stream which runs into Calico creek, a water of Coneloga, which falls into the Susquehannah; 26 miles N.E. of Lancaster.

REEF, a river of Norway, in the province of Drammen, which runs into the Glomme; 20 miles N. of Opal.

REEF Mølla, a name used by fome for the mountain coralloides, or rein-deer mofs.

REEENBERG, Theocarus, in Biography, a celebrated Danish poet, was born at Viborg in 1656, where he was educated. In 1680 he set out on his travels into foreign countries, after having undergone an examination by the theological faculty, and he returned to Denmark in 1682. In 1703 he was appointed fourth judge in Jutland. In 1730 he became counsellor of justice, and he died in 1742. His poetical works were published at Copenhagen in 1769, by his grandson Tielmann, with a preface by Kofod Anker, and annotations by Laxdorph. Gen. Biog.

REEENKLOESSER, in Geography, a town of Norway; 12 miles N.N.W. of Drammen.

RE-ENTER.
REE-ENTERING ANGLE, in Fortification. See Angle, and Construction, according to M. Vauhns's first method.

REE-ENTRY, in Law, the returning or retaking that posession which any one had lately forgone.

As, if I make a leaf of land or tenement, I do thereby forego the posession: and if I condition with the leffe, that he cannot pay the rent at the day, it shall be lawful for me to re-enter: this is as much as if I conditioned to take again the lands, &c., into my own hands, and to recover the posession by my own act, without the assistance of judge or other procurs. But words in a deed give no re-entry, if a clause of re-entry be not added. (Wood's Inst. 140.) All persons who would re-enter on their tenants for non-payment of rent, are to make a demand of the rent; and, to prevent the re-entry, tenants are to tender their rent, &c. (1 Inst. 201.) If there is a lease for years, rendering rent, with condition, that if the leasee assigns his term, the lessor may re-enter; and the leasee assigneth, and the lessor receiveth the rent of the assignee, not knowing or hearing of the assignment, he may re-enter, notwithstanding the acceptance of the rent. (3 Rep. 65. Cro. Eliz. 553.) See Kent. A feoffment may be made upon condition, that if the seffor pay to the seffee, &c., a certain sum of money at a day to come, then the seffor to re-enter, &c. Litt. § 322. See Entry and Use.

REEPHAM, in Geography. See Reepham.

REEER, in Geography. See Reef.

REEERSOE, in Geography, a small island of Denmark, in the Great Belt, near the coast of Zealand. N. lat. 55° 32'. E. long. 11° 7'.

REEFS, REES, or REES, in Commerce, monies of account in Portugal, 1,000 of which make a milreu or milre. In the notation of accounts, the milrees are separated from the rees by a crossed cypher, called "Cifraum," and the milreess from the millions by a colon; thus Rs. 2, 700 £ 500, means 2,700 mil. and 500 rees. The crudufo of exchange, or old crudofo, is 400 rees; the new crudofo, 480 rees; the teffoon, 100; the vintin or vintim, 20 rees. Thus the milre is 2 1/2 old crudofos, 2 1/2 new ditoes, 10 teftoons, or 50 vintins. The gold pieces, coined before 1722, are now 20 per cent. higher than their original value; so that the old dora, coined at 20,000 rees, are worth 24,000; the lithoonions or moidores, coined at 4000 rees, are worth 4800; and the halves and quarters in proportion; but few of these coins are now in circulation. The gold coins, struck since 1722, are the dora of 12,800 rees; the mea dora, Joines, or Portuguese piece of 6400 rees; the half Joines, of 3200; the dora estilo, of 1600; the quatro, of 1200; the vintin or vintim, of 800; the old crudofo, of 400; now very scarce; and the new crudofo, of 480 rees. The silver coins are now crudofos, of 480 rees; halvees, quarters, and eighths, or pieces of 240, 120, and 60 rees; teftoons or of 100, and halves of 50; and vintins of 20 rees.

There are also copper pieces of 10, 5, 3, and 1 1/2 rees. The pieces coined in Brazil, called patacas, of 600 and 640 rees, are current only in that country, and their intrinsic value is 10 per cent. less than that of the Portuguese coins. There is, besides, a gold milreu, struck for the Portuguese posseffions in Africa, and also a silver coin, of the value of 12 macutas, or 600 rees; the macuta being a money of account, worth 50 rees. The Spanish patacas, or dollar, are reckoned at Lisbon at 850 rees, more or less.

Portuguese gold coins are 22 carats (the mark fine being 24 carats), wrought gold is 20 1/2 carats, and gold dust from 21 1/2 to 22 carats fine. The fineeas of silver is exprefled in dinheiros and grains, the mark fine being 12 dinheiros, and the dinheiro subdivided into 24 grains. Silver coins are

10 diaheiros 19 grains fine, and wrought silver 10 1/2 fine.

The rate of coinage of gold and silver coins is as follows: 8 doraes of 12,800 rees, 16 Joines of 6400 rees, 32 half Joines of 3200 rees, 64 doraes estilos, 128 ditoes, or 256 old crudofoe, are to weigh a Portuguese mark of gold, 22 carats fine. Hence (the mark being 3542-3543 English grains) the dora contains 44 2/4 grains; the piece of 6400 rees 221 2/4 grains of English standard gold, and the other pieces in proportion. These coins, moreover, are not, in general, exactly 22 carats fine; but there is a remedy which amounts from 2 1/2 to 2 1/2 of a carat; and the new crudofoes are found to be only 21 1/2 carats fine. The silver coin is 10 din. gr. as above; and the mark is coined into 131 new crudofoes; hence the new crudofo weighs 34 3/4 Portuguese grains, or 265 English grains; halves, quarters, and eighths, in proportion. It, therefore, contains 258 grains of English standard silver. The gold piece of 6400 rees is worth 352. 11d. fterling; and the old crudofo, 22. 3d.; and thus the milreu, valued in gold, is worth 67 1/2d. fterling. The new silver crudofo is worth about 21. 9d. fterling; and, therefore, the milreu, valued in silver, is worth 68 1/2d. fterling. Gold is to silver as 16 to 1.

At Bombay each quarter of a rupee is divided into 100 rees. See Rupee.

REE, in Geography, a town of the duchy of Cleves; 8 miles E. of Cleves. N. lat. 51° 47'. E. long. 6° 20'.

REE, ul Ain, or Refaina, a town of Asfatic Turkey, in the province of Diarbekir; 80 miles S. of Diarbekir.

REEPTZ, a town of the New Mark of Brandenburg; 50 miles N.E. of Cuftrim. N. lat. 53° 18'. E. long. 15° 56'.

REEVE, in Ornithology, the name of a bird which is the female of the avis pugnus; the male of which, from the long feathers round his neck, is called the ruff. See Tringa Pugnax.

REEVE of a Church, is the guardian of it, or the churchwarden.

So-fire-ree is the sheriff, or guardian of a county; and port-reeve, the warden of a port or haven.

REEVE-LAND. See Reveland.

REEVING, in the Sea Language, is the putting a rope through any hole, as the channel of a block, &c. Hence, to pull a rope out of a block, is called unreeving.

RE-EXCHANGE, in Commerce, a second payment of the price of exchange, or rather the price of a new exchange, due upon a bill of exchange that comes to be protested; and to be refunded the bearer, by the drawer or inderor. See Exchange.

The occasion of re-exchange is, when the bearer of a bill of exchange, after protesting it, for want either of acceptance, or of payment, borrows money on his own promissory bond, or the like; or draws a bill of exchange in the place where the payment was to be made, on the person who furnished the first for which he pays a second exchange; which, being added to the first already paid, the drawer of the first bill is answeable for two exchange, properly called exchange and re-exchange.

The bearer of a protested bill has a right to recover both the one and the other on the drawer. Yet the simple protestation which the bearer makes in the act of protest, that he will take up a like sum at re-exchange, for want of his bill being accepted or paid, is not sufficient to entitle him to demand the reimbursement of his re-exchange, unless he make it appear, that he has actually taken up money in the place on which the bill was drawn.

Otherwise the re-exchange will only amount to the restitution of the first exchange, with interest, the expenses of protesting, and those of the journey, if there have been any.
If a bill of exchange, payable to the bearer or order, come to be protested, the re-exchange is only due upon the drawer for the place where the remittance was made, not for those places where it may have been negotiated; at least the drawer has a right to be refunded his re-exchange for those places by the indorser.

Indeed, the re-exchange is due from the drawer upon all places where a power of negotiation is given by the bill; and upon all others, if the power of negotiating be indefinite.

Lastly, the interest of the re-exchange, of the expenses of the protest, and the journey, are only due from the day of the demand.

It is supposed to be the Gibeins driven out of Italy by the faction of the Guephis, and flattered at Amsterdam, who first established the custom of re-exchange, on pretence of the interests, damages, and expenses they underwent, when the bills given them for the effects they had been obliged to abandon, were not accepted, but came to be protested.

Ref. Extent, in Law, a second extent made upon lands or tenements, on complaint that the former extent was partially made. See Extent.

Ref. B. F. in Geography, a town of Egypt, on the coast of the Mediterranean, anciently called "Raphis," (which see) 18 miles N.E. of El Arish.

Deflection, or deflexion, among Monks and Ecclesiastics, a spare meal or repast, just sufficing for the support of life. Deflection is also used, in Ancient Authors, for a duty or service incumbent on any person to provide meals for ecclesiastics, or even for princes.

Defactory, or defactory, a spacious hall in convents, and other communities, where the monks, nuns, &c. take their refectations or meals in common.

The refectory of the Benedictines of St. George at Venice, designed by Palladio, is one of the finest in the world.

Defiler.

Reference, in Writing, &c., a mark relative to another similar one in the margin, or at the bottom of the page, where something, omitted in the text, is added; and which is to be inserted either in reading or copying. A copyist must be very expert at taking references.

References are also used in books, where things being but imperfectly handled, the reader is directed to some other part or place where they are more amply explained.

Dictionaries are full of references, denoted by see or vide.

By means of these references the dictionary writer fetters a correspondence between the several parts of his work, and may give his dictionary molt of the advantages of a continued treatise.

Indices or tables are only references to the several parts of the work where the several matters are handled.

Reference, in Law, denotes the sending of any matter by the court of chancery to a master; and by the courts at law to a prothonotary, or secratary, to examine and report to the court. 2 Lil. Abr. 432. If a matter in difference be referred to the secratary; and one of the parties will not attend at the time appointed, after notice given, to hear the busines referred; the other party may proceed in the reference alone, and get the secratary to make his report without hearing of the party not attending. 2 Lill. 342. If a question of mere law arises in the course of a cause in chancery, as whether, by the words of a will, an estate for life or in tail is created, or whether a future interest devised by a testator shall operate as a remainder on an executory devise; it is the practice of that court to refer it to the opinion of the judges of the court of king's bench, or common pleas, upon a case filed for that purpose, in which all the material facts are admitted, and the point of law is submitted to their decision; who thereupon have it solemnly argued by counsel on both sides, and certify their opinion to the chanceller; and on such a certificate the decree is usually founded. It seems that the matter of the rolls, fitting for the chanceller, may make such reference; but not when fitting at the rolls. 2 Bro. C. C. 88.

The court of exchequer is both a court of law and of equity: therefore, if a question of mere law arises in the course of the exercise of its equitable jurisdiction, the barons will decide upon it in that suit, without referring it to another jurisdiction. Bl. Comm. iii.

Referendary, Referendaries, in Ancient Customs, an officer who exhibited the petitions of the people to the king, and acquainted the judges with his commands.

An officer of this kind, Spelman observes, we had in England, in the time of the Saxons. The like office was afterwards discharged by others, called masters of requests.

Refining, in Metallurgy and Assaying. In the former it signifies the means of obtaining metals from their ores, and from any other impurities, natural or artificial: for which see the metals under their respective heads.

In the latter it is employed for ascertaining the quantity of the noble metals in the different alloys: for which see CUPEL; where the methods of refining in the furnace are fully treated. And for the humid procés called parting, see Gold.

It may be proper here to observe, that although the processes of parting by nitric acid is still practiced, we are inclined to recommend the method propounded by Bergmann, which consists in dissolving the alloy of gold and silver in nitric-muriatic acid. The silver falls to the bottom in the state of muriate of silver, and the gold is precipitated by the green sulphate of iron. The gold, by this means, is obtained perfectly pure, which is seldom the case in the processes of parting. The trouble of telling to know what silver to add to the alloy, to make the gold equal to one-fourth of the silver, will be saved, and, with heat, the nitric-muriatic acid dissolves the gold quicker as soon as the silver is dissolved in the common method. The muriate of silver, which is easily separated by washing, may be readily reduced by heating it with sod in an iron crucible. The soda combines with the muriatic acid, and is sublimed in white fumes.

Refining of Sugar. This operation is begun by several strong lixiviums or leads of lime-water and eggs, shells and all, mixed and beaten together.

The first refining is performed in the Caribbees, and other places, where the sugar-canes are cultivated; and only leaves to make the brown or coarse sugars.

When these are imported into Europe, the sugar-bakers take them up, and refine them farther, by a second operation, or rather a repetition of the first.

To render the sugar very fine, fit for confections, &c. they give it a third refining; in which they only use the whites of eggs and their shells beaten together, and thrown into the melted sugar; which is called clarifying the sugar. See Sugar.

Refining of Salt-petre. The salt being put into an earthen or iron vessel, as much spring-water is poured on it as suffices to dissolve it. The vessel is then put over a gentle fire; and as soon as the water begins to boil, alum powder is thrown into it: the proportion is, one pound of alum to one hundred and twenty-eight pounds of salt-petre; and a little vinegar is added. As it boils, the scum is to be taken off; and it is to be evaporated till a pellicle appears on it, and then set to shoot.
For the refining of other matters, as camphor, cinnabar, sulphur, salt, borax, &c. see Camphor, Cinnabar, Sulphur, Salt, &c.

REFRiTH Voe, in Geography, a bay on the E. coast of the island of Yell. N. lat. 60° 58'. W. long. 1° 25'.

REFrITING, in Sea Language, denotes the repairing of any damages which a ship may have sustained in her sails and rigging, by battle or tempestuous weather.

REFrcted Ray. See Ray.

REFrcted Vision. See Reflex and Vision.

REFrCTING, or REFrCTive Dial, is a fort of dial, which shows the hour by means of a thin piece of looking-glass plate, duly placed to cast the sun's rays to the top of a ceiling, on which the hour-lines are drawn.

REFrCTing Microscope. See Microscope.

REFrCTing Level. See Level.

REFrCTing Telescope. See Telescope.

REFrCTION, or REFrCTION, in Mechanist, the return, or regressive motion of a moveable, occasioned by the refractivity of a body, which hindered its pursuing its former direction.

It is controverted whether there be any moment's rest or interval between the incidence and the reflection. For the affirmative stand the Peripatetics, and all who conceive the reflected motion to be different from the incident one of the same body. The motion of incidence, according to these authors, is wholly lost, and destroyed, by the refractivity of the obstacle struck against; and the moveable is thus rendered absolutely quiescent in the point of contact, till a new motion of reflection is produced in it, from a contrary cause.

The Cartesians affirm the negative; absolutely denying any rest at all between the incidence and reflection; urging, that if the motion were once destroyed, though but for a moment, there would be nothing to excite it again; but the body would perforce remain in that static state, as much as if it had been at rest a thousand years.

Accordingly Rohault, and others, define reflection to be no other than a change of determination; or a continuation of the former motion in a new direction.

As, say they, a pendulum, when arrived at its greatest sweep, does not stop; so a hard body, by striking on another hard one, does not rest, but pursues its motion the contrary way, according to the established law of nature; and this from the immediate influence or impulsion of the cause that first moved it. But this doctrine is now generally set aside.

Reflection is conceived, by the late and best authors, as a motion peculiar to elastic bodies, whereby, after striking on others which they cannot remove, they recede, or turn back by their elastic power.

On this principle, it is asserted, that there may be, and is, a period of rest between the incidence and the reflection; since the reflected motion is not a continuation of the other, but a new motion, arising from a new cause or principle, viz., the power of elasticity.

It is one of the great laws of reflection, that the angle a reflected body makes with the plane of a reflecting obstacle, is equal to that in which it struck on that obstacle. For the several laws of motion observed in the reflections of bodies, see Percussion.

Reflection of the rays of light, in Optics, is a motion of the rays, by which, after impinging on the solid parts of bodies, or rather, after a very near approach to them, they recede, or are driven from them.

When rays of light arrive at a surface, which is the boundary of two mediums not homogeneous, they continue their progress without deviating from those planes in which their former paths lay, and which are perpendicular to the surface of the mediums, but they no longer retain the same direction, a part of them, and sometimes nearly the whole, being reflected back from the surface, while the remaining part is transmitted and refracted, or bent. No influence occurs of the abrupt change of the density of a medium, without a partial reflection of the light passing either into the denser, or into the rarer medium; and the more obliquely the light falls on the surface, the greater, in general, is the reflected portion. No body is so black as to reflect no light at all, and to be perfectly invisible in a strong light; although at the surface separating two very rare bodies, as two kinds of gas, the reflection is too faint to be perceptible; but in this case the separation is seldom perfectly abrupt. The quantity of light reflected, when other circumstances are equal, appears to be always greatest when the difference of the optical or refractive density of the two substances is the greatest.

Thus, the reflection from the common surface of glasses and water is much weaker than from a surface of glasses exposed to the air. Metals, generally, reflect a great proportion of the light falling on them; and even the reflection from the common surface of glasses and mercury appears to be but little weaker than the reflection from the surface of mercury immediately exposed to the air, so that the optical density of the metals must be exceedingly great. It appears, also, that a portion of the light falling on a reflecting surface, is always transmitted to a certain depth, notwithstanding the apparent opacity of any large masses of the substance. Thus, if we cover a small hole of a window-shutter with the thinnest leaf-gold, we shall find that it transmits a greenish light, which must have passed the reflecting surface, but which, if the gold had been but one ten-thousandth of an inch in thickness, would have been wholly interrupted, and probably in the same manner as by passing through 700 feet of water. See Light and Refraction.

The reflection of the rays of light from the surfaces of bodies, is the means by which bodies become visible.

And the disposition of bodies to reflect this or that kind of rays most copiously, is the cause of their being of this or that colour.

The reflection of light from the surfaces of mirrors, makes the subject of optics; which see. See also Mirror.

The reflection of light, sir Isaac Newton has shown, is not effected by the rays striking on the very parts of the bodies; but by some power of the body equally diffused throughout its whole surface, by which it acts upon the ray, attracting or compelling it without any immediate contact.

This power he shews to be the same, by which, in other circumstances, the rays are refracted; and by which they are at first emitted from the lucid body. See Refraction.

The arguments he produces to prove this are as follow: 1. Because the surfaces of polished glasses, to which the eye appears smooth, are yet, in reality, very rugged and uneven (polishing being nothing but the grating, scratching, and breaking off the outer protuberances, by means of sand, glafs, putty, tripoli). If the rays of light, therefore, were reflected by striking on the solid parts of the glass, the reflections would never be so accurate as we find they are, but the rays would even be as much scattered by the most polished glasses, as by the roughest. It remains, therefore, a problem how glases, polished by fretting substances, can reflect light so regularly as it does; which problem is fearlessly otherwise to be solved, than by supposing, that the reflection of a ray is effected, not by a single point of the reflecting
REFLECTION.

reflecting body, but by some power of the whole body, evenly diffused all over its surface, and by which it acts on a ray without immediate contact; so that the parts of bodies do act upon light at a distance, is already shewn under the articles Refraction and Light.

2. If the colours, separated by a prism placed at the entrance of a beam of light into a darkened room, be successively call on a second prism placed at a greater distance from the former, in such manner as that they fall alike, or with an equal obliquity, upon it; the second prism may be so inclined to the incident rays, that those which are of a blue colour shall be all reflected by it; and yet those of a red colour pretty copiously transmitted. Now, if the reflection were caused by the parts of the air or glas, we would ask, why, at the same obliquity of incidence, the blue should wholly impinge on those parts so as to be all reflected; and yet, the red find pores enough to be, in a great measure, transmitted.

3. Where two glases touch one another, there is no sensible reflection; and yet we see no reason why the rays should not impinge on the parts of the glas, as much when contiguous to other glases, as when contiguous to air.

4. When the top of a water bubble, by the continual subfuding and exhaling of the water, grows very thin, there is such a little, and almost insensible quantity of light reflected from it, that it appears intensely black; whereas round about that black spot, where the water is thicker, the reflection is so strong, as to make the water seem very white. Nor is it only at the leafy thickens of thin plates or bubbles, that there is no manifest reflection, but at many other thickenes, gradually greater and greater. For, in one of our author’s observations, the rays of the same colour were, by turns, transmitted at one thickens, and reflected at another thickens, for an intermediate number of successions: and yet, in the superficies of the thickened body, where it is of one thickens, there are as many other parts for rays to impinge on, as where it is of any other thickens.

5. If the red and blue rays, separated by a prism, fall successively on a thin plate of any pellucid matter, whose thicknes inerates in continual proportion, (such as a plate of air between two glases, the one plane, and the other a little convex,) the same plate will, in the same part, reflect all the rays of one colour, and transmit all those of the other; but, in different parts, will reflect the rays of one and the same colour at one thickens, and transmit them at another; and thus alternately, and in infinitum. Now, it can never be imagined that at one place the rays, which, for instance, exhibit a blue colour, should happen to strike on the void parts of the body; and at another place, where the body is either a little thicker, or a little thinner, that, on the contrary, the blue should hit on the pores, and the red upon the solid parts.

6. In the passage of light out of glas into air, there is a reflection as strong as in its passage out of air into glas, or rather a little stronger, and by many degrees stronger than in its passage out of glas into water. Now, it seems improbable, that air should have more reflecting parts than water or glas: but if that should be supposed, yet it will avail nothing; for the reflection is as strong, or stronger, when the air is drawn from the glas by the air-pump, as when it is adjacent to it. If any should here objects on Descartes’s hypothesis, that, though the air be drawn away, there is a subtle matter remaining to supply its place, which, being of a denser kind, is better fitted for the reflection of light than any other body; besides that we have elsewhere shewn such subtle matter to be fictitious, and that, supposing its existence, and its reflecting power, no light could ever have been propagated, but must have been all reflected back to the lucid body, immediately after it was first emitted, the following experiment does evidently convict it of futility.

7. If light, in its passage out of glases into air, frile mor-robliquely than at an angle of forty or forty-one degrees, it is then wholly reflected; if obliquely, it is in great measure transmitted. Now, it is not to be imagined, that light at one degree of obliquity should meet with pores enough in the air to transmit the greater part of it, and at another degree should meet with nothing but parts to reflect it wholly; especially considering, that, in its passage out of air into glas, how oblique soever be its incidence, it finds pores enough in the glas to transmit a great part of it. If any supposes, that it is not reflected by the air, but by the utmost superficial parts of the glas, there is still the same difficulty; besides, that such a supposition is unintelligible, and will also appear to be false, by applying water behind some part of the glas, instead of air; for in a convenient obliquity of the rays, suppose of forty-five or forty-fix degrees, at which they are all reflected, where the air is adjacent to the glas, they shall be in great measure transmitted where the water is adjacent to it; which argues, that their reflection or transmition depends on the constitution of the air and water behind the glas, and not on the striking of the rays upon the parts of the glas, the rays not being reflected until they have reached the last part of the surface, and have begun to go out. For if, in going out, they fall upon a surface of oil and water, they proceed, the attraction of the glas being balanced by an equal force the contrary way, and prevented from having its effect by the attraction of the liquor adhering to it: but if the rays, in passing out of this last surface, fall into a vacuum, which has no attraction, or into air, which has but little, not enough to counterbalance the effect of the glas in this case, the attraction of the glas draws them back, and reflects them.

This will appear still more evident by laying two glases, prunis, or the object-glasses of two telescopes, the one plane, and the other a little convex, upon each other, so as they may neither touch, nor yet be too far apart; for that light which falls on the hinder surface of the first glas, where the glases are not above an eighth part of an inch apart, will be transmitted through the surface, and through the air or vacuum between the glases, and will pass into the second glas; but if the second glas be taken away, then the light passing out of the second surface of the first glas into the air or vacuum, will not proceed, but will return into the first glas, and be reflected.

Whence it follows, that the rays are drawn back again by some force in the first glas, there being nothing else to occasion their return. And hence too it follows, that the reflection is not effected by means of any subtle matter contiguous to the hinder surface, according to the principles of Descartes; since that matter ought to reflect them when the glases were nearly contiguous, as well as when the second glas is quite removed.

Lastly, it if be asked, how some of the rays come to be reflected, and others transmitted; and why they are not all alike reflected, supposing the reflection owing to the action of the whole surface: the same great author shews, that there are, both in the rays of light, and in the bodies themselves, certain vibrations (or some such property) impressed on the rays, by the action either of the luminary that emits them, or of the bodies that reflect them; by means of which it happens that those rays, in that part of their vibration which
which conspire with the motion of the parts of the body, enter the body, are refracted and transmitted; but those in a contrary part of their vibration are reflected.

Add, that every ray of light, in its passage through any refracting surface, is put into a certain transient constitution or state, which, in the progress of the ray, returns at equal intervals, and disposes the ray, at each return, to be easily transmitted through the next refracting surface; and between each return, to be easily reflected by it.

These alternate dispositions, which Mr Isaac Newton calls fitted of easy reflection, and of easy transmission, he accounts for by supposing, that they are occasioned by the vibrations of a subtle fluid, in which the ray passes, which happening to move faster than the rays, when a ray is in that part of the vibration which conspires with its motion, it passes through; but when in the contrary part of the vibration, it is heat back again: whence every ray is successively disposed to be easily reflected, or easily transmitted, by every vibration which overtakes it.

He also thought that these vibrations might be excited by the mutual action and re-action of light, of bodies and of this medium, at the instant of reflection or refraction; so that, in fact, he supposes two causes of this disposition to be reflected or transmitted, when rays of light arrive at any new surface. One of them is the regular vibration of the etherial medium, affecting them through the whole of their progress from the luminous body; and the other the tremulous motion, or irregular vibration of the same medium at the surfaces of bodies, occasioned by the action and re-action between light and them: for this last cause can hardly be supposed to affect the whole etherial medium equally, and produce the regular returns of these fits in every ray.

M. Bocovich supposes with Newton, that the fits of reflection or transmission affect the rays themselves, in the whole of their passage from the luminous body, but that they arise from an alteration in their form, by means of the elasticity of their component parts, having been originally driven from the luminous body by a force which acted more strongly on the hinder parts than on the rest of the mass, and thereby put them into a vibratory motion. He also supposes, that the intervals of the fits of easy reflection and transmission may be different in different rays, on the three following accounts. 1. The rays that are differently refrangible have different velocities, at least after refraction; so that, though the fits should return at equal intervals, it will affect different rays in different parts of their progress.

2. The unequal action between the points that compose the same particle of light may make a difference in their oscillations, at the time of changing their medium. And lastly, rays coming in different inclinations to the new surface, the internal motions of these points will be in different directions with respect to the surface, and consequently the whole mass of the medium will act upon all the points differently.

Upon the whole, says Dr. Priestley, is it not more probable that the rays of light are transmitted from the sun, with an uniform disposition to be reflected or refracted, according to the circumstances of the bodies on which they impinge; and that the transmission of some of the rays under the same circumstances, apparently, with others that are reflected, is owing to the minute vibrations of the small parts of the surfaces of the mediums through which the rays pass; vibrations that are independent of action and re-action between the bodies and the particles of light at the time of their impinging, though probably excited by the action of preceding rays. As to the transmission or reflection of certain kinds of light only, producing colours in thin plates, the cause may be this; viz. that every particle of the medium has a great number of equal alternate intervals of attraction and repulsion, relatively to the particles of light; but that these intervals are of different magnitudes, according as the particles of light are of different colours. Now if the thickness of any transparent medium in which the particles of matter are uniformly placed is such, that the attracting intervals of the extreme particles, as well as the repelling intervals, coincide with one another, i.e. attracting with attracting, and repelling with repelling, in regard to any one kind of rays, e.g. the red; by the united force of these extremes, (all the intermediate particles of the medium mutually destroying each other's effects,) these rays will be reflected. But where the plate is of an intermediate thickness between this and the next thickness, where the attracting intervals coincide, attracting with attracting, and repelling with repelling, the attracting intervals will coincide with the repelling ones, and the repelling ones with the attracting ones, and these mutually destroying one another's effects, these rays will pass on freely, and be transmitted. But as the intervals of attraction and repulsion are different for differently coloured rays, the thickness of the plates at which these coincidences will or will not happen, in the differently coloured rays, will be different. So that it appears probable, says Dr. Priestley, in conformity to a doctrine first suggested to him by Mr. Mitchell, that the whole mystery of coloured plates depends upon the attractions and repulsions of the particles of the bodies that compose them, affecting different rays in a different manner, according to their thicknesses.

Sir Isaac Newton concludes his account of the reflection of light with observing, that if light be reflected not by impinging on the solid parts of bodies, but by some other principle, it is probable that as many of its rays as impinge on the solid parts of bodies are not reflected, but flatted and lost in the bodies. Otherwise, he says, we must suppose two kinds of reflection; for should all the rays be reflected which impinge on the internal parts of clear water or crystal, those substances would rather have a cloudy colour than a clear transparency. To make bodies look black, it is necessary that many rays be stopped, retained, and lost in them; and it does not seem probable, that any rays can be stopped and flatted in them, which do not impinge on their parts; and hence, he says, we may understand, that bodies are much more rare and porous than is commonly believed. However, M. Bouguer disputes the fact of light being flatted or lost by impinging on the solid parts of bodies. See Absorbing.

For other facts and observations relating to the subject of this article, see Light. See also Rays of Light, and Rays of Heat.

Reflection, in Optics, is the return of a ray of light from the polished surface of a speculum or mirror, as driven thence by some power refiding in it. The ray, thus returned, is called a reflex, or reflected ray, or a ray of reflection; and the point of the speculum, whence the return commences, is called the point of reflection.

Thus the ray AB (Plate I. Optics, fig. 3.) proceeding from the radiant A, and striking on the point of the speculum B, being returned thence to C, BC represents the reflected ray, and B the point of reflection; in respect of which AB represents the incident ray, or ray of incidence, and B the point of incidence.

Again, a line CG drawn from any point, as C, of the reflected
REFLECTION.

reflected ray BC, perpendicular to the speculum, is called the catenart of reflection, or catenart of the eye: as a line AF, drawn from the radiant perpendicular to the speculum, is called the incidence.

Of the two angles which the reflected ray BC makes with the mirror, the smallest, CBE, is called the angle of reflection: as of the two angles the incident ray makes with the speculum, the smallest, ABD, is called the angle of incidence.

If the mirror be either concave or convex, the smallest angles the ray makes with the tangent to the point of reflection and incidence, are the angles of reflection and incidence.

The angle C BH, which the reflected ray makes with a perpendicular to the point of reflection, is called the inclination of the reflected ray: as the angle A BH is called the inclination of the incident ray.

Reflection. general laws of.—1. If a ray of light be reflected from a speculum of any form, the angle of incidence is ever equal to the angle of reflection. This law obtains in perfections of all kinds of bodies; and consequently must do in those of light. See Laws of Perfection; see also Angle.

It might therefore be here assumed as an axiom: but it is of that importance, and its demonstration so beautiful, that we cannot omit it. Suppose, then, DC (Plate XVII. Optics, fig. 14.) an incident ray, propagated from the radiant D; here, though the motion of the ray be simple, yet its determination in the line DC, being oblique with respect to the obstacle, is really compounded of two determinations: the one along DE, the other along DG.

The force along DC, therefore, is equal to the two forces along DG and DE. For the obstacle GC only opposes one of the determinations: viz. that along DG (for it cannot oppose a determination parallel to itself, as DE); therefore, only the force along DG will be lost by the stroke, that along DH or GC remaining entire. But a body perfectly elasie (such as we suppose the ray of light) will recover by its elasieity the force it lost by the shock.

The ray, therefore, will recover the force DG or CH: thus, retaining both its forces, and both its former determinations DE and CF, after percussion, it will be impelled along CF and CH by the force of the process as before along DH and DG. By its compound motion, therefore, it will describe the right line CE, and that in the same time as DC; and HE and DH will be equal, as being described by the same force. Now, the two triangles DCH and CFE are equal, and consequently their similar angles are equal. Since then HCA = HCF; DCA, the angle of incidence, is equal to ECF; the angle of reflection.

Q. E. D.

This law is confirmed in light by an easy experiment. For a ray of the light falling on a mirror, in a dark room, through a little hole, you will have the pleasure to see it rebound, so as to make the angle of reflection equal to that of incidence. See Camera Obscura.

The same may be shown various other ways: thus, e. g., placing a Lune circle F IG, (Plate I. Optics, fig. 3.) on a mirror DE, its centre on B, and its limb perpendicular to the speculum; and assuming equal arcs, F a and G c, place an object in A, and the eye in C: then will the object be seen by a ray reflected from the point B. And if B be covered, the object will cease to be seen.

For the conclusions drawn from this general doctrine of reflection, see the doctrine of Mirrors, &c.

II. Each point of a speculum reflects rays falling on it, from each part of an object. See the doctrine of Mirrors, &c.

III. If the eye C, and the radiant point A, change places, the point will continue to radiate upon the eye, in the same course or path as before.

For if the object be removed from A to C, it will fall on its former point of reflection, B; but there can be but one right line drawn between the two points G and D; and the rays are right lines. Therefore, that which was before the ray of reflection, will now be the ray of incidence; and since it will be reflected under the same angle as that under which it fell, that which was before the ray of reflection, will now be the ray of reflection. So that the object removed to C, will radiate on the eye placed in A, by the right lines CB and BA. Q. E. D.

Hence, an object is seen by the reflected ray AB, with the eye placed in A, the same as if the eye were in C, and the object in A.

The truth of this theorem is so easily confirmed by experiment, that some, with Euclid, assume it as a principle, and demonstrate the great law of reflection from it. Thus: suppose the angle of incidence a little greater than the angle of reflection; then will the angle ABE be greater than the angle CBE. Therefore, changing the places of the eyes and the object, the angle CBE will become the angle of incidence, and therefore CBE greater than ABE by the supposition. So that the same angle ABE will be both greater and smaller than the other, CBE; which being absurd, ABE cannot be greater than CBE. The same absurdity will follow, if you suppose the angle of incidence less than the angle of reflection. Since then the angle of incidence can neither be greater nor less than that of reflection, it must be equal to it.

IV. The plane of reflection, that is, the plane on which the incident and reflected rays, and also the angles of incidence and of reflection, are found, is perpendicular to the surface of the speculum; and in spherical specula, it passes through the centre.

Hence the catenart, both of incidence and reflection, is in the plane of reflection.

That the plane of reflection is perpendicular to the speculum, is allowed by Euclid, Alhazen, and others, as a principle, without any demonstration; as being evident from all observation and experiment.

V. The image of an object seen in a mirror is in the catenart of incidence. This the ancients assumed as a principle; and hence, since the image is certainly in the reflected ray, as they inferred, it must appear in the point of concourse of the reflected ray, with the catenart of incidence; which indeed holds universally in plane and spherical mirrors, and usually also in concave ones, a few cases only excepted, as is shown by Kepler.

For the particular laws of reflection, arising from the circumstances of the several kinds of specula, or mirrors, plane, concave, convex, &c. see them laid down under the article Mirror.

Reflection, Caustic by. See Caustic Curve.

Reflection of Cold. See Cold.

Reflection of Sound. See Sound.

Reflection of the Moon, is a term used by some authors for what we otherwise call her variation, being the third inequality in her motion, by which her true place out of the quadratures differs from her place twice equated. See Moon and Variation.

Reflection is also used, in the Copernican system, for the distance of the pole from the horizon of the sun; which
which is the same thing as the sun’s declination in the Ptolemaic system.

Reflection is also used figuratively for an operation of the mind, by which, turning as it were back upon itself, it makes itself, and its own operation, its object; and considerers or contemplators the manner, order, and laws, which it observes in perceiving, reasoning, willing, judging, doubting, believing, &c. and frames itself new ideas of the relations discovered in them.

REFLECTOIRE CURVE. See Curve Reflectoire.

REFLECTOR for Light-houses, a combination of a number of square plain glass mirrors, resembling those with which Archimedes is said to have burnt the Roman fleet at the siege of Syracuse. (See Burning-Glass.) Each of these mirrors is about an inch square; and they are all arranged close to each other in the concave of a parabolic form formed of flucco, which has been found to answer the purpose best. The idea of thus illuminating light-houses, instead of using coal-fires, in this country, without any previous knowledge of a similar method practised in France, was first suggested by Mr. Ezekiel Walker, of Lynn Regis, who made, and fixed up reflectors under his direction, in a light-house on the coast of Norfolk, in the year 1779. Accordingly, in the year 1787, at the request of the trustees appointed by act of parliament for erecting four light-houses in the northern parts of Great Britain, he instructed Mr. Thomas Smith, tin-plate worker, of Edinburgh, to whom the original invention is erroneously ascribed in the supplement to the Encyclopædia Britannica, in this mode of constructing light-houses. His parabolic moulds are from three to five or six feet in diameter; and in the centre of each is placed a long shallow lamp of tin-plate, filled with whale-oil. In each lamp are flaxen wicks, almost contiguous to one another, so disposed as to burn without trimming for six hours. The light of these is reflected from each mirror spread over the concave surface, and is thus multiplied, as it were, by the number of mirrors. The flucco moulding is covered with the tin-plate, from which a tube, immediately over the lamp, proceeds to the roof of the light-room, and serves as a funnel, through which the smoke escapes without fouling the faces of the mirrors. The light-room is a cupola or lantern of from eight to twelve sides, composed entirely of glasses, fixed in cast iron frames or slates, and roofed with copper. On circular branches passing round the inside of this lantern, at about 18 inches from the glass frames, are placed the reflectors with their lamps, so as that the concave surfaces of two or three of the reflectors meet every point of the compacts, and throw a blaze of light in all directions. In the roof, immediately over the centre of the room, is a hole, through which pass all the funnels already mentioned, and which serves likewise to admit fresh air to the lamps. This light-room is firmly fixed on the top of a round tower, so as to be immovable by the weather; and the number of the reflectors, and the height of the tower, are less or greater according as it is intended that the light should be seen at a less or a greater distance. Experience, it is said, has obviated several objections to which light-houses of this kind were thought to be liable; and it has been found that light-houses, with lamps and reflectors, are, in every point of view, preferable to those with fires burning in the air. They are supported at a much less expense; their light is more brilliant, and seen at a greater distance, whilst it can never be obscured by smoke, or beaten down, on the lee-side, by a violent gale of wind; and they may be so variously placed, that one light-house cannot be mistaken for another. Besides, the lamps do not need trimming so often as open fires require fuel, and the man who attends them is never exposed either to cold or wet in the performance of his duty, so that they are less likely to be neglected in stormy weather than those with open fires.

It has been proposed to make the concave surface of the paraboloe one speculum of metal, instead of covering it over with a number of plain glass mirrors; or to diminish the size of each mirror, if it be thought best to retain them instead of introducing the speculum. To this proposed alteration it has been objected, that the brightest metal does not reflect such a quantity of light as well foliated clear glasses; and by diminishing the size of the mirrors, the number of joinings would be increased, in each of which some light is lost, not merely in the beam, but from its being almost impossible to foliate glasses perfectly at its edge.

REFLEX, Reflect, in Painting, is understood of those places in a picture which are supposed to be illuminated by a light reflected from some other body represented in the same piece. Or, reflectors may be defined those places which, besides the general light that illuminates the whole piece, receive some particular light from their situation with respect to some more illuminated polished body, that reflects part of the rays it receives upon them.

Reflectors are feecely sensible, except in the shadowed parts. The management of the reflectors requires great accuracy and skill. All reflected light is supposed to carry with it part of the colour of the body which reflects it; so that those places which receive this light, must have their colour mixed or tinged with that colour. But the same place may receive reflectors from different objects, differently coloured, and those again reflectors from others. The painter, therefore, must have a view to every circumstance of the colour, light, and position of each figure; he must consider what effect each has on others, and pursue nature through all the variety of mixtures. See Clair-obscure, and Light.

REFLEX Shadow, or REFLECTED vision, is that performed by means of rays reflected from the polished surfaces of objects to the eye.

Reflex vision is the subject of catoptrics. Under reflex vision come all the phenomena of specula or mirrors of all kinds.

REFLEXIBILITY of the Rays of Light, is that property by which they are disposed to be reflected. See Reflection.

Or, it is their disposition to be turned back into the fame medium, from any other medium on whose surface they fall; hence those rays are said to be more or less refrangible, which are returned back more or less easily under the same incidence.

Thus, if light passes out of glass into air, and by being inclined more and more to the common surface of the glass and air, begins at length to be totally reflected by that surface, those forts of rays which at like incidences are reflected most copiously, or the rays which, by being inclined, begin soonest to be totally reflected, are the most refrangible rays.

That rays of light are of different colours, and endued with different degrees of reflectibility, was first discovered by Sir Isaac Newton; and is shewn by the following experiment. Applying a prism D F E (Plate XVII. Optics, fig. 15.), whose angles are each 45°, to the aperture C of a darkened room, in such manner as that the light is reflected from the base in G; the violet rays are seen first reflected into H G; the other rays continuing still refracted in I K. After the violet the blue are all refracted, the green, &c.
REFLEXION. See Reflection.

REFLEXITY, a term employed by Mr. Brougham to denote a property of light, which causes the different rays to be acted upon by bodies, and to begin to be refracted, reflected, inflected, and deflected, at different distances. This property observes the same law with the other optical properties of light; the red ray having most reflexity, and the violet the least. (See Phil. Trans. for 1797, p. 360.) Mr. Brougham has expressed this property by the three words, "refrangibility," "reflectivity," and "flexity?" but the power being the same, if such a property exist, different names seem to be unnecessary.

REFLUX of the Sea, the ebbing of the water; or its return from the shore. It is thus called, as being the opposite motion to the flood, or flux. See Tide.

REFORM, a re-establishment, or revival of former neglected discipline; or a correction of some reigning abuses in it.

The term is much used in a monastic sense, for the reducing an order or congregation of religious to the ancient severity of the rule from which it had gradually swerved; or even for the improving on the ancient rule and institution itself, and voluntarily making it more severe.

In this sense the order of St. Bernard is said to be only a reform of that of St. Benedict.

To Reform, in a Military Sense, is, after some evolution or manoeuvre, to bring a line to its natural order, by aligning it on some given point. See Battalion.

To Reform, is also to reduce a company, regiment, or other body of men, either by disbanding the whole, or only breaking a part, and retaining the rest; or sometimes by incorporating them with other regiments. Hence, Reformed, one who has submitted to a change of plan, or has conformed to a new system.

REFORMADO, or Reformed officer, one whole troop or company is suppressed in a reform, whilst he is continued either in whole or half-pay, doing duty in the regiment. A reformed captain of foot follows the company, and assists the standing officer as a second; but he still maintains his degree and precedence.

REFORMATION, the act of reforming, or correcting an error, or abuse, in religion, discipline, or the like.

The reformation of religion, called, by way of eminence, the Reformation, was begun by the elector of Saxony, at the solicitation of Luther, about the beginning of the sixteenth century. See Luther and Lutheranism.

There were many circumstances which conurred at this time to bring about that happy reformation in religion, which rescinded one part of Europe from the papal yoke, mitigated its rigour in the other, and produced a revolution in the sentiments of mankind, the greatest as well as the most beneficial that has happened since the publication of Chrifiianity. How far the sale of indulgences, published by Leo X., contributed to this event, we have already thrown under the article Luther. We shall here observe, that the same corruptions in the church of Rome which Luther condemned, had been attacked long before his appearance, and the same opinions which he propagated had been published in different places, and supported by the same arguments. Waldus in the 12th century, Wickliffe in the 14th, and Hus in the 15th, had inveighed against the errors of Popery with great boldness, and confuted them with more ingenuity and learning than could have been expected in those illiterate ages in which they flourished. But all these premature attempts towards a reformation proved abortive.

Many powerful causes contributed to facilitate Luther's progress, which either did not exist, or did not operate with full force in their days: the principal of these we shall here enumerate. The long and scandalous fechism which divided the church, during the latter part of the 14th, and the beginning of the 15th centuries, had a great effect in diminishing the veneration with which the world had been accustomed to view the papal dignity. The proceedings of the councils of Conjiance and Bail spread this disrepute for the Romish See still wider, and by their bold exertion of authority in deposing and electing popes, taught the world that there was in the church a jurisdiction superior even to the papal power, which they had long believed to be supreme. The wound given on that occasion to the papal authority was fearfully healed, when the pontificates of Alexander VI. and Julius II. both able princes, but detestable ecclesiastics, raised new scandal in Christendom. Besides, many of the dignified clergy, secular as well as regular, neglected the duties of their office, and indulged themselves, without referve, in all the vices to which great wealth and idlenes naturally give birth; and gross ignorance and low debauchery rendered the inferior clergy as contemptible as the others were odious. So that we find, long before the 16th century, that many authors of reputation give such description of the difflcult morals of the clergy, as seems almost incredible in the present age. The scandal of those crimes, which very generally prevailed, was greatly increased by the facility with which such as committed them obtained pardon. The exorbitant wealth of the church, the vilt personal immunities of ecclesiastics, and their encroachments on the jurisdiction of the laity, and their various devices to secure their usurpations, created much dissatisfaction among the people, and disposed them to pay particular attention to the invecives of Luther. Besides these causes of his rapid progress, we may also reckon the invention of the art of printing, about half a century before his time, the revival of learning at the same period, and the bold spirit of inquiry which it excited in Europe; so that many were prepared to embrace his doctrines, who did not truly with successe to his undertaking. In the writings of Reuchlin, Hutten, and the other revivers of learning in Germany, the corruptions of the church of Rome are censured with an acrimony of style and inferior to that of Luther himself. The ralillery and oblique cenures of Erasmus in particular, upon the errors of the church, as well as upon the ignorance and vices of the clergy, prepared the way for Luther's invecives and more direct attacks. To all which we may add, that the theological doctines of Popery were so repugnant to the spirit of Chrifiianity, and so detestable of any foundation in reason, in the word of God, or in the practice of the church, that this circumstance combined in favouring the progress of Luther's opinions, and in weakening the resistence of his adversaries.

The rife of the reformation in Switzerland was at least as early as in Germany; for Ulric Zwingle had, in the year 1516, begun to explain the scriptures to the people, and to cenure, though with great prudence and moderation, the errors of a corrupt church. He had very noble and extensive ideas of a general reformation, at the time when Luther retained almost the whole viglem of Popery, indulgences excepted; and he had actually called in question the authority and supremacy of the pope, before the name of Luther was known in that country. In the year 1524, Nuremberg, Francfort, Hamburgh, and several other cities in Germany, of the first rank, openly embraced the reformed religion, and by the authority of their magistrates abolished the
the maus, and the other superfluous rites of Popery. The elector of Brandenburgh, Saxony, the marquis of the landsgrave of Helft, the dukes of Brunfick and Lunenburgh, and prince of Anhalt, became arroved patrons of Luther's opinions; and counseled the preaching of them among their subjects. The reformers derived great advantage from the transafions of the diet at Nuremberg, which preferred to the pope a catalogue of a hundred grievances, which the empire imputed to the iniquitous dominion of the papal see. The progress of the reformation in Germany was likewise promoted by the proceedings of the diet held at Spire in the years 1526 and 1529. See Luther and Protestants.

During these transafions in Germany, the dawn of truth arose upon other nations. The light of the reformation spread itself far and wide; and almost all the European states welcomed its salutary beams, and exulted in the prospect of an approaching deliverance from the yoke of superfluous and spiritual despotism. Some of the most considerable provinces of Europe had already broke their chains, and openly withdrawn themselves from the discipline of Rome and the jurisdiction of its pontiff. The reformed religion was propagated in Sweden, soon after Luther's rupture with Rome, by Olaus Petri, one of his disciples, who was counsenaed and encouraged by the valiant and public-spirited prince Gustavus Vasa Erichson, to whose firmness and magnanimity it was owing, that from the year 1527 the papal empire in Sweden was entirely overthrown, and Gustavus declared head of the church. The light of the reformation was also received in Denmark so early as the year 1521, in conseqence of the ardent desire discovered by Chriilian or Christian II., for purposes of mere ambition, of having his disciples instructed in the doctrines of Luther. His successor Frederic, duke of Holstein and Silecia, contributed greatly to the progress of the reformation, by his successful attempts in favour of religious liberty, at the assembly of estates that was held at Odensee, in the year 1527, when he procured the publication of the famous edict which declared every subject of Denmark free, either to adhere to the tenets of the church of Rome, or to embrace the doctrine of Luther; that no person should be molested on account of his religion; that a royal protection should be granted to the Lutherans; and that ecclesiastics of every order should be allowed to marry. But the honour of accomplishing this glorious work was reserved for Chriilian III. a prince equally distinguished by his piety and prudence. The religious doctrine, discipline, and worship of this kingdom, were settled according to a plan laid down by Bugenhagins. And the assembly of the estates at Odensee, in 1539, gave a solemn fann to all these transafions, and thus the work of reformation was brought to perfection in Denmark.

In the same year the reformation was established in every part of Saxony. Upon the death of George, duke of Saxony, who was an inverteate enemy to the reformation, the succession fell to his brother Henry, whose attachment to the Protestant religion surpassed, if possible, that of his predecessor to Popery. Henry invited some Protestant divines, and among them Luther himself, to Leipzig; and by their advice and assistance, he learned, in a few weeks, the whole system of ancient rites, establishing the full exercice of the Protestant religion, with the universal applause of his subjects, who had long wished for this change, which the obstinacy of their former duke had alone prevented. This revolution delivered the Protestants from the danger to which they were exposed by having an inverteate enemy settled in the middle of their territories; and their dominions now extended in a great and almost unbroken line from the shore of the Baltic to the banks of the Rhine.
their decrees; and the Protestant princes in the diet of Ratibion protested against their authority; and were, in consequence of this, proffered by the emperor, who raised an army to reduce them to obedience. Thus commenced the war of Smalcald, which was prosecuted with various success on both sides, till, in the year 1552, Charles was surprised at Infruprick by Maurice of Saxony, and was constrained to conclude with Paffau the famous treaty of pacification, (which fee,) with the Protetants, which is considered by those of Germany as the basis of their religious liberty; and to promise in six months to assemble a diet, in which all the tumults and diffentions, that had been occasioned by a variety of sentiments in religious matters, should be entirely removed. This diet, though not assembled at the stipulated time, met, however, at Augsburg, in the year 1555, and terminated those deplorable scenes of bloodshed, defolation, and discord, that had so long afflicted both church and state by that religious peace, as it is commonly called, which secured to the Protetants the free exercise of their religion, and established this incontestable liberty upon the firmest foundations.

For, after various debates, the following memorable acts were passed; that the Protetants who followed the confession of Augsburg, should for the future be considered as entirely exempted from the jurisdiction of the Roman pontiff, and from the authority and superintendance of the bishops; that they were left at perfect liberty to enact laws for themselves, relating to their religious sentiments, discipline, and worship; that all the inhabitants of the German empire should be allowed to judge for themselves in religious matters, and to join themselves to that church whose doctrine and worship they thought the purest and most consonant to the spirit of Christianity; and that all those, who should injure or persecute any person under religious pretences, and on account of their opinions, should be declared, and proceeded against, as public enemies of the empire, invaders of its liberty, and disturbers of its peace.

In the year 1533, Henry VIII. king of England, who, in the beginning of these troubles, had opposed the doctrine and views of Luther with the utmost vehemence, partly because he had spokken with contempt of Thomas Aquinas, the king's favourite author, having sued for a divorce from Catharine of Aragon, his brother's widow, at the court of Rome, for almost six years, during which period Clement VII. negotiated, promised, retracted, and concluded nothing, determined to apply to another tribunal for that decree which he had unsuccessfully solicited at Rome. Cranmer, archbishop of Canterbury, by a sentence founded on the authority of universitieS, doctors, and rabbles, who had been consulted with respect to the point, annulled the king's marriage with Catharine; and Anne Boleyn, whose charms had captivated the king, was acknowledged as queen of England. Clement, apprehensive left England would revolt from the holy see, determined to give Henry such satisfaction as might still retain him within the bosom of the church. But the violence of the cardinals precipitated him, in 1534, to infus a bull reconding Cranmer's sentence, confirming Henry's marriage with Catharine, and declaring him excommunicated, if, within a time specified, he did not abandon the wife he had taken, and return to her whom he had deserted. Enraged at this unexpected decree, Henry kept no longer any measures with the court of Rome; his subjects feconded his resentment; an act of parliament was passed, abolishing the papal power and jurisdiction in England; by another the king was declared supreme head of the church, and all the authority of which the popes were deprived was vested in him; the monasteries, (which fee,) were suppressed, and their revenues applied to other purposes.

The people had been gradually prepared for this great innovation. Each succeeding session of parliament had made some retribution from the power and profits of the Roman pontiff. Care had been taken, during some years, to teach the nation that a general council was more superior to a pope. But now a bishop preached every Sunday at Paul's Cross, in order to inculcate the doctrine, that the pope was entitled to no authority at all beyond his own diocese.

The laws passed during this session (1534) sufficiently evince, that the king was determined not to surrender any part of his assumed prerogative. All payments made to the apostolic chamber: all provisions, bulls, dispensations, were abolished: monasteries were to be subjected to the regulation and government of the king alone: the law for punishing heretics was moderated: the ordinary was prohibited from imprisoning or trying any person upon suspicion alone, without prementment by ten lawful witnesses: and it was declared that to speak against the pope's authority was no heresy: bishops were to be appointed by a coué d'élire from the crown, or, in case of the dean and chapter's refuful, by letters patent; and no recourse was to be had to Rome for palls, bulls, or provisions. Campagagio and Ghinucci, two Italians, were deprived of the bishoprics of Salzburg and Worzelter, which they had hitherto enjoyed: the law which had been formerly made against paying annats, or first fruits, but which had been left in the king's power to suspend or continue, was finally established: and a submission which was exacted two years before from the clergy, and which had been obtained with great difficulty, received this session the sanction of parliament. In this submission, the clergy acknowledged that convocations ought to be assembled by the king's authority only: they promised to enact no new canons without his consent: and they agreed that he should appoint 32 commissioins, in order to examine the old canons, and abrogate such as should be found prejudicial to his royal prerogative. An appeal was also allowed from the bishop's court to the king in chancery. But the most important act passed this session, was that which regulated the succession to the crown: the marriage of the king with Catharine was declared unlawful, void, and of no effect: the primates sentence annulling it was ratified; and the marriage with queen Anne was established and confirmed. The crown was appointed to descend to the issue of this marriage, and falling there, to the king's heirs for ever. An oath was likewise enjoined to be taken in favour of this order of succession, under the penalty of imprisonment during the king's pleasure, and forfeiture of goods and chattels: and all lados against the king, queen, or their issue, was subjected to the penalty of misprision of treason. These several acts, so contemptuous towards the pope, and so destructive of his authority, were passed at the very time that Clement pronounced his faithful sentence against the king. The king found his ecclesiastical subjects as compliant as the laity. The convocation ordered that the act against appeals to Rome, together with the king's appeal from the pope to a general council, should be affixed to all the doors of all the churches in the kingdom; and they voted that the bishop of Rome had, by the laws of God, no more jurisdiction in England than any other foreign bishop; and that the authority which he and his predecessors had there exercised, was only by usurpation, and by the suavishment of English princes. The bishops went so far in their compliance, that they took out new commissioins from the crown, in which all their spiritual and episcopal authority was expressly affirmed to be derived ultimately from the civil magistrate, and to be entirely dependent on his good pleasure.

Henry,
REFORMATION.

Henry, however, with the caprice peculiar to his character, continued to defend the doctrines of the Romish church as fiercely as he attacked their jurisdiction. He alternately perverted the Protestants for rejecting the former, and the Catholics for acknowledging the latter.

Nothing more forwarded the first progress of the reformers, than the offer which they made, of submitting all religious doctrines to private judgment, and the summons given every one to examine the principles formerly imposed upon them. And what can be more just and reasonable? and yet the multitude, says Mr. Hume, were totally unqualified for this undertaking, though they were highly pleased with it. They fancied that they were exercising their judgment, while they opposed to the prejudices of ancient authority more powerful prejudices of another kind. The novelty itself of the doctrines; the pleasure of an imaginary triumph in dispute; the servent zeal of the reformed preachers; their patience, and even alacrity, in suffering persecution, death, and torments; a disgust at the refrains of the old religion; an indignation against the tyranny and interested spirit of the ecclesiastics:—these motives, says the same historian, whilst, as some may imagine, he is deprecating the principles of the reformation, were prevalent with the people; and by such considerations were men so generally induced, during that age, to throw off the religion of their ancestors. In proportion, says the same author, as the practice of submitting religion to private judgment was acceptable to the people, it appeared, in some respects, dangerous to the rights of sovereigns, and seemed to destroy that implicit obedience on which the authority of the civil magistrate is chiefly founded. When some Englishmen, such were Tindall, Joye, Constanine, and others, retired to Antwerp, through fear of the exertion of the king's authority, they employed themselves in writing English books against the corruptions of the church of Rome; against images, relics, and pilgrims; and they excited the curiosity of men with regard to that question, which is the most important in theology, the terms of acceptance with the Supreme Being. These books, having been secretly conveyed to England, began to make converts everywhere; but it was a translation of the scriptures by Tindall that was esteemed the most dangerous to the established faith. Against Wolsey, a favourite minister of Henry VIII., it was one article of impeachment, that, by his conneivation, he had encouraged the growth of heresy, and that he had protected and acquitted some notorious offenders. Wolsey was succeeded in the office of chancellor by Sir Thomas More, who, irritated by polemics, became so fanatically attached to the ancient faith, that few inquisitors have been guilty of greater violence in their prosecution of heresy. Several persons were not only brought into the courts for heretical offenses, such as teaching their children the Lord's prayer in English, for reading the New Testament in that language, or for speaking against pilgrimages; and others were charged with the capital offenses of harbousing perjured preachers, neglecting the faults of the church, and declining all the vices of the clergy. Some were tried, condemned, and committed to the flames. Notwithstanding the inconfident conduct of Henry, his subjects having been encouraged, by his example, to break some of their fetters, were so impatient to shake off all that remained, that in the following reign, under his son Edward VI., with the general applause of the nation, a total separation was made from the church of Rome in articles of doctrine, as well as in matters of discipline and jurisdiction. (See Articles.) In 1553, his death retarded the progress of the reformation; but his sister Mary, who succeeded him, imposed a new the arbitrary laws and tyrannical yoke of Rome upon the people of England. But the execution of a great number of persons, who were burnt for the Protestant faith in the five years of her perverting and bloody reign, so alienated the people from Poper, that queen Elizabeth, her daughter, found it no hard matter to deliver her subjects from the bondage of Rome, and to establish that form of religious doctrine and ecclesiatical government, which still subsists in England.

The seeds of the reformation were very early sown in Scotland, by several noblemen of that nation, who had reigned in Germany during the religious disputes that divided the empire. The first and most eminent opposer of the Papal jurisdiction was John Knox, a disciple of Calvin, who fled from Geneva for Scotland in 1550, and in a little while prevailed with the greatest part of the Scotch nation entirely to abandon the superstitions of Rome, and to aim at nothing less than the total extirpation of Poper. In the following year, viz. 1550, the parliament ratified a confession of faith, agreeable to the new doctrines, and passing a statute against the mafs, not only abolished it in all the churches, but enacted, that whoever, any where, either officiated in it, or was present at it, should be shot, for the first offence, with consecration of goods, and corporal punishment, at the discretion of the magistrate; for the second, with banishment; and for the third, with loss of life. A law was also voted for abolishing the Papal Jurisdiction in Scotland; the Presbyterian form of discipline was settled, leaving only at first some shadow of authority to certain ecclesiastics, whom they called superintendents. From that period to the present times the form of doctrine, worship, and discipline, that had been established at Geneva by the ministry of Calvin, has been maintained in Scotland with invincible obstinacy and zeal; and every attempt to introduce, into that kingdom, the rites and government of the church of England, has proved inept and unsuccessful. See Presbyterians.

The cause of the reformation in Ireland underwent the fame vicissitudes that had attended it in England. When Henry VIII., after the abolition of the Papal authority, was declared supreme head of the church of England, George Brown, a native of England, and a monk of the Augustinian order, whom that monarch had created, in the year 1535, archbishop of Dublin, began to act with the utmost vigour, in conformance of this change in the hierarchy. He purged the churches of his diocese from superstition in all its forms, pulled down images, destroyed relics, abolished abury and idolatrous rites, and, by the influence as well as authority he had in Ireland, caufed the king's supremacy to be acknowledged in that nation. Henry showed soon after, that this supremacy was not a vain title; for he banished the monks out of that kingdom, confiscated their revenues, and destroyed their convents. In the reign of Edward VI. farther progress was made in the reformation, but the accession of Mary retarded it, in consequence of which Brown and other Protestant bishops were deprived of their dignities in the church. When Elizabeth ascended the throne, the Irish were again obliged to submit to the form of worship and discipline established in England.

The reformation had not been long established in Britain, when the Belgic provinces, united by a respectable confederacy which still subsists, withdrew from their spiritual allegiance to the Roman pontiff. The means which Philip II. of Spain used to obstruct the reformation, promoted it: the nobility formed themselves into an association, in the year 1566, and roused the people; who, under the heroic conduct of William of Nassau, prince of Orange, seconded by the succours of England and France, delivered this state from
from the Spanish yoke: in consequence of which the reformed religion, as it was professed in Switzerland, was established in the United Provinces; and, at the same time, an universal toleration granted to those whose religious sentiments were of a different nature, whether they retained the faith of Rome, or embraced the reformation in another form, provided that they made no attempts against the authority of the government, or the tranquility of the public.

Whilst Mr. Hume attributes the quick and surprizing progress of the reformation in part to the late invention of printing, and revival of learning, he denies that reason had any considerable share in opening men's eyes with regard to the impostures of the Romish church; alleging that philosophy had made little progres, at least not till long after the period of the reformation, and that no indifference occurs in which argument has ever been able to free the people from that enormous load of absurdity with which superstition has every where overwhelmed them: to which he adds, that the rapid advance of the Lutheran doctrine, and the violence with which it was embraced, prove sufficiently that it owed not its success to reason and reflection. The art of printing, and the revival of learning, he says, forwarded its progress in another manner. By means of that art, the books of Luther and his sectaries, full of vehemence, declamation, and a rude eloquence, were propagated more quickly, and in greater numbers. The minds of men, somewhat awakened from a profound sleep of so many centuries, were prepared for every novelty, and scrupled less to tread in any unusual path which was opened to them. And as copies of the scriptures, and other ancient monuments of the Christian faith, became more common, men perceived the innovations which were introduced after the first century; and though argument and reasoning could not give conviction, an historical fact, well supported, was able to make impression on their understandings. As the ecclesiastics would not agree to poffefs their privileges, though ancient and prior to almost every political establishment in Europe, as matters of civil right, which time might render valid, but appealed still to a divine right, they thus tempted men to look to their primitive charter, which, with little difficulty, they could perceive to be defective in truth and authenticity. Besides, Luther and his followers, not satisfied with oppoiting the pretended divinity of the Romish church, and displaying the temporal inconveniences of that establishment, proceeded to treat the religion of their ancillors as abominable, detestable, and damnable; foretold by sacred writ itself as the source of all wickedness and pollution. They denominated the pope antichrist, called his communion the scarlet whore, and gave to Rome the appellation of Babylon; expressions which, however applied, were to be found in scripture, and which were better calculated to operate on the multitude than the most solid arguments. Excited by contlct and persecution on the one hand, by succefs and applause on the other, many of the reformers carried to the greatest extremities their opposition to the church of Rome; and in contradiction to the multiplied superstitions with which that communion was loaded, they adopted an enthusiastic ftrain of devotion, which admitted of no observances, rites, or ceremonies, but placed all merit in a mysterious species of faith, in inward vifion, rapture, and ecftacy. The new fectaries, feized with this spirit, were indefatigable in the propagation of their doctrine, and yet at defiance all the anathemas and punifhments with which the Roman pontiff endeavoured to overthrow them.

Thus, in terms which appear to us too disparaging, does our historian describe the origin and progrefs of the reformation; nor does he pay due reftpect to the principles on which it was founded, and to the character of the persons who were the principal agents in accomplishing it. We are ready to acknowledge, that the collateral circumstances above recited rendered its advances more rapid and more extensive; but we cannot allow that it did not owe much of its succces to reafon and reflection. But whatever may be our opinion of the primary causes that produced it, its influence on the minds and manners of mankind, on the state of society in general, and on the interests of liberty, religion, and virtue, has been eminently and extensively beneficial. Luther had no sooner begun to attack the papal supremacy, than the charm, which had bound mankind for fo many ages, was broken at once. The human mind, which had long continued as tame and passive, as if it had been taught to believe whatever was taught, and to bear whatever was imposed, rofcd of a fudden, and became inquisitive, mutinous, and difdainful of the yoke to which it had hitherto submitted. The reformation, wherever it was received, increased that bold and innovating spirit to which it owed its birth. Men who had the courage to overturn a fystem, supported by every thing which can command respect or reverence, were not to be overawed by any authority, how great or venerable forever. After having been accustomed to consider themselves as judges of the most important doctrines in religion, to examine these freely, and to reject, without scruple, what appeared to them erroneous, it was natural for them to turn the fame daring and inquisitive eye to government, and to think of rectifying whatever disorders or imperfections were discovered there. As religious abuses had been reformed in feferal places, without the permission of the magistrate, it was an easy transition to attempt the redif of political grievances in the fame manner. But though the spirit of innovation, that was excited and promoted by the reformation, might in fome inffances prove the occasion of turbulence and tumult, the good that eventually accrued from its operation far exceeded the partial and temporary evil that resulted from it. The prevalence of this spirit was fo general, that it must have been excited by caufes that were natural, and of powerful efficacy; and the confequences that flowed from them must have been as important and interefting as the caufes that produced them. The kingdoms of Denmark, Sweden, England, and Scotland, and almost one half of Germany, threw off their allegiance to the pope, abolished his jurisdiction within their territories, and gave the fanaclion of law to modes of discipline and fylltems of doctrine, which were not only independent of his power, but hostile to it. Nor was this spirit of innovation confined to those countries which openly revolted from the pope; it spread through all Europe, and broke out in every part of it with various degrees of violence. It penetrated early into France, and made fuch rapid progrefs, that the number of converts to the opinions of the reformers was fo great, their zeal fo enterprising, and the abilities of their leaders fo distinguished, that they soon ventured to contend for superiority with the refolid church, and were sometimes on the point of obtaining it. In all the provinces of Germany which continued to acknowledge the papal supremacy, as well as in the Low Countys, the Protestant doctrines were secretly taught, and had gained fo many profelytes, that they were ripe for revolt, and were restrained merely by the dread of their rulers from imitating the example of their neighbours, and affifting their independence: hence in Spain and Italy, symptoms of the fame disposition to shake off the yoke appeared. The pretentions of the pope to infallible knowledge and supreme power were treated by many persons of eminent learning and abilities with fuch fcorn, or impugned with
with such vehemence, that the most vigilant attention of the civil magistrate, the highest strains of pontifical authority, and all the vigour of the inquisitorial jurisdiction, were requisite to check or extinguisht it. The defection of so many opulent and powerful kingdoms from the papal see was a fatal blow to its grandeur and power, and produced a very considerable diminution of its revenues. It likewise obliged the Roman pontiffs to adopt a different system of conduct towards the nations which continued to recognize their jurisdiction, and to govern them by new maxims, and with a milder spirit. They became afraid of venturing upon any such exertion of their authority as might alarm or exasperate their subjects, and excite them to a new revolt. Hence it happens, that the popes, from the era of the reformation, have ruled rather by address and management than by authority. They have been obliged not only to accommodate themselves to the notions of their adherents, but to pay some regard to the prejudices of their enemies. In process of time, and before the convulsions which have lately agitated Europe, they sunk almost to a level with the other petty princes of Italy; and they hardly retain any shadow of the temporal power which they anciently possessed. Nevertheless, whilst the reformation has been fatal to the power of the popes, it has contributed to improve the church of Rome both in science and in morals. Many motives have arisen out of the reformation, and the existence of two rival churches, which have served to engage the Catholic clergy to apply themselves to the study of useful science, and to pay a strict attention to the manners of their clergy. In those countries where the members of the two churches have mingled freely with each other, or have carried on any considerable intercourse, either commercial or literary, an extraordinary alteration in the ideas, as well as in the morals, of the Popish ecclesiastics is manifest. The beneficial influence of the reformation has not only been felt by the clergy, and the inferior members of the Roman Catholic church; but it has extended to the see of Rome, and to the sovereign pontiffs themselves, whose character, at a later period, has been very different from that of several of their predecessors. Many of them have been conspicuous for the virtues becoming their high station; and by their humanity, their love of literature, and their moderation, have made some atonement to mankind for the crimes of those who in former times occupied their places. Thus the reformation has eminently contributed to increase purity of manners, to diffuse science, and to inspire humanity. With the progress of the reformation we may also connect a variety of other important benefits, both to individuals and to society; and as they pertain to the investigation of truth and the improvement of science, to the promotion of liberty both civil and religious, to the diffusion of knowledge and virtue, and to the advancement of the civil interests of mankind. But the details of the advantages resulting from the reformation to nations and private persons, to religion in general, and genuine Christianity in particular, would far exceed the limits to which we are confined.

See, on the subject of this article, Robertson's Hist. of Charles V. vol. ii. p. 113, &c. vol. iii. p. 44, &c. Muheim's Eccl. Hist. Eng. ed. 8vo. vol. iii. Burnet's Hist. of the Reformation, 2nd ed. For a comprehensive, and, upon the whole, a just sketch of the predisposing causes, and beneficial consequneces of the reformation, we refer the reader to a work which obtained the prize proposed by the National Institute of France, 15th of Germinal, in the year X. viz. "What has been the influence of the reformation by Luther on the political situation of the different states of Europe, and on the progress of knowledge?" The work is entitled "An Essay on the Spirit and Influence of the Reformation by Luther," by C. Villiers. We have two English translations, one by B. Lambert, and the other by James Mill, 8vo. 1805.

Reformation, Right of, jus reformationis, is a right which the princes of Germany claim to reform the church in their respective territories; as being involved with the spiritual as well as the temporal power.

The jus reformationis is annexed to the sovereignty; by this they have the power of conscience, the disposition of ecclesiastical revenues, &c. as they enjoyed the same at the treaty of Munster in 1624.

Reformation of Images, in Optics. See Anamorphosis.

Reformed Calendar and Church. See the subjacent.

Reformed Office. See Reformado.

Refracted Angle, in Optics, the angle contained between the refracted ray and the perpendicular.

Refracted Dials, are such as shed the hour by means of some refracting transparent fluid. See DIALS, Refracted.

Refracted Ray, or ray of refraction. See Ray and Refraction.

Refracted Vision. See Vision.

Refracting Telescope. See Telescope.

Refraction, Refractio, in Mechanics, the deviation of a moving body from its direct course, by reason of the different density of the medium it moves in; or a flexion and change of determination, occasioned by a body’s falling obliquely out of one medium into another of a different density.

Thus a ball A (Plate XXXVI. Mechanics, fig. 14.) moving in the air in the line A B, and falling obliquely on the surface of the water C D, does not proceed straight to E, but deviates, or is refracted, to F. Again, if the ball, moving in water in the same line A B, should fall obliquely on a surface of air C D; it will not proceed straight to E, nor yet deflect to F, but to G. Now the deflection in each case is called the refraction; and the two cases are distinguished by means of the perpendicular M I; that B C being called refraction towards the perpendicular, or to the axis of refraction; and the other B F, refraction from the perpendicular, or from the axis of refraction.

These refractions are supposed to arise hence, that the ball arriving at B, in the first case finds more resistance or opposition on the one side O, i.e. from the side of the water, than it did from the side P, or that of the air; and in the latter more resistance from the side P, which is now the side of the water, than the side O, which is that of the air.

The great law of refraction, then, which holds in all bodies, and all mediums, is that a body, passing obliquely into a medium which resists it more, is refracted towards the perpendicular; and in passing out of a medium which opposes it less into another which opposes it more, it is refracted from the perpendicular.

Hence the rays of light falling out of air into water are refracted towards the perpendicular; whereas a ball thrown into the water is refracted from it; because water, which resists the motion of light less than air, resists that of the ball more; or to speak more truly, because water, by its greater attraction, accelerates the motion of the rays of light more than air does; for that this is the true cause of refraction, at least in light, shall be shewn under Refraction of light.

To have a body refracted, it is necessary that it should fall obliquely on the second medium. In perpendicular incidence there is no refraction.
REFRACTION.

Vonius indeed, and Snellius, imagined they had observed a perpendicular ray of light undergo a refraction; a perpendicular object appearing in the water nearer than in reality it was; but this was to attribute that to a refraction of the perpendicular rays, which was owing to the divergency of the oblique rays after refraction, from a nearer point.

Yet there is a manifest refraction even of perpendicular rays found in (land Crystal, which fee. Rohault adds, that though an oblique incidence be necessary in all other mediums we know of, yet the oblique must not exceed a certain degree; if it do, the body will not penetrate the medium, but will be reflected instead of being refracted. Thus cannon-balls, in sea-engagements, falling very obliquely on the surface of the water, are observed to mount aloft again, and frequently to sweep the men from off the opposite decks; and the like happens to the little flones with which children make their ducks and drakes.

The ancients confounded refraction with reflection, and it was for Isaac Newton who first taught us the juit difference between them. He shows likewise, that there is a good deal of analogy between them, and particularly in the cafe of light.

The laws of refraction of the rays of light in mediums differently terminated, i.e., whole surfaces are plane, concave, convex, &c. make the subject of optsica; which fee.

By refraction it is, that convex glasses, or lenses, collect the rays, magnify objects, burn, &c. and hence the foundation of microscopes, telescopes, &c.

By refraction it is, that all remote objects are seen out of their real places; particularly, that the heavenly bodies are apparently higher than they are in reality, &c.

The refraction of the air has many times so uncertain an influence on the places of celestial objects, very remote from the zenith, that wherever refraction is concerned, the conclusions deduced from observations that are much affected by it, will always remain doubtful, and too precarious in many cafes to be relied upon. See Dr. Bradley, in Phil. Trans. N. 485.

See Atmospheric Refraction.

Refraction of Light, in Optica, is an inflexion or deviation of the rays from their rectilinear course upon falling obliquely out of one medium into another, of a different dentity.

The term refraction is derived from the distortion which it occasions in the appearance of an object viewed in part only by refracted light; thus, an oak, partially immersed in water, appears to be bent, on account of the refraction of the light, by which its lower part is seen, in its passage out of the water into the air.

Although no sensible light can penetrate more than 700 feet deep into the sea, and a length of seven feet of water has been found to intercept one-half of the light which enters into it; yet in transparent substances (no medium being, strictly speaking, absolutely transparent) the greater part of the light penetrates to all distances with little interruption, and all rays, of the same kind, thus transmitted by the same surface, form with the perpendicular an angle of refraction, which is ultimately in a certain constant proportion to the angle of incidence; that is, for instance, one-half, three-fourths, or two-thirds, according to the nature of the surface. Thus, if the refractive properties of the substance were such, that an incident ray, making an angle of one degree with the perpendicular, would be so refracted as to make an angle of only half a degree with the same line, another ray, incident at an angle of two degrees, would be refracted, without sensible error, into an angle of one degree. But when the angles are larger, they vary from this ratio, their lines only preferring the proportion with accuracy; for example, if the angle of incidence at the supposed surface were increased to 90°, the angle of refraction would be 30° only, instead of 45°.

It does not appear that, before Descartes, any person attempted to explain the physical cause of the refraction, and also the reflection of light, which he undertook to do by the resolution of forces, on the principles of mechanics; in consequence of which he was obliged to suppose that light pafles with more ease through a dense medium than a rare one; thus the ray A B (Plate XVIII. Optics, fig. 10,) falling obliquely on a denser medium at B, is supposed to be acted on by two forces, one of them impelling it in the direction A C, and the other in A D, which alone can be affected by the change of medium; and since, after the ray has entered the denser medium, it approaches the perpendicular B H, it is plain that this force must have received an increase, whilst the other continued the same; for if B E be taken equal to B D, or C A, the consequence of the angle I B H being less than A B C will be, that B H must be longer than B C or A D.

The first person who questioned the truth of this explanation of the cause of refraction was M. Fermat, who asserted, contrary to Descartes, that light suffers greater resistence in water than in air, and greater in glafs than in water; and he maintained that the resistence of different mediums, with respect to light, is in proportion to their deninties. M. Leibnitz adopted the fame general idea; and they reasoned upon the subject in the following manner. Nature, they say, accomplishes her ends by the shortest methods; light, therefore, ought to pafs from one point to another, either by the shortest road, or that in which the least time is required. But it is plain that the line in which light paffes, when it falls obliquely upon a denser medium, is not the most direct or the shortest; so that it must be that in which the least time is spent. And, whereas it is demonstrable, that light falling obliquely upon a denser medium (in order to take up the least time possible, in palling from a point in one medium to a point in the other), must be refracted in such a manner, that the lines of the angles of incidence and refraction must be to one another, as the different facilities with which light is transmitted in those mediums; it follows that, since light approaches the perpendicular when it paffes obliquely from air into water, (so that the line of the angle of refraction is less than that of the angle of incidence,) the facility with which water suffers light to pafs through it is less than that of the air; so that the light meets with greater resistence in water than in air. This method of arguing from final causes could not satisfy philosophers. Dr. Smith observes that it agrees only to the cafe of refraction at a plain surface; and that the hypothesis is altogether arbitrary. If he had endeavoured to accommodate his principle to concave and convex surfaces, as he had once proposed, he would soon have perceived its insufficiency. The easiest way for a ray to pafs from a given point in any refilling medium into a vacuum, is in a perpendicular to the refracting surface; this being the shortest way, through any difficulty or resistence whatever; but this being reduced to nothing at the refracting surface, it may then take any other course in vacuo, without any further difficulty; and, on the contrary, in returning back from the vacuum into the dense medium, it must take the shortest course through the same perpendicular as before. Thus, when the sun shines upon the atmosphere, all his rays should be refracted into lines tending to the centre of the earth, as being the shortest and easiest way through the atmosphere, and then we should see the sun exactly over our heads, in all places and at all times. Such is the strange conflag-
consequence that follows from an hypothesis so arbitrary.

Dechales, in order to explain the law of refraction, supposed that every ray of light is composed of several smaller rays, which adhere to one another; and that they are refracted towards the perpendicular, in passing into a denser medium, because one part of the ray meets with more refrangibility than another part; so that the former traverses a smaller space than the latter; in consequence of which the ray must necessarily bend a little towards the perpendicular. This hypothesis was adopted by the famous Dr. Barrow, who, as some say, was the author of it. On this hypothesis, it is plain that mediums of a greater refractive power must give greater refraction to the passage of the rays of light than mediums of a less refractive power, which is contrary to fact.

The Bernouillis, both father and son, have attempted to explain the cause of refraction on mechanical principles; the former on the equilibrium of forces, and the latter on the same principles with the supposition of ethereal vortices; but neither of these hypotheses have gained much credit. M. Maclaurin supposes a fluid fluid, filling the pores of all bodies, and extending, like an atmosphere, to a small distance beyond their surfaces; and he supposes that the refraction of light is nothing more than a necessary and mechanical effect of the incidence of a small body in those circumstances. There is more, he says, of the refracting fluid in water than in air, less in water than in glass, and in general less in a denser medium than in one that is rarer. M. de Maupertuis supposes that the course which every ray takes, in passing from one medium into another, is that which requires the least quantity of action, which depends upon the velocity of the body, and the space it passes over; so that it is in proportion to the sum of the spaces multiplied by the velocity with which bodies pass over them. From this principle he deduces the necessity of the sine of the angle of incidence being in a constant proportion to that of refraction: and also all the other laws relating to the propagation and reflection of light.

Dr. Smith (in his Optics, Remarks, p. 72.) observes, that all other theories for explaining the reflection and refraction of light, except Sir Isaac Newton's, suppose that it strikes upon bodies, and is reflected by them, which has never been proved by any deduction from experience. On the contrary, it appears by various considerations, and might be shown by Mr. Malouneux's and Professor Bradley's observations on the parallax of the fixed stars, that their rays are not at all impelled by the rapid motion of the earth's atmosphere, nor by the object-glass of the telescope through which they pass. And by Sir Isaac Newton's theory of refraction, which is grounded on experience only, it appears, that light is so far from being reflected and retarded by refraction into any denser medium, that it is twister there than in vacuo, in the ratio of the sine of incidence in vacuo to the sine of refraction into the denser medium. From some cases of the production of colours, we are led to suppose, says Dr. Young (Lect. Phil. vol. i. p. 466.) that the intensity of light must be smaller in a denser than in a rarer medium; and supposing this fact to be established, the existence of such an attractive force as Sir Isaac Newton suggests could no longer be allowed; nor, he says, could the system of the emanation of light, in opposition to that of the undulation of an ethereal medium, be maintained by any one. Priestley's Hift. of Light, &c. p. 102, &c. p. 533, &c.

The refraction of light, sir Isaac Newton shews, is not performed by the very rays falling on the surface of bodies; but it is done without any contact, by the action of some power belonging to bodies, and extending to a certain distance without their surfaces; by which same power, acting in other circumstances, they are also emitted and reflected.

Admitting that certain powers of attraction and repulsion belong to bodies, and extend to a certain distance beyond their surfaces, and supposing also that light consists of particles emitted from luminous bodies, sir Isaac Newton demonstrates, in his "Principia," that the angle of the angle of incidence must be always to the sine of the angle of refraction in some certain ratio. For, as he proves geometrically, if two similar mediums be separated from each other by a space terminated on both sides by parallel planes, and a body, in its passage through that space, be attracted or impelled perpendicularly towards either of those mediums, and not agitated or hindered by any other force; and if the attraction be every where the same, at equal distances from either plane, taken towards the same hand of the plane, the sine of incidence upon either plane will be to the sine of emergence from the other plane in a given ratio.

In a corollary to this proposition he also shews, that if, instead of one parallel space, bodies be surrounded with several, or an infinite number of them, the attractive power of each of which differs from the next, increasing or decreasing still, the ratio respecting any two contiguous ones being given, the ratio of the extremes will be given. He also demonstrates, that, if the cause of refraction be the attraction of the refracting medium, the velocity of light before its incidence will be to its velocity afterwards, as the sine of the angle of refraction is to the sine of the angle of incidence; and that light, in passing from a rarer medium into a denser, receives an increase of velocity. The same things being suppos'd, he shews, that if the velocity before incidence be greater than afterwards, so that the angle of emergence must always increase, in consequence of the repulsive power prevailing over the attractive one, the body will at length be reflected; and that, in this case, the angle of reflection must necessarily be equal to the angle of incidence.

That light does not consist of any mode of action upon a fluid medium, he concludes from having demonstrated that pressure cannot be propagated through a fluid in rectilinear directions, unless where the particles of the fluid lie in a right line, but must diverge into the unmoved spaces; and that every tremulous body, in an elastic medium, propagates the motion of the pulses on every side straight forwards. Admitting this, there is hardly any hypothesis that will agree with the phenomena of light; but that of particles emitted from the luminous body, affected by the attractions and repulsions of other bodies.

The same arguments by which we have proved, that reflection (which is) performed without immediate contact, will go a great way towards demonstrating the fame of refraction: to which may be added the following ones.

1. Because, if when light falls out of glass into air with the utmost obliquity it will be transmitted at, it be then made to fall a little more obliquely, it becomes wholly reflected: for the power of the glass, after it has refracted light emerging as obliquely as possible, supposing the rays to fall still more obliquely, will be too strong to let any of the rays pass; confequently, instead of being refracted, they will all be reflected.

2. Because in thin lamelle, or plates of glass, light is reflected and transmitted several times alternately, as the thickness of the lamelle increases in arithmetical proportion; for here it depends on the thickness of the lamina which of the two the glass shall do, whether reflect it, or let it be transmitted.

3. Because, whereas the power of other bodies both to reflect and refract light are very nearly proportional to their Vol. XXIX.

densities;
REFRACTION.

densities; yet anctuous and fulploruous bodies are found to reflect more strongly than according to their mere densities; for as the rays act more strongly on these bodies to kindle them than on others, to do they again, by their mutual attraction, act more strongly on the rays to refract them.

Lastly; Because not only those rays transmitted through glafs are found to be refracted, but also those paffing in the air, or in a vacuum near its extremities, or even near the extremes of many opaque bodies, e. gr. the edge of a knife, undergo a similar inflection, from the attraction of the body.

See Light, and also Reflection.

The manner in which refraction is performed by mere attraction, without contact, may be thus accounted for: Suppose N H (Plate XVIII. Optics, fig. 11.) the boundary of two mediums, N and O; the firft the rarer, e. gr. air; the second the denser, e. gr. glafs; the attractions of the mediums here will be as their densities. Suppose p S to be the distance to which the attraction force of the denser medium exerts itself within the rarer. Let now a ray of light A a fall obliquely on the surface which separates the mediums, or rather on the surface p S, where the action of the second and more refilling medium commences. All attraction being performed in lines perpendicular to the attractive body, as the ray arrives at a, it will begin to be turned out of its rectilinear course by a superior force, with which it is attracted by the medium O, more than by the medium N, i.e. by a force with which it is driven towards it in a direction perpendicular to its surface; hence the ray is bent out of its right line in every point of its passage between p S and R T, within which distance the attraction acts. Between these lines, therefore, it describes a curve a B b; but beyond R T, being out of the sphere of attraction of the medium N, it will proceed uniformly in a right line, according to the direction of the curve in the point b.

Again, suppose N the denser and more refilling medium, O the rarer, and H I the boundary, as before; and let R T be the distance to which the denser medium exerts its attractive force within the rarer; even when the ray has palled the point B, it will be within the sphere of inferior attraction of the denser medium; but that attraction acting in lines perpendicular to its surface, the ray will be continually drawn from its rectilinear course B M perpendicularly towards H I: thus, having two forces or directions, it will have a compound motion, by which, instead of B M, it will describe B m, which B m will in like manner be a curve.

Lastly, after it has arrived in m, being out of the influence of the medium N, it will perffit uniformly in a right line, in the direction in which the extreme of the curve leaves it.

Thus we fee how refraction is performed, both towards the perpendicular, and from it.

But note, the attraction of the denser medium, e. gr. N, is continually diminishing, as the ray proceeds from B, towards the limit of attraction R T; because fewer and fewer parts will come to act at A; at H I, e. gr. all the parts between that and p S attract; but at R T, none but thofe in the line H I. Note, also, that the distance between p S and R T being small, when we consider refractions, no notice is taken of the curve part of the ray, but we confider it as confifting of two straight lines, C B, A B, or m B, A B.

Sir Isaac Newton, not content with ascribing the reflection, refraction, and inflection of light to poffefions of attraction and repulfion, extending beyond the surfaces of bodies and producing effect in the manner above explained, produces a conjecture concerning the physical caufe of this attraction and repulfion; but his hypothesis is no lefs liable to difficulties and objections than the hypothesis of the mechanical production of the motion of light without attraction or repulfion. Does not the refraction of light, he fays, arise from the different density of an ethereal medium in different places, the light always receding from the denser parts of the medium? And is not the density of it greater in free and open spaces void of air, and other grofs bodies, than within the pores of water, glafs, cryftal, gems, and other compact bodies? For when light paffes through glafs or cryftal, and falling very obliquely upon the farther surface, is all reflected, the total refection ought to arife rather from the density and vigour of the medium without and beyond the glafs, than from the rarity and weaknefs of it.—Does not the ethereal medium, in paffing out of water, glafs, cryftal, and other compact and denfe bodies, into empty spaces, grow denser and denser by degrees, and by that means refact the rays of light, not in a point, but by bending them gradually in curve lines? And does not the gradual condenfation of this medium extend to some distance from the bodies, and thereby caufe the inflections of the rays of light, which pafs by the edges of the denfe bodies, at some distance from the bodies?

Refraction, in Dioptrics, is the inflection or bending of the rays of light, in paffing the surfaces of glafses, lefles, and other transparent bodies of different densities.

Thus a ray, as A B (Plate XVIII. Optics, fig. 11.) falling obliquely from the radiant A, upon a point B, in a diaphanous surface, H I, rarer or denser than the medium along which it was propagated from the radiant; has its direction there altered by the action of the new medium; and instead of proceeding to M, it deviates, e. gr. to C.

This deviation is called the refraction of the ray; B C the refracted ray; or line of refraction; and B the point of refraction.

The line A B is called the line of incidence, or ray of incidence; and, in respect of it, B is also called the point of incidence.

The plane in which both the incident and refracted rays are found, is called the plane of refraction; a right line E D, drawn in the refracting medium perpendicular to the refracting surface, in the point of refraction B, is called the axis of refraction; and a right line D B, drawn perpendicular to the refracting surface, in the point of incidence B, along the medium through which the ray fell, is called the axis of incidence.

The angle A B I, included between the incident ray and the refracting surface, is called the angle of incidence; and the angle A B D, included between the incident ray and the axis of incidence, is called the angle of inclination.

The angle M B C, which the refracted ray makes with the incident, is called the angle of refraction; and the angle C B E, which the refracted ray makes with the axis of refraction, is called the refracted angle.

Refraction, general laws of. 1. A ray of light in its passage out of a rarer into a denser medium, e. gr. out of air into glafs, is refracted towards the perpendicular, i. e. towards the axis of refraction.

Hence, the refracted angle is lefs than the angle of inclination; and the angle of refraction lefs than that of incidence; as they would be equal were the ray to proceed in a right line from A to M. Hence, also, a ray perpendicular to the refracting surface, will pass through without being refracted, as it cannot be refracted to the perpendicular. The phyfical caufe of which is, that the attraction of the denser medium, which, in an incidence oblique to its surface acts perpendicularly to that surface, draws the ray out of its course; this attraction, we fay, is a perpendicular incidence, acts in the direction of the ray.

2. The ratio of the fine of the angle of inclination, to the
REFRAC.ION.

The refracted angle is fixed and constant; viz. if the
refraction be out of air into glass, it is found greater than
as 114 to 76, but less than 115 to 76; that is, nearly as
3 to 2.

This ratio, assigned by Huygens, agrees with another of
Sir Isaac Newton, who makes the line of the angle of in-
clination to the line of the refracted angle, as 31 to 20;
which is, likewise, nearly as 3 to 2. Indeed, there is some
difference in the quantity of refraction, in different kinds
of glass; but in physical matters, precifeness is not necessary.
In rain-water, Descartes found the ratio of the line of
the angle of inclination, to the line of the refracted angle,
as 250 to 187, that is nearly as 4 to 3; which agrees with
Sir Isaac Newton’s observation, who makes it as 529 to 396.
In spirit of wine, the same great author makes the ratio
as 100 to 75; which is not far from the sesquiterian ratio.
In air he makes it as 3201 to 3200; and as to air, he
shews, that a ray of light, in traversing quite through the
atmosphere, is refracted the same as it would be, were it to
pass with the same obliquity out of a vacuum into air of equal
density with that in the lower part of the atmosphere.

See the following table, in which the proportion of
the lines which measure the refractions of several bodies; the
densities of the bodies, estimated by their specific gravity;
and their refractive power, in respect of their densities, are
set down in separate columns.

Newton’s Optics, edit. 3. p. 247.

M. Euler the younger, purusing a scheme suggested by
his father for ascertaining the refractive powers of trans-
parent liquors, made use of two Menisicus glasses, which he
put together when they were plunged in the fluid, the
refractive power of which he wanted to determine: the
edges of these glasses being ground flat, they immediately
cooled, so that none of the fluid could escape; and then
they might both together be wiped, and used as one object-
glass in a long tube, which he could lengthen or shorten at
pleasure; and applying an eye-glass to it, the whole ob-
ervation he had to make was to measure the exact length
of his tube, when he could see through it most distinctly a
turret, which was at a considerable distance from him.

Or, when the focal distance was less than a foot, he only
observed, at what distance from a wall the image of an op-
posite window was the most distinct. Ac. Berlin. 1762, p. 302.

The refractive power of the fluids which he examined in
this manner, he expressed in the following tables.

That the refractive power of these fluids, thus determined by M. Euler, may be more easily compared with Mr. Haukbee's and Sir Isaac Newton's experiments, he reduced the result of their observations into the following table, exactly similar to his own.

The refractive power of certain fluids found by Mr. Haukbee, see his Experiments, p. 292.

See Priestley's Hist. of Light, &c. p. 479, &c.

Whence the different refractive power in different fluids arises, is not determined. Sir Isaac Newton allowed, that in many bodies, e. g. gls crystal, a femtis, pseudo-topaz, &c. the refractive power is proportional to their densities; only in sulphurous bodies, as camphor, linseed oil, olive, amber, spirit of turpentine &c. the power is two or three times greater than in other bodies of equal density; yet even these have the refractive power with respect to each other nearly as their densities.

Water has a refractive power in a middle degree between those two kinds of substances, and is, probably, of a middle nature. Salts and vitriols have refractive powers in a middle degree between those of earthly substances and water, and accordingly are composed of those two forts of substances. Spirit of wine has a refractive power in a middle degree between those of water and oily substances; and accordingly seems to be composed of both, united by fermentation. It appears, therefore, that all bodies seem to have their refractive powers proportional to their densities, or very nearly, excepting so far as they partake of more or less sulphurous oily particles, and thereby have their refractive powers made greater or less. Whence it seems reasonable to attribute the refractive power of all bodies.
REFRACTION.

bodies chiefly, it not wholly, to the sulphureous parts with which they abound.

From the observations of M. Euler it appears, that there is no fluid, and probably no transparent substance of any kind, the refractive power of which is less than that of rain-water, or distilled water; and between air and rain-water there is no substance that has an intermediate refractive power.

After rain-water immediately follows well-water; but there are probably as many varieties in its refractive power as there are different wells. We may, however, conclude, that the ratio of refraction from air into well-water is contained between the limits of 1.336 to 1, and 1.337 to 1.

Spirituous liquors have a greater refractive power in proportion to their strength: but the ratio of refraction from air into any spirituous liquor is never less than 1.34, nor greater than 1.37.

There is, probably, no kind of salt, but what, being dissolved in water, increases its refractive power.

The solutions of salt of urine and of vitriol have the least refractive powers, and those of rock-salt and sal ammoniac the greatest; but the ratio of refraction from air into any saline solution, preferring the proportion of one ounce of salt to twelve of water, will be contained between the limits of 1.34 to 1, and 1.35 to 1.

Distilled vinegar, and the solution of gum arabic, have nearly the same refractive power with common French wine; and the refractive power of white of egg is the same as that of rectified spirit of wine.

Mineral salts saturated, seems to have the same refractive power with very strong brandy.

Spirit of nitre and oil of tartar per deliquium have a medium refractive power between spirituous liquors and oils.

The refractive powers of oils approach the nearest to that of glas, especially oil of turpentine, which had the greatst refractive power of all the fluids on which he had made experiments.

Sir Isaac Newton suspected that different degrees of heat might have some effect on the refractive power of bodies, but his method of determining the general refraction was not sufficiently accurate to ascertain this circumstance; but happily this method of M. Euler’s proved to be well adapted to this purpose.

From his experiments made for this purpose, he infers, that the focal distance of a single lens of glass diminishes with the heat communicated to it; and this diminution of the focal distance is not owing to the increase of bulk in the glass by heat; for the effect of this change is both incalculable, and of a contrary nature. There can be no doubt, therefore, but that this alteration in the focal distance is owing to a change in the refractive power of the glass itself, which, as well as, probably, that of all other transparent substances, is increased by heat, and diminished by cold.

It may seem surprizing that the focal distance of a single lens should decrease with heat; and yet that of the menisci filled with any fluid, should increase with heat; but M. Euler observes, that it by no means follows from hence, that these fluids are affected by heat in a manner different from glasses; and, after computing the effect of every circumstance of this complex experiment, of the two glasses, and the fluid combined, he concludes, that heat increases the refractive power of water, and of other fluids, as well as that of glasses.

He further observes, that as 66 degrees of heat diminished the focal distance 5/6th part, 33 degrees ought to have diminished it 5/6th part; whereas the diminution in this case was 1/6th. From hence, says he, one may perhaps conclude, that when it is very cold, the same change in the thermometer has a greater effect on the refractive power of the glafs than when it is very hot. But he acknowledges that experiments of this kind are not capable of so much precision as one could wish, and that, perhaps in reality, the 66 degrees made a change of 5/6th, and the 33 degrees of 1/6th; but he imagined that a great number of experiments, made in different temperatures of the air, might decide this question, especially if object-glasses of a very great focal distance were made use of. Ac. Berl. 1762.

The duke de Chaulnes, not satisfied with the methods used by Newton and others for determining the refractive power of glafs, proposed another mode of doing it, which is very ingenious, and, when well conducted, promising success. He formed the glafs into plates, the surfaces of which were truly plane and parallel, and having placed small objects on each of them, he found, by means of a compound microscope, to which he applied the most exquisite micrometer, the different distances at which they were distinctly visible, and compared them with the thickness of the glafs. This, he says, gives the proportion of the fines of the angles of incidence and refraction in that kind of glafs directly. In this method he ascertained the mean refractive power of 15 kinds of glafs. Ac. Par. 1767. See Priestley’s Hist. of Light, &c. p. 483, &c.

Dr. W. H. Wellhöfn has proposed a new method of examining refractive as well as dispersive powers, by prismatic reflection. This method was suggested by a consideration of sir Isaac Newton’s prismatic eye-glafs, the principle of which depends on the reflection of light at the inner surface of a dense refracting medium.

Since the range of inclination, within which total reflection takes place, depends not only on the density of the reflecting prism, but also on the ratio of the medium adjacent to it, the extent of that range varies with the difference of the densities of the two media. When, therefore, the refractive power of one medium is known, that of any rarer medium may be learned, by examining at what angle a ray of light will be reflected from it.

For instance, when any object is laid under a prism of flint-glafs, with air alone interposed, the internal angle of incidence at which the visual ray begins to be totally reflected, is about 39° 10'; but when the object has been dipped in water, and brought into contact with the glafs, it continues visible, by means of the higher refractive power of the water, as far as 57° 30' of incidence. When any kind of oil, or any refrinous cement, is interposed, this angle is still greater, according to the refractive power of the medium employed; and, by cements that refract more strongly than the glafs, the object may be seen through the prism, at whatever angle of incidence it is viewed.

In examining the refractive powers of fluids, or of fusible substances, the requisite contact is easily obtained; but, with solids, which can in few instances be made to touch to any great extent, this cannot be effected without the interposition of some fluid, or cement, of higher refractive power than the medium under examination. Since the surfaces of a stratum so interposed are parallel, it will not affect the total deviation of a ray passing through it, and may therefore be employed without risk of any error in consequence.

Thus, refin, or oil of fatty acids, interposed between plate-glafs and any other prism, will not alter the result.

If, on the same prism, a piece of selenite and another of plate-glafs be cemented near each other, their powers may
be compared with the same accuracy as if they were both in absolute contact with it.

For such a mere comparison of any two bodies, a common triangular prism is best adapted; but, for the purpose of actual measurement of refractive powers, Dr. Wolfsoten has preferred the use of a square prism, because, with a very simple apparatus, it shews the fine of refractive power sought, without the need of any calculation.

Let \( A \) (Plate XVII. Optics, fig. 12.) be a square or rectangular prism, to which any substance is applied at \( A \), and let any ray of light parallel to \( ef \) be refracted through the prism, in the direction \( bd \).

Then, if \( ef \) and \( ed \) be taken proportional to the lines that represent the refractive powers of the prism and of air, \( fg \), which is intercepted between \( f \) and the perpendicular \( eg \), will be the corresponding line to represent the refractive power of the medium \( b \). For since \( cd \) (opposite to \( ef \)) is the angle of refraction, \( cdg \) (opposite to \( ed \)) must be equal to the angle of incidence \( bd \); and \( ef : fg :: bd : dh \); fine of \( cdh \) : fine of \( bd \).

All, therefore, that is requisite for determining the refractive power of \( b \), is to find the means of measuring the line \( fg \). On this principle, the instrument in fig. 13 is constructed. On a board, \( ab \), is fixed a piece of flat deal \( cd \), to which, by a hinge at \( c \), is jointed a second piece \( ds \), 10 inches long, carrying two plane glass at its extremities. At \( e \) is a second hinge, connecting \( ef \), 15.83 inches long; and a third at the other extremity of \( ef \), by which \( fg \) is connected with it. At \( i \) also is a hinge, uniting the radius \( ig \) to the middle of \( ef \); and then, since \( g \) moves in a semicircle \( egf \), a line joining \( e \) and \( g \) would be perpendicular to \( fg \).

The piece \( cd \) has a cavity in the middle of it, so that, when any substance is applied to the middle of the prism \( P \), it may continue to reflect horizontally on its extremities. When \( cd \) has been so elevated, that the yellow rays in the fringe of colours (observable where perfect reflection terminates) are seen through the lights, the point \( g \), by means of a vernier which it carries, shews by inspection the length of the sign of refraction sought.

The advantages which this method possesses above the usual mode of examining refractive powers, are greater than they may at first sight appear. The usual practice has been, to form two faces of the substance under examination, so inclined to each other that the deviation occasioned by them might be measured. The inclination of these surfaces to each other must also be known; and hence the refractive power might be computed. But, in the method here propounded, it is sufficient to have only one surface, and the result is obtained at once, without computation.

The facility of determining refractive powers is consequently such as to render this property of bodies a very convenient test in many philosophical inquiries.

The following table exhibits a series of substances, arranged according to their refractive powers.

Atmospheric air (Hauksbee)

See Phil. Trans. vol. xcii. for 1802. art. 12. See Dispersion of Light.

From the law laid down in the beginning of this article, it follows, that one angle of inclination, and its corresponding refracted angle, being found by observation, the refracted angles, corresponding to the several other angles of inclination, are easily computed. Now, Zahnius and Kircher have found, that if the angle of inclination be 70º, the refracted angle will be 38º 50'; on which principle Zahnius has constructed a table of refractions out of air into glafs, for the several degrees of the angle of inclination; a specimen of which follows:

<table>
<thead>
<tr>
<th>Angle of Inclination</th>

</table>

Hence it appears, that if the angle of inclination be less than 20º, the angle of refraction out of air into glafs is almost one-third of the angle of inclination; and, therefore, a ray is refracted to the axis of refraction, by almost a third part of the quantity of its angle of inclination. And on this principle it is that Kepler, and most other dioptrical writers, demonstrate the refractions in glafs; though in eliminating the law of these refractions, he followed the example of Alhazen and Vitelio, and sought to discover it in the proportion of the angles, and not in that of the lines.

The true law of refraction was first discovered by Willebrord Snellius, professor of mathematics at Leyden; who found by experiment that the sines of the complements, or co-sines, of the angles of incidence and refraction, are always in the same ratio. It is vulgarly attributed, however, to Descartes; who having seen it in Snellius's MS., first published it in his Dioptrics, without naming Snellius; as we are informed by Huygens. The form in which Descartes gives this law is different from that of Snellius, and in general more commodious; but it might have been easily deduced from it. According to him, the sine of the angle of refraction always bears the same proportion to the sine of the angle of incidence. Indeed, as the rays of light are not all of the same degree of refrangibility, this conflagrant ratio must be different in different kinds. The ratio, therefore, observed by authors, is to be understood of rays of the mean refrangibility, i.e. of green rays. The difference of refraction between the leaf and most refrangible rays, that is, between violet and red rays, for Isaac Newton shows is about the 27th part of the whole refraction of the mean refrangible; which difference he owns is so small, that there seldom needs to be any regard paid to it.

3. When a ray puffs out of a denser medium, e. g. out of glafs into air, it is refracted from the perpendicular, or from the axis of refraction. And hence the angle of refraction is greater than the angle of inclination.

Hence, also, if the angle of inclination be less than 30º, M B C (Plate XVIII. Optics, fig. 11.) is nearly equal to one-third of M B E; therefore M B C is one-half of C B E; consequently, if the refraction be out of glafs into air, and the angle of inclination be less than 30º, the ray is refracted from the axis of refraction by almost one-half part of the angle of inclination. And this is the other dioptrical principle used by most authors after Kepler, to demonstrate the refraction of glafs.

If the refraction be out of air into glafs, the ratio of the angle of inclination to the angle of the refracted ray is as 3 to 2, or, more accurately, as 17 to 11; if of air into water, as 4 to 3; therefore, if the refraction be the contrary way, viz. out of glafs or water into air, the ratio of the lines, in the former case, will be as 2 to 3, or 11 to 17, and in the latter as 3 to 4.

Hence, if the refraction be from water or glafs into air, and the angle of incidence or inclination be greater than about 40º in water, or greater than about 45º in glafs, the ray will not be refracted into air, but will be reflected into a line, which makes the angle of reflection equal to the angle of incidence; because the lines of 48º and 40º are to the radius as 3 to 4, and as 11 to 17 nearly, and therefore when the line has a greater proportion to the radius than as above, the ray will not be refracted.

4. A ray falling on a curve surface, whether concave or convex, is refracted after the same manner as if it fell on a plane which is a tangent to the curve in the point of incidence.

For the curve and plane surface touching it, having an infinitely small part common to them both (each being originally generated by the flux of a point). But a ray is refracted in such a little part; therefore it is the same as if it were refracted in such a plane.

5. If a right line E F (Plate XVIII. Optics, fig. 14.) cut a refracting surface, G H, at right angles; and if, from any point in the denser medium, as D, be drawn D C parallel to the incident ray A B: this will meet the refracted ray at C; and will be to it as the sine of the refracted angle to the sine of the angle of inclination.

For $\alpha = \chi$; but if B C pafs out of a denser medium into a rarer, $y > x$; and out of a rarer into a denser, $y < x$; therefore, in the former case, $y > 0$, in the latter $y < 0$; consequently, in the former, $0 + y < y + u$; in the latter, $y + u < 0 + u$. But in one case, $0 + y$, in the other, $y + u$; are equal in two right angles; therefore, $u + 0$ in this, and $y + u$ in the other, are less than two right angles, and consequently D C will meet B C. But since $\alpha = \chi$, or the angle of inclination, and $y$ is the refracted angle, it is evident that C B is to C D as the sine of the angle $\alpha$ to the sine of the angle $y$, or in the ratio of the sine of the angle of inclination to the sine of the refracted angle.

Hence, if B C pafs out of glafs into air, it is in a sub-refugulate ratio to C D; if, on the other hand, it puffs out of air into glafs, it is in a sub-refugulate ratio to C D.

Hence, also, if light puffs out of water into air, C B is in a sub-refugulate ratio to C D; if out of air into water, in a lefquilterian. See figs. 14 and 15.

Refraction in plane surfaces, leaves off. 1. If parallel rays be refracted out of one transparent medium into another of a diff-
a different density, they will continue parallel after refraction.

The physical reason is, that, being parallel, their obliquity, or angle of incidence, is the same; but, at equal obliquities, we have shown the refraction is equal; consequently the parallelism, which they had before the refraction, will be retained after it.

But this may be also demonstrated geometrically: thus, if the rays be perpendicular to the refracting surface, they will pass without any refraction; consequently being parallel before their passage, they will be so after it. If they fall obliquely, as $AB$ and $CD$ (fig. 16.), the angles of incidence $\alpha$ and $\alpha'$, and, consequently, also the angles of inclination $\kappa$ and $\kappa'$, will be equal. But the sines of the angles of inclination $\kappa$ and $\kappa'$ have the same ratio to the sines of the refracted angles $\alpha$ and $\alpha'$; therefore the refracted angles $\alpha$ and $\alpha'$, and also the sines $s$ and $s'$, equal; consequently the refracted rays are parallel.

Hence a glafs, plane on both sides, being turned directly to the sun, the light palling through it will be propagated after the same manner as if the glafs were away; for the rays being perpendicular, will pass without refraction. If the glafs be turned obliquely to the sun, the light, after refraction, will be of the same intensity as before, the intensity depending on the spifitude or closeness of the rays, and on the angle with which they strike the object, or the eye; both which are here unvaried.

2. If two rays $DC$ and $CP$ (fig. 17.) proceeding from the same radiant $C$, and falling on a plane surface of a different density, so that the points of refraction $D$ and $P$ are equally distant from the cathefus of incidence $GK$, the refracted rays $DF$ and $PF$ have the fame virtual focus, or the fame point of refraction $G$.

Hence, 1. Since, in rays very near each other, the distance from the cathefus is the fame as to fense, very near rays will diverge from the fame point $G$, i.e. they will have the fame virtual focus $G$.

And hence, 2. When refracted rays, falling on the eye placed out of the cathefus of incidence, are either equally distant from the cathefus, or very near each other, they will flow upon the eye, as if they came to it from the point $G$; consequently the point $C$ will be seen by the refracted rays as in $G$.

3. If a ray $CD$ fall obliquely out of a thinner into a denfer medium, having a plane surface, the distance of the radiant point $C$ will have a less ratio to the distance of the point of defpersion, or virtual focus, $KG$, than the fine of the refracted angle to the fine of the angle of inclination. But if the distance of the point of refraction, from the cathefus of incidence $KD$, be less than the seventh or nineteenth part of the distance of the radiant point $C$; and if in the former case the tenth, and in the latter the hundredth, part of it be fo small, that it cannot be affigned, or need not be minded, then will $CK$ be to $KG$, as to fense, in the ratio of the fine of the refracted angle, to the fine of the angle of inclination.

Hence, 1. If the refraction be out of air into glafs, the distance of the point of defpersion of rays near the cathefus is feguialterate of the radiant point; of more remote rays greater than feguialterate. But if the refraction be out of air into water, the distance of the fame point will be feguialterate, when the rays are near the cathefus; and when more remote, greater than feguialterate.

Hence, 2. If the eye be placed in a denfer medium, objects in a rarer will appear more remote than they are; and the place of the image, in any given cafe, may be determined from the ratio of the refraction. Thus, to fihes fumatting under water, objefts out of the water must appear farther distant than in reality they are.

4. If a ray $DG$ fall obliquely out of a denfer into a rarer medium $AB$, the distance of the radiant point $G$ has a greater ratio to the distance of the point of defpersion $KC$, than the fine of the refracted angle has to the fine of the angle of inclination. In the other cafe of the preceding theorem, $KG$ will be to $KC$, as to fense, in the ratio of the fine of the refracted angle, to the fine of the angle of inclination.

Hence, 1. If the refraction be out of glafs into air, the distance of the point of defpersion of the rays near the cathefus of incidence is feguialterate of the distance of the radiant point; that of the more remote rays is less than feguialterate.

But, 2. If the refraction be out of water into air, the distance of the point of defpersion of rays near the cathefus is fubfeguialterate; of thofe more remote, les than fubfeguialterate.

And, 3. The eye, therefore, being placed in a rarer medium, objefts, placed in a denfer, appear nearer than they are; and the place of the image may be determined in any given cafe by the ratio of refraction. Hence, the bottom of a vessel full of water is raised by refraction to a third part of its height, with refpect to an eye perpendicularly over the refracting surface; and hence figures, and other bodies under water, appear nearer than they really are.

5. If the eye be placed in a rarer medium, an objeft seen in a denfer medium, by a ray refracted in a plane surface, will appear larger than it really is. If the objeft be in a rarer, and the eye in a denfer medium, the objeft will appear less than it is. And, in each cafe, the apparent magnitude is to the real one in a ratio compounded of the distance of the point to which the rays tend before refraction, from the refracting surface $DE$ (fig. 18.) to the distance of the eye $GL$ from the fame, and of the distance $GM$ of the objeft $AB$ from the eye, to its distance $FM$ from a point $F$, to which the rays tend before refraction.

Hence, 1. If the objeft $AB$ be very remote, $FM$ will be physically equal to $GM$; and, therefore, the real magnitude $AB$ is to its apparent one $MH$, as $GL$ to $FL$, or the distance of the eye $G$ from the refracting plane to the distance of the point of convergence $F$ from the same plane.

Hence, 2. Objecfts under water, to an eye in the air, appear larger than they are; and to fihes under water, objefts in the air appear less than they are.

REFRACTION, Laws of, in spherical surfaces, both concave and convex. 1. A ray of light $DE$ (fig. 19.) parallel to the axis of a denfer fphere, after a single refraction in $E$, falls in with the axis in the point $F$, beyond the centre $C$.

For the femidiameter $CE$, drawn to the point of refraction $E$, is perpendicular to the surface $KL$, and is therefore the axis of refraction; but a ray out of a rarer into a denfer medium, we have shown, is refracted towards the perpen- dicular, or the axis of refraction; therefore the ray $DE$ will converge to the axis of the fphere $AF$; and will, therefore, at length concourse with it, and that beyond the centre $C$, in $F$; because the angle of refraction $FEH$ is less than the angle of inclination $CEH$.

2. If a ray $DE$ fall on a spherically convex surface of a denfer medium, parallel to its axis $AF$; the femidiameter $CE$ will be to the refracted ray $EF$ in the ratio of the fine of the angle of refraction, to the fine of the angle of inclination; but the distance of the focus, or point of concurrence from the centre $C$, is to the refracted ray $FE$, in the
ratio of the sine of the refracted angle to the sine of the angle of inclination.

3. If a ray D E on a denser spherical convex surface K L, parallel to the axis A F, the distance of the focus from the refracting surface F B must be to its distance from the centre F C, in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle B C E be very small, B F will be to C F very nearly in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

And, 2. If the ray be out of air into water; in the former case, B F : F C :: 1 : 3; and in the latter, B F : F C :: 4 : 3. Consequently, in the former, B C : B F :: 1 : 4; and in the latter, B C : B F :: 1 : 3.

Hence, since the sun’s rays are parallel as to fience, if they fall on the surface of a solid glass sphere, or of a sphere full of water, they will not concur with the axis within the sphere; so that Vitello was mistaken, when he imagined, that the sun’s rays, falling on the surface of a crystalline sphere, were refracted to the centre.

4. If a ray D E (fig. 20.) parallel to the axis A F, fall out of a denser into a rarer spherical medium, after refraction, it will diverge from the axis; and the distance of the point of deviation, or the virtual focus from the centre of the sphere F C, will be to its semi-diameter C E in the ratio of the sine of the refracted angle, to the sine of the angle of refraction; but to the portion of the refracted ray drawn back, F E, it will be in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

5. If a ray D E fall parallel to the axis A F on the spherically convex surface K L, of a rarer medium, out of a denser, the distance of the point of deviation from the centre F C, is to its distance from the surface F B, in a ratio greater than that of the sine of the refracted angle to the sine of the angle of inclination. But if the rays D E be very near the axis A F, the ratio will be very nearly the same with that of the sine of the refracted angle to the sine of the angle of inclination.

Hence, 1. If the ray be out of glafs into air, in the case of rays near the axis, F C : F B :: 1 : 3; consequently, B C : B F :: 1 : 2. Therefore, in the case of rays more remote from the axis, F C : F B :: 3 : 2. II. If the ray be out of water into air; in the former case, F C : F B :: 4 : 3. Consequently, B C : B F :: 1 : 3; in the latter case therefore, F C : F B :: 4 : 3.

3. Since then the point of deviation is more remote from the refracting surface K L, if the rays proceed out of water, than if they pass out of glafs into air; parallel rays are less dispersed in the former case than in the latter.

6. If a ray H E (fig. 19.) fall parallel to the axis A F, out of a rarer, on the surface of a spherically concave denser medium; the refracted ray E F will be driven from the point of the axis F; so that E F will be to F C in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

7. If a ray E H fall parallel to the axis B F on the concave surface K L of a spherically denser medium, from a rarer; the distance of the point of deviation from the refracting surface F B, is to its distance from the centre F C, in a ratio greater than that of the sine of the angle of inclination, to the sine of the refracted angle. But if the rays be very near the axis, and the angle B C E be very small, B F will be to C F very nearly in the ratio of the sine of the angle of inclination, to the sine of the refracted angle.

Hence, 1. If the ray be out of air into glafs; in the case of rays near the axis, F B : F C :: 3 : 2; in the case of rays more remote from the axis, F B : F C :: 3 : 2; consequently, in the former, B C : F C :: 1 : 2. And hence, in the latter, B C : F C :: 1 : 2.

Hence also, 2. If the ray be out of air into water; in the case of rays near the axis, F B : F C :: 4 : 3; in the case of rays more remote from the axis, F B : F C :: 4 : 3; consequently, in the former case, B C : F C :: 1 : 3. And hence, in the latter, B C : F C :: 1 : 3.

And, 3. Since the point of deviation F is further from the centre C, if the ray be in water than in air; rays will be less dispersed in the latter case than in the former.

8. If the ray H E (fig. 20.) fall parallel to the axis A F, from a denser upon the surface of a spherically concave rarer medium, the refracted ray will concur with the axis A F, in the point F; so that the distance of the point of concurrence from the centre C F, may be to the refracted ray F E, in the ratio of the sine of the refracted angle, to the sine of the angle of inclination.

9. If a ray H E fall parallel to the axis A F on the concave surface of a rarer medium, out of a denser, the distance of the focus from the centre F C will be to its distance from the refracting surface F B in a greater proportion than the sine of the refracted angle, to the sine of the angle of inclination. But if the rays be very near the axis, F C will be to F B in the proportion of these lines.

Hence, 1. If the ray be out of glafs into air; in the case of rays near the axis, F C : F B :: 3 : 2; in the case of rays more remote from the axis, F C : F B :: 4 : 3. Whence, in the former case, B C : B F :: 1 : 2. If the ray be out of water into air; in the case of rays near the axis, F C : F B :: 4 : 3; in the case of rays more remote, F C : F B :: 4 : 3. Whence, in the former case, B C : B F :: 1 : 3. For the demonstration of these several laws of refraction, we refer to Wolthus’s Elem. Math. &c. tom. iii. p. 179. &c. See also LENS.

Refraction in a glafs prism. If a ray of light D E (fig. 21.) fall obliquely out of air on a prismatic ABC; being refracted towards the perpendicular, instead of proceeding to F, it will decline to G, i.e. towards a line HI, drawn perpendicular to the surface A B in the point of refraction E. Again, if the ray E G, passing out of the glafs into air, falls obliquely on C, it will be refracted at N, so as to recede from the perpendicular NG O. And hence arise the various phenomena of the prism. See COLOUR and REFRACTORINESS.

Refraction in a convex lens. If parallel rays, A B, C D, and E F (fig. 22.) fall on the surface of a lens 2 B 3 K, the perpendicular ray A B will pass unrefracted to K, where emerging into air perpendicular, as before, it will proceed straight to G. But the rays C D and E F, falling obliquely out of air into glafs, in D and F, will be refracted towards the axis of refraction (i.e. towards lines H I and L M, drawn perpendicular to the refracting surface in the points of refraction D and F) and decline to Q and P. Again, emerging obliquely out of the glafs into the surface of the air, they will be refracted from the perpendicular, and, therefore, D Q will not proceed to X, but to G; and P F, not to V, but to G; thus, likewise, might all the other rays, falling on
the surface of the glass, be shown to be refracted so as to meet the rod about the point G. See Focus and Lenses.

Hence the great property of convex glasses; viz. that they select parallel rays, or make them converge into a point.

REFRACTION in a concave lens. Parallel rays A B, C D, and EF (fig. 23.) falling on a concave lens G H I M K, the ray A B, falling perpendicular on the glass at B, will pass unrefracted to M; where being still perpendicular, it will pass into the air without refraction, to L. But, the ray C D, falling obliquely on the surface of the glass, will be refracted towards the perpendicular N D O, and proceed to Q; and the ray D Q, again falling obliquely out of the glass upon the surface of air, will be refracted from the perpendicular P Q S, and proceed to V. After the same manner might the ray E F be shown to be refracted to Y, and thence to Z.

Hence the great property of concave glasses; viz. that they differ from parallel rays, or make them diverge. See Lenses and Mirrors.

REFRACTION in a plane glass. If parallel rays E F, G H, I L (fig. 24.) fall obliquely on a plane glass A B C D, the obliquity being the same in all, by reason of their parallelism, they will be all equally refracted towards the perpendicular; and accordingly, being still parallel at M, O, and Q, they will pass out into the air equally refracted again from the perpendicular, and still parallel.

Thus will the rays E F, G H, and I L, at their entering the glass, be inflected towards the right; and in their going out as much inflected to the left; so that the first refraction is here undone by the second: though not so as that the object is seen in its true place. For the ray B Q, being produced back again, will not coincide with the ray I L, but will fall to the right of it; and thus the more as the glass is thicker; however, as to matter of colour, the second refraction does really undo the first. See Colour.

REFRACTION in Iceland or Iceland crystal. See Iceland Crystal. Dr. Young, who maintains that radiant light conflits in undulations of the luminiferous ether, takes occasion to make some remarks on Sir Isaac Newton's theory of the peculiar refraction in Iceland crystal. Newton, he says, has advanced the singular refraction of the Iceland crystal, as an argument that the particles of light must be projected corpuscles; since he thinks it probable that the different sides of these particles are differently attracted by the crystal, and hence Huygens has confided his inability to account, in a satisfactory manner, for all the phenomena. But contrarily to what might have been expected from Newton's uttial accuracy and candour, he has laid down a new law for the refraction, without giving a reason for rejecting that of Huygens, which Mr. Hady has found to be more accurate than Newton's; and, without attempting to deduce from his own system any explanation of the more universal and striking effects of doubling spars, he has omitted to observe, that Huygens's most elegant and ingenious theory perfectly accords with these general effects, in all particulars, and of course derives from them additional pretensions to truth; this he omits, in order to point out a difficulty for which only a verbal solution can be found in his own theory, and which will probably long remain unexplained by any other.

Dr. Wollaston, in his paper on the oblique refraction of Iceland crystal, confirms the experiments of Huygens on this subject, with additional evidence, deduced from the superior part of his mode of examining the powers of refraction. He observes that Dr. Young has already applied the Huygenian theory with considerable success to the explanation of several other optical phenomena, and that it appears to be strongly supported by such a coincidence of the calculations deduced from it, with the results of these experiments, as could have scarcely happened to a fallacious theory.

In ordinary cases, the incident undulations are of a spherical form; but in the Iceland crystal light appeared to Huygens to proceed as if the undulations were portions of an oblate spheroid, of which the axis is parallel to the short diagonal of an equilateral piece of the crystal, and its centre the point of incidence of its ray. From this spheroidal form of the undulations, he deduces the obliquity of refraction; and lays down a law observably in all refractions, at any surface of the spar, whether natural or artificial, which bears the like analogy to that which obtains, universally, at other refractory surfaces; for, as, in other cases, the ratio is given between the sine of incidence and sine of refraction, (or ordinate of the spherical undulation propagated,) so in the Iceland crystal, the ratio between the sine of incidence and ordinate of refraction (in any one section of the spherical undulation) in a given ratio, but different in different planes.

Dr. Wollaston observes, that though we do not fully understand the existence of a double refraction, and are utterly at a loss to account for the phenomena occurring upon a second refraction, by another piece of the spar, yet that the oblique refraction, when considered alone, is nearly as well explained as any other optical phenomenon. Phil. Trans. for 1801 and for 1802.

REFRACTION, Particular laws of, in different kinds of leades; see Lens.

REFRACTION, Atmospheric, is generally considered under two distinct heads; viz. astronomical refraction, which is that relating to the refraction of the moon, stars, and other celestial bodies; and terrestrial refraction, or that which takes place in terrestrial observations.

It appears, from the article REFRACTION, that a ray of light is refracted in passing obliquely out of one medium into another of different density; and as the atmosphere may be considered as composed of an infinitude of strata, whose density increases as they are peopled nearer the earth, the luminous rays which pass through it are acted on as if they passed successively through media of increasing density, and are therefore inflected more and more towards the earth, as the density augments, that is, as they approach the eye of the observer. In consequence of this it is, that rays from objects, whether celestial or terrestrial, proceed in curves which are concave towards the earth; and since the mind always refers the place of objects to the direction in which the rays reach the eye, that is, to the direction of the tangent to the curve at that point, it follows, that the apparent or observed elevation of objects is always greater than the true one, at least with the exception of some few remarkable anomalies which sometimes, in terrestrial observations, produce a contrary effect, and of which we have stated a few particular instances under the article Mirage, and on which subject some other curious facts are related in the memoir of professor Vine's, in the Phil. Trans.; in Nicholson's Philosophical Journal, and more particularly by M. Monge, in vol. i. of the "Decade Egyptian." Referring the reader therefore to those works to which we have added to the memoir by M. Dior, in vol. x. of the National Institute, for an account and explanation of those phenomena, we shall confine our present observations to those cases only, in which an uniform law is supposed to have place, and which, as we have seen, has a constant tendency to augment the observed altitude of both terrestrial and celestial objects.
REFRACTION.

In order to submit the phenomena of refraction to strict mathematical investigation, it must be observed that, in consequence of the inconsiderable height of the atmosphere, and its spheric form, a luminous ray impinging upon it, even in the most unfavourable case, that is directly in the horizon, traverses only a small quantity of this medium; and in this space, if the atmosphere is calm, the density of the air at equal heights above the level of the sea is everywhere the same. Therefore, in supposing the earth spherical, a supposition which may be admitted, in the present case, without any sensible error, we may consider the atmosphere as composed of successive spheric concentric shells, or strata, of which the density diminishes from the surface of the earth upwards.

Let us conceive, now, a luminous ray, coming from a distance, to penetrate into one of the suppos'd spheric shells; then, if through the common centre of these shells, which is the centre of the earth, we suppose a plane to pass in the direction of the luminous ray, the spheric beds of the atmosphere will be divided into two equal portions, which act upon equally upon the ray; can produce no deviation of it from that plane; whence it follows, that the effect of refraction is entirely produced in a vertical direction, and in such a manner as to augment the apparent altitudes of the heavenly bodies, and consequently to diminish their zenith distances.

But the intensity of these effects will not be the same at all heights, for we know that in all cases the quantity of refraction depends upon the obliquity of incidence, and therefore the refraction in the zenith is equal to zero, and increases from that point to the horizon, where it is the greatest.

If, now, we knew the law by which the density of the air is diminished in ascending from the earth, that is, if we knew the difference in the density of any two consecutive strata, it would be comparatively a direct and easy problem to find the whole amount of refraction for any given angle of observation; but unfortunately the uniformity of decrease in the density of the atmosphere, which, according to theory, is in geometrical progression, is so much interrupted by the multitude of causes which may tend to produce this effect, that it is found that the quantity of refraction computed on this principle, will by no means agree with that deduced from actual observation. It has been, however, demonstrated, that the quantity of refraction, in all cases exceeding 10 or 12 degrees of elevation, is not sensibly affected by any irregularity in the law of density, in the strata of which we have supposed the atmosphere to be composed, but that it depends simply upon its pressure and temperature at the time and place of observation, which are indicated at the time by the barometer and thermometer. It was formerly thought, also, that refraction was influenced by the degree of purity and dryness of the air; but from a great variety of interesting and accurate experiments, carried on by M. M. Biot and Arrago, it appears indisputably established, that no sensible effect is thence produced.

See a memoir on this subject by the former author, in vol. x. of the National Institute.

But before we proceed farther in this interesting subject, it will be proper to give a sketch of the several improvements which the theory has experienced in the hands of different celebrated astronomers: in doing which we shall avail ourselves of a memoir, published by Dr. T. S. Evans in the Philosophical Magazine, which contains a minute and circumstantial detail of many important particulars connected with this subject. There appears to be but little doubt that the astronomic refraction was known to the ancients, since it is expressly mentioned by Ptolemy, although not made use of in his calculations. He says, near the end of the 8th book of the Almagest, that in the rising and setting of the heavenly bodies, there are changes which depend upon the atmosphere, and he mentions it more at length in a work on optics, which, unfortunately, has not been handed down to us. Alhazen, an Arabian writer, who is generally supposed to have lived about the year 1000, and to have taken the greater part of his optics from the works of Ptolemy, speaks also decidedly of it, and shews the manner of computing our refractions by experiment. "Take," says he, "an armillary, which turns round its poles, and measure the distance of a star from the pole of the world when it passes near the zenith in the meridian, and when it is rising or setting near the horizon, and you will find the distance from the pole less in the latter case." He then demonstrates that this must arise from refraction, but he does not state its quantity.

In the collection of observations made by Bernard Walter, and published by Willemoke Snell in 1618, it is stated, that the observations were so exact, that they pointed out to Walter the quantities by which the altitudes of the stars and planets were increased on account of the refraction.

Tycho Brahe, however, appears to be the first who attempted, with any degree of accuracy, that the refraction elevates the heavenly bodies rather than half a degree when on the horizon. (See Progym. p. 15.) But either his instruments or his observations were not sufficiently correct to determine it with certainty for all degrees from the zenith to the horizon; and, accordingly, where these failed, they were supplied by conjecture. He believed that the sun's refraction was 34° in the horizon, and that it became insensible at 45° of altitude. For the stars, however, he assumed an entirely different quantity, viz. 30° in the horizon; but this, according to him, terminated at only 20° of altitude.

The following is the manner in which it is related (Ency. Method.) that Tycho made this discovery. He had determined, with one or two instruments extremely well made, the latitude of the place by observations of Polaris above and below the pole. He determined it also by the sun's altitude in both follicles, and found it four minutes less in the latter. At first he doubted the goodness of his instruments, and therefore constructed, with the utmost care, as many as ten others, of different sizes and forms, but they all gave nearly the same results. He could, therefore, no longer attribute this difference in the two determinations of the latitude to any defect in the observations, but endeavoured, by an attentive consideration of the subject, to find out the cause of this singular phenomenon. At length he found that this could only arise from the refraction which elevated the sun at the winter follicle, having then only 11° of elevation above the horizon. This refraction agreed very well with the principles of optics, but ill Tycho Brahe could scarcely persuade himself that the refraction was sufficiently large to produce so great a difference. On this account, he made other instruments of ten feet diameter, whose axes corresponded exactly with the pole of the world, and with these he measured the declination of the stars out of the meridian. He then found, that even in summer the refraction, although insensible at the meridian, was very considerable near the horizon, and amounted to half a degree in the horizon. See Progyma. p. 79—104. Street's Alfr. Carol. p. 119.
Tycho Brahe's table of refraction is as follows:

In this state the refraction remained for many years. Even Riccioli, in 1665, supposes it nothing at about 26° of altitude; but he thought the moon had only 29' of horizontal refraction in summer, the sun 30', and the stars 30° 30'. It was not till after the year 1672, that a tolerable near table of refraction made its appearance, when the older Callini took the subject into consideration. (Mem. de l'Acad. tom. v. p. 81.) What led to this was the voyage of Richer to Cayenne in that year, upon the utility of which some very excellent remarks were made by Callini, shewing how far observations made in a situation so near the equator tended to confirm or disprove certain theories derived from observations made in Europe. Several very useful deductions were drawn from a comparison of those made both at Paris and Cayenne; among others, the refraction was settled upon more accurate elements than heretofore, and a new table computed, for the first time, of its quantity, for all degrees, up to the zenith; an abridgment of which is given below:

</table>

From the relation of his grandson it appears, however, that Callini had at one time computed three tables of refraction for all altitudes; one for winter, another for summer, and a third for spring and autumn; but several doubts having been suggested to him respecting this arrangement, although in appearance conformable to nature, and principally the observations of Richer at Cayenne, where the refraction was found little different from that at Paris, he changed his opinion; and judging, that since the great difference of heat of the torrid zone from that of the temperate zone, which we inhabit, does not cause sensible differences in the refraction; therefore the greatest heat or cold of our climate could not change it much; and he then fixed upon one table, which was that used by the astronomers of the Royal Observatory at Paris up to the year 1745.

It was always thought, before the time of Callini, that the refraction did not extend its influence higher than 45° of altitude; and he is generally considered as the first who proved that it reached all the way to the zenith. He also supposed that near the equator the horizontal refraction was less than in our climate by about one-third; that this difference decreased as far up as 60°, after which it was the same nearly for both climates.

From this discovery it followed, as a natural consequence, that the refraction must be greater near the pole than at Paris; and this was shortly afterwards proved to the Academy by the publication of a work expressly on that subject. (Refraction solis inconstit. &c. Holmiae, 4to. 1695.) The king of Sweden, being, in 1694, at Tornea, in Well Bothnia, near the latitude of 65° 45', and observing that the sun did not set there in the summer solstice, sent the following year some mathematicians to make more certain and exact observations of this curious phenomenon. They are contained in this book, and Meffs. Callini and de la Hire concluded from them, that in the latitude of 65° 45' the horizontal refraction must be 58', or nearly double of that at Paris.

According to an observation made by some Dutchmen who passed the winter of 1599-7 in Nova Zembia, in latitude 76° north, the sun, which had entirely disappeared the 14th of November, began to rise again the 24th of January, viz. six days sooner than was expected, according to astronomical calculations. If so, when the sun has been two or three months under the horizon, as the Dutchmen observed in 1597, the cold becomes dreadful, and perhaps the refraction increases prodigiously. M. le Monnier affirms, that he found by the observations printed in 1599, that on the 24th and 25th of January 1597, there were more than 45 degrees of refraction; that he could not explain these observations, reject them as doubtful, nor suppose any error, as was done by most of the other astronomers, Kepler, Callini, Scotia, and lastly, M. le Gentil, in his Voy. dans les Mers des Indes, tom. i. p. 395, tom. ii. p. 832, who maintained that there were errors in the observations, and accordingly read a memoir on the subject. If it were not so difficult a task to winter in these high latitudes, we might expect such observations as would remove all doubt on the subject; and, perhaps, bring others to light of as great or greater importance.

The refraction of the north being so considerable, is very useful to the inhabitants, who are deprived of the sun's light during many months; as it makes the sun rise much earlier, and set much later to them, than it otherwise would.

About the year 1725, Mr. Flamsteed, the English astronomer royal, published his table computed from his own observations: and this was the one commonly used in England for many years afterwards.

Sir Isaac Newton also constructed one from theory, which was first published by Dr. Halley in the Philosophical Transactions, No. 368, for 1721. He made the horizontal refraction 33° 45'; whereas Mr. Flamsteed's was only 33° 00'.

But although the refraction might be determined within a few seconds at all altitudes by observation; yet, the law of its increase from the zenith to the horizon was a subject that occupied the principal mathematicians and astronomers for more than a century. Newton having discovered the general principles of attraction, found that the refraction was a consequence of this law of nature; and that it arose from the attraction of the atmosphere on the particles of light. On this principle the curve which a ray of light describes might be determined; since it is successively attracted...
of the variation of density in the atmosphere, as indicated by the barometer and thermometer, is due to Messrs. Lowther and Haukblée; the former of whom, in 1698, proved by a very simple experiment, in the presence of the Royal Society, that the refractive power of air is directly proportional to its density; and the latter, by repeating and extending the same course of experiments in the year 1708, with the machinery pointed out by the former, found that the variations of refraction, depending on the barometer, are proportional to the alteration of height of the mercury in the tube; and by a series of these experiments, he furnished us with a table of the corrections which it is necessary to make on account of the changes of heat indicated by the thermometer. These experiments, although not quite conclusive on the subject, were yet made with as much accuracy and care as the nature of the machinery, and the state of experimental philosophy of that time, would admit. An example is also given, towards the end of his paper, on the mode of applying them to correct the refraction. By these, Haukblée found that a volume of air expressed by unity, when the thermometer was at 180° above zero, became, at 50° below, one-eighth more dense; or, which is the same thing, that the air lost one-eighth of its density, for an elevation of 160° Fahrenheit's thermometer; which is exactly the difference of heat between melting ice and boiling water. But although this one-eighth, as will be shown hereafter, was too small; yet it laid the foundation for other experiments, since made by several philosophers, by which the quantity of expansion has been determined more accurately.

We have already shewn that the refraction near the pole is greater than in our climate; the degree of cold being more intense. It was also found to be less in the torrid zone, where the heat is greater than in Europe. Bouguer made a variety of observations at Peru, the result of which he has given us. In 1745, he came down into an island situated in the river of Emeralds, called Ile de Inca, where he determined the refraction from 1° to 9° of altitude; and the table which he afterwards computed shews the refraction to be about one-twelfth less than in Europe. The horizontal refraction he found to be 27° at 6° of altitude and 45° it is 44°. Bouguer then gives a table for Quito, which was the reference place at that time. Here, the refraction was elevated above the level of the sea. M. le Gentil found it greater at Pondicherry in India, although in the torrid zone.

The refraction diminishes when we are elevated above the level of the sea. Bouguer observed the quantity of it at Chimbaco, 2388 toises above the level of the sea, and found it in the horizon 103°. At the crofs of Pichincha, 2044 toises above the sea, he found it 20° 46'; at Quito, 1479 toises above the sea, 21° 50' but at the level of the sea 27°. These observations, when joined with the theory, produced the following rule; viz. if we take the excess of 5158 toises above the elevation of the place, with regard to the level of the sea, the refraction will be as the square root of this excess. Thus the square root of 5158 toises is 27°, for the horizontal refraction, at the level of the sea, in the torrid zone; and the square root of the excess of 5158 above the elevation of the place will be its horizontal refraction. The quantity 5158 is the height above which the refractive matter no longer produces any sensible effect; at least in the torrid zone.

But although by this time considerable attention had been paid to the subject, yet great differences were to be found in the tables then most in use. Thus at the altitude of 30°, according to Flammel, the refraction was 1° 28'; Newton, 1° 32'; Caffini, 1° 42'; and de la Hire, 1° 55'; leaving an uncertainty of more than half a minute; and it must have been very mortifying to an observer, after having taken the utmost
Refraction.

It is indeed rather extraordinary, that in a memoir published by Cassini de Thury, among those of the Academy for 1745, he attempted to reconcile a number of observations with each other, by considering the state of the barometer only, without at all noticing that of the thermometer; although that at that time Haukibee’s experiments had been published about 37 years.

He concludes his paper, as it is very natural to suppose, without being able to make the observations agree: nor does it clearly appear that the French noticed the above-mentioned experiments made by Haukibee till about the year 1749. It is also worthy of remark, that although the necessity of introducing corrections on account of the alterations of the barometer and thermometer were likewise shown to be absolutely necessary by Dr. Halley (Phil. Trans. No. 364), and the circumstance mentioned, and in some degree admitted by Le Monnier (Hilt. Célébrit.), yet it does not appear that he followed the advice of his illustrious contemporary, but merely endeavoured, as Cassini did, to reconcile his observations with the state of the thermometer at the time of making these observations, without taking the barometer into account.

It would be endless to notice the different opinions respecting both the terrestrial and the astronomic refraction which are to be met with in the writings of various authors on the subject: and it would be equally useless to notice all the tables of its quantity given by them, some of which differ very much from others. It will be sufficient to mention those only who made some considerable advances towards obtaining it with greater accuracy.

The next of these in order was La Caille (Mem. de l’Ac. de Berl., 1754, p. 131.), who in determining it certainly bellowed very great pains, by making and reducing an immense number of observations, and afterwards comparing them with others made at Greenwich by Dr. Bradley, at Gottingen by Mayer, at Bologna by Zanotti, and by La Lande, who was then at Berlin. From these it appeared that the refraction at 45° of altitude was 1° 6½’; but this, as will hereafter be seen, was too great by some seconds. In his paper on the subject, which is divided into four parts, he proves, first, that the mean refractions are very nearly the fame for the same apparent altitudes throughout the whole extent of the temperature zone; since those which were observed at Paris did not exceed those observed at the Cape of Good Hope but by 4° at most. In the second he determines the absolute quantity of the mean refraction for the apparent height of the pole at Paris, and gives the result of his observations with regard to the latitude of Paris and of the Cape of Good Hope. In the third he gives his table of mean refraction, and another of corrections depending upon the state of the barometer and thermometer; concluding with some reflections on its construction and use. In the fourth he compares his new table with the most celebrated of those that had before that time been in use among astronomers: and he then shews how it agrees with the observations of Bradley, Zanotti, and Mayer.

But by La Caille’s memoir it appears, that previous to this time M. Mayer had formed and communicated to him a table of astronomic refractions which he computed by means of an algebraic formula, the co-efficients of which he deduced from his own observations, and took into account the variations relative to those of the barometer and thermometer. He found the alteration of refraction for a depression of 15 lines in the barometer, the same as for a rise of 10° in the thermometer, and the variation for each degree of the latter, according to his table, ½ of the whole mean refraction, which he adapted for 28 inches of the barometer, and 0° of the thermometer. This proportion takes place down to 80° of zenith distance. Mayer considered also the mean refraction is the same for all parts of the earth; and that the only variation which takes place depends on the changes of the weight and temperature of the atmosphere.

La Caille, in comparing Mayer’s table with observations, found that his correction for the thermometer was a little over-rated; and accordingly, for his new table, altered it to ½ for each degree. And here it may be observed that La Caille did not correct his altitudes above 36° at Paris, and 30° at the Cape; first, because he only noted the barometer and thermometer in the night, when he observed stars below 30° of altitude. Secondly, because, that at 36° of altitude, where the mean refraction is about 1½ minutes, the variation which belongs to 10° of the thermometer only amounts to 3½ seconds; a quantity about equal to the limits of the errors of observations made with an instrument of fix feet.

The formula given by Euler (Mem. de l’Ac. de Berl., 1754, p. 131.), appeared also about this time. It took into account the variation of the refraction depending upon the thermometer and barometer, but was certainly too complicated to be generally adopted. He shews, however, that in very different hypotheses the refraction will be sufficiently exact, if taken in the inverse ratio of the degrees of heat, when the star or planet is not too near the horizon, but the precise quantity of this ratio was unknown to him.

In this state the refraction stood when Dr. Bradley took the subject into consideration, and began to find its quantity from his own observations. The rule which he adopted, although a very elegant one, he neither lived to complete nor to present to the world; but it was published after his death by Dr. Malkeley, (Pref. to 11 vol. of Obs. 1765. Phil. Trans. 1764. and 1787. p. 157. Req. Tables, &c.), and has commonly been used in England up to the present time. He found the mean refraction at 45° of altitude 57”, and, that at all other altitudes, it was equal to 57” multiplied by the tangent of the zenith distance, diminished by three times the refraction. Then supposing the mean state of the atmosphere to be at 29.6 inches of the barometer, and 50° of Fahrenheit’s thermometer, he made the true or corrected refraction equal to 57” × (Z. D. − 3r) × 400

barom. × 400

29.6 + 350 + ther., where it is to be understood that the mass of air is supposed to increase in bulk 4½ for each degree of Fahrenheit’s scale.

A variety of experiments has been made at various times to ascertain the increase in bulk of a quantity of air represented by unity for a certain number of degrees of rise of the thermometer. The following is a list of some of those:

The
REFRACTION.

The refraction deduced from Bradley's very neat and simple formula was, in a few years, adopted by nearly all the astronomers of eminence throughout Europe. The extreme facility with which it might be computed, and the corrections applied, whether from the formula itself, or from tables ready calculated for that purpose, was a powerful recommendation in its favour; but its near agreement with observation soon established it.

We must now, without entering farther into detail of minor improvements, proceed at once to the chapter given by La Place on this subject, in his "Mécanique Céleste," vol. iv. p. 231, where he has drawn, from an investigation which we cannot undertake to exhibit in this place, the following general formula, for expressing the refraction for all angles of elevation above 12 decimal, or 10.8 sexagesimal degrees, viz.

\[ r = \frac{a \cdot \tan z}{0.76 (1 + f \cdot 0.00375)} - \frac{a \cdot 0.00125234}{\cos^2 z} \tan z 
+ \frac{\frac{1}{2} a \cdot \tan 1^\circ}{0.76 (1 + f \cdot 0.00375)} \times \frac{(1 + 2 \cos z \cdot \tan z)}{\cos^2 z} \]

where all the quantities are known except \( r \) and \( a \); which latter represents a constant co-efficient; \( z \) is the observed zenith distance under the barometric pressure \( p \), in metres, and \( t \) the temperature of the centigrade thermometer, \( r \) being the refraction; all, therefore, that is required for determining \( r \), is the value of the unknown co-efficient \( a \); which is to be drawn from observations on the circumpolar stars, in the following manner.

Let \( Z \) be the distance of one of these stars from the zenith, in its superior meridian passage; \( Z' \), this distance at the inferior meridian passage, observed from the same point of the terrestrial surface; \( r \) and \( r' \), the corresponding refractions. Now all the other quantities, except \( a \), being known, we may, for the sake of simplicity, put the above formula for both passages under this form,

\[ r = A a + B a', \]

where \( A, B, A', B' \) are all known quantities. Writing also \( Z, Z' \) for the observed zenith distances, the true zenith distance, \( D \), corrected for refraction, will be

\[ Z + Z' + (A + A') a + (B + B') a' = 2 D; \]

in which all the quantities are known, except \( a \) and \( D \). But by repeating similar observations on some other star, and denoting by \( Z'', Z''', A'', A''', B'', B''' \), the similar quantities before represented by \( Z, Z', A, A', B, B' \), &c. also \( a \) and \( D \) remaining the same for all stars observed in the same place, we shall have these two equations:

\[ Z + Z' + (A + A') a + (B + B') a' = 2 D, \]
\[ Z'' + Z''' + (A'' + A''') a + (B'' + B''') a' = 2 D; \]

from which it is obvious, the constant co-efficient \( a \) may be obtained by the usual methods of elimination.

In the above operation, however, we have supposed the polar distances of the same star to be the same for its superior and inferior passage; whereas we know that, in consequence of the effect of precession, nutation, and aberration, this distance is constantly varying; and we ought, therefore, to introduce these variations into the above equation. But our object being merely to give a general view of the principles made use of for the determination of the co-efficient \( a \), we have not thought it necessary to enter into the minutia of the computation. It appears from the above, that the constant co-efficient \( a \) may be determined by means of four observations on two different circumpolar stars; and consequently, that every such set of observations ought to produce the same result, or the same value of \( a \). Considering, however, the extreme accuracy required in such cases, both in the instruments and the application of them, some little disagreement is to be expected; and indeed one is surprised to see it so small, as it has been found to be in various observations undertaken for this purpose, and the mean of which we have every reason to consider as perfectly correct; and which is rated by M. Biot, who has interested himself very much on this subject, at 187°, 24 for the decimal division, or 60°, 666 for the sexagesimal.

But now, in order to simplify our first formula, by taking \( p = 0.76 \) metres, and \( t = 0 \), this may be put under the form,

\[ r = a \tan Z \left( 1 - \frac{0.00125234}{\cos^2 z} \right) + \frac{1}{2} a \sin 1^\circ \frac{1 + 2 \cos z \cdot \tan z}{\cos^2 z} \tan Z; \]

in which substituting for \( \cos z \), its value \( \frac{1}{1 + \tan^2 z} \), and the proper numerical value of \( a \), as above found, as also of \( \sin 1^\circ \), the whole is reduced to the following form, viz.

\[ r = 0.99918761 \cdot a \tan Z - 0.001105823 \cdot a \tan Z; \]

which latter form of M. Biot has shewn to be equivalent to

\[ r = 187' 24 \cdot \tan (Z - 3' 25 r) \] for the decimal division;
\[ r = 60°' 666 \cdot \tan (Z - 3' 25 r) \] for the sexagesimal division.

But the reduction of it to this form would occupy more space than can be allowed for this article. This last form is as simple as can be devised, from which the following rule in words may be deduced, viz. The refraction under the same barometric pressure, and the same degree of temperature, is proportional to the tangent of the apparent zenith distance of the star, diminished by \( \frac{3}{2} \times \) the refraction.

It must be remarked, however, that the formula \( r = A \tan (Z - 3' 25 r) \), though it exhibits the law of refraction as if simple a form as can be devised, is not well adapted for calculation, in consequence of \( r \) entering on both sides of the equation; and astronomers have, therefore, given different methods of rendering the above formula more commodious. In order to which, it is first put under the form,

\[ \tan n r = \tan^2 n R \tan (Z - n r); \]

\( R \) representing the refraction, answering to \( Z = 90^\circ \).

Let us now add successively to both sides of this equation, the quantities \( \tan n r \tan^2 n R - \tan n r \tan^2 n R \), and we shall have,

\[ \tan n r (1 + \tan^2 n R) = \tan n R [\tan (Z - n r) + \tan n r], \]
\[ \tan n r (1 + \tan^2 n R) = \tan n R [\tan (Z - n r) - \tan n r]. \]

Now, dividing these equations, member by member, \( n r \) will be eliminated, and we obtain

\[ \frac{1 + \tan^2 n R}{1 - \tan^2 n R} = \frac{\tan (Z - n r) + \tan n r}{\tan (Z - n r) - \tan n r}, \]

or

\[ \frac{1}{\cos n R} = \frac{\tan Z}{\tan (Z - 2 n R)}; \]

whence we draw

\[ \tan (Z - 2 n R) = \cos n R \cdot \tan Z. \]

Now
REFRACTION.

Now \( Z \) and \( n R \) being known, we may compute the second side of this equation; whence the arc \( Z' = 2 \tan r \) is known, and consequently \( 2 \tan r \); which, divided by \( 2 n \), will give \( r \), as required. But it may be found still more simply by the formula,

\[
\tan \, ur = \tan \, n \, R \, \tan \, \frac{1}{2} \, n;
\]

\( \tan \, n \) being found by means of the auxiliary equation,

\[
\tan \, u = \sin \, n \, R \cdot \tan \, Z.
\]

On the principle above explained, the following table of refractions has been computed, agreeing with the temperature of +14° on the centigrade thermometer, and under a preflure of 0.76 metres of the barometer; which is the same as 57.2 Fahr. and 29.922 English inches. And for any other temperature and preflure, the corresponding correftions must be made as indicated in Tables II. and III.; which tables are computed by means of the general formula given in the preceding part of this article.

We had intended to give here a short abftrait of a very interesting paper on this subject, published by Mr. Groomebridge, in the Philofophical Transactions for 1810; but having already exceeded our usual limits, we can only refer the reader to the volume itself, where he will find several neat and useful formulæ.

Having thus given a sketch of the method of determining the quantity of astronomical refraction for all angles of elevation, and under various degrees of temperature and barometric preflure, let us add a few words on the subject of terrestrial or horizontal refraction; for the determination of which, the following method has been successfully practiced in the English Trigonometrical Survey.

Let \( A, A' \) (Plate XIX. Astronomy, fig. 11.) be two elevated places on the surface of the earth; \( B, B' \), the intercepted arc of the earth's surface; \( C \), the centre of the earth; \( A', A' \), the horizontal lines at \( A, A' \), produced to meet the oppofite vertical lines \( C, C' \). Let \( a, a' \), represent the apparent places of the objects \( A, A' \); then is \( \Delta A A' \) the refraction obferved at \( A \), and \( a A' A' \) the refraction obferved at \( A' \); and half the fum of these angles will be the horizontal refraction, if we assume it equal at each fation.

Now an instrument being placed at each of these fations \( A, A' \), the reciprocal obfervations are made at the fame in-stant of time, which is determined by means of signals or watches previously regulated for that purpofe; that is, the obfERVER at \( A \) takes the apparent refpiration of \( A' \), at the
### REFRACTION.

</table>
To observe the Refraction of a Star, &c. 1. Observe the meridian altitude of a star near the zenith, whence the latitude of the place being known, the true declination of the star is easily had, the star being now void of any sensible refraction. 2. Observe the altitude of the same star in any other degree, and note the time by a pendulum. 3. For the given time of observation, from the declination of the star compute its true altitude.

This being thus found less than the altitude observed, subtract the one from the other; and the remainder is the refraction for that moment, in that degree.

Refraction of Altitude, is an arc of a vertical circle, by which the altitude of a star is increased by the refraction.

Refraction of Declination, is an arc of a circle of declination, by which the declination of a star is increased or diminished by the refraction.

Refraction of Afternoon and Deflection, is an arc of the equator, by which the ascension and declination of a star, whether right or oblique, is increased or diminished by means of the refraction.

Refraction of Longitude, is an arc of the ecliptic, by which the longitude of a star is increased or diminished by means of refraction.

Refraction, in Commerce, is a term sometimes used by merchants, where there has been an oversight in an account, to the prejudice of a person; who thereupon demands restitution of so much, added or omitted by mistake.

You must make me a refraction of five pounds forgot in your account. I will deduct or make you a refraction of 30s. charged inadvertently in my bill.

Refractory, in Chemistry. See an explanation of the term under Apyrous.

Refraint, Fr., in Music, the termination of every verse or stanza of a song, by the same words and the same melody. (See Burden.) The word, according to Megna (Dit. Etym.) is derived from the Spanish refran.

Refraint, Span., a proverb; the burden of a song in that language, being usually sententious, and including some moral precept.

Refrangible, whatever is capable of being refracted. See Refrangibility.

Refrangibility of Light, the disposition of the rays to be refracted.

A greater or less refrangibility is a disposition to be more or less refracted, in falling at equal angles of incidence, into the same medium.

That the rays of light are differently refrangible, is the foundation of Sir Isaac Newton's whole theory of light and colours. The truth of the principle, which was investigated and established by our great philosopher in the year 1666, will appear from the following experiments.

1. Let E G (Plate XIX. Optics, fig. 1.) represent the window-shutter of a dark room, and F a hole in it, through which the light is transmitted to the prism A B C, which refracts it towards P T, where it appears in an oblong form; its length being about five times greater than its breadth, and exhibiting the various colours of the rainbow. In fig. 2. a g b represents a second prism, which refracts the light back again to Q, where the image is round, whereas, without the intervention of this second prism, the light would have proceeded to P T, and, consequently, have been oblong, as before. In this experiment Sir Isaac Newton took care that the plane a g was placed exactly parallel to B C, and also b g to A C, that the rays might be equally refracted, though in contrary ways, by both prisms. He also observed, that both prisms must be placed very near to one another; for if their distance be so great, that colours begin to appear in the light, before its incidence on the second prism, those colours will not be destroyed by the refraction of that prism.

2. Having placed one of two boards behind the prism at the window, so that the light might pass through a small hole made in it for the purpose; and fall on the other board at the distance of about twelve feet, a hole being made in it to admit the passage of the incident light, he then placed another prism behind the second board, so that the light which was transmitted through both the boards, might pass through that also, and be again refracted before it arrived at the wall. This being done, he took the first prism in his hand, and turned it about its axis so much, as to make the several parts of the image, cast on the second board, successively to pass through the hole in it, that he might observe to what places on the wall the second prism would refract them; and he saw, by the change of those places, that the light tending to that end of the image, towards which the refraction of the first prism was made, did, in the second prism, suffer a refraction considerably greater than the light which tended to the other end. The true cause, therefore, of the length of that image was discovered to be no other, than that light is not similar or homogenel, but that it confines of rays, some of which are more refrangible than others; so that without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

To make this capital experiment, which Sir Isaac Newton himself justly calls the experimentum crucis, let S P (fig. 3.) represent a ray of the fun, which, after passing through a hole in the window-shutter F, is received by the prism in A B C, close behind which is placed a board D E, with a hole in it at G, to admit any of the rays after they have been separated by the prism; then d e will represent the other board, placed at a considerable distance from the former, with a hole in it, g, to receive any part of the light transmitted through the other board. Behind this board is placed another prism, a b c, through which different, rays of light, falling upon it in the very same place, and with precisely the same angle of incidence, will be refracted higher or lower, on the opposite wall M N. This experiment was conducted with the utmost circumspection and accuracy; and it is observed, that neither the different magnitude of the hole in the window-shutter, nor the different thicknesses of the prism, at the place where the rays passed through it, nor the different inclinations of the prism to the horizon, nor the different matter of the prisms, made any sensible change in the length of the image.

3. In order farther to establish this famous hypothesis of the different refrangibility of the rays of light, he held a prism in a beam of the sun, which was transmitted into the room through a hole in the window-shutter, so that its axis might be perpendicular to that beam; and having turned the prism about its axis to make the image ascend and descend, and when it seemed to be stationary between these contrary motions, he fixed the prism so that the refractions of both sides might be equal to each other. In this situation he looked at the hole through the prism, and observed the length of its refracted image to be many times greater than its breadth; the most refracted part of it was violet, the least refracted red, the middle parts blue, green, and yellow, in order. The same thing happened when he removed the prism.
out of the sun's light, and looked through it upon the hole
shining by the light of the clouds beyond it.

2. Considering that if the image of the sun should be
drawn into an oblong form, either by a dilatation of every ray,
or by any other casual inequality of the refractions, the same
oblong image would, by a second refraction, made sidewayes,
had drawn out as much in breadth, he placed a second prism
immediately after the first, in an oblique position with respect
to it, that it might again reftar the light of the beam of the
sun's light, which came to it through the firft prism; so that
in the firft prism, the beam would be refracted upwards, and
in the second sidewayes. But he found that the breadth of the
image was not increafed by the refraction of the second
prism, but only its upper part, which in the firft prism suf-
ftered the greatest refraction, and appeared violet and blue,
did again, in the second prism, suffer a greater refraction,
more than the lower part of it, which was red and yellow,
and this without any dilatation of the breadth of the image.
Thus let S (fig. 4.) represent the fun, T the hole in the
window, A B C the firft prism, and D H the fe-
cond. If Y represent the round image of the fun, made
by a direct beam of light, when the prisms are taken
away, P T will be the oblong image of the fun, made
by the fame beam passing through the firft prism only, and
P T will be the image made by the crofs refractions of both
prisms together. Sometimes he placed a third prism after
the second, and sometimes a fourth after the third; by
all which the image might be often refracted sidewayes, but
the rays which were more refracted than the refi in the firft
prism, were also more refracted in all the others, and that
without any dilatation of the image sidewayes; and, there-
fore, thofe rays, on account of their conftancy of a greater
refraction, he called the more refrangible ones. He obferves,
in order to render the meaning of this experiment more evi-
dent, that all the rays, which are equally refrangible, fall
upon a circle anfwering to the fun's dife. Let, therefore,
A G (fig. 5.) represent the circle which all the moft re-
frangible rays, transmitted from the whole dife of the fun, would
illuminate, and paint upon the other wall, if they were
alone. Let L L be the circle which all the leaft refrangible
rays would, in like manner, illuminate and paint, if they
were alone, and let B H, C J, and D K, be the circles
which fo many intermediate kinds of rays would succelfively
paint upon the wall, if they were fringely propagated from
the fun, the refi being always intercepted, and conceive that
there are other intermediate circles without number, which
other innumerable intermediate kinds of rays would succel-
Sively paint upon the wall, if the fun fould successively
emit every kind by itself. Now fince the fun emits rays of
all these kinds at once, they must altogether illuminate and
paint innumerable equal circles, of all which, being ranged
according to their diferent degrees of refrangibility, the
oblong image P T before defcribed is compofed.

Now if the fun's circular image, Y, which is made by an
unrefracted beam of light, was by any dilatation of the fin-
gle rays, or by any other irregularity in the refraction of the
firft prism, converted into the oblong image P T, then
ought every circle in the image to be in like manner drawn
out into a fimilar oblong figure, contrary to the refult of
this experiment.

He confidered farther, that by the breadth of the hole
through which the light enters into the dark chamber, there
is a penumbra made in the circumference of the image Y,
which is alfo visible at the fides of the oblong images P T
and P T. He, therefore, placed at that hole a lens, or ob-
ject-glafs of a telescope, which might call the image of the
fun dillinctly on Y, without any penumbra at all; and he
found that the penumbra of the rectilinear fides of the ob-
long images P T and P T was alfo thereby taken away, so
that they were as dillinctly defcribed as the circumference
of the firft image Y.

There are fome other circumftances attending this exper-
iment, by which the conclusion drawn from it is made still
more plain and convincing.

Let the fefond prifm, D H, (fig. 6.) be placed not im-
mediately after the firft, but at fonie diftance from it, fo
that the light from the firft prifm may fall upon it in the
form of an oblong fpeftrum g r, parallel to this fefond
prifm, and may be refracted sidewayes, to form the oblong
image, P r, upon the wall, and it will be found that this
image, P r, is inclined to the image P T, which the firft
prifm would have formed without the fefond; the blue
ends, P and r, being farther diftant from one another than
the red ones, T and r; and, confequently, the rays which
go to the blue end, p r, of the image q r, and which, there-
fore, suffer the greateft refraction in the fefond prifm, are
again, in the fefond prifm, more refracted than the refl.

At two holes made near one another in his window-
flutter, he placed two prifms, one at each, which might
call upon the opposite wall two oblong coloured images of
the fun; and at a little diftance from the wall he placed a
long flender paper, with ftraight and parallel edges; and he
placed the prifms and papers, fo that the red colour of one
image, at T, (fig. 7.) might fall directly upon one half of
the paper, and the violet colour, M, of the other image,
on the other half of the fame paper. Then washed all a
black cloth he covered the wall behind the paper, that no light
might be reflected from it to disturb the experiment; and
viewing the paper through a third prifm, held parallel to i, it
faw that half of it which was illumined by the violet
light to be divided from the other half, by a greater refra-
cion, especially when he retired to a confiderable diftance
from the paper.

He farther caufed the two images, P T and M N (fig. 8.)
to coincide, in an inverted order of their colours, the red
end of each falling on the violet end of the other; and then
viewing them through a prifm D H, held parallel to their
length, they no longer appeared coincident, as when they
were viewed with the naked eye, but in the form of two
difficult images, p t and m n, crossing one another in the
middle; which fhews that the red of the one image, and the
violet of the other, which were coincident at P N and M T,
being parted from one another by a greater refraction of the
violet to p m, than that of the red to n r, differ in de-
gree of refrangibility.

Having placed a prifm, whose two angles at its bafe
were equal to one another, and half right ones, and the third
a right one, in a beam of the fun's light, admitted into the
room as before, he turned it slowly about its axis, till all
the light which went through one of its angles, and was
refracted by it, began to be reflected by its bafe, (at which,
til then, it went out of the glafs,) and then he obferved
that those rays which had suffered the greateft refraction
were sooner reflected than the refl. He imagined, therefore,
that those rays of the reflected light, which were moft re-
frangible, did firt all of them, by a total reflection, become
more copious in that light than the refl; and that afterwards
the refl, also, by a total refLECTION, became as copious as they
were. To try this, he made the reflected light pafs through another
prifm, and, being reflected by it, to fall afterwards upon
a sheet of white paper, at fonie diftance behind it, and there
to paint the uflal colours of the prifm. Then caufing the
first prifm to be turned about its axis, he obferved, that
when those rays which, in this prifm, had suffered the
greatest
greatest refraction, and were of a blue and violet colour, began to be wholly reflected, the blue and violet light on the paper, which received the rays from the second prism, was visibly increased, above that of the red and yellow, which was least refracted; and after that, when the rest of the light, which was green, yellow, and red, began to be wholly reflected in the first prism, the light of those colours on the paper received as great an increase as the violet and blue had done before. From this it is manifest, that the beam reflected by the base of the prism, being augmented first by the more refrangible rays, and afterwards by the less refrangible ones, is compounded of rays differently refrangible. This experiment is illustrated by fig. 9, in which A B C represents the first prism, on the base of which the light falls, at M. When this prism is turned about its axis, according to the order of the letters A B C, the more refrangible rays, M H, emerge more and more obliquely; and at length, after their most oblique emergence, are reflected towards N, and going on to P, increase the number of rays N P. By continuing the motion of the first prism, the less refrangible rays, M G, are reflected to N, and increase the number of rays N T.

Since it appears from Sir Isaac Newton's experiments, that different rays of light have different degrees of refrangibility, it necessarily follows that the rules laid down by preceding philosophers, concerning the refractive power of water, glafs, &c. must be limited to the middle kind of rays, as it may be supposed that Kepler, Snellius, and others would attend to them principally. Sir Isaac, however, proves that the line of the incidence of every kind of light, considered apart, is to its line of refraction in a given ratio. This he deduces both by experiment, and also geometrically, from the supposition that bodies refract the light by acting upon its rays in lines perpendicular to their surfaces.

Upon the whole it appears, that the blue rays are more refracted than the red ones, and that there is, likewise, unequal refraction in the intermediate rays; and upon the whole it appears, that the sun's rays have not all the same refrangibility, and, consequently, are not of the same nature. It is also observed, that those rays which are most refrangible are also most refrangible. See the proof of this under Reflexibility. Newton's Optics, p. 22, &c.

The difference between refrangibility and reflexibility was first discovered by Sir Isaac Newton, in 1671-2, and communicated in a letter to the Royal Society, dated February 6, 1671-2, and published in the Philosophical Transactions, N. &c. 80, p. 307, and from that time vindicated by him from the objections of several authors; particularly F. Pardies, M. Mariotte, Fr. Linus, or Lin, and other gentlemen at the English college at Liege; and at length it was more fully laid down, illustrated, and confirmed, by a great variety of experiments, in his excellent treatise of Optics.

But farther, as not only those colours of light produced by reflection in a prism, but also those reflected from opaque bodies, have their different degrees of refrangibility and reflexibility; and as a white light arises from a mixture of the several coloured rays, the same great author concluded all homogeneous light to have its proper colour, corresponding to its degree of refrangibility, and not capable of being changed by any reflections, or any refractions; that the sun's light is composed of all the primary colours; and that all compound colours arise from a mixture of the primary ones, &c.

The different degrees of refrangibility he conjectures to arise from the different magnitude of the particles of which the different rays consist. Thus the most refrangible rays, i.e. the red ones, he supposes to consist of the largest particles; the least refrangible, i.e. the violet rays, of the smallest particles; and the intermediate rays, yellow, green, and blue, of particles of intermediate sizes.

Having given a general view of the Newtonian theory of colours, as they depend upon the refraction of light, under the article Colours, we shall here add some farther particulars on this subject. From a review of that part of the article, and of what has been above delivered, we may infer that, as the rays of light differ in refrangibility, they also differ in their disposition to exhibit this or that particular colour; so that colours are not modifications of light, derived from refractions or reflections of natural bodies, but original and constant properties, which are different in different rays. Moreover, to the same degree of refrangibility always belongs the same colour, and to the same colour the same degree of refrangibility; nor are the same species of colour, and degree of refrangibility, that are proper to any particular kind of rays, susceptible of change by refraction and by reflection of natural bodies, nor by any other cause which Sir Isaac Newton could observe. Although a seeming transmutation of colours may be made by a mixture of different kinds of rays, yet, in such mixtures, the component colours themselves do not appear; but, by their mutually alloying each other, consitute a middle colour; and, therefore, by refraction, the different rays be separated, colour will emerge different from that of the composition. Thus blue and yellow powders, finely mixed, appear green to the naked eye; and yet the colours of the component particles are not thereby really changed, but only blended: for when they are viewed with a microscope, they still appear blue and yellow. It appears that there are also two sorts of colours: the one original and simple; the other compounded of these. The original and primary colours are red, orange, yellow, green, blue, indigo, and a violet purple, and an indefinite variety of intermediate gradations. The same colour in a specie with those primary ones may be also produced by a composition: thus a mixture of yellow and blue makes green; of red and yellow, orange; and of orange and yellown-green, yellow. In general, if any two colours are mixed, which, in the feries of those that are produced by the prism, are not too far distant from one another, they, by their mutual alloy, compose that colour which appears in the midway between them; but those which are situated at too great distance have not this effect: e.g. orange and indigo do not produce the intermediate green, nor scarlet and green the intermediate yellow.

The most wonderful composition is that of whiteness, which no one sort of rays alone can exhibit, but which is always compounded; so that all the aforementioned primary colours, mixed in a certain proportion, are necessary to form it. See Colour.

Having shewn, in the preceding part of this article, the extremes of the different degrees of refrangibility in the different kinds of light, we shall now proceed to give the result of Newton's investigation, concerning the different degrees of refrangibility of all the different kinds of light, according to their several colours; particularizing this part of the subject with an explanation of the method which he made use of to define the boundaries of each colour, in the oblong image of the sun above described. In that image, though there was a manifest difference of colour, not only between the two extremes, but also in the intermediate parts, yet the exact place at which any one colour ended, and another began, was far from being sufficiently distinguishable.
guifiable. The reason of this indiscrimination is, that rays of every kind coming from all parts of the sun's disc, an entire image of the sun is projected on the paper, conflating of a circle of each particular colour; and as the rays differ in kind by infinitesimal degrees, from the extreme red to the extreme violet, there must, in fact, be thousands of these circles in the same oblong image, the centres of which are infinitely near to one another; so that the light is intimately mixed, especially in the middle of the image, where it is the brightest.

If these circles, as he observes, whist their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of heterogeneous rays, would be proportionably diminished. Thus, in P T (fig. 10.) the circles of which the solar image consists, expand into one another; but in the same figure, P T, being composed of less circles, but having their centres at the same distance as the former, do not extend into one another, the mixture being diminished in proportion to the diameters of the circles.

Now these circles would be diminished, if, without the room, at a great distance from the prism, towards the sun, some opaque body was placed, having a round hole in the middle of it, to intercept all the sun's light, excepting so much as, coming from the middle of its disc, could pass through that hole to the prism; for so the separate circles would no longer answer to the whole disc of the sun, but only to that part of it which can be seen from the prism, through that hole. But that these circles may answer more distinctly to the hole, a lens is to be placed by the prism, to cast the image of the hole, that is, of each separate circle, distinctly upon the paper; and if this be done, it will not be necessary to place that hole very far off, not even beyond the window. Instead, therefore, of that hole, he made use of the hole in his window-flutter, in the following manner.

At about 10 or 12 feet from the window, he placed a lens, by which the image of the hole might be distinctly cast upon a sheet of white paper, at the distance of 6, 8, 10, or 12 feet from the lens. Then, immediately after the lens, he placed a prism, by which the refracted light might be thrown upwards, or sideways; and he moved the paper that received it, either towards the prism, or from it, till he found the exact distance at which the sides of the image appeared most distinct. By this means the circular images of the hole were terminated most distinctly, without any penumbra, and therefore extended into one another the leaf that they could; and consequently the mixture of the heterogeneous rays was the leaf of all. And by using a greater or lesser hole in the window-flutter, he made the circular images greater or less at pleasure, and thereby the mixture of rays in the oblong image was as much or as little as he chose. He sometimes made the breadth of the image 40 times, and sometimes 60 or 70 times less than its length. In this manner, he says, light is made sufficiently simple, and homogeneal, for trying any of his experiments about simple light; for that the heterogeneous rays in this light are so few, as hardly to be perceived, excepting, perhaps, in the indigo and violet, which, being dark colours, do easily suffer a sensible alloy by that little scattering light, which used to be refracted irregularly by the inequalities of the prism. The whole process of this experiment is so evident, by inspection of fig. 11., that it needs no particular illustration.

Instead of a circular hole, our author recommends a hole shaped like a long parallelogram, with its length parallel to the prism. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image will be as simple as before, or more simple, and the image will become much broader, and therefore more fit for these experiments.

Or, instead of this hole, another may be formed of a triangle of equal sides, whose base may be about the 10th part of an inch, and its height an inch or more. For, by this means, if the axis of the prism be parallel to the perpendicular of the triangle, the image pt (fig. 12.) will now be formed of equiangular triangles, a f, b f, c f, d f, e f, m, &c. and inscribable other intermediate ones, answering to the triangular hole in shape and bigness, and lying one after another in a continual series, between two parallel lines, a f, g m. These triangles are a little intermingled at their bases, but not at their vertices; and therefore the light on the brighter side, a f, of the image, where the bases of the triangles are, is a little compounded, but on the darker side, g m, it is altogether uncompounded; and in all places between the sides, the composition is proportionable to the distances of the places from that oblique side g m; and having an image of such a composition, we may try experiments either in its stronger and less simple light, near the side a f; or in its weaker and more simple light, near the other side g m, as shall seem most convenient.

In making these experiments, he advises, that the chamber be made very dark, that the lens he very good, being made of glafs free from bubbles and veins, the sides of the prism truly plane, and its polish elaborate, with an angle of about 65 or 70 degrees; and the edges of the prism and lens, as far as they may make any irregular refraction, should be covered with black paper glued on them. He also observes, that all the useless light should be intercepted with black paper, or other black obstacles. It being difficult to get glafs prisms fit for these nice experiments, he sometimes used prismatic vessels made with pieces of broken looking-glasses, and filled with rain-water; and to increase the refraction, he sometimes strongly impregnated the water with ficcatum.
between 77 and 78 be divided, as the line GM is divided by those intervals, there will be 77, 77, 77, 77, 77, 77, 77, 77, 78, for the lines of refraction of those rays out of glass into air, their common line of incidence being 50. So then the lines of the incidences of all the red-making rays out of glass into air were to the lines of their refractions not greater than 50 to 77, nor less than 50 to 77; but they varied from one another according to all their intermediate proportions, and of the other colours.

Having demonstrated that the light of the sun consists of a certain proportion of differently coloured light, our author proves, by another series of experiments, what has been already demonstrated by a single one mentioned above, that when a beam of light has been divided into its component parts, if they be again mixed, they will produce white; or if any one of them be intercepted, the image will appear tinged, and in a different manner, according to the different colours that are thereby prevented from mixing with the rest; and to complete the whole, he observes, that intercepting all the colours that compose the white image except one, and thereby making it to exhibit the appearance of all the colours in order; yet, if he made this succession of all the colours very quick, the appearance was always white, though it was demonstrable that only one colour took place at any one time; and he judiciously observes, that if each of these colours in succession give the idea of whiteness, much more will they produce that effect, when they are so intimately mixed as they are in a natural fun-beam.

Not content with composing whiteness from the separately coloured rays of the sun, he attempted, and succeeded in his attempt, to do the same with natural coloured bodies, observing the same proportions of the respective colours that he had found in the solar image. The coloured powders which he made use of at first produced only a kind of grey; but this was in fact a dull white, or whiteness mixed with shade: for when he contrived to throw a very strong light upon it, it became intensely white, so that a friend of his, who happened to call upon him while he was busy about these curious experiments, and who knew nothing of what he had been doing, pronounced that the powders he had been mixing, when thus illuminated, made a better white than some very fine white paper, with which he was comparing it.

As the preceding proportion of all the prismatic colours makes a white, it is evident that when they are mixed in different proportions, or when only a few of them are used, they will make different colours; and our philosopher has given us the following ingenious method of knowing, in a mixture of primary colours, the quantity and quality of each being given, the colour of the compound. With the centre O1 (Fig. 14.) and the radius OD, describe a circle ADEF, and divide the circumference into seven parts, proportional to the seven musical notes or intervals contained in an octave, that is in proportion to the numbers \(\frac{1}{3}, \frac{2}{3}, \frac{3}{3}, \frac{4}{3}, \frac{5}{3}, \frac{6}{3}, \frac{7}{3}\). Let the first, DEF, represent a red colour, the second, EFG, orange, and of the rest; and let all these colours be supposing to pass gradually into one another. Let \(\rho\) be the centre of gravity of the arc DEF, and \(\frac{4}{3}, \frac{5}{3}, \frac{6}{3}, \frac{7}{3}\) be the centres of gravity of the other arcs; and about those centres let circles, proportional to the number of rays of each colour in the given mixture, be described. Then find a common centre of gravity of all those circles; and if a line be drawn from the centre of the circle O, through this point, as supposing to \(\rho\), the point Y, in which it terminates at the circumference, will shew the colour that arises from the mixture; and the line OZ will be proportioned to the fullness or intenseness of the colour, the centre O representing perfect white. But if only two of the primary colours, which in this circle are opposite to one another, be mixed in an equal proportion, the point Z will fall upon the centre O, and yet the colour compounded of those two will not be perfectly white, but some faint anonymous colour; for he could never, by mixing only two primary colours, produce a perfect white. Whether it might be the result of three taken at equal distances in the circumference he could not tell; but he did not much question, but that four or five of them would be sufficient. These, however, as he observes, are curiosities of little or no moment to the understanding of the phenomena of nature, since, in all natural whites, there is a mixture of all kinds of rays. Newton's Optics. Priestley's Hist. of Light and Colours.

For the method of correcting the effect of the different refrangibility of the rays of light in glasses, see ABE
RREATION and Telescope; see also Dispersion of Light.

Refrangibility of Radiant Heat. See Rays of Heat. Radiant heat, as well as light, is not only refrangible, but it is also subject to the laws of the dispersion, arising from its different refrangibility. The prism refracts radiant heat, so as to separate that which is less efficacious from that which is more so. The whole quantity of radiant heat contained in a fun beam, if this different refrangibility did not exist, would inevitably fall uniformly on a space equal to the area of the prism; and if radiant heat were not refrangible at all, it would fall upon an equal space, in the place where the shadow of the prism, when covered, may be seen. But neither of these events taking place, it is evident that the radiant heat is subject to the laws of refraction, and also to those of the different refrangibility of light. Whence Dr. Herchel is led to tumulate, that radiant heat consists of particles of light of a certain range of momenta, which range may extend a little further, on each side of refrangibility, than that of light. (See Rays of Heat.) Dr. Herchel having found that two degrees of heat were obtained from that part of the prismatic spectrum which contained the violet rays, while the full red colour, on the opposite side, gave no less than seven degrees, infers from these facts the different refrangibility of the rays which occasion heat, as clearly and certainly as it is concluded that the refrangibility of light is ascertained by the dispersion and variety of the colours. But he proceeds farther, and observes, that the rays of heat are of a much more extensive refrangibility than those of light. In order to make this appear, he delineates a spectrum of light, by assuming a line of a certain length; and, dividing it into seven parts, according to the dimensions assigned to the seven colours by Sir Isaac Newton, in the fourth figure of the second part of his Optics, represents the illuminating power of which each colour is possessed, by an ordinate drawn to that line. And here, as the absolute length of the ordinates is arbitrary, provided they be proportional to each other, he assumes the length of that which is to express the maximum, equal to \(\frac{1}{3}\) of the whole line.

Thus, let GQ (Fig. 15.) represent the line that contains the arrangement of the colours, from the red to the violet. Then, erecting on the confines of the yellow and green the line LR = \(\frac{1}{3}\) of GQ, it will represent the power of illumination of the rays in that place. For, by experiments already delivered, we have shown that the maximum of illumination is in the brightest yellow or palest green rays. From the fame experiments we collect, that the illuminations of yellow and green are equal to each other, and not much inferior to the maximum; this gives us the ordinates K and M. Then, by the rest of the same experiments, we obtain the
the ordinates H, I, N, O, P, with sufficient accuracy for the purpose here intended. All these being applied to the middle of the spaces which belong to their respective colours, we have the figure G R O G, representing what may be called the spectrum of illumination.

We are now, in the same manner, to find a figure to express the heating power of the refracted prismatic rays, or what may be called the spectrum of heat. In order to determine the length of the base, Dr. Herchel examined the extent of the invisible rays, and found, that at a distance of two inches beyond visible red, his thermometer, in a few minutes, acquired 16 degrees of heat. The extent of the coloured spectrum at that time, or the line which answered to G O in his figure, measured 2.997 inches. If two inches had been the whole of the extent of the invisible part, it might be stated to be in proportion to the visible one as 2 to 3; but we are to make some allowance for a small space required beyond the last ordinate, that the curve of the heating power drawn through it may reach the base; and indeed, at 2½ inches beyond visible red, Dr. Herchel could still find ¾ degree of heat. It appears therefore sufficiently safe, to admit the base of the spectrum of heat A Q, to be to that of the spectrum of light G Q, as 54 to 3; or, conforming to the Newtonian figure before mentioned, the base of which is 3.3 inches, as 57 to 33. Now, if we assume for the maximum of an ordinate of an equal length with that which was fixed upon for the maximum of light, it will give us a method of comparing the two spectra together. Accordingly, Dr. Herchel has drawn the several ordinates B, C, D, E, F, G, H, J, K, L, M, N, O, P, of such lengths as, from experiments made on purpose, it appeared they should be, in order to express the heat indicated by the thermometer, when placed on the base, at the several stations pointed out by the letters.

A mere inspection of the two figures, which have been drawn as lying upon one another, will enable us now to see how very differently the prismatic disperses the heat-making rays, and those which occasion illumination, over the areas A S Q A, and G R O G, of our two spectra! These rays neither agree in their mean refrangibility, nor in the situation of their maxima. At R, where we have most light, there is but little heat; and at S, where we have most heat, we find no light at all.

REFRESHMENT, Quarters of. See Quarters.
REFRET, Fr. the burden of a long. This word is only to be found in the second folio edition of Bailey's Dictionary, 1736. In no French dictionary is there authority for it. Cotgrave, Dict. du Vieux Langage; Trévoux, Dict. de l'Académie; and Glossaries, have been confuted in vain.

REFRIGERATOR, Refrigerative, in Medicine, or coolings, frigus, cold, an appellation given to such remedies as were supposed to polífes a power of cooling the internal parts. Hence all diaphoretic, such as ptisan, gruel, and other thin drinks, vegetable and mineral acids, neutral salts, and other subfiances, which are dililutes of stimulating qualities, and communicate a fermentation of coals to the tongue and throat, have been considered as refrigerant. As they have no actual power of generating cold in the animal body, the term is somewhat incorrect; but as it expresses the opposite quality to that of stimulating, which is used also as synonymous with heating, it is still retained, and applied to diet, drink, and medicine of a non-stimulant quality. In this sense, the term is nearly synonymous with febrif.

Whatever, in fact, increases the circulation, increases the heat of the body, and vice verfa; potentially, therefore, all medicative medicines may be said to be refrigerant. The use of refrigerants will thence be inferred to be proper in all those cases in which there is an over-reaction of the circulation, either locally or generally; such as local inflammations, febrile diatheses, hemorrhages, and the like. In the case of external inflammations, indeed, actual refrigeration may be produced, by the application of cold substances, water or ice, or by the abstraction of heat by means of evaporation; both of which afford the means of directly diminishing the activity of the vessels of the part. Thus, in burns and scalds, the pain is instantly relieved, and the inflammation effectually reduced, by the immersion of the part in cold water, if sufficiently perforeved in. But in respect to internal refrigerants, their operation is of a negative kind, and conflicts rather in the removal of uneasy sensations, and in the exclusion of stimulant subfiances, than in the actual suppression of increased action. See Sedative.

REFRIGERATION, denotes the act of cooling, or the abstraction of heat from various subfiances. This is effected in a variety of ways, and for various purposes of domestic use and of art; and the degree of cold that is produced is estimated by an instrument called the thermometer, which fees. Under this head it is needless to repeat the principles of refrigeration, and the differentproceses that are used for this purpose, which are amply stated and described under the articles Cold, Congestion, Cooling, Freezing, Heat, Ice, Ice-boxes, &c.

REFRIGERATORY, Refrigeratorium, in Chemistry, a copper vessel filled with cold water, folded round the capital of an alembic, to cool and condense the vapours raised by the fire, and to convert them into a liquor, to be discharged thence through the head. See ALEMBIC.

The water in the refrigerator is to be changed from time to time, as it begins to grow warm. Sometimes they content themselves with wrapping a wet cloth about the head of the alembic, instead of a refrigeratory; but the more usual method now is, to supply the place of the refrigeratory by a worm, or spiral pipe, running through a tub of cold water.

Distillation chiefly consists in evaporation and refrigeration. See Distillation.

REFUGE, Refugium, in our Old Customs, a sanctuary, or asylum; which fees respectively.
At Paris there is an hospital called the Refuge, in which diffolute women are shut up.

REFUGE, City of, in Scripture History, six cities selected from the 48 appropriated to the residence of the Levites, which were appointed for the protection of persons from the rigour of the laws, who were chargeable with involuntary homicide. Some have supposed that all the cities of the Levites were asylums; but it appears from Numb. xxxv. 6, that only six of them were appointed to this use. These asylums were intended not only for Jews, but for Gentiles, or for foreigners who dwelt among them. (Numb. xxxv. 15.) They were not designed as sanctuaries for wilful murderers and all forts of atrocious villains among the Jews, as they were among the Greeks and Romans, and as such places have since been in Roman Catholic countries, but merely for securing those who had been guilty of involuntary homicide (Deut. xix. 4—15.) from the effects of private revenge, until they were cleared by a legal process. It is observable, that the Israelites are commanded to “prepare the way,” that is, to make the road good, “that every voyer may see thither,” without impediment, and with all expediency. (Deut. xix. 3.) By having good roads to them, at least 32 cubits, or about 48 feet in breadth, and bridges wherever
REG

wherever they were necessary, those cities were to be easy of access; and at cross roads posts were erected with inscriptions, directing the way to the "city of refuge." Upon this Hottinger remarks, that it was probably in allusion to this custom, that John the Baptist is described as "the voice of one crying in the wilderness, prepare ye the way of the Lord, make his paths straight." (Luke, iii. 4—6.) He was the Melliah's forerunner, and in that character was to remove the obstacles to men's flying to him as their asylum, and obtaining salvation by the salvation of God. Every year, on the 15th of Adar, (February,) the magistrates were to inspect the roads, and ascertain their good condition. Thee cities were to be supplied with water and provisions; but they were not to be the residence of any artificers who made weapons, by the use of which the relations of the deceased might gratify their revenge. It was necessary that those who took refuge in these places should understand some occupation, that might prevent their being chargeable, whilist they were waiting for their trial. In order to excite and maintain the greater horror even of involuntary bloodshed, the law punished it by a kind of banishment, for the accused person was to remain in this city, without departing from it, till the death of the high-priest, but after the high priest's death, he might safely go wherever he pleased.

REFUGEES, French Protestants, who, by the revocation of the edict of Nantes, in 1685, have been constrained to quit their country, and retire for refuge into Holland, Germany, England, &c. to save themselves from the necessity of abandoning their religion.

REFUGIO, L., in Geography, a harbour in one of the islands of Mayorga, where Maurelle was supplied with water in 1781, and which, he says, afforded shelter from the most furious winds. S. lat. 18° 56'. E. long. 177° 32'.

REVINGE, a town of Sweden, in the province of Halland; nine miles N.N.W. of Halmstad.

REFUSAL, in Law, is where one hath by law a right and power of having or doing something of advantage to him, and he declines it. An executor may refuse an executorship: but the refusal ought to be before the ordinary; if an executor be summoned to accept or refuse the executorship, and he doth not appear upon the summons and prove the will, the court may grant administration, &c. which shall be good in law till such executor hath proved the will; but no man can be compelled to take upon him the executorship, unless he hath intermeddled with the estate. (1 Lees. 154. Cro. Eliz. 588.) Where there are several executors, and they all refuse, none of them shall administer afterwards; but if there is a refusal by one, and the other proves the will, the refusing executor may administer when he will, during the life of his co-executor. (1 Rep. 28.) If there is but one executor, and he administers, he cannot refuse afterwards, and if once he refuse, he cannot administer afterwards.

There is a refusal of a clerk presented to a church, for want of literature, &c. and if a bishop once refuses a clerk for insufficiency, he cannot accept of him afterward, if a new clerk is presented. (5 Rep. 59. Cro. Eliz. 27.) In action of trever and conversion, a demand of the goods, and refusal to deliver them must be proved, &c. 10 Rep. 56.

REFUTATION, REFUTATIO, in Rhetoric, that part of the anwser made to an opponent, which disproves what had been advanced by him.

REGA, in Geography, a river of Pomerania, which rises three miles N.W. of Dramburg, passes by Regenwalde, Plate, Griiflenberg, Trepotg, &c., and then runs into the sea, 12 miles S.W. of Collberg.

Vol. XXIX.

REGA, a town of Egypt, on the left bank of the Nile; six miles N. of Athiel.

REGAL, REGIAL, or REGALIS, something belonging to a king. Regal is of the same import with royal; the former being formed of the Latin rex; the other of the French roi, king.

Regal, Fr., a musical term, which the Encyclopaedia defines, "a fife, an ancient instrument composed of many flrets of fonorous wood of different lengths, forming a scale, played upon by an ivory ball fastened to the end of a stick." This is exactly the description of the thuceco, said to be invented by the brother of Brenner, the late musician, in the Strand, who published a book of instructions for playing upon it.
